Yang–Mills and the mass gap

Volume 3 Toward the mass gap — the questions that remain, and this book's results

Kiichi, Shiori and Rin · Edition of 2026-11-14 · https://computoergosum.com/en/principia/yang-mills/

> This PDF is a print of the chapters of the web edition. Interactive figures are frozen in the state in which they were printed. Links between chapters lead to the web edition, which holds the latest text.

Chapter		Page
Part 16 Where things stand, and the questions that remain		
16-01	How far the world has come	9
16-02	Five open questions	26
16-03	The infrared edge of the published construction	35
16-04	Where this book stands	44
16-05	Where the two ways of digging part	51
16-06	Candidates for new concepts	66
16-07	The list of open tasks	82
16-08	Common misconceptions	101
16-09	The stages a proof must contain — the table of seven stages	117
16-10	A map of the tools — where the known tools used by this book live	130
16-11	A map of ideas for crossing the band — living ideas, broken ideas, mathematics that seems to be needed	140

Chapter		Page
Part 17 From the side of physics		
17-01	How physics sees it	156
17-02	Mechanisms of confinement	169
17-03	The string picture	182
17-04	Large N	195
17-05	String theory and extra dimensions	207
17-06	How extra dimensions become invisible	219
17-07	Where gauge fields come from	231
17-08	Holography	243
17-09	The mass gap becomes geometry	255
17-10	Back to four dimensions	268
17-11	Supersymmetry and Seiberg–Witten	280
17-12	The sentence that plays the role of an equivalence principle	292
17-13	Where the way physics digs parts from mathematics	304
Part 18 A dictionary of two languages		
18-01	How to read the dictionary	317
18-02	A dictionary of the theory itself	331
18-03	A dictionary of mass and length	348
18-04	A dictionary of scales and limits	365
18-05	The physical counterparts of our assumptions	380
Part 19 Objects, and the statements to be shown		
19-00	Entrance — how to read objects, firm theorems and premises	393
19-01	The lattice, link variables and the Wilson measure	398

Chapter		Page
19-02	Twisted boundary conditions, the vortex ratio θ and Polyakov loops	408
19-03	Reflection, the transfer operator and the vessel of reconstruction	417
19-04	The block map and one step of renormalisation	427
19-05	The fermion weight	438
19-06	Objects and their Lean definitions — a table of correspondence	446
19-07	The statements to be shown — written with defined objects only	455
Part 20 Firm theorems — the vessel and strong coupling		
20-00	Entrance — what can be said at one lattice spacing	462
20-01	Reflection positivity — three forms	468
20-02	Decay of correlations at strong coupling	479
20-03	The infinite-volume limit — no subsequence, translation invariance, clustering	489
20-04	Reconstruction and the mass gap — inside the strong-coupling window	499
20-05	The vessel with fermions	508
20-06	The area law at strong coupling, and an upper bound on the vortex free energy	515
20-07	What this part says, and what it does not	530
Part 21 Firm theorems — the vortex floor and Polyakov loops		
21-00	Entrance — vortices in a twisted box	537
21-01	Three results on sign systems — the covering inequality, monotonicity, comparison	541
21-02	The thin-vortex floor	553
21-03	The thick-vortex floor — statement and route	562

Chapter		Page
21-04	The thick-vortex floor — parts of the proof	572
21-05	The minimal action of a vortex — positivity, and a certificate for the upper bound	582
21-06	The sign of θ and pairs of Polyakov loops	592
21-07	The vortex ratio — continuity, limit, matching	603
21-08	What this part says, and what it does not	614
Part 22 Firm theorems — the rarity of large plaquettes		
22-00	Entrance — the rarity of large plaquettes	620
22-01	Rarity of large plaquettes — the chessboard estimate	626
22-02	What this part says, and what it does not	635
Part 23 The first road, first half — from the direction of time		
23-00	Entrance — the staircase, and the random walk, the ruler and the clock	641
23-01	The line of construction and the diffusive-relaxation-time assumption	654
23-02	Roads tried on the four-dimensional lattice, and walls	680
23-03	The four steps of the staircase — why we start from 0+1 dimensions	704
23-04	The path measure of the double well, and kinks	715
23-05	The statement of the first step — the four double-well conditions and the upper-bound proposition	729
23-06	The in-phase local Poincaré condition	751
23-07	The map of the saddle-tube condition — seven routes and the seam of the ring	768
23-08	What computer-assisted means — the conditions on the chain inside the window	781

Chapter		Page
23-09	The sector framework and the three strands of the window log-Sobolev route	795
23-10	The list of detour plans — types of breakage	815
23-11	Box reduction and the gap inside the box — the constant of the core	824
23-12	The integrated table and the dependency graph	849
23-13	Lean statements and the limits of machine checking	866
23-14	Reconciliation — the numbers of the record and the known numbers	875
23-15	What remains and its cost — the distance to a theorem	889
23-16	What is not claimed	907
23-17	Insights and small questions	918
Part 24 The first road, second half		
24-00	Entrance — what we take over from Part 23	933
24-01	One form that obstructs the diffusive-relaxation-time assumption — a nearly conserved global quantity	942
24-02	Choosing the ruler and the coordinates again — the length at which conservation breaks	950
24-03	Two ways to repair the relaxation-time assumption — the sector assumption and the local assumption	960
24-04	Which form of the relaxation-time assumption the one-sided bridge needs	980
24-05	Making time continuous — the Hamiltonian lattice and the vacuum measure	994
24-06	Paying with rarity instead of convexity — renormalisation on groups and log-Sobolev	1005
24-07	Because it is four dimensions — the dimensionless coupling and topology	1025

Chapter		Page
24-08	Questions, and what is not claimed	1045
24-09	Table of notation for the first road, second half	1052
Part 25 The second road — from the direction of space		
25-00	Entrance — space, not time	1059
25-01	The twisted T^2 and 't Hooft flux	1071
25-02	Vortices and fractional instantons	1085
25-03	Containers — conditioning on the frame makes things independent	1099
25-04	Slab confinement	1114
25-05	Vortex-insertion identities	1126
25-06	Driven insertion and the flow lemma	1141
25-07	Why fixed maps fail	1158
25-08	The measured record	1174
25-09	Where this road stops — widening the T^2 is the band	1184
Part 26 The crossover band		
26-00	Entrance — confluence	1189
26-01	The correct form of the band	1202
26-02	Reduction to a single inequality	1212
26-03	The only place where non-abelian enters	1225
26-04	Structure alone cannot cross	1235
26-05	The chessboard and simultaneous flips	1250
26-06	Renormalisation comparison — a comparison that distinguishes groups	1263
26-07	The band seen from the side of time	1285

2026-10-01 · chapter Yang–Mills and the mass gap Part 16 Where things stand, and the questions that remain timeline and where things stand

How far the world has come — reading where things stand from a timeline and tables by dimension

> In this chapter, § 01– § 06 are established knowledge, § 07 is a map of open questions and § 08 is guide material.

What this chapter shows — A timeline of the main results from 1954 to 2026 (37 rows, including the four-dimensional construction published in 2026). A board showing, for each dimension, how far through the six steps there are theorems, and how it got filled in. A comparison with abelian groups and scalar fields. Where on the number line of β the lattice theorems lie.

Prerequisite chapters — 7-10 Where four dimensions stops. The six stages are in 7-01, and the content for each dimension in 7-02, 7-06 and 7-07.

Said first — This chapter rearranges known literature and shows no theorem. The existence of four-dimensional Yang–Mills (a theory satisfying the Wightman axioms, as a limit of Wilson's lattice gauge theory) was shown by the construction published in 2026, as a formalisation in Lean, and the committee assessed it as “proving” this Assessment (Part 6). The uniqueness of the infinite-volume limit and the mass gap have not been shown (16-02). The timeline covers what was checked in the main text or the abstract (some rows from the reference list of a review), and is not exhaustive. The articles on this site have not moved any cell of the board (the label Assessment means "according to the committee's assessment report"; for details, see “Labels” in 6-00).

The order of this chapter

1. Reading one result along six axes
2. Timeline I (1954–1999)
3. Timeline II (2000–2026)
4. The board: moving through the years — moving figure, computed
5. Tables by dimension
6. Comparison with neighbouring theories: the scope of "it has been done in two and three dimensions"

7. Where the lattice theorems lie on the number line of β — moving figure, computed (the β knob)
8. Detour: what the timeline leaves out

01

Reading one result along six axes

Every theorem about Yang–Mills comes with conditions on "where it holds". Drop the conditions, and a two-dimensional theorem looks like a statement about four dimensions, a lattice theorem like a statement about the continuum. This chapter gathers the conditions into six axes and calls them the **address**.

$$\text{address} = \big(d,\ \text{lattice or continuum},\ \text{volume},\ \text{coupling side},\ G,\ \text{matter fields}\big)\ \text{(1)}$$

d is the dimension of Euclideanised spacetime, and the coupling side is whether the lattice inverse coupling $\beta = 2N/g^2$ (table of notation) is small (strong coupling) or large (weak coupling). The address of the problem statement is "4, continuum, $\mathbb{R}^4$, any compact simple group, none", and there it is required to pass through all six stages. Known The continuum limit of the four-dimensional lattice is believed to lie on the $\beta \to \infty$ side (Chatterjee 2018 § 5). Physics

Example: Driver 1989 reaches the ultraviolet-limit step and the infinite-volume step at (2, continuum, $\mathbb{R}^2$, —, connected compact, none), and Shen–Zhu–Zhu 2022 gives exponential decay on the lattice at (any, lattice with fixed spacing, infinite, strong, $SU(N)$, none). The "Scope" in the timeline abbreviates this address; the year is the year of first public appearance (the arXiv year if there is one), and the year in parentheses is the year of publication. Rows that combine several papers give a range of years.

02

Timeline I (1954–1999): words, tools, and the first constructions

The first half-century had three strands. In physics, the theory was written down (1954), and asymptotic freedom was found in perturbation theory (1973). In the framework, the axioms (1973, 1975) and the lattice (1974) were put in place. In construction came the strongly coupled lattice (1978), ultraviolet estimates in three and four dimensions (1985, 1987–89), the two-dimensional continuum measure (1989), and in four dimensions an outline of a construction that removes the ultraviolet cutoff while keeping the infrared one (1993). Known The formulas of 1974 and 1973 are the following two (5-01, 4-06).

$$S_W = \beta \sum_P \Big(1 - \tfrac{1}{N} \operatorname{Re} \operatorname{tr} U_P\Big), \qquad \mu \frac{dg}{d\mu} = -b_0\, g^3 + \cdots, \qquad b_0 = \frac{11N}{3} \cdot \frac{1}{16\pi^2} \tag{2}$$

Example: for $SU(2)$, $\beta = 2.5$ is $g^2 = 2N/\beta = 1.6$. The sign $b_0 > 0$ is asymptotic freedom. The "Comparison" rows are neighbouring theories, abelian groups and scalar fields, and do not move cells. The physics rows continue in Part 17 (17-04, 17-11, 17-09; lattice numbers in 5-08).

Known Table 1 Timeline I (except rows with the Physics label). Pressing a row sets Figure 1 to that year.

Year	Event	Scope
1954	Yang–Mills: classical theory of non-abelian gauge fields	Classical
1973	Gross–Wilczek, Politzer: asymptotic freedom	Coefficient in perturbation theory
1973, 1975	Osterwalder–Schrader: Euclidean axioms and reconstruction of a Wightman theory (conditions revised in 1975)	Axioms
1974	Wilson: lattice gauge theory (a gauge-invariant lattice action)	All dimensions, lattice
1974	't Hooft: the large-N expansion	Physics
1976	Feldman–Osterwalder: the Wightman axioms and a mass gap for weakly coupled ϕ^4_3	Comparison, 3D
1978	Osterwalder–Seiler: reflection positivity and the transfer matrix on the lattice; infinite-volume limit and area law at strong coupling (convergence of the cluster expansion in outline)	Lattice, strong coupling
1978	Singer: a global continuous gauge fixing cannot in general be taken	Geometry
1979–81	Brydges–Fröhlich–Seiler: the two-dimensional abelian Higgs model up to the OS axioms	Comparison, 2D
1980, 1982	Guth, Fröhlich–Spencer: a non-confining phase at large β for four-dimensional lattice U(1)	Comparison, lattice
1981–82	Aizenman, Fröhlich: ϕ^4 is trivial for $d \geq 5$	Comparison
1983–87	Gross, King, Driver: continuum limit of U(1) (3D, 4D, including with Higgs)	Comparison
1985	Bałaban: ultraviolet stability on the three-dimensional lattice (torus; uniform upper and lower bounds on the partition function)	3D, lattice, finite volume
1987–89	Bałaban: ultraviolet stability on the four-dimensional lattice; Theorem 1 of the final paper assumes the effective coupling is small	4D, lattice, finite volume
1989	Driver, Gross–King–Sengupta: the continuum measure on the plane $\mathbb{R}^2$ (Driver also convergence of the lattice approximation)	2D, continuum, infinite volume

Year	Event	Scope
1992–93	Sengupta: the measure on closed surfaces	2D, continuum, finite volume
1993	Magnen–Rivasseau–Sénéor: the "foundations" for constructing the Schwinger functions of four-dimensional SU(2) without ultraviolet cutoff, with the infrared cutoff held fixed (in a regularised axial gauge) (no detailed proof)	4D, continuum
1994	Seiberg–Witten: gap and confinement in a supersymmetric theory	Physics
1997–98	Maldacena, Witten: holography, and models that see the gap as geometry	Physics
1999	Morningstar–Peardon: lattice numbers for SU(3) glueballs	Physics Numerical

03

Timeline II (2000–2026): after the problem statement

On 24 May 2000 the Clay Mathematics Institute announced the Millennium Prize Problems in Paris. The problem statement (Jaffe–Witten) describes the state of four dimensions as follows. Known

> 'at present we do not know any non-trivial relativistic field theory that satisfies the Wightman (or any other reasonable) axioms in four dimensions.' (JW § 6)

Since then, new constructions in two dimensions, the state space and dynamics in three dimensions, and new theorems on the lattice have been added, but a 2004 report writes 'The state of the art remains the works of Balaban and of Magnen, Rivasseau and Sénéor'. Known A 2018 review put the question on the lattice into a formula (the lattice correlation-length problem (Chatterjee's Problem 5.1); 5-09). $f_\beta(x)$ is the correlation of the Wilson loops of the plaquettes nearest to the origin and to the point x.

$$\lim_{|x|\to\infty} \frac{\log f_\beta(x)}{|x|} = -\frac{1}{\xi(\beta)}, \quad \xi(\beta) \in (0,\infty) \ \ (\text{for all } \beta > 0), \qquad \lim_{\beta\to\infty} \xi(\beta) = \infty \ (3)$$

Example: there are 17 rows from 2000 on (11 of them in the 2020s), and the rows that changed a colour on the board are the 2 rows of 2022 (Shen–Zhu–Zhu and Adhikari–Cao) and the 1 row of the construction published in 2026 (three cells). Computed The lattice correlation-length problem is a question on the lattice, and is a different thing from the requirements of the problem statement (continuum, $\mathbb{R}^4$, axioms, non-triviality) (0-03).

Known Table 2 Timeline II.

Year	Event	Scope
2000	The Clay prize problem (the problem statement of Jaffe–Witten)	Problem
2001 (2003)–10	Lévy: random holonomy fields on closed surfaces (non-trivial bundles in 2006)	2D, continuum
2004	Douglas's report: the state of the art is still Bałaban and MRS	Assessment
2013 (2014)	Hairer: regularity structures (renormalisation of stochastic PDEs)	Tool
2018	Chatterjee's review: the lattice correlation-length problem (Problem 5.1) and the problem of the continuum limit of Wilson loops (5.2)	Lattice formulation
2019 (2021)	Aizenman–Duminil-Copin: the limit of four-dimensional ϕ^4 is Gaussian	Comparison
2020 (2022)	Chandra–Chevyrev–Hairer–Shen (CCHS): the two-dimensional stochastic Yang–Mills heat flow and the space of gauge orbits	2D, T^2
2021 (2024)	Cao–Chatterjee: the three-dimensional state space (under the assumption that the theory behaves like a Gaussian free field [GFF; 1-09])	3D, conditional
2022 (2024)	CCHS: stochastic quantisation of three-dimensional Yang–Mills–Higgs (local solutions and a Markov process; the measure not yet reached)	3D, T^3
2022	Chevyrev's review: the three-dimensional measure is not constructed even on T^3	Assessment
2022 (2023)	Shen–Zhu–Zhu: uniqueness and a positive mass gap on the strongly coupled lattice, in an explicit range independent of N	Lattice, strong coupling
2022 (2025)	Adhikari–Cao: exponential decay of correlations at weak coupling on the four-dimensional lattice for finite groups (including non-abelian)	Lattice, weak coupling
2023 (2026)	Chevyrev–Shen: the measure on T^2 is the unique invariant measure of the Langevin dynamics, independent of the lattice action	2D, T^2
2024 (2026)	Chatterjee: a special scaling limit of SU(2) Yang–Mills–Higgs is a Gaussian field	Comparison, Higgs
2025	Cao–Nissim–Sheffield: the area law in the 't Hooft regime (in 't Hooft's convention, multiplying the action by βN, the side with β small independently of N; 7-10 § 05) (not peer-reviewed)	Lattice, strong coupling
2026	Chevyrev–Klose–Mohamed, Chhaibi et al.: representations of the two-dimensional measure, and a construction not via the lattice (not peer-reviewed)	2D

Year	Event	Scope
2026	The published construction (a formalisation in Lean; submitted 2026-10-28, published 2026-11-10 together with the committee's assessment report; the committee's statement is dated 2026-11-09): for any compact simple group, builds a theory satisfying the Wightman axioms as a limit of four-dimensional Wilson lattice gauge theory. In a periodic box it converges along the whole sequence of cutoffs, and it passes to infinite volume along a subsequence. The uniqueness of the infinite-volume limit and the mass gap are not shown Assessment (6-00, 16-02)	4D, continuum (the committee's assessment)

Words in Table 2: **stochastic quantisation** = a method that builds a measure as the invariant measure (a measure whose distribution does not change over time) of some stochastic time evolution. **Langevin dynamics** = a gradient flow with noise that leaves the measure invariant. **Stochastic Yang–Mills heat flow** = the flow in the direction that decreases the Yang–Mills action (heat flow), with noise added. **Regularity structures** = a framework that gives meaning to singular stochastic partial differential equations and renormalises them. All of these are in 7-09. **Markov process** = a stochastic process whose future distribution is determined by the present state alone (7-02).

04

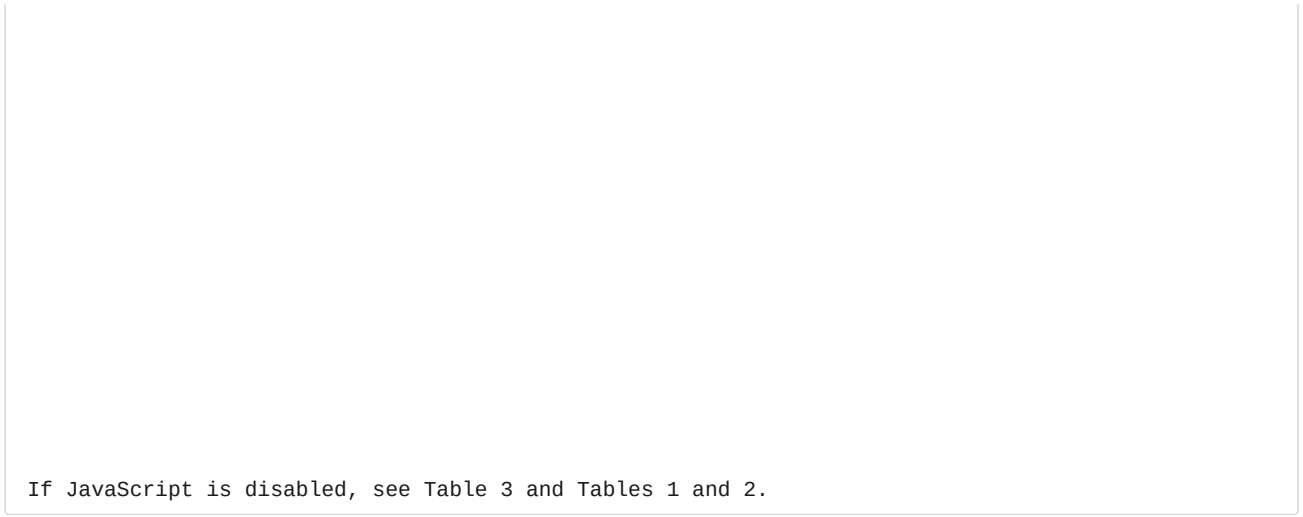
The board: moving through the years

We transfer the timeline onto cells. The rows are continuum non-abelian Yang–Mills (no matter fields) in $d = 2, 3, 4$ and the four-dimensional lattice, and the columns are the six steps (7-01). The regularisation step and the finite-volume step build the measure $\mu_{a,L}$ on the lattice, and close on the lattice (7-10 § 03). In three and four dimensions the finite-volume measure has not yet been built while staying in the continuum, so the finite-volume step there is written "Closed (lattice)". The construction published in 2026 does not build a continuum probability measure either (16-02 § 03), so the four-dimensional finite-volume cell stays "Closed (lattice)".

The names of the states are the same as in Table 2 of 7-01: **Closed** (there is a theorem), **Partial** (with assumptions, in outline, up to estimates of the partition function, or only part of the requirements; "with a hypothesis" in Table 2 of 7-10 also goes here), **Not yet**, and — (the question is hard to pose in that form; 7-02). The state in year y is fixed by the record of the last change (y_k, c_k, v_k) at or before y.

$$s_C(y) = v_k, \qquad k = \max\{\, k : \; y_k \le y, \; c_k = c \,\} \quad (4)$$

Figure 1 Moving the year with the knob fills the cells with the theorems up to that year (press a row of Table 1 or Table 2, or select a row and press Enter, to go to that year)



Computed The numbers in this figure were computed on this machine (formula (4)). How the cells are divided and how the states are decided is this chapter's choice.

Computed Table 3 The board in 2026 (state, and the year it reached that state). The three four-dimensional cells of 2026 are at the level of the committee's assessment. The three cells of the lattice row do not correspond to the step columns.

	1 Regularisation	2 Finite volume	3 Ultraviolet limit	4 Infinite volume	5 Axioms	6
2D continuum	Closed 1974	Closed 1974	Closed 1989	Closed 1989	Partial 1989	—
3D continuum	Closed 1974	Closed (lattice) 1974	Partial 1985	Not yet	Not yet	N
4D continuum	Closed 1974	Closed (lattice) 1974	Closed 2026 (Partial from 1989)	Partial 2026	Closed 2026	N
Lattice cells	**Strong coupling**		**Weak coupling, continuous group**		**Weak coupling, finit**	
4D lattice (fixed spacing)	Closed 2022 (Partial from 1978)		Not yet		Closed 2022	

Example: the board moved in six years, 1974, 1978, 1985, 1989, 2022 and 2026, and the continuum cells did not move from 1989 to 2025. Of the 21 cells, 12 are Closed, 3 Partial, 5 Not yet and 1 —. Computed The three cells of 2026 (the four-dimensional ultraviolet limit, infinite volume and axioms) are filled in with the published construction, at the level at which the committee assessed it as “proved in Lean” Assessment . The infinite-volume cell is made "Partial" because the limit is taken along a subsequence and uniqueness is not shown (16-02 § 02). Table 2 of 7-10 makes the infinite-volume step of the lattice "Closed" at strong coupling by OS 1978. The lattice cells of this chapter count the infinite-volume step and the uniform-gap step (gap) as one, so 1978 is "Partial". The axiom step in two dimensions goes as far as Euclidean invariance of gauge-invariant expectations (Corollary 6.7 of Driver 1989), with no claim in the form of the OS axioms, so it is "Partial". The uniform-gap step in two dimensions has no propagating degrees of freedom and the question is hard to pose, so it is "—" (both as in Table 2 of 7-01). Known

The strong-coupling lattice cell becomes "Partial" in 1978 and "Closed" in 2022. Osterwalder–Seiler 1978 gave the convergence of the cluster expansion in outline, and the gap (exponential clustering) follows from that convergence. The proof of uniqueness and a positive mass gap in an explicit range is Shen–Zhu–Zhu 2022 (both according to the introduction of SZZ; the abstract of OS 1978 states the existence and analyticity of the infinite-volume limit at strong coupling and Wilson's confinement estimate; 5-02 § 08). Known That the continuum cells did not move from 1989 to 2025 is not because there was no progress. Progress *inside* the cells, such as the characterisation of the two-dimensional measure by Langevin dynamics and the dynamics in three dimensions, did not show up on the coarse board (this chapter's reading; for the words of the literature step by step, see 7-10).

05

Tables by dimension

We rewrite the rows of the board in the language of addresses. The columns are the lattice (fixed spacing), the inside and the outside of the double limit (7-01), and the axioms and the gap. $\mu_{a,L}$ is the measure on a box with lattice spacing a and side L.

$$\mu = \lim_{L\to\infty} \underbrace{\lim_{a\to 0} \mu_{a,L}}_{\text{continuum, finite volume}} \tag{5}$$

Known Table 4 Where things stand, by dimension (non-abelian, no matter fields).

d	Lattice (a fixed)	Continuum, finite volume	Continuum, infinite volume	Axioms, gap
2	Exactly solvable (7-02)	Closed surfaces, T^2: Sengupta, Lévy, CCHS, Chevyrev–Shen	$\mathbb{R}^2$: Driver, Gross–King–Sengupta	The literature makes no claim (the observables are loops)
3	Infinite volume and exponential decay at strong coupling	Ultraviolet stability (estimates of the partition function). The measure not constructed; up to the state space and dynamics	Not yet	Not yet

d	Lattice (a fixed)	Continuum, finite volume	Continuum, infinite volume	Axioms, gap
4	Infinite volume and exponential decay at strong coupling. At weak coupling, finite groups only	The continuum limit in a periodic box (the published construction, 2026; correlation functions converge along the whole sequence of cutoffs; no continuum probability measure is built) Assessment . Before that, ultraviolet stability with a hypothesis (Bałaban) and an outline with an infrared cutoff (MRS)	Limits along subsequences and phase decomposition (the published construction). Convergence and uniqueness of the limit are not shown Assessment	The Wightman axioms phase by phase (the published construction) Assessment . The gap: not yet

That **two dimensions** is closed up to continuum and infinite volume is due to its exactly solvable structure (independence of plaquettes and the heat kernel of the group; 7-02). **Three dimensions** is said to be easier, but the continuum measure is 'open, even in finite volume' (7-06). In **four dimensions**, up to 2025 the ultraviolet-limit step was with a hypothesis and in outline in finite volume, and there were no theorems from the infinite-volume step to the uniform-gap step (7-07) Known . The construction published in 2026 filled the ultraviolet-limit step, the infinite-volume step (along a subsequence) and the axiom step Assessment (6-01). The uniform-gap step remains open (16-02 § 04).

Example: the four-dimensional "Continuum, finite volume" of Table 4 corresponds to the ultraviolet-limit step of Table 3 (Closed from 2026), and the "Lattice" column to the lattice row of Table 3. The outline of MRS removes the ultraviolet cutoff but keeps the infrared cutoff. The published construction takes the ultraviolet limit in a periodic box and then passes to infinite volume along a subsequence (8-05).

06

Comparison with neighbouring theories: the scope of "it has been done in two and three dimensions"

Saying "it has been done in two and three dimensions" is correct for non-abelian Yang–Mills only in two dimensions. What it fits up to three dimensions is abelian groups and scalar fields (16-08). We line up the "Comparison" rows of the timeline. None of them moves a cell of the board. Known

Known Table 5 How far neighbouring theories have got (the "Comparison" rows of the timeline).

Theory	d	How far it has got
U(1) Higgs (an abelian gauge field and a charged scalar field)	2, 3	In two dimensions up to the OS axioms (Brydges–Fröhlich–Seiler). The problem statement calls it "the only complete example of an interacting gauge theory satisfying the axioms". In three dimensions, the continuum infinite-volume limit (King)

Theory	d	How far it has got
ϕ^4_3 (weak coupling)	3	The Wightman axioms (JW § 6.2) and a mass gap (Feldman–Osterwalder)
Pure U(1) gauge theory	4	The limit from lattice to continuum (Driver 1987). The limit is expected to be the free electromagnetic field (the explanation in 7-10). The lattice has a non-confining phase at large β (Guth, Fröhlich–Spencer)
ϕ^4_4	4	The limit of lattice-regularised $\lambda\phi^4$ at infinite volume and zero lattice spacing is Gaussian (Aizenman–Duminil-Copin). Triviality for $d \geq 5$ is Aizenman, Fröhlich
Two-dimensional O(3) and O(4) sigma models (asymptotically free, with non-abelian global symmetry)	2	There is a manuscript with claims in `github.com/openai/math` (result group 215), made public on 2026-10-06. Exponential decay of correlations on the lattice at all temperatures (n ≥ 3, uniform over finite subgraphs) comes **with a Lean formalisation**. The continuum limit of O(3) (OS axioms, a unique vacuum, a positive mass gap, non-Gaussian) and the asymptotics of the lattice mass for O(4), m ∼ 32e^(π/4−1/2) √ β e^(−πβ) (the same constant as predicted by Hasenfratz–Maggiore–Niedermayer 1990), are **in a paper manuscript only, unverified**

Two-dimensional sigma models, unlike two-dimensional YM (7-02), have asymptotic freedom and dimensional transmutation, so they are the closer example of "a problem of the same shape" as four-dimensional YM. They have no gauge symmetry and no confinement. This row does not move the four-dimensional cells of the board (Table 3).

The two four-dimensional rows are both examples where the limit is a free (Gaussian) field. For asymptotically free (4-06) Yang–Mills a non-trivial limit is expected, but there is no proof (7-08). Physics Even in the same four dimensions, ϕ^4 becomes strongly coupled at short distances, while Yang–Mills becomes weakly coupled. The directions are opposite, so the triviality theorems for ϕ^4 do not apply to Yang–Mills. Example: comparing in three dimensions, ϕ^4_3 has passed all six steps (Table 2 of 7-01). Non-abelian Yang–Mills is Partial at the ultraviolet-limit step, and Not yet from the infinite-volume step on (Table 3).

07

Where the lattice theorems lie on the number line of β

At strong coupling the high-temperature expansion (expansion in powers of small β, also called the strong-coupling expansion; 5-02) works routinely, and gives exponential decay even for continuous Lie groups (according to the introductions of Adhikari–Cao and Shen–Zhu–Zhu; Osterwalder–Seiler 1978 abstract only). At weak coupling, uniqueness of the infinite-volume limit of lattice gauge theory is in general not known for $d > 2$ with large β (Chatterjee 2018 § 3). That is the side the continuum limit needs (5-05). Known

Converting the conditions of two theorems to one β

Converting the conditions of Shen–Zhu–Zhu, with weight $\exp(N\beta\,\mathrm{Re}\sum_P \mathrm{Tr}\,U_P)$, and of Adhikari–Cao, with weight $\exp(-\beta\sum_P \mathrm{Re}(\chi(1)-\chi(U_P)))$ (χ is the character of a representation), to the β_W of formula (2) gives

$$\beta_W = N^2\beta_{\mathrm{SZZ}} < \frac{N^2}{16(d-1)}, \qquad \beta_W = 2\beta_{\mathrm{AC}} \geq \frac{2\,(114+4\log|G|)}{\Delta_G}, \qquad \Delta_G = \min_{g\neq 1} \mathrm{Re}(\chi$$

(Δ_G is the notation of Adhikari–Cao, not the mass gap Δ_G of 16-05 and 16-08). It is related to the β of 7-10 § 05 (Chatterjee's convention $e^{-\beta\sum_p \mathrm{Re}\,\mathrm{tr}(I-U_p)}$) by $\beta_W = N\beta_{\mathrm{Ch}}$, and the $|\beta| < N/48$ of 7-10 is the same condition as $\beta_W < N^2/48$ ($d=4$) in this chapter. Adhikari–Cao allow any unitary representation ρ of G, with $\chi = \mathrm{tr}\,\rho$. Here we take ρ to be the inclusion $G \subset SU(2)$, which gives Wilson's model with link variables restricted to G ($\chi(1)=2$, so $\beta_W = 2\beta_{\mathrm{AC}}$). log is the natural logarithm.

The former is $\beta_W < 0.25,\ 0.125,\ 0.083$ for $d = 2, 3, 4$ with $SU(2)$, and 9/4 times that for $SU(3)$. Computed Example: $\beta_W < 1/12$ at $d=4$ is 1/27 of the $\beta_W = 2.25$–2.60 ($SU(2)$, Lucini–Teper 2001) Physics that lattice numbers use to extrapolate to the continuum, and the condition $\beta_W \geq 697$ for the binary icosahedral group is 268 times the upper end of that range. Computed

Figure 2 Choosing a finite group $G \subset SU(2)$ with the knob moves the position where the Adhikari–Cao theorem starts to apply (the left end of the green on the right). The green on the left is the strong-coupling theorem, and the dashed lines are lattice numbers

Computed The numbers in this figure were computed on this machine (the groups built by closure from generators with their orders checked, and formula (6) computed). The range of lattice numbers is from the literature.

Computed Table 6 Finite subgroups of $SU(2)$ (defining representation) and the condition of formula (6). The defining representation is the matrices themselves, and the character is the trace (1-02). The smallest angle is the θ of the eigenvalues $e^{\pm i\theta}$ of the element nearest the identity.

Group	Order	Smallest angle	Δ_G	$\beta_W \geq$
$\{\pm 1\}$	2	180°	4	58.4

Group	Order	Smallest angle	Δ_G	$\beta_W \geq$
Quaternion group Q_8	8	90°	2	122.3
2T (binary tetrahedral group)	24	60°	1	253.4
2O (binary octahedral group)	48	45°	0.5858	442.1
2I (binary icosahedral group)	120	36°	0.3820	697.2
$2D_{50}$ (binary dihedral group)	200	3.6°	0.00395	68512

How to read Table 6

(a) The thresholds are constants that appear in the proofs, not the positions of phase transitions. (b) The finite subgroups of $SU(2)$ are only the cyclic groups, the binary dihedral groups, and three exceptions of order 24, 48 and 120. Known The groups whose names carry "binary" are rotation groups in $SO(3)$ pulled back by the double cover $SU(2) \to SO(3)$ (1-02). The binary tetrahedral, octahedral and icosahedral groups are the inverse images of the rotation groups of the regular polyhedra, and the binary dihedral group $2D_n$ is the inverse image of the rotation group of the regular n-gon (the dihedral group of order $2n$); each has twice the order of the original. For $2D_n$ (order $4n$), $\Delta_G = 2 - 2\cos(\pi/n) \approx \pi^2/n^2$, so the condition recedes roughly in proportion to n^2. Computed (c) With the one-loop $\xi \propto e^{3\pi^2 \beta_W/11}$ ($SU(2)$), each reduction of the lattice spacing to 1/10 increases β_W by about 0.86 (a one-loop rough guide; for two-loop corrections and the fact that asymptotic scaling does not yet hold in this range of β, see 5-05). Physics Why results for finite groups do not carry over to continuous groups is in 5-10, and the strong-coupling expansion in 5-02.

The β knob — two shores and a band on one axis

On the number line of Figure 2 we overlay the correlation length ξ in lattice units. The left shore is the strong-coupling theorems (the condition (9) of SZZ, and the paper of this site Paper ; 23-01 The line of construction and the diffusive-relaxation-time assumption) and the leading strong-coupling term $\xi = -1/(4 \ln u)$; the right shore is the two-loop formula (16-05 (10), $C = 185$) and Bałaban's hypothesis. The hypothesis is that the effective coupling is small enough, and no value is written (7-07 § 04), so a rough guide reading $g^2 \leq \gamma$ as $\beta \geq 4/\gamma$ is moved with the γ knob. In the middle are the numerical window 2.25–2.60 (Lucini–Teper 2001) and the band 1.75–2.6 where neither leading term is within 5% for the plaquette (16-05 Figure 1). Physics

The lower panel is the range of β over which the statements of 23-01 The line of construction and the diffusive-relaxation-time assumption are needed (this book's arrangement). The role of crossing the band falls to the infinite-volume uniqueness statement, the physical-unit gap statement and the relaxation-time band at the

bookkeeping length, which are needed at each β. The reflection-positivity preservation statement holds at every β; the Wilson-loop limit statement, the rotation-recovery statement and the non-triviality statement are statements about the $\beta \to \infty$ limit; and the OS reconstruction statement is a theorem independent of β. Known Theorems exist only at the left end, and the smaller γ is made, the further the rough guide for the right shore recedes.

Figure 3 Moving the vertical line with the β knob shows below the ξ at that β (leading strong-coupling term, two loops, numerical) and what exists there. The γ knob moves the side of Bałaban's hypothesis (the rough guide $\beta \geq 4/\gamma$). Both axes logarithmic

Computed The curves are (9)(10) of 16-05 computed on the spot (Bessel functions by series; Table 7 gives the same values with scipy). The points and window values are Lucini–Teper 2001 Physics .

Computed Table 7 Markers of β in Figure 3 and ξ (in lattice units; the column "ξ numerical" is the $1/(am)$ of 16-05 Table 3).

β	ξ leading strong-coupling term	ξ two loops (C=185)	ξ numerical	What is at this β
0.08333	0.065	—	—	Edge of condition (9) of SZZ (β < 1/12)
0.2722	0.093	—	—	Edge of the condition of this site's paper (β < 0.2722)
1.5	0.234	0.127	—	Right end where the leading strong-coupling term is within 5% for the plaquette
1.75	0.266	0.233	—	Left end of the band (neither leading term within 5%)

β	ξ leading strong-coupling term	ξ two loops (C=185)	ξ numerical	What is at this β
2.25	0.333	0.806	0.72	Left end of the numerical window
2.3	0.340	0.914	0.92	
2.4	0.354	1.17	1.05	
2.475	0.365	1.42	1.33	
2.55	0.375	1.72	1.71	
2.6	0.383	1.95	1.95	Right end of the numerical window and of the band
2.75	0.405	2.85	—	Left end where the leading weak-coupling term is within 5% for the plaquette
3.243	—	10	—	ξ = 10 at two loops (rough guide for extrapolation)
4.136	—	100	—	ξ = 100 at two loops (rough guide for extrapolation)
5.022	—	1000	—	ξ = 1000 at two loops (rough guide for extrapolation)
8	—	2.49×10^6	—	Side of Bałaban's hypothesis if γ = 0.5 (rough guide β ≥ 4/γ)
20	—	1.8×10^20	—	Side of Bałaban's hypothesis if γ = 0.2 (rough guide β ≥ 4/γ)

08

Detour: what the timeline leaves out

A section you may skip.

One comes across postings claiming to have proved the Yang–Mills problem. This chapter puts a row in the timeline under two conditions.

$$\text{include} \iff (\text{text or abstract checked}) \wedge (\text{address (1) can be written}) \quad (7)$$

Preprints that have not been peer-reviewed are included with a mark. Postings claiming to have proved the prize problem itself are not included unless there is a record of verification by experts (there are also cases where arXiv moderators withdrew one on grounds of the standard of its content). Physical numbers and holographic models measure after putting that "the theory exists" (17-13), and do not move cells. Example: the 1999 row of lattice numbers does not change the colour of any cell. The study in Part 23 of this book (23-01) is also outside the board.

The construction published in 2026 is included because there are the committee's assessment report and statement.

What this chapter can say

	Content
What is said	The content of the 37 rows of the timeline (the kind of checking is in the table of sources) Known . The row of the construction published in 2026, and the three 2026 cells of the board, are at the level of the committee's assessment Assessment
What is said	The board and the counts of rows under this chapter's way of deciding the cells. The conversion of formula (6), and the orders, Δ_G and condition values of the finite subgroups Computed . The ξ of Figure 3 and Table 7 restate the formulas and numbers in the text, and the assignment of β ranges to the eight statements of construction is this book's arrangement
What is not said	That the timeline is exhaustive. Other ways of dividing the cells. The grounds for the 1978 judgement of the strong-coupling cell are statements in the introductions of Shen–Zhu–Zhu and Adhikari–Cao; the main text of Osterwalder–Seiler 1978 has not been read. That the limit of Driver 1987 is the free electromagnetic field (main text: bibliographic data only). Drawing conclusions about the relation between finite-group models and weakly coupled $SU(2)$ from the thresholds of Table 6. This site shows nothing about any of the steps in four dimensions from the ultraviolet-limit step to the uniform-gap step (what moved cells in 2026 is the published construction). Whether the proof of the published construction is correct (cited as the committee assessed it)

Next chapter to read: 16-02 Five open questions. The questions left by the published construction are read following the five in the assessment report. The places where the ways physics and mathematics dig come apart are in 16-05.

Five open questions

This chapter is a map of what is unsolved. § 01 is existing knowledge (quotations from the assessment report).

What this chapter shows — For the construction of the existence of four-dimensional Yang–Mills published in 2026, we read one by one the five questions that the committee's assessment report lists as "the main points this work does not address". For each question we set out (1) what is needed, as mathematics, to answer it, (2) what is present on the side of the construction's Lean code as preparation for it, and (3) what is absent. Present: polynomial estimates uniform in the phase, uniqueness of the vacuum in each component, and parallel transport along lattice paths. Absent: exponential decay, continuum Wilson loops, and boundary conditions other than periodic ones.

Chapters this one relies on — 6-04 What is not shown, 12-05 Arzelà–Ascoli and the properties that pass to the limit, 12-07 Phase decomposition, 4-11 The definition of the mass gap.

Said first — The results of the published construction are cited at the level of "the committee's assessment is that they are proved in Lean". What this book's study has checked goes only as far as reading the definitions and the forms of the statements in the source. "Absent" means "not found within the range of a search of names and documentation strings"; the possibility that the same content exists under another name cannot be excluded. This chapter is a map of questions, and answers none of them.

Order of this chapter

1. The five questions of the assessment report — a summary of § 8 of the report
2. Convergence and uniqueness — the ultraviolet along the whole sequence, infinite volume along a subsequence
3. A continuum probability measure — the table of correlation functions and the reconstruction space
4. A uniform mass gap — polynomial estimates, and uniqueness of the vacuum in each component

5. Wilson loops and the area law — as far as parallel transport along lattice paths
6. One-particle states — tools for single-insertion states
7. Summary (Table 1) — what is needed, what is present, what is absent
8. Notes on reading — what "absent" means, and how the questions relate

---

Labels — Source = the source of the published construction was read / Inferred = this book's inference / Assessment = according to the committee's assessment report (for details, see “Labels” in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are labels used throughout the book; Reading is this book's reading of numbers, and Lean is a Lean theorem of this book.

Names of the sources: the code of the published construction is `yang-mills-group/OpenAI-YM-20261028` (Apache-2.0, submitted 2026-10-28), and the assessment report is `docs/assessment-1.pdf` in `yang-mills-group/YM` (2026-11-10). Locations in the code are given as relative paths within that repository, with declaration names and line numbers.

01

The five questions of the assessment report

At the opening, the assessment report judges that the submission proves that, for any simple compact group, a relativistic quantum field theory satisfying the Wightman axioms can be constructed as a scaling limit of four-dimensional Wilson lattice gauge theory, and writes that it does not prove that the infinite-volume limit is unique, nor the mass gap Assessment (the summary at the opening of the report). The way of construction — correlation functions first take the limit in a finite physical volume, and pass to infinite volume along a subsequence obtained by compactness — is also explained in the same place Assessment . § 8 lists five main points the construction does not address Assessment . In summary:

1. **Convergence and uniqueness.** To show convergence and uniqueness of the infinite-volume limit, rather than finding a convergent subsequence.
2. **A continuum probability measure.** To define a probability measure of the continuum theory on a suitable space, and have the Schwinger functions of the construction arise from it.
3. **A uniform mass gap.** To show a uniform mass gap: exponential decay of the corresponding correlations, and a gap in the spectrum of the Osterwalder–Schrader

Hamiltonian.

4. **Wilson loops and the area law.** To build Wilson-loop observables and connect them with the local observables of the construction. To show the area law for Wilson loops.
5. **One-particle states.** To build one-particle states and analyse the energy–momentum spectrum. The report adds that this analysis has been carried out in many constructive models in two and three dimensions.

What the Jaffe–Witten problem statement (0-03) asks for is existence and a mass gap. Of the five, 3 corresponds to the latter half; 1, 2, 4 and 5 are questions for bringing the construction closer to "a complete description of Yang–Mills theory". Below we read each question in the order: what is needed as mathematics, what is present on the side of the code, and what is absent.

02

Convergence and uniqueness

What is needed. That the correlation functions converge along the whole sequence of increasing volumes (without taking a subsequence), and that the limit does not depend on how the sequence is chosen. In other words, that the infinite-volume limit is determined uniquely Proved here .

What is present.

- The ultraviolet limit (the limit sending the lattice spacing to 0) is taken along the whole sequence of cutoffs once the volume is fixed. The conclusion of the construction theorem `constructed` (`Construction.lean:15`) contains the position statement `FullVolume.PositionsUV` along the whole sequence (`Extraction.Sequence.full`) Source . In the public theorem `JointExistence` (`ChallengeSpec.lean:186`) as well, the convergence field `Converges` (`PublicWilson.lean:85-90`) requires, in each volume, convergence along the whole sequence of cutoffs; only the volume side is a subsequence Source . The strong form with kernels and differences (`PositionsUV … Sequence.full`) is present only in the construction theorem `constructed` Source .
- The infinite-volume limit is taken as a subsequence, by Arzelà–Ascoli from boundedness and equicontinuity (`Extraction.first_surface`, `YM/Extraction/Lipschitz.lean:166`; `crops`, `YM/Extraction/Held.lean:136`) Source . For how to read this, see 12-05.
- The uniqueness lemma for limits `Extraction.Order.unique` (`YM/Extraction/Orders.lean:70`) is the general fact about Hausdorff spaces that two limits along the same subsequence are equal Source . It does not say that the limit is

independent of the choice of the sequence of volumes. In the record of how declarations are used, it is not reached from any headline theorem (outside) Source .

What is absent. Estimates of the difference when the volume is changed, decay of correlations, and material for uniqueness of the limit do not enter where the infinite-volume limit is taken Source . The only inputs are upper bounds for boundedness and equicontinuity.

Uniqueness in the volume and the "uniqueness of the vacuum in each component" of the phase decomposition (§ 04) are different questions. The former is uniqueness of the limiting measure; the latter is uniqueness of the vacuum in each component within one limit.

03

A continuum probability measure

What is needed. A probability measure on a space of distributions (or a suitable quotient of the space of connections) whose moments are the Schwinger functions of the construction Proved here . It would also be the foundation for handling non-local observables such as Wilson loops.

What is present. The objects of the construction are a table of correlation functions indexed by labels of local fields (`Table`) and the Osterwalder–Schrader space built from it Inferred (for how to read this, see 12-08). On the lattice side, the Wilson measure at each lattice spacing and each volume is defined as a probability measure (`law` in `YM/Wilson/Law.lean:87`) Source .

What is absent. No definition of a probability measure of the continuum theory has been found Inferred (within the range of a name search). There is neither a statement taking the limit of the sequence of lattice measures as a measure, nor a definition giving a name to the limiting measure. For the effective density at a fixed coarse step, there is as far as convergence of that sequence (16-03).

04

A uniform mass gap

What is needed. That there is some $m > 0$ such that the spectrum of the reconstructed Hamiltonian H lies in $[m, \infty)$ away from the vacuum. In the language of correlations, the same thing is that two-point correlations decay exponentially in the distance at a rate at least m (4-11). If the limit splits into components (phases), that m must also be uniform over the components Proved here .

What is present.

- **Polynomial estimates uniform in the phase.** For a finite word w, for all phases i and $u \in (0,1]$, the spectral weight at energy $(0,u]$ is $\leq M\,u^2$ (`EveryPhase.light_bound`, `YM/EveryPhase/Light.lean:221`). For the heat semigroup, for all phases and $s \geq 1$, $0 \leq \langle A, (e^{-sH} - P_0)A\rangle \leq M\,s^{-2}$ (`EveryPhase.inverse_square`, `YM/EveryPhase/Decay.lean:173`; P_0 is the projection onto the zero-energy space) Source . The constant M does not depend on the phase.
- **Uniqueness of the vacuum in each component.** That, in each component of the phase decomposition, the zero-energy space consists only of multiples of the vacuum (`UniqueHeat`, `YM/Phase/Mixture.lean:35`) is stated for all components (`EveryPhase.every`, `YM/EveryPhase/Vacuum.lean:146`) Source . No speed (rate) is attached.

The polynomial estimates come from a far-distance estimate that comes from local commutativity (`EveryPhase.late`, `YM/EveryPhase/Light.lean:208`) Source . The estimate of the weight by u^2 is of a form compatible even with a theory whose spectrum continues down to 0, and does not contain a mass gap Inferred . In other words, the mass-gap question is to "make this u^2 weight 0 below some m" Inferred .

What is absent. No statement of exponential decay (clustering with a rate, a spectral gap) has been found Source (within the range of a name search).

05

Wilson loops and the area law

What is needed. (a) To define Wilson-loop observables (the trace of parallel transport along a closed curve) in the continuum theory. On the lattice they can be written as products of links along a path, but in the continuum the connection itself is a distribution, so arguments of regularisation and limits are needed. (b) To connect them with local fields (the basic observables of the construction). (c) That for large loops the expectation becomes exponentially small in the enclosed area (the area law) Proved here .

What is present. There are parallel transport along lattice paths, `Lattice.travel` (`YM/Lattice/Path.lean:105`), and lemmas for its concatenation, reversal and gauge transformation Source . These are the material for writing Wilson loops on the lattice. The predictor of the probability kernel of one step of renormalisation is also built from framed parallel transport (9-04) Source .

What is absent. Continuum loop observables, the area law, and the relation between loops and local fields have not been found Inferred (within the range of a name search). The lattice Wilson measure is defined only on the periodic torus Source , and other

boundary conditions such as 't Hooft twists, or a quantity corresponding to the vortex free energy, have not been found Inferred (within the range of a name search).

This book's study has the area law in the strong-coupling window on the lattice (20-06) and estimates of the vortex ratio with twisted boundary conditions (Part 21). Both are statements with the lattice spacing fixed, and do not answer (a)–(c) of this question. Their place is described in 16-04.

06

One-particle states

What is needed. A subspace with an isolated spectral shell of mass m ($p^2 = m^2$ in energy–momentum), and tools to build scattering states from it (of Haag–Ruelle type) Proved here . Usually the mass gap (§ 04) is presupposed.

What is present. There is a module dealing with single-insertion states and the spectral representation (`YM/TraceExtension/Damping.lean` , titled "Single insertion point states and spectral representation") Source . Its documentation says it "does not assume mass-gap or cone-support results" Source . Whether this amounts to preparation for one-particle analysis has not been checked Inferred .

What is absent. A definition of one-particle states, isolated shells and scattering states have not been found Inferred (within the range of a name search).

07

Summary (Table 1)

Question	What is needed	What is present on the side of the code	What is absent
Convergence and uniqueness	Convergence along the whole sequence of volumes, uniqueness of the limit	The ultraviolet (cutoff) along the whole sequence, also in the public theorem; infinite volume along an Arzelà–Ascoli subsequence Source . The strong form with kernels and differences only in `constructed` Source . Uniqueness on the same subsequence, `Order.unique` Source	Estimates of the difference when the volume changes, decay, material for uniqueness Source
A continuum probability measure	A measure whose moments are the Schwinger functions	The table of correlation functions and the reconstruction space Inferred . The lattice Wilson measure Source	A definition of the continuum measure Inferred (within the range of a name search)

Question	What is needed	What is present on the side of the code	What is absent
A uniform mass gap	Exponential decay, a spectral gap, a rate uniform over components	Polynomial estimates u^2, s^{-2} uniform in the phase Source . Uniqueness of the vacuum in each component (no rate) Source	A statement of exponential decay Source (within the range of a name search)
Wilson loops and the area law	Continuum loop observables, their relation to local fields, the area law	Parallel transport along lattice paths, `travel` Source	Continuum loops, the area law Inferred (within the range of a name search). Boundary conditions other than periodic Inferred (within the range of a name search)
One-particle states	Isolated shells, scattering states	Tools for single-insertion states and the spectral representation Source	A definition of one-particle states Inferred

Table 1 The five open questions, and the preparation on the side of the code. The wording of the questions follows § 8 of the assessment report Assessment .

08

Notes on reading

- **What "absent" means.** It means not found by searching names, documentation strings (moddoc) and the record of how declarations are used. The possibility that the same content exists under another name cannot be excluded.
- **The level of "present".** What is present is part of what "the committee assessed as proved in Lean", and this book's study has only read the forms of the statements. Which declarations enter the dependency chain of the public theorem is stated only for those checked by following the chain (6-02). For many of the declarations listed in this chapter, the chain has not been checked.
- **How the questions relate.** 3 (the mass gap) is tied to 1 (uniqueness): clustering with a rate is usually a tool for deriving uniqueness of the limit Inferred . 5 (one particle) usually presupposes 3. 4 (the area law) and 3 are different statements, and no general argument deriving one from the other is known Inferred (16-09).
- **This chapter does not answer.** For none of the questions does this book show an answer. The holdings of this book's study and their distance from the questions are described in 16-03 and 16-04. A map of the ideas this book's study has tried for the band is in 16-11.

What this chapter says

What is said	What is not said
Assessment The assessment report accepts the construction of existence, and writes that uniqueness in infinite volume and the mass gap are not proved. The five questions of § 8	Whether the judgements of the assessment report are right
Source Also in the public theorem, the ultraviolet (cutoff) is along the whole sequence and infinite volume along a subsequence (`Converges`; `first_surface`, `crops`). The strong form with kernels and differences is present only in the construction theorem `constructed`	A route to uniqueness in the volume
Source There are polynomial estimates uniform in the phase (`light_bound`, `inverse_square`), uniqueness of the vacuum in each component (`UniqueHeat`, `every`), lattice parallel transport (`travel`), and tools for single-insertion states (`TraceExtension/Damping.lean`)	Whether these enter the dependency chain of the public theorem (not checked)
Inferred A continuum probability measure, continuum Wilson loops, the area law, boundary conditions other than periodic, and one-particle states are not found. The u^2 estimate does not contain a mass gap	Excluding the possibility that they exist under other names

Words used in this chapter — open question, infinite-volume limit, uniqueness, subsequence, probability measure, Schwinger function, mass gap, spectral gap, phase

decomposition, uniqueness of the vacuum, Wilson loop, area law, one-particle state. Their meanings are in the A-02 Glossary.

Next chapter to read: 16-03 The infrared edge of the published construction — reads what is and is not said where the construction stops (the step with lattice spacing 1).

The infrared edge of the published construction

This chapter is existing knowledge (a reading of the published construction). § 05 and § 06 are a map of what is unsolved.

What this chapter shows — We read where the sequence of renormalisation steps of the published construction ends, and what is said there. Every step is carried within the weak-coupling band; the coarsest step has lattice spacing 1, and the coupling there is matched to a large reference value $\bar{\beta}$. The effective density at that step converges uniformly along the whole sequence of cutoffs once the volume is fixed. On the other hand, its limiting measure is not defined as an object, and reflection positivity, the relation to coarse Wilson loops, estimates uniform in the volume, and renormalisation to coarser scales are not stated. We set out precisely that restating the remaining questions as "long-distance questions of the effective theory at the step with lattice spacing 1" is likely right in direction, but that some statements needed to assert this are missing.

Chapters this one relies on — 16-02 Five open questions, 8-02 Sequences of spacings and of volumes, 9-01 The block kernel, 11-10 Convergence at a fixed step, and the step that removes the step index.

Said first — The results of the published construction are cited at the level of "the committee's assessment is that they are proved in Lean"; what this book's study has checked goes only as far as reading the definitions and the forms of the statements in the source. "Not stated" means not found within the range searched. This chapter describes the form of the remaining questions; it does not show a route to answering them.

Order of this chapter

1. A map of the steps — every step at weak coupling, step 0 at spacing 1 — the band of couplings and the reference value
2. The effective density at step 0, and its convergence — uniform in the cutoff, along the whole sequence
3. Correlations are read from fine steps — step 0 is where units are fixed
4. What is not stated about the objects at step 0 — five things

5. Restating the remaining questions — what is right and what is missing — the direction, the points that are not precise, the missing statements
6. From weak coupling to strong coupling — correspondence with this book's "crossover band"
7. What this chapter does not say

Labels — Source = the source of the published construction was read / Inferred = this book's inference / Assessment = according to the committee's assessment report (for details, see “Labels” in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are labels used throughout the book; Reading is this book's reading of numbers, and Lean is a Lean theorem of this book. Sources: relative paths, declaration names and line numbers in `yang-mills-group/OpenAI-YM-20261028` (Apache-2.0); the assessment report is `docs/assessment-1.pdf` in `yang-mills-group/YM` (2026-11-10).

01

A map of the steps — every step at weak coupling, step 0 at spacing 1

The construction starts from the Wilson measure at cutoff N (the finest step), applies one step of renormalisation by a probability kernel (9-01) N times, and coarsens through steps $N, N-1, \dots, 0$.

- **The lattice.** The lattice at step m is a periodic lattice of side $L_p \cdot D_m$, with lattice spacing $a_m = 1/D_m$ (`Schedule.side`, `YM/Lattice/Scale.lean:67`) Source . Step 0 has side L_p and lattice spacing 1, and is the coarsest step. The volume L_p is measured in the units of step 0 Source .
- **The coupling.** At every step $m \le N$, the coupling $\beta(N, p, m)$ of step m lies in the band $[\hat\beta_m/2,\ 2\hat\beta_m]$ (the field `Conv.band` of the induction hypothesis, `YM/RG/History.lean:218`) Source . $\hat\beta_m$ is the reference value $\bar\beta$ plus the one-loop running $s\log(1/a_m)$ (`Calendar.hatBeta`, `YM/RG/History.lean:79`; `scale`, `YM/Lattice/Scale.lean:115`), and at step 0, since $a_0 = 1$, $\hat\beta_0 = \bar\beta$ Source . s is the one-loop slope, with value $11C_g/(24\pi^2)$ (`slopeConstant`, `YM/Gauge/Colors.lean:184`) Source .
- **Matching at step 0.** For all N, p, $\beta(N, p, 0) = \bar\beta$ (`Selected.reaches`, `YM/RG/History.lean:239`) Source . The bare coupling at each cutoff is chosen by the

shooting method so as to satisfy this condition (10-04).

The size of the reference value. In the record of the construction (`Paid.bar`, `YM/Price/Intent.lean:148`), the reference value $\bar{\beta}$ is set equal to the barrier value `Bar.value`, and the barrier is subject to the condition "$x^{-1/2} e^{(\log\log x)^2} \le 1$ for all $x \ge \bar{\beta}$" (`Bar.threshold`, `YM/Price/Intent.lean:127`) Source. From this condition alone, $\bar{\beta}$ comes out at roughly 9×10^5 or more (the threshold being 8.97×10^5) Reading (a floating-point computation of the threshold $x \approx 8.97 \times 10^5$ beyond which the inequality holds for all x). The other condition is that the entry value `betaEntry` (same file, `:116`) is at most $\bar{\beta}$ (same file, `:126`), but the source gives no formula or number for the entry value, only its existence Source. Since the coupling at every step is at least $\hat{\beta}_m/2 \ge \bar{\beta}/2$ Source, it reads that **every step is within the weak-coupling band, and the strong-coupling region is never passed through** Inferred. This is a design choice of the construction, in a form that avoids the difficulty on the strong-coupling side (that there is no estimate that works with the same constants in every band) Inferred.

02

The effective density at step 0, and its convergence

The density. The effective density $\mathrm{eval}_{N,p,m}$ at step m, for cutoff N and volume p, is a function on configurations of the coarse lattice at step m; it is non-negative, and its integral against the reference measure (the product of Haar probability measures over links) equals the partition function Z_N (`History.partition_eq`, `YM/RG/History.lean:242`) Source. Successive steps are linked by the push-forward identity with the probability kernel that uses the coupling $\beta(N, p, m+1)$ of step $m+1$ (`Transfer`, `YM/RG/History.lean:223`) Source. In the language of measures, the normalised $\mathrm{eval}_{N,p,m}/Z_N$ is the density of the probability measure obtained by pushing the bare Wilson measure forward $N - m$ times by the kernel Inferred (combining the three identities; there is no statement in the form of an identity of measures).

Since the kernel depends on $\beta(N, p, m+1)$, this push-forward is not "the Wilson measure sent by a fixed map"; the map itself moves with N Source.

Uniform convergence in the cutoff. Fixing the step m and the volume p, and viewing the density coals_N, with the vacuum constant $e^{-v|\Lambda|}$ removed, as a sequence in N:

- It is uniformly bounded and uniformly Cauchy in the sup norm on the configuration space (`FullVolume.Retreat.Flux.fanned`, `YM/FullVolume/Fields/Cement.lean:50`) Source.

- Its integral (the normalisation constant) is also Cauchy (`Flux.lacks`, same file, `:56`) Source .
- Within the construction, this is obtained for every step $m \geq 0$ (including step 0) and every p, along the whole sequence of cutoffs (without subsequences) (`sees`, `YM/FullVolume/Fields/Filled.lean:30`) Source .

Uniform convergence of the normalised density eval/Z_N is not a named statement, but it follows in one line from the uniform Cauchy property of the numerator, the Cauchy property of the denominator, and a positive lower bound on the denominator independent of N (`lingers`, `YM/FullVolume/Fields/Till.lean:20`) Inferred . Since the configuration space is compact and the reference measure is a probability measure, convergence in the sup norm includes convergence in total variation, and is stronger than weak convergence Inferred .

03

Correlations are read from fine steps

Continuum correlations are read not from step 0 but from a fine step j. The difference between the value computed on the representation at step j using the step-j image of the observable and the true lattice correlation is bounded by a quantity independent of N (`Sever.echoes`, `YM/FullVolume/Fields/Peat.lean:42`), and becomes small as $j \to \infty$ under a condition on the separation of points Source . Combining this with the Cauchy property at a fixed step j (`latter`, `YM/FullVolume/Fields/Timber.lean:58`), the true lattice correlation becomes Cauchy in N (`arrives`, same file, `:74`) Source .

In this line of argument, step 0 is "where units are fixed by $\bar{\beta}$", and is not used in estimating correlations Inferred . For distances longer than step 0, the volume L_p is simply placed in the units of step 0, and the infinite-volume limit is taken by compactness along a subsequence (12-05) Source .

04

What is not stated about the objects at step 0

1. **The limiting measure.** The $N \to \infty$ limit of the measure at step 0 (or at any step) is not defined as an object. No definition giving a name to a limiting density or limiting representation has been found Source (within the range of a name search). What there is goes only as far as the materials of the representation (couplings, activities, path data) being Cauchy in N, or converging to some limit Source . That the limit has a representation of the same form, or that it is consistent across steps, is also not stated.

2. **Reflection positivity.** The statement of reflection positivity (`Slice.reflected_positive`, `YM/Slice/Reflection.lean:98`) is only about the bare Wilson measure Source . Reflection positivity of the pushed-forward measure at step 0 is not stated Source (within the range of a name search). Since the support of the kernel can be large enough to straddle the mirror plane (`fitsPatch`, `YM/RG/History.lean:110`), we infer that the push-forward does not automatically inherit reflection positivity Inferred .
3. **The relation to coarse Wilson loops.** The relation between Wilson loops of configurations at step 0 and Wilson loops of the fine field (or the continuum) is not stated Source (within the range of a name search). Since a coarse bond is a prediction from framed parallel transport multiplied by a fluctuation (`connector`, `YM/RG/Block.lean:39`), we infer that a coarse loop is close to "parallel transport along a thick path, with fluctuations" Inferred .
4. **Estimates uniform in the volume.** Estimates for the objects at step 0, such as the lower bound on the normalisation constant (`till`, `YM/FullVolume/Fields/Till.lean:9`) and the constant in the difference estimate (`refreeze`, `YM/FullVolume/Fields/Flight.lean:28`), contain exponentials of the number of lattice points $|\Lambda|$, and are not uniform in the volume p Source . What could be read as estimates uniform in the volume are things like the size of observables measured by the chessboard root on the side of the Wilson measure (`Extraction.Wcmain`, `YM/Extraction/Center.lean:38`; for how to read this, see 12-02), and these are not estimates of the measure at step 0 Source . The bookkeeping of one step itself (the norms of activities and the contraction constants) consists of pointwise sums and does not depend on the volume Source .
5. **Renormalisation to coarser scales.** Step numbers are natural numbers, and step 0 is the coarsest step. No theorem continuing renormalisation to scales coarser than step 0 has been found Source (within the range of a name search). The group of modules with ultraviolet extension in their names (`YM/Extension/UV/`) is a separate route on the ultraviolet side, not a continuation to the coarse side Source (documentation).

05

Restating the remaining questions — what is right and what is missing

Among the open questions of the assessment report, uniqueness in infinite volume, the mass gap and the area law (1, 3 and 4 of 16-02) are all questions about long-distance behaviour. We consider restating them as "long-distance questions, as $L_p \to \infty$, of the effective lattice theory at step 0 (with large coupling $\bar{\beta}$ and lattice spacing 1)".

Facts that can be read from the source Source .

- Every step is carried within the weak-coupling band, and at step 0, $\beta = \bar{\beta}$.
- The volume L_p is measured in the units of step 0.
- Behaviour at distances longer than lattice spacing 1 (exponential decay, the area law, uniqueness of the volume limit) is not dealt with in any theorem Source (within the range of a name search).

On the basis of these facts, restating the remaining questions as "long-distance questions of the theory at step 0 ($\bar{\beta}$ large, $L_p \to \infty$)" is likely right in direction Inferred. Since the coupling at that step is on the weak-coupling side, it is this book's inference that they can be further restated as "the question of following the effective lattice theory at spacing 1 from weak coupling to strong coupling" Inferred.

Neither can be asserted. The theory at step 0 is not a theory with the Wilson action but a theory with an effective action given by a representation made of a truncated action, activities and path data, and $\bar{\beta}$ is a coefficient in that representation. The representation is not unique Source. Reflection positivity of that measure is not stated either (§ 04). What can be written is only "the main part of the remaining questions is likely to be reducible to exponential decay at long distances in the effective theory at step 0" Inferred.

Points where this is not precise.

- (a) Continuum correlations are not functions of the measure at step 0 alone. The true correlation can be sent to step 0 as the push-forward of a density with the observable inserted, but to write it as an expectation under the measure at step 0, the image of the observable at step 0 is needed Source.
- (b) Convergence of the image of an observable at step m (`Rising.hail`, `YM/FullVolume/Fields/Capital.lean:57`) is stated only for m at or above a reference step for each observable. For observables whose reference step is above 0, the image at step 0 is not dealt with Source (a field of the hypotheses).
- (c) The estimate of the difference between a fine step and the true correlation (§ 03) is used only in the direction $j \to \infty$, and the error of reading out at step 0 is not small Source.

Statements missing for the restatement (the same root as § 04).

1. The existence and naming of the $N \to \infty$ limit of the measure at step 0. It is likely to follow from the convergence of § 02 Inferred, but there is no statement.
2. Reflection positivity of the pushed-forward measure at step 0 (or at any step). Because of the support of the kernel, it is not obvious Inferred.

3. The relation between Wilson loops of coarse configurations and Wilson loops of the fine field (or the continuum).
4. Estimates for the objects at step 0 that are uniform in the volume p.
5. The limit of the images of observables at step 0 (at every order), and an identity connecting expectations at step 0 with continuum correlations.

In particular, without the three of 1 (the limiting object), 4 (local estimates uniform in the volume) and 5 (images of observables at step 0), one cannot state that "the remaining questions are long-distance questions of the effective theory at step 0". With all five, the remaining questions could be stated as "questions about one named family of lattice measures". Until they are all in place, the restatement is a guide to direction.

06

From weak coupling to strong coupling

The coupling $\bar{\beta}$ at step 0 is large (weak coupling), and the lengths at which confinement and the mass gap become visible are expected to lie much further on, even in the units of that step Inferred . If the one-loop running is formally extended to the side coarser than step 0, the length at which the coupling becomes of order 1 is of order $e^{\bar{\beta}/s}$ in the units of step 0 Inferred (an extrapolation, not a statement of the construction). Getting there would need new steps flowing from step 0 further to the coarse side until the strong-coupling region is entered Inferred . What is needed at the entrance to them is 1–3 of § 05 (the limiting measure, reflection positivity, the relation to coarse Wilson loops) Inferred . This is a different set from the three needed to turn the restatement into a statement (1, 4 and 5 of § 05).

This book has called the intermediate region connecting weak and strong coupling "the crossover band" (26-00). If the remaining questions may be restated as above, they correspond to questions of crossing this band Inferred . The holdings of this book's study lie at the two ends of the band, and the middle remains open (16-04).

One caution. The renormalisation of this book's study (the push-forward by a deterministic block map, 19-04) and the push-forward of the published construction (a coupling-dependent probability kernel) are not the same, even if their objects are similar. Convergence of one does not give convergence of the other Inferred .

07

What this chapter does not say

- It shows nothing about the long-distance behaviour of the theory at step 0.

- It says neither that the five statements of § 05 hold nor that they do not. About 2, it only infers that it is not obvious.
- "Not stated" is the result within the range searched. The possibility that the same content exists under another name cannot be excluded.
- Whether the proof of the published construction is correct stays at the level of the committee's assessment.

What this chapter says

What is said	What is not said
Source The coupling at every step is in the band $[\hat{\beta}_m/2, 2\hat{\beta}_m]$; step 0 has lattice spacing 1 and $\beta = \bar{\beta}$ (`Conv.band`, `Selected.reaches`, `Schedule.side`)	An explicit value of $\bar{\beta}$ (from the condition, roughly 9×10^5 or more Reading ; the entry value is given only as existing)
Source The effective density at each step, including step 0, is uniformly Cauchy in the sup norm along the whole sequence of cutoffs with the volume fixed, and the normalisation constant is also Cauchy (`Flux.fanned`, `lacks`, `sees`)	Convergence uniform in the volume
Inferred Convergence of the normalised density in total variation follows in one line	Its form as a named statement
Source The limiting measure, its reflection positivity, the relation to coarse Wilson loops, estimates uniform in the volume for the objects at step 0, and renormalisation coarser than step 0 are not stated within the range searched	Excluding the possibility that they exist under other names
Source Every step is in the weak-coupling band, step 0 is at the reference value, the volume is in the units of step 0, and distances longer than spacing 1 are dealt with in no theorem (within the range of a name search). Inferred On that basis, restating the remaining questions as "long-distance questions of the theory at step 0" is likely right in direction, and they can be further restated as "the question of following it from weak coupling to strong coupling". Five statements are missing to make this a statement	The answer to that question

Words used in this chapter — renormalisation step, lattice spacing, band of couplings, reference value, probability kernel, push-forward, effective density, uniformly Cauchy, total variation, reflection positivity, chessboard root, crossover band. Their meanings are in the A-02 Glossary.

Next chapter to read: 16-04 Where this book stands — sets out at which end, weak coupling or strong coupling, the holdings of this book's study lie, and guides the reading of Volume 3.

Where this book stands

> This chapter is a guide. § 02 is a map of what is unsolved.

What this chapter shows — We line up the theorems that this book's study has machine-checked in Lean along the axis of the coupling. The holdings lie at both ends. At the strong-coupling end there are the infinite-volume limit, the mass gap (in lattice units), the area law and an upper bound on the vortex free energy; as things that hold at any coupling there are the vortex floors and properties of the vortex ratio; and on the weak-coupling side there is the rarity of large plaquettes. The middle (the crossover band) remains open. Finally, we guide the reader through what each part of Volume 3 deals with.

Chapters this one relies on — 16-02 Five open questions, 16-03 The infrared edge of the published construction.

Said first — Every theorem listed here is a statement with the lattice spacing fixed, and a formalisation of a result of a known type. Neither the continuum limit nor the mass gap in the sense of the problem statement is shown. Statements of kinds that the published construction does not deal with are included, but this does not mean that any open question has been answered.

Order of this chapter

1. Holdings on the axis of the coupling — Table 1
2. The middle remains open — what is missing in the crossover band
3. Overlaps and differences with the published construction — the same direction, different kinds
4. How to read Volume 3 — one line per part, and three reading orders
5. What this chapter does not say

Labels — Source = the source of the published construction was read / Inferred = this book's inference / Assessment = according to the committee's assessment report (for details, see "Labels" in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are labels used throughout the book; Reading is this book's reading of numbers, and Lean is a Lean theorem of this book.

01

Holdings on the axis of the coupling

We view the coupling β of lattice gauge theory as a single axis. The side of small β is strong coupling, the region where confinement and the mass gap can be shown by expansions of known type (5-02). $\beta \to \infty$ is weak coupling, and the continuum limit is taken at this end (5-05). Placing the theorems of this book's study on this axis gives Table 1.

Place	Theorem	Range	Chapter
Strong-coupling end	Exponential decay of correlations (constants free of the volume)	$18 \tanh \lvert\beta\rvert < 1$, etc.	20-02
	The infinite-volume limit (no subsequence), translation invariance, clustering	$\beta \neq 0$, $18 \tanh \lvert\beta\rvert < 1$	20-03
	The mass gap of the vessel of reconstruction (lattice units, a lower bound)	The same window	20-04
	The area law for Wilson loops (finite volume, infinite volume)	In a finite box $\beta < 1.135 \cdot 10^{-3}$ (the version with constant 441); in infinite volume $\beta < 1.22 \cdot 10^{-4}$ (the version with constant 4096; also $\beta > 0$ and $18 \tanh \beta < 1$)	20-06
	An upper bound on the vortex free energy (the rate per unit area does not depend on the transverse size; the prefactor N^2 (the transverse area) remains)	$\beta < 1.22 \cdot 10^{-4}$ in the basic version (constant 4096), $\beta < 1.135 \cdot 10^{-3}$ in the sharp version (constant 441)	20-06

Place	Theorem	Range	Chapter
At any coupling	Reflection positivity (three forms)	All real β (depending on the form)	20-01
	The thin-vortex floor (the rate depends on the transverse size N)	All β	21-02
	The thick-vortex floor, the minimal action of a vortex	For each sufficiently large β (the threshold only as existing)	21-03, 21-05
	The sign of θ, pairs of Polyakov loops	Even vertical size M	21-06
	Continuity of the vortex ratio, the $\beta \to \infty$ limit, the largest solution of the matching, a lower bound on the deficit of the twisted box	With the lattice fixed	21-07
Weak-coupling side	Rarity of large plaquettes (uniform in the volume)	$\beta \geq 81$ (explicit threshold)	22-01

Table 1 Where the firm theorems of this book's study are placed. Each is a formalisation in this book's Lean, with the lattice spacing fixed, of a result of a known type Lean . The values of the windows are floating-point readings Reading .

Two notes on reading it.

- **The strong-coupling end is "the side where things are easier to show".** The mass gap and area law here are statements different from the mass gap of the continuum theory that the problem statement asks for, and they lie on the opposite side from the weak-coupling end where the continuum limit is needed.
- **What holds at any coupling is not uniform in the transverse size.** The rate of the vortex floor tends to 0 as the transverse size N is made large (the thin floor), or the threshold depends on N (the thick floor). Restricted to the strong-coupling window, there is a form whose rate does not depend on N. The prefactor N^2 (the transverse area) remains, and outside the window there is no uniform form (20-06).

02

The middle remains open

The strong-coupling window for the infinite-volume limit and the mass gap is $|\beta| < 1/19$ (≈ 0.053; an explicit sufficient condition for 18 $\tanh|\beta| < 1$, the window itself being $\operatorname{artanh}(1/18) \approx 0.0556$; 20-03), and the threshold for rarity is $\beta \geq 81$; the band of interest in physics (β around 2 to 3) falls in neither. We have called this middle "the crossover band" (26-00). What is missing to cross the band is set out in 19-07 as statements written with defined objects only (matching, convergence of the full sequence, non-degeneracy, equicontinuity, uniform decay, the band). Each of them asks for estimates **uniform** in the lattice spacing and the size of the box, and they do

not follow from the firm theorems of this book (each a statement at one lattice spacing). A map of the ideas this book's study has tried for the band is in 16-11, and a list of the models on which arguments about the band are tested is in 26-12.

Seen from the side of the published construction too, the remaining questions are in the same place. The construction carries every step at weak coupling and stops at the step with lattice spacing 1 (16-03). The main part of the remaining questions (the mass gap, the area law, uniqueness) is likely to be reducible to exponential decay at long distances in the effective theory at that step Inferred . However, the theory at step 0 is not one with the Wilson action but a theory with an effective action given by a representation (the reference coupling $\bar{\beta}$ is a coefficient in it, and the representation is not unique), and its reflection positivity is not stated either Source . To state this, three things are needed: the limiting object, local estimates uniform in the volume, and images of observables at step 0. Under this expectation, the questions gather around the band from both sides Inferred .

About the band, what this book's study has is a conditional implication and a list of premises (27-01, 28-04). It has not shown that the premises are satisfied.

03

Overlaps and differences with the published construction

Things in the same direction. Reflection positivity of the lattice Wilson measure and the Chessboard Estimate are present in both Source . The published construction has, for the original Wilson measure, reflection positivity in planes through lattice points and in planes through midpoints of edges, along all four axes ($\beta \geq 0$), and also the triangle inequality for the chessboard root Source (12-01, 12-02). The line of argument that takes subsequential limits and transfers properties to them is also of the same type.

Kinds of things not found in the published construction (within the range searched).

- **Rarity of large plaquettes.** The published construction uses the Chessboard Estimate to measure the size of observables, not to estimate the probability of sets of large plaquettes Inferred (22-00).
- **Twisted boundary conditions and the vortex free energy.** The Wilson measure of the published construction is defined only on the periodic torus, and no statement about twists has been found Inferred (within the range of a name search).
- **The mass gap and area law inside the strong-coupling window.** The published construction does not pass through the strong-coupling region (16-03 § 01), so statements of this kind appear to be absent Inferred (within the range of a name search).

This difference is not a comparison of which has got further. The published construction gives the existence of the four-dimensional continuum theory, as assessed by the committee Assessment . This book's study does not have that. Conversely, the three items above are statements with the lattice fixed, and answer none of the open questions of the assessment report (16-02). This book's strong-coupling results (the infinite-volume limit, the mass gap, the area law, the vortex floors) are statements at the **opposite end** (strong coupling, with the lattice spacing fixed) from the remaining questions (a uniform mass gap of the continuum theory, and so on). They deal with the same kinds of quantities in a different region, and we do not say that they give a route to the open questions.

04

How to read Volume 3

Part	Title	What it deals with
Part 16	Where things stand, and the questions that remain	The timeline, the open questions, the infrared edge of the published construction, where this book stands, the seams, tasks, misconceptions, the table of seven stages, the map of tools
Part 17	From the side of physics	Mechanisms of confinement, the string picture, large N, the mass gap as geometry. An arrangement of views that are not mathematical theorems
Part 18	A dictionary of two languages	Correspondence between the words of physics and the words of mathematics; this book's assumptions in the language of physics
Part 19	Objects, and the statements to be shown	Definitions of the lattice, the Wilson measure, twists, reflection and the block map (with Lean definitions), and the statements to be shown
Part 20	Firm theorems — the vessel and strong coupling	Reflection positivity, decay at strong coupling, the infinite-volume limit, reconstruction and the mass gap, the vessel with fermions, the area law
Part 21	Firm theorems — the vortex floor and Polyakov loops	Sign systems, the thin- and thick-vortex floors, the minimal action of a vortex, the sign of θ, the vortex ratio — continuity, limit, matching
Part 22	Firm theorems — the rarity of large plaquettes	The Chessboard Estimate, and rarity uniform in the volume at weak coupling
Parts 23 and 24	The first road — from the direction of time	The record of the study heading for the band from relaxation times and correlation lengths
Part 25	The second road — from the direction of space	The record of the study heading for the band from small twisted tori and confinement
Part 26	The crossover band	The correct form of the band, reduction, what cannot be crossed by structure alone, the comparison with renormalisation

Part	Title	What it deals with
Part 27	Closing — conditional statements	The conditional statement and the ledger of conditions, the index of questions and of what is not said
Part 28	The tree of premises	Three implications, the list of premises, what depends on design choices, the places that are open

Table 2 The parts of Volume 3.

Suggested reading orders.

- **If you want only what is firm.** Part 19 (objects) → Parts 20–22 (firm theorems). The last chapter of each part has a table of "what it says, and what it does not".
- **If you want the shape of the remaining questions.** This part (16-02 to 16-04) → 19-07 (the statements to be shown) → Part 26 (the band) → Part 28 (the tree of premises).
- **If you want to start from motivation.** Parts 17 and 18 (the physical view and the dictionary) → this part → Parts 20–22.

Parts 23–25 are records of the study along the two roads towards the band, and have not been rewritten. Most of their conclusions are gathered in Parts 26–28.

05

What this chapter does not say

- It does not claim to have shown anything about the mass gap proper (a mass gap of the continuum theory, uniform in the lattice spacing).
- Every theorem of Table 1 is a formalisation of a result of a known type, and no novelty is claimed.
- What is "not found" in the published construction is the result within the range searched; the possibility that it exists under another name cannot be excluded.
- It says neither that the band statement is true nor by which route it could be shown.

What this chapter says

What is said	What is not said
`Lean` The theorems of Table 1 (the strong-coupling end, any coupling, the weak-coupling side) are machine-checked in Lean. Details are in each chapter	Estimates uniform in the lattice spacing, the continuum limit, the band

What is said	What is not said
Source Reflection positivity and the chessboard are present in both. Inferred The published construction does not pass through the strong-coupling region (depending on the size of $\bar{\beta}$)	—
Inferred Rarity of large plaquettes and twisted boundary conditions are not found in the published construction (within the range of a name search). This book's strong-coupling results are statements at the opposite end from the remaining questions	Answers or routes to the remaining questions

Sources and reproduction

Item	Kind	Source, tools

Words used in this chapter — strong coupling, weak coupling, crossover band, area law, vortex floor, vortex free energy, rarity of large plaquettes, statements to be shown, tree of premises. Their meanings are in the A-02 Glossary.

Next chapter to read: 16-05 Where the two ways of digging part — maps where the two roads of this book's study are cut off. To read from the firm theorems, go to 19-00.

Where the two ways of digging part — seeing the mismatch of two tunnels in seven seams

This chapter is a map of open questions. § 05 is this book's own investigation.

What this chapter shows — For each of the seven seams, the sentence of physics, the mathematical statement and the partial bridges, and three types. Comparing, for a local quantity and for a mass, how far the two shores are from the numbers (calculations on this machine).

Prerequisite chapters — 7-11 Obstacles beyond divergence and 17-13 Where the way physics digs parts from mathematics. The tools are 4-10 (reflection positivity), 5-01 (the lattice) and 4-07 (dimensional transmutation).

Said first — This chapter names the seams; it fills none of them. The count of seven and the types are this book's arrangement. The record of this book's study has worked only around the seam of "there is one scale", and has not reached a theorem. This chapter shows neither the existence of the mass gap nor the construction of the continuum limit. The seam of existence has been bridged by the construction published in 2026 (the committee's assessment Assessment ; Part 6). The label Assessment means "according to the committee's assessment report" (“Labels” in 6-00).

The order of this chapter

1. Two ways of digging — from existence, or from values. A parallel table of walls (six obstacles and seven moves)
2. A map of the seams — seven seams and three types (Table 1)
3. The type in which a premise becomes a goal — existence, a single scale
4. The type of limits and uniformity — shores, finite and infinite, extra dimensions
5. Measuring between the shores — the plaquette and the mass (Figure 1, computed)
6. The type in which the same word points to different things — spacetime and space, particles
7. Overlaying the two lists — partial bridges

01

Two ways of digging

There are two directions in which to dig at this problem (0-02). Mathematics starts from "there is no theory yet" and passes through the six stages (7-01) in order; physics starts from "the theory exists" and computes quantities inside it. As a metaphor, they are two tunnels dug into the same mountain from both sides; more precisely, there are places where a sentence on one side cannot be handed over as it is to the other. The goal of mathematics has the following form (0-03) Known .

$$\forall G \ \exists \mathcal{T}_G : \quad \text{axioms} \ \wedge \ \text{non-trivial} \ \wedge \ \text{agrees with asymptotic freedom at short distances} \ \wedge \ \text{s}$$

G is a compact simple group, $\mathcal{T}_G$ the quantum Yang–Mills theory on $\mathbb{R}^4$, and H its Hamiltonian. The physical sentence "computing the quantity Q in $\mathcal{T}_G$ gives q" includes $\exists \mathcal{T}_G$ among its premises. We translate a sentence of physics P into a mathematical statement M, and call a place where the translation does not become a theorem a **seam**.

$$\text{seam} = (P, M) : \quad P \text{ is used in physics}, \quad M \text{ is not a theorem, or points at something other t}$$

Example: the $m_{0^{++}}/\sqrt{\sigma} = 3.844(61)$ of $SU(2)$ (Lucini–Teper 2001) Physics is a prediction in physics, and in mathematics a target that the constructed theory must hit (17-13 § 01).

A parallel table of walls — the six obstacles of mathematics and the seven moves of physics

The seams of Table 1 were made by pairing rows of the lists on the two sides. Before that, we give a parallel table of the rows by name. On the left are the six obstacles of 7-11 Table 4, and on the right the seven moves of 17-13 Table 5. The stock phrases are the expressions each side uses when pointing at that wall. Some rows exist on one side only.

Parallel table Names of the walls (the correspondence is this book's arrangement)

Name in mathematics (7-11)	Name in physics (17-13)	Stock phrase (mathematics / physics)	One side only?
Obstacle 1 No small parameter in the infrared	Moving to a neighbouring theory and coming back with a knob, Looking from the side of a small parameter	"No uniform estimate across the scale where the coupling is $O(1)$" / "Below Λ it is non-perturbative"	Both sides

Name in mathematics (7-11)	Name in physics (17-13)	Stock phrase (mathematics / physics)	One side only?
Obstacle 2 Invisible to perturbation theory	Looking from the side of a small parameter, Regarding as one	"All Taylor coefficients of $e^{-c/\alpha}$ are 0" / "$\Delta = c\Lambda$"	Both sides
Obstacle 3 Not collapsing to a free field	Measuring after putting that it exists	"Show that the limit is not a free field" / "The theory exists"	Both sides
Obstacle 4 The state space is curved	Looking after choosing a gauge	"There is no global gauge fixing" / "Compute with the gauge fixed"	Both sides ("Outside the table: gauge" in Table 4)
Obstacle 5 Few regularisations preserve reflection positivity	—	"A regularisation that preserves positivity" / —	**Mathematics only**. Numerical calculations in physics also use improved actions that lose positivity (the entry "improved action" in 18-04)
Obstacle 6 The structure of infinitely many degrees of freedom	—	"The representations are inequivalent (Haag's theorem)" / —	**Mathematics only**. Perturbative calculations in physics proceed using the interaction picture
—	Taking σ from the string picture (§ 03, § 04)	— / "A string is stretched, the area law"	**Physics only**. Confinement (the area law) is outside what the problem statement requires, an extension problem (17-02)

Name in mathematics (7-11)	Name in physics (17-13)	Stock phrase (mathematics / physics)	One side only?
— (outside the six: the ultraviolet side)	Extrapolating from finite β	"Construction of the continuum limit" / "Extrapolate in a^2"	Not among the six of 7-11. In mathematics it is a problem on the ultraviolet side (7-07, 7-10)

The four rows on both sides call the same wall by different words. The rows on one side only are places that, in that side's language, are not seen as walls. Positivity and equivalence of representations pass unasked in the procedures of physics, and the area law passes unasked in the mathematical problem statement. Rearranging this parallel table into seams gives Table 1, and lining it up with the partial bridges gives Table 4 of § 07.

02

A map of the seams — seven seams and three types

Table 1 lines up the seven seams. The order of mathematics (existence → axioms → gap) and the order of physics (values → mechanisms) run in opposite directions, so stages at the same position do not correspond. As a metaphor this is the mismatch of the tunnels; more precisely, a premise on one side becomes the goal of the last stage on the other.

Table 1 The seven seams (the division and the types are this book's arrangement)

Seam	Sentence of physics	Mathematical statement	Type
1 The premise of existence	Put that the theory exists, and compute quantities in it	Make the limit satisfying the axioms, not as a subsequence	Type in which a premise becomes a goal
2 A single scale	Mass and string tension are both constant multiples of one Λ	Formula (5) holds uniformly in β	Type in which a premise becomes a goal
3 Different shores	Compute on the side of g→0, small β, N→∞	Control every scale at finite N	Type of limits and uniformity
4 Finite and infinite	Measure in finite boxes, and extrapolate in a^2	A gap uniform in the volume (Chatterjee's lattice correlation-length problem, Problem 5.1)	Type of limits and uniformity
5 Spacetime and space	Think in a spacetime where particles fly and there is causality	Come back from a Euclidean measure by reflection positivity	Type in which the same word points to different things

Seam	Sentence of physics	Mathematical statement	Type
6 The word "particle"	The gap is the mass of the lightest glueball	A spectral gap (an isolated one-particle state is an extension problem)	Type in which the same word points to different things
7 Extra dimensions	Get the gap from the geometry of the cigar	The R→0 (λ→0) limit, and exchanging limits	Type of limits and uniformity

The type in which a premise becomes a goal is a seam where a premise of physics becomes a goal of mathematics; **the type of limits and uniformity** is a seam where physics computes at a particular value (a shore) of a parameter p, and mathematics needs the limit that moves p to the value p_* of the problem statement; **the type in which the same word points to different things** is a seam where the same word points at different objects. The type of limits and uniformity has the following form.

$$\text{physics}: \ F(p_{\text{shore}}) \text{ computed}, \qquad \text{mathematics}: \ \lim_{p \to p_*} F(p) \text{ exists, and } \inf_{p} \Delta(p) > 0 \text{ and}$$

Example: in the seam of finite and infinite, $p = L$ (the side of the box) with $p_* = \infty$; in the seam of extra dimensions, $p = R$ (the size of the extra dimensions) with $p_* = 0$.

The following sections are ordered by type (the type in which a premise becomes a goal is 1 and 2, the type of limits and uniformity is 3, 4 and 7, and the type in which the same word points to different things is 5 and 6).

03

The type in which a premise becomes a goal

The seam of the premise of existence

The calculations of physics stand on the existence of the theory (a measure and a Hilbert space), and mathematics has to make that existence. Partway through the making, neither mass nor string tension is defined. The problem statement writes 'one does not yet have a mathematically complete example of a quantum gauge theory in four-dimensional space-time, nor even a precise definition' Known . Mathematics shows $\exists\,\mathcal{T}$ as the limit of approximations $\mu_{a,L}$ with lattice spacing a and side L.

$$\mu = \lim_{L \to \infty} \lim_{a \to 0} \mu_{a,L} \qquad \text{(not a subsequence: the limit itself exists and is unique)} \ (4)$$

The problem statement writes, in footnote 2 of § 6.5, that a subsequential limit obtained by compactness (weak existence) alone is not accepted as a solution (unless the properties of the limit are established by another method) Known . Example: in two dimensions the measure has been built up to $\mathbb{R}^2$ (7-02); in three dimensions, 'a construction of the 3D YM measure and a description of its gauge-invariant

observables, even on T^3, remains open' (Chevyrev 2022)[Known] ; and in four dimensions, up to 2025, the stage reached was ultraviolet stability in finite volume obtained with a hypothesis (7-07).

The construction published in 2026 built, for any compact simple group, a theory satisfying the Wightman axioms as a limit of four-dimensional Wilson lattice gauge theory. The committee's assessment is that this is “proved in Lean”[Assessment] (6-00). The inner limit $a \to 0$ of formula (4) is taken with the periodic box fixed, along the whole sequence of cutoffs, and the outer limit $L \to \infty$ is along a subsequence obtained by compactness (8-05, 12-05). The assessment report writes that convergence and uniqueness of the infinite-volume limit are not shown[Assessment] (16-02 § 02). This chapter does not judge what this construction amounts to in the sense of footnote 2. Seen from the side of physics, half of "the theory exists" in this seam has become a mathematical statement. What remains is that the quantities in that theory (the mass gap, the string tension) be determined as mathematics, and that is a question on the side of the seam of "there is one scale" and the seam of finite and infinite.

The seam of "there is one scale"

In physics every quantity with a dimension is taken to be a constant multiple of a single scale Λ (4-07) [Physics] . Translated into mathematics, for example for the mass $m(\beta)$ and string tension $\sigma(\beta)$ in lattice units ($\beta = 2N/g^2$ is the lattice inverse coupling, not an inverse temperature), it is that the following holds.

$$0 < c \le m(\beta)^2/\sigma(\beta) \le C < \infty \qquad (\beta \ge \beta_0 \text{ uniformly}) \quad (5)$$

This is peculiar to four dimensions because $[g^2] = (\text{mass})^{4-d}$ [Known] . For $d < 4$, if the theory exists, dimensional analysis gives a single scale; at $d = 4$, $\Lambda = \mu\, e^{-1/(2b_0 g^2(\mu))}$ is born as a quantum effect from the running of the coupling [Physics] . But dimensional analysis fixes only the form. For example at $d = 3$, g^2 has the dimension of mass, so one can write $m = c_1 g^2$ and $\sigma = c_2 g^4$, but this does not forbid the constants c_1, c_2 from going to 0 or ∞ in the limit. Example: examples where one scale breaks are three-dimensional compact $U(1)$ (said to have $\sigma/m^2 \to \infty$ in the continuum limit with the mass fixed in physical units; the abstract of Göpfert–Mack writes that in the continuum limit with m_D fixed the string tension in physical units is infinite; main text not read) and the supergravity regime ($m^2/\sigma \sim 1/\lambda$) [Physics] (17-12 § 08). The record of this book's study cut out a sentence close to (5) as the diffusive-relaxation-time assumption and split it into three chains (17-12, 23-01), but it has not become a theorem.

> 04

The type of limits and uniformity

The seam of the different shores

Theorems and calculations work at three shores: perturbation theory at $g \to 0$, the strong-coupling expansion at small β, and holography at $N \to \infty$ together with $\lambda = g^2 N \to \infty$. The theory of the problem statement is on none of these shores. Converting the lattice coupling to the 't Hooft coupling gives the following.

$$\lambda = g^2 N = 2N^2/\beta \quad (6)$$

On the strong-coupling side, the infinite-volume limit and exponential clustering (the gap) at sufficiently small β go back to Osterwalder–Seiler 1978 (range not made explicit; according to the introduction of Shen–Zhu–Zhu) Known . The condition of the theorem with an explicit range (Shen–Zhu–Zhu; arXiv 2022, CMP 2023) is $\beta < N^2/(16(d-1))$ in Wilson's normalisation (16-01) Known . Converted by (6), it is $\lambda > 32(d-1)$, or $\lambda > 96$ in four dimensions, independent of N Computed . The continuum limit is in the direction $\lambda \to 0$, and the lattice numbers are at $\beta = 2.25$–2.60 for $SU(2)$, which is $\lambda = 3.6$–3.1 Computed (a rough guide, since the conventions differ). Example: both strong shores are places where the cutoff and the physical scale are not separated (on the strongly coupled lattice the correlation length is shorter than the lattice spacing, and in supergravity the KK tower stays at the same height as the glueballs; 17-10).

The seam of finite and infinite

In a finite box at finite β the entries of the transfer matrix are positive, so the gap is always positive (17-13) Known . What is asked is that it does not collapse as the box is enlarged.

$$\text{for each } L\,,\ \Delta_L > 0 \qquad \text{and} \qquad \inf_L \Delta_L > 0 \qquad \text{are different claims} \quad (7)$$

On the latter, the problem statement writes 'no present ideas point the direction to establish the existence of a mass gap that is uniform in the volume' Known , and the form on the lattice is Chatterjee's 2018 lattice correlation-length problem (16-08 § 08). Physics measures in finite boxes, checks volume effects with rules of thumb such as $L\sqrt{\sigma} \geq 3$ (L is the physical length of the side of the box), and extrapolates in the lattice spacing with a^2 (17-13 § 05) Physics . Example: for a strip of the two-dimensional Ising model, the gap closes as $1/L$ at the critical point, but it is positive for every L (2-09). $\inf_L$ cannot be read from numbers in finite boxes.

The seam of extra dimensions

In holography the gap comes from the geometry of the extra dimensions (the cigar where a circle shrinks) (17-09) Physics . To return to four dimensions one sends the size of the extra dimensions $R = 1/M_{\mathrm{KK}}$ to 0 with Λ fixed, but from the one-loop estimate

$$\Lambda/M_{\mathrm{KK}} \approx \exp\!\left(-24\pi^2/(11\lambda)\right) \qquad (\lambda \text{ is the value at } M_{\mathrm{KK}}\ ) \quad (8)$$

$R \to 0$ is the same direction as $\lambda \to 0$ (17-10) Physics . Supergravity can be used for $\lambda \gg 1$, and Csáki et al. write 'This is the opposite of the limit that is required for the supergravity description to be valid' Physics . Example: at $\lambda \approx 16.6$ converted from the Sakai–Sugimoto fit (a fitted value from a model with quarks, not a value for pure Yang–Mills; $N = 3$; can be off by a factor of about 2 by convention), (8) is 0.27, and the scales are not separated Computed . Within the range we searched, we found no justification for exchanging the limits.

05

Measuring between the shores — the plaquette and the mass

How far the shores are depends on the quantity. For the four-dimensional $SU(2)$ Wilson action $S = \sum_P \left(1 - \frac{1}{2}\operatorname{tr} U_P\right)$ with weight $e^{-\beta S}$ ($\beta = 4/g^2$; 5-01), we compare the leading terms of the two shores with the numbers, for a local quantity (the plaquette) and a long-distance quantity (the mass). Both leading terms are the standard lowest-order expansions (the strong-coupling expansion is treated in 5-02).

$$\left\langle \tfrac{1}{2}\operatorname{tr} U_P \right\rangle \approx u(\beta) = \frac{I_2(\beta)}{I_1(\beta)} \ \ (\beta \text{ small}), \qquad \left\langle \tfrac{1}{2}\operatorname{tr} U_P \right\rangle \approx 1 - \frac{3}{4\beta} \ \ (\beta \text{ large}) \quad (9)$$

What is inside the two leading terms

I_n is the modified Bessel function, defined by the following integral.

$$I_n(\beta) = \frac{1}{\pi}\int_0^{\pi} e^{\beta\cos\theta}\cos n\theta \, d\theta$$

The leading strong-coupling term u is the average of $\frac{1}{2}\operatorname{tr} U$ with weight $e^{\beta\cdot\frac{1}{2}\operatorname{tr} U}$, treating one plaquette as a $SU(2)$ variable unrelated to its surroundings. Under the Haar measure on the group (5-01 § 06) the density of $\frac{1}{2}\operatorname{tr} U = \cos\theta$ is proportional to $\sin^2\theta$ ($0 \le \theta \le \pi$), and this average is exactly I_2/I_1 Known (agreeing to 10 digits by numerical integration Computed). When β is small the ties with the surrounding plaquettes are weak, and this single-plaquette average is the leading term Known .

The leading weak-coupling term is a count by **equipartition**. Equipartition means that under the weight $e^{-\beta S}$, each degree of freedom entering S quadratically contributes $\frac{1}{2}$ to $\langle \beta S \rangle$ (from $\int x^2 e^{-\beta x^2}\,dx / \int e^{-\beta x^2}\,dx = 1/(2\beta)$). When β is large the plaquettes are pressed close to 1, and S can be approximated by a quadratic form in small fluctuations of the links. Per lattice point there are 4 links, and $SU(2)$ has 3 directions, making 12. Of these, the 3 gauge-transformation directions do not change the action and are not counted, leaving 9. There are 6 plaquettes per lattice point, so per plaquette $\langle 1 - \frac{1}{2}\operatorname{tr} UP \rangle \approx \frac{9/2}{6\beta} = \frac{3}{4\beta}$ Known .

The mass is the rate at which correlations decrease. At strong coupling, joining two distant plaquettes needs the space between them filled with plaquettes in the shape of a tube, and each lattice step the tube grows picks up u^4 for the 4 plaquettes of its side. Correlations decrease with distance t like $u^{4t} = e^{-(-4\ln u)t}$, so $am \approx -4 \ln u$ Known . On the weak-coupling side, expanding am as a power series in g^2 gives coefficient 0 at every order (because of the form e^{-1/g^2}), and only the form comes from asymptotic freedom Physics .

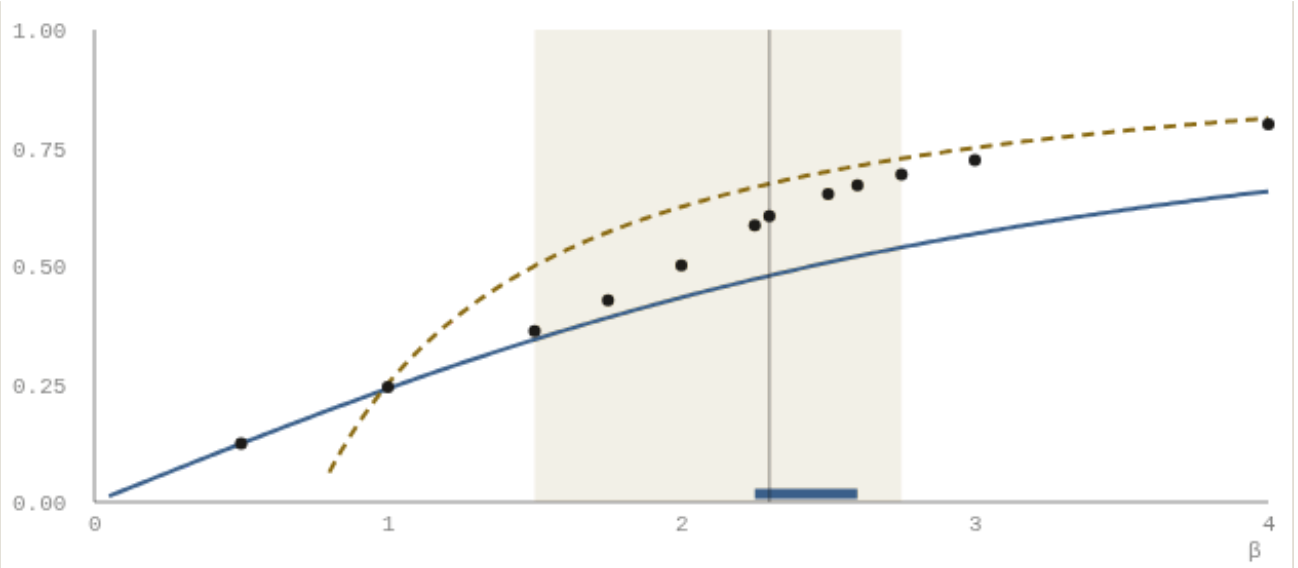
$$am \approx C\,(b_0 g^2)^{-51/121}\, e^{-3\pi^2\beta/11}, \qquad b_0 = \frac{22}{48\pi^2}$$ (10)

This is two-loop asymptotic scaling (4-06). The constant C is not fixed by asymptotic freedom, and it is the very information of the gap.

Setting them beside the numbers

The numbers are, for the plaquette, the heat-bath method on a 6^4 lattice on this machine Computed , and for the mass, Table 1 of Lucini–Teper 2001 Physics . The heat-bath method is a Monte Carlo method that repeats updates redrawing one link at a time directly from its conditional distribution with the surrounding links fixed (5-07).

Figure 1 Choosing the quantity with the buttons and moving β with the knob changes the readings at the vertical line. The solid line is the leading strong-coupling term, the dashed line the leading weak-coupling term (for the mass, (10) fitted at β = 2.6), and the points are the numbers. Only on the plaquette plot are drawn the shaded band (the interval containing the measured points β = 1.75–2.6 where neither leading term is within 5%; at its ends, 1.5 and 2.75, one of them is within 5%) and the thick line at the bottom (β = 2.25–2.60, where there are numbers for the mass)



β = 2.30, leading strong-coupling term 0.4793, leading weak-coupling term 0.6739, numerical 0.6051 (deviation −20.8%, +11.4%)

Computed The plaquette points (Table 2) and the curves ((9) and (10) computed on the spot) were computed on this machine. Physics The mass points are Table 1 of Lucini–Teper 2001.

Computed Table 2 $\langle \frac{1}{2} \operatorname{tr} UP \rangle$: heat-bath method on 6^4 (in parentheses a rough guide to the statistical error; extracted from the 15 points measured) and the two leading terms. Deviations are percentages of the numerical value.

β	Numerical	Strong coupling u	Deviation	Weak coupling	Deviation
0.50	0.1234(2)	0.1237	+0.3%	—	—
1.00	0.2438(3)	0.2402	−1.5%	0.2500	+2.5%
1.50	0.3616(4)	0.3441	−4.8%	0.5000	+38.3%
1.75	0.4271(4)	0.3906	−8.6%	0.5714	+33.8%
2.00	0.5010(7)	0.4331	−13.6%	0.6250	+24.7%
2.25	0.5856(7)	0.4720	−19.4%	0.6667	+13.8%
2.30	0.6051(9)	0.4793	−20.8%	0.6739	+11.4%
2.50	0.6526(5)	0.5072	−22.3%	0.7000	+7.3%
2.60	0.6705(4)	0.5203	−22.4%	0.7115	+6.1%
2.75	0.6935(4)	0.5391	−22.3%	0.7273	+4.9%
3.00	0.7235(2)	0.5679	−21.5%	0.7500	+3.7%
4.00	0.7997(1)	0.6580	−17.7%	0.8125	+1.6%

Table 3 Mass am (lattice units). Physics The numerical am column is Table 1 of Lucini–Teper (the master copy when this book cites the six SU(2) points; $a\sqrt{\sigma}$ and lattice sizes

are in 5-09 Table 1). Computed The columns $\xi = 1/(am)$, strong coupling and (10) are calculations on this machine, with (10) fitted to the point $\beta = 2.6$ ($C = 185$).

β	Numerical am	ξ	Strong coupling $-4\ln u$	Strong coupling / numerical	(10)
2.25	1.390(30)	0.72	3.004	2.16	1.241
2.30	1.090(33)	0.92	2.942	2.70	1.095
2.40	0.953(19)	1.05	2.825	2.96	0.851
2.475	0.754(10)	1.33	2.742	3.64	0.705
2.55	0.586(10)	1.71	2.663	4.55	0.583
2.60	0.514(8)	1.95	2.613	5.08	0.514

Example: for the plaquette, the leading strong-coupling term is within 5% of the numbers for $\beta \le 1.5$, and the leading weak-coupling term for $\beta \ge 2.75$ (the agreement at $\beta = 1$ is only where the curves cross); at the points with $1.75 \le \beta \le 2.6$ neither is within 5% Computed . The $\beta = 2.25$–2.60 used to extrapolate the continuum value of the mass is inside this band. For the mass, the leading strong-coupling term is 2.2–5.1 times the numbers, and (10) reproduces the other five points to within 11%, but C is a fitted number Computed . For a local quantity the numbers fill the space between the two leading terms; for a long-distance quantity the weak-coupling shore has no value (7-11 § 03), and the strong-coupling shore does not reach.

The physical continuum value 3.844(61) is the ratio $m/\sqrt{\sigma}$ of the six points in this band ($\xi \le 2$) extended to $a^2\sigma \to 0$ (Lucini–Teper Table 5; for how it is extended, see 17-13 § 05) Physics . This is an extrapolation to the continuum limit ($a \to 0$), and volume effects are checked separately with rules of thumb for finite boxes (the seam of finite and infinite).

06

The type in which the same word points to different things

The seam of spacetime and space

The intuition of physics lives on spacetime (Minkowski), where particles fly and there is causality. The construction of mathematics is a probability measure on Euclidean $\mathbb{R}^4$, with neither light cones nor causality (0-04). The way back is reflection positivity (4-10). With Θ the reflection of time, F, G functions on the positive-time side, and τ_t translation in time,

$$\langle F, G\rangle_{\mathcal{H}} := \langle \Theta F\, G\rangle, \qquad \langle F, F\rangle_{\mathcal{H}} \ge 0, \qquad \langle F, e^{-tH} G\rangle_{\mathcal{H}} = \langle \Theta F\, \tau_t G\rangle \quad (11)$$

the inequality in the middle is reflection positivity, and only with it can $\mathcal{H}$ and $H \geq 0$ be built (the Osterwalder–Schrader reconstruction) Known . "Time", "energy" and "particle" are words that acquire meaning through (11). That the Wilson action preserves reflection positivity is due to Osterwalder–Seiler 1978 Known . On the other hand, the lattice itself breaks rotational symmetry. The problem statement writes that when reflection positivity is lost through regularisation, there are few ways to recover it (quotation in 0-03 § 03) Known . Example: for the Pauli–Villars two-point function an F with $\langle F, F \rangle_{\mathcal{H}} < 0$ can be built (7-11 § 06).

The seam of the word "particle"

Physics counts glueball masses Physics . What the problem statement asks for is a spectral gap, and the existence of an isolated one-particle state at the bottom is set aside among the 'natural extensions' (0-03 § 09) Known .

$$\text{problem statement}: \ \operatorname{spec}(H) \cap (0, \Delta) = \varnothing, \qquad \text{physics}: \ m_{0^{++}} \text{ is an isolated eigenvalue of}$$

($\mathbf{P}$ is the momentum.) Example: the way correlations measured on the lattice decrease tells the position of the bottom, but not whether it is an isolated point or the edge of a continuous spectrum (16-08 § 05). The unit GeV does not come out of pure Yang–Mills either, and Athenodorou–Teper note 'Strictly speaking this is of course not possible: the pure gauge theory and QCD … are two different theories' Physics .

07

Overlaying the two lists — obstacles, moves, partial bridges

7-11 listed the obstacles on the side of mathematics, and 17-13 the moves of physics. The seams pair their rows. The partial bridges that already exist all have the following form.

$$A \implies (M \text{ , in part}), \qquad A \text{ in four dimensions, at weak coupling, in the continuum, in infin}$$

Example: in Shen–Zhu–Zhu, A is $\lambda > 96$ (an explicit range; below $N^2/48$ in Wilson's β, with the conversion in Table 4 of 5-01), the conclusion is a gap in infinite volume, and A does not hold in the direction of the continuum limit $\lambda \to 0$.

Known Table 4 The seams with the obstacles of 7-11, the moves of 17-13 and partial bridges (the correspondence is this book's arrangement)

Seam	Obstacle	Move	Partial bridge
1 Existence	3, 6	Putting that it exists	The measure on $\mathbb{R}^2$ (7-02). In four dimensions, the published construction (the continuum limit in a periodic box, infinite volume along a subsequence, the Wightman axioms; the committee's assessment Assessment , Part 6). There is no uniqueness of the infinite-volume limit
2 One scale	2	Regarding as one (scale)	Not found within the range we searched (17-12 is at the stage of cutting it out as an assumption)
3 Shores	1	Expansion, neighbouring theories	The infinite-volume limit, area law and exponential clustering at strong coupling (Osterwalder–Seiler 1978; range not made explicit). A gap and a log-Sobolev inequality in the explicit range $\lambda > 96$ (Shen–Zhu–Zhu)
4 Finite and infinite	1, 6	Extrapolation, the string picture	Exponential decay at weak coupling for finite groups (Adhikari–Cao). The lattice correlation-length problem for continuous non-abelian groups remains open. The published construction passes to infinite volume along a subsequence, but there is no gap uniform in the volume (16-02)
5 Spacetime and space	5	All the premises	On finite lattices, reflection positivity of the Wilson action and a positive transfer matrix (preserved in weak limits too). The recovery of rotational symmetry remains
6 Particles	—	Regarding as one (seeing the gap as the mass of a particle; 17-13 § 09)	Within the range we searched, not found in four dimensions
7 Extra dimensions	1	Neighbouring theories	The eigenvalue problem after fixing the background (17-09). No exchange of limits found
Outside the table: gauge	4	Choosing a gauge	A wall common to both sides. A conditional theorem stating confinement in terms of gauge-invariant quantities (Wilson loops) without choosing a gauge (Chatterjee 2021: if centre symmetry is unbroken there is confinement; 17-13 § 08, 16-08 § 06)

Apart from the bridge over the seam of existence, the partial bridges all lie on the side of the shores (strong coupling, low dimensions, finite lattices), and within the range we searched none extends towards the problem statement. The bridge over the seam of existence (the published construction), too, carries every step of renormalisation at weak coupling and stops at the step with lattice spacing 1. It does not enter the behaviour at long distances (a uniform gap, the area law) (16-03). Gauge is not put among the seven because local gauge fixing is a wall common to both mathematics (7-05) and physics. Chatterjee's 2021 theorem is one road that goes on in front of this wall without choosing a gauge. Topological sectors and θ (7-11) could also be counted as a

seam, in that the problem statement does not touch θ. What would need to be known to move which rows is lined up in 16-07, and the list of questions remaining after the published construction in 16-02.

What this chapter can say

	What is said	What is not said
Known	For each seam, the sentence of physics, the mathematical statement, and the current state and partial bridges as stated by the primary sources	That seven is exhaustive (the counting, the types and the correspondences of Table 4 are this book's arrangement)
Computed	The plaquette on 6^4, and the β where the two leading terms are within 5%. The ratio of the leading strong-coupling term to the masses of the primary source. That u equals the single-plaquette average I_2/I_1 (numerical integration). The conversions (6) and (8)	Infinite-volume values (finite-volume effects not estimated). The 5% line is this chapter's choice
Physics	The estimates (8) and (10), and the reading of the examples where one scale breaks	That asymptotic scaling and the exchange of limits are correct
Overall	—	This site fills none of the seams (the bridge over the seam of existence belongs to the published construction). It does not show the existence of the mass gap

Next chapter to read: 16-06 Candidates for new concepts, which looks from the side of concepts at what seems to be needed to cross the seams. The rearrangement as tasks is in 16-07.

Candidates for new concepts — what plays the part of "Ricci flow"

> This chapter is a map of open questions. § 02, § 03 and § 04 are established knowledge.

What this chapter shows — The three components of Ricci flow (flow, monotone quantity, surgery). That in the two-dimensional σ model the renormalisation group at one loop is Ricci flow itself, and the scale at which the sphere shrinks away is Λ. Where the candidates for each component stop in four dimensions.

Prerequisite chapters — 7-09. We also use 7-05, 4-07 and 7-11. Geometric tools such as Ricci curvature and scalar curvature are defined on the spot with the example of the sphere.

Said first — This chapter lines up candidates; it cannot say which one will work. "What plays the part of Ricci flow is the renormalisation group" and "what plays the part of $R = T$ is a duality transformation" are analogies (only the one loop of the σ model is not an analogy but an agreement). This site shows neither the mass gap nor the construction of the continuum limit. The label Assessment means "according to the committee's assessment report" (“Labels” in 6-00).

The order of this chapter

1. Where the setters asked for "new ideas"
2. Ricci flow: moving a metric by its curvature
3. Perelman's components: flow, monotone quantity, surgery
4. Where the renormalisation group becomes Ricci flow: the two-dimensional σ model — the scale at which it shrinks away is Λ. Figure 1, Table 1. Detour: a flat circle does not shrink
5. What flows in four dimensions — the flow of the coupling and the gradient flow of the field
6. Monotone quantities: c in two dimensions and a in four — monotonicity comes from reflection positivity. Figure 2, Table 2
7. What plays the part of surgery

8. Another type: identification
9. The candidates on one sheet

01

Where the setters asked for "new ideas"

The Clay problem statement (Jaffe–Witten 2000), § 6, takes the construction on T^4 to be within reach as an extension of known methods, and then writes: "no present ideas point the direction to establish the existence of a mass gap that is uniform in the volume. Nor do present methods suggest how to obtain the existence of the infinite volume limit $T^4 \to \mathbb{R}^4$". § 6.5 reads "New ideas are needed". The same § 6, however, also treats the construction on T^4 as unfinished. What can be said is only "the side where the setters asked for new ideas is the infrared" (7-10 § 01). Known

Later, the construction published in 2026 gave the continuum limit in a periodic box and an infinite-volume theory along a subsequence (satisfying the Wightman axioms). The committee's assessment is that this is “proved in Lean” Assessment (Part 6). A mass gap uniform in the volume and the uniqueness of the infinite-volume limit remain among the open questions listed in the assessment report (16-02). The infrared side, where the setters asked for new ideas, is still open.

We write "uniform in the volume" as a formula. For the gap Δ_L of a box of side L,

$$\Delta_L > 0 \ \ (\text{for every } L) \qquad \text{and} \qquad \inf_L \Delta_L > 0 \ \ (1)$$

are different claims. Example: for a free field of mass m the gap is at least m for every L, and the right-hand one also holds. If $\Delta_L = 1/L$ held, only the left-hand one would hold.

Among the new concepts that worked on other great problems, two types can be seen: a flow with a monotone quantity (Perelman, the Poincaré conjecture), and the identification of two objects (Wiles, Fermat's Last Theorem) (this book's arrangement).

02

Ricci flow: moving a metric by its curvature

A Riemannian metric g is an inner product on the tangent space at each point (1-05), with components written g_{ij}. The Ricci curvature Ric (components R_{ij}) is, for a direction v of length 1, the sum of the bending (sectional curvatures) of $n-1$ mutually

orthogonal planes containing v (n is the dimension of the manifold). Equivalently, it is $n-1$ times the average. Precisely, it is a contraction of the curvature tensor. We use only the following example.

$$\text{sphere of radius } r \text{ in } n \text{ dimensions}: \qquad \mathrm{Ric} = \frac{n-1}{r^2}\, g \quad (2)$$

On a sphere of radius r, the bending of every plane is $1/r^2$. Adding $n-1$ of them gives the coefficient $n-1$. The trace of Ric (the sum of the diagonal components in an orthonormal basis) is called the scalar curvature R. On this sphere $R = n(n-1)/r^2$.

Ricci flow is the equation that moves a metric by its Ricci curvature, and Perelman's paper starts from this equation, introduced by Hamilton (1982). Known

$$\frac{\partial g}{\partial t} = -2\,\mathrm{Ric}(g) \quad (3)$$

Positively curved directions shrink. Along the flow the scalar curvature obeys $\partial_t R = \Delta R + 2|\mathrm{Ric}|^2$. Δ is the Laplacian on the manifold (not the Δ of the mass gap), which in flat coordinates is $\sum_i \partial^2/\partial x_i^2$ (a different symbol from the gap Δ_L of § 01). $|\mathrm{Ric}|^2$ is the sum of squares of the components of Ric in an orthonormal basis.

If the right-hand side were ΔR alone it would be the heat equation, and just as heat evens out temperature, it would shave the peaks of R and fill its valleys. Precisely, the non-negative term $2|\mathrm{Ric}|^2$ is added upward everywhere. For equations of heat-equation type, a solution cannot create a new minimum in the interior (the maximum principle). So the minimum of R does not decrease along the flow. Perelman's introduction, presenting Hamilton's work, writes this equation and conclusion in this form. Known

Example: a sphere of initial radius $r(0)$ stays round and only its radius changes. From $g = r^2 \hat{g}$ ($\hat{g}$ is the metric of the unit sphere) and (2),

$$\frac{d(r^2)}{dt} = -2(n-1), \qquad r(t)^2 = r(0)^2 - 2(n-1)\,t, \qquad t_* = \frac{r(0)^2}{2(n-1)} \quad (4)$$

and at time t_* (the extinction time) it shrinks to a point. For the unit two-sphere $t_* = 1/2$. For a general shape the curvature becomes infinite somewhere. Perelman writes "The most natural way of forming a singularity in finite time is by pinching an (almost) round cylindrical neck", and continues the flow by surgery that cuts the thin neck and puts small caps on it.

03

Perelman's components: flow, monotone quantity, surgery

We split Perelman's proof into three components. The first, the flow, is (3) of § 02. The second is a quantity that increases monotonically along the flow. We define the tools first. M is a closed manifold (a compact manifold without boundary), f an auxiliary function on M, and dV the volume element determined by the metric ($\int_M dV$ is the volume of M). ∇f is the gradient of f, and $|\nabla f|^2$ the square of its length. $\nabla_i \nabla_j f$ is the second derivative of f, which in flat coordinates is $\partial_i \partial_j f$.

$$\mathcal{F}(g, f) = \int_M \left(R + |\nabla f|^2\right) e^{-f}\, dV$$

When the metric is moved by (3), f is moved at the same time by $\partial_t f = -\Delta f + |\nabla f|^2 - R$. This way of moving preserves the measure $e^{-f} dV$ up to a change of coordinates, and the total integral $\int_M e^{-f} dV$ does not change. Then

$$\frac{d\mathcal{F}}{dt} = 2 \int_M \left| R_{ij} + \nabla_i \nabla_j f \right|^2 e^{-f}\, dV \;\geq 0 \quad (5)$$

holds (Perelman § 1.2). The right-hand side is the integral of a square, so it is not negative. Known

The flow behaves as if it climbs the slope of $\mathcal{F}$. Precisely, the flow $\partial_t g_{ij} = -2(R_{ij} + \nabla_i \nabla_j f)$ with the measure $e^{-f} dV$ held fixed is a gradient flow in the direction that increases $\mathcal{F}$, and a change of coordinates takes it to the pair of (3) and the equation for f above (Perelman § 1.1–1.2). On the choice of the measure held fixed, Perelman writes "the choice of m is analogous to the choice of gauge". The m of the original is this measure, not the mass of § 06. Whatever the choice, the flow is the same up to a change of coordinates. Known

Further, seen up to changes of coordinates and of scale, the flow has no non-trivial periodic orbits (Perelman § 2, § 3). The trivial ones are called solitons (solutions that keep their shape under changes of coordinates and scale alone), and in this view they correspond to fixed points. Known Example: on a flat torus $R_{ij} = 0$, and taking f constant, the right-hand side of (5) is 0 and the flow stands still (a fixed point).

The third component is to classify in advance the shapes of the regions of large curvature, and to remove by surgery only what has been classified. What could play the same roles for Yang–Mills: for the flow, the renormalisation group and gradient flow (§ 05); for the monotone quantity, c and a (§ 06); for classification and surgery, large fields, instantons and topological sectors (§ 07). As another type there is identification (§ 08). Every one of these correspondences is an analogy.

04

Where the renormalisation group becomes Ricci flow: the two-dimensional σ model

Within one-loop perturbation theory, the place where the correspondence stops being an analogy is the two-dimensional non-linear σ model. The field ϕ is a map from the plane to a manifold M. In this section we write the metric of M as h (components h_{ij}).

$$S[\phi] = \frac{1}{2}\int_{\mathbb{R}^2} h_{ij}(\phi)\,\partial_\mu\phi^i\,\partial_\mu\phi^j\,d^2x \quad (6)$$

The coupling constant is not a number but the metric h itself. The abstract of Friedan (1980) writes "the renormalization group acting on the infinite-dimensional space of Riemannian metrics". At one loop, for the scale $\ell = \ln(\mu_0/\mu)$ (larger means seen more coarsely),

$$\frac{dh_{ij}}{d\ell} = -\frac{1}{2\pi}\,R_{ij}(h) + \cdots \quad (7)$$

and setting $t = \ell/4\pi$ gives (3) itself. Physics "$\cdots$" stands for corrections at two loops and beyond. From two loops a term quadratic in the curvature is added (of the form $R_{iklm}\,R_j{}^{klm}$, where R_{iklm} are the components of the curvature tensor), and the flow departs from Ricci flow. The abstract of Friedan (1985) says the coefficients of the renormalisation group were computed in the two-loop approximation. Physics

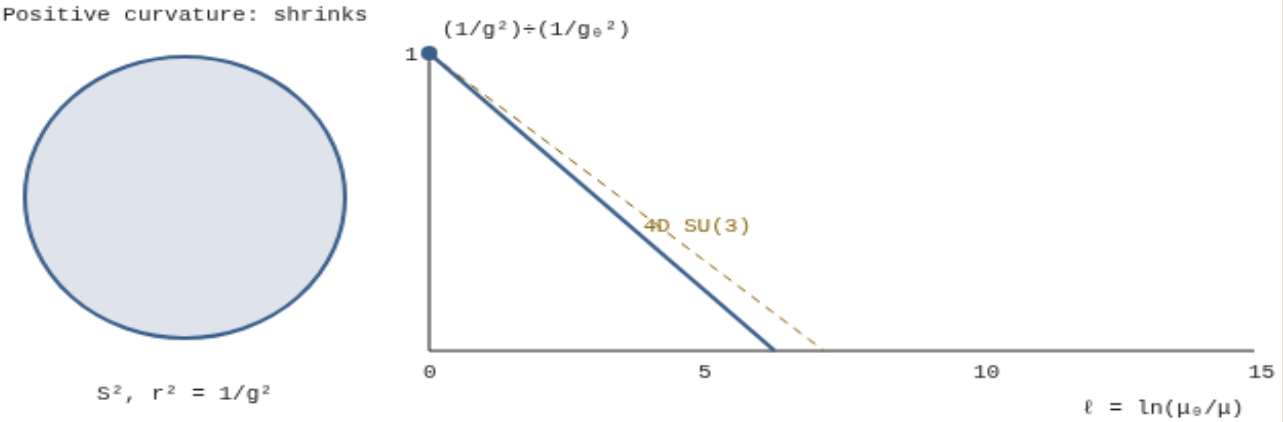
Example: taking M to be the sphere S^{N-1} of radius r gives the $O(N)$ model, with $r^2 = 1/g^2$. With $n = N-1$ in (2),

$$\frac{d}{d\ell}\Big(\frac{1}{g^2}\Big) = -\frac{N-2}{2\pi}, \qquad \ell_* = \frac{2\pi}{(N-2)\,g_0^2}, \qquad \Lambda = \mu_0\,e^{-\ell_*} \quad (8)$$

The more coarsely one looks, the more the sphere shrinks and the stronger the coupling becomes. This is the "asymptotic freedom" of the abstract of Polyakov (1975). The scale ℓ_* at which it shrinks away is 4π times the extinction time t_* of (4), and it determines the one-loop Λ (4-07). For four-dimensional $SU(N)$ too, $1/g^2$ decreases along the straight line $1/g_0^2 - 2b_0\ell$.

Perelman touches on this relation in section 2 of his introduction, writing "this connection between the Ricci flow and the RG flow suggests that Ricci flow must be gradient-like; the present work confirms this expectation". That the flow is gradient-like (moves along the slope of some quantity) was expected from the intuition of the renormalisation group, and (5) confirmed it: that is how Perelman puts it. Known

Figure 1 Change N and g_0^2 with the knobs, and advance ℓ with "Play". Left: a cross-section of the sphere whose radius squared is $1/g^2$. Right: the ratio of $1/g^2$. The dotted line is four-dimensional $SU(3)$



N = 3, g_0^2 = 1.0, ℓ = 0.00, 1/g² = 1.000, ℓ* = 6.28, Λ/μ₀ = 1.87×10⁻³, SU(3): ℓ* = 7.18

Computed The straight lines of the figure are formula (8) and $b_0 = 11N/(48\pi^2)$ drawn on the spot. Table 1 was computed on this machine.

Model	g_0^2	ℓ_*	$\Lambda/\mu 0$	Note
$O(2)$	Any	∞	–	The circle is flat and does not flow
$O(3)$	1	6.283	1.87×10⁻³	Ricci flow $t_* = 0.5$
Four-dimensional $SU(2)$	1 / 2	10.77 / 5.38	2.11×10⁻⁵ / 4.59×10⁻³	$b_0 = 0.04644$
Four-dimensional $SU(3)$	1 / 2	7.178 / 3.589	7.63×10⁻⁴ / 2.76×10⁻²	$b_0 = 0.06966$

Table 1 The scale at which the one-loop $1/g^2$ reaches 0. $\ell_* = 4\pi t_*$ was checked against formula (4). Computed

Before the straight line reaches 0 the coupling becomes large and the one-loop formula can no longer be used. As near a singularity of Ricci flow, what matters is what happens after the coupling becomes $O(1)$. The gap of the two-dimensional $O(N)$ model ($N \geq 3$) is a conclusion at the level of physics. Physics Douglas's report (2004) goes no further than citing an example in which a gap was shown for a regularised version of the $O(N)$ model (Kopper 1999). Its later status as a theorem has not been checked in this chapter.

Detour: a flat circle does not shrink

A subsection you may skip.

For $N = 2$ the target is a circle with curvature 0, and the coefficient $N - 2$ vanishes. The two-dimensional $O(2)$ model has a massless phase at low temperature. At high temperature correlations decay exponentially with distance (there is a mass); at low temperature they decay only as a power of the distance (massless). The transition between these two phases is called

the Kosterlitz–Thouless (KT) transition. Fröhlich–Spencer (1981) proved that this transition exists, for the two-dimensional lattice rotator model ($O(2)$), the Coulomb lattice gas and others. Known Set beside four-dimensional $U(1)$ (5-06), the picture "it shrinks because it is curved (non-abelian)" comes to mind, but it is an analogy.

05

What flows in four dimensions: the flow of the coupling and the gradient flow of the field

In four dimensions there are two different "flows". The **flow on the space of theories** (the renormalisation group, 7-05) has no picture of a sphere, but the one-loop $1/g^2$ is a straight line of the same form (Table 1). Bałaban's ultraviolet stability on T^4 comes with a hypothesis, and the limit is only along subsequences (7-07). The construction published in 2026 stacked one step of a coupling-dependent probability kernel into many steps and carried it as far as the continuum limit in a periodic box Assessment (Part 9 to Part 11). It carries every step within the weak-coupling band, however, and stops at the step with lattice spacing 1 (where the coupling has a large reference value) (16-03). Where the method of Bauerschmidt–Brydges–Slade reached $d = 4$ is the side where the coupling flows to 0 in the infrared (the $|\phi|^4$ model and the weakly self-avoiding walk), the exact opposite of the infrared of Yang–Mills. What is missing is "a controlled step after the coupling has reached $O(1)$" (this book's arrangement).

The **flow on the space of fields** (gradient flow) smooths a single configuration along the slope of the action. For an abelian field, following the gradient of the action $S = \frac{1}{4}\int F_{\mu\nu}F_{\mu\nu}\,d^4x$ backwards gives

$$\partial_t A_\mu = -\frac{\delta S}{\delta A_\mu} = \Delta A_\mu - \partial_\mu(\partial_\nu A_\nu), \qquad \frac{dS}{dt} = -\int \left|\frac{\delta S}{\delta A}\right|^2 \le 0 \quad (9)$$

(for a non-abelian field, replace ∂ by the covariant derivative). Since it is a gradient flow, the action always decreases. Example: after a Fourier transform, the component perpendicular to the wave number k decays as $e^{-k^2 t}$, and fluctuations with $|k| \gg 1/\sqrt{t}$ disappear. The component parallel to k (the gauge direction) does not move. In Ricci flow the same thing happens through invariance under changes of coordinates, and DeTurck (1983) fixed it by adding a term. The same device appears in the stochastic quantisation of Yang–Mills (7-09 § 07).

The abstract of Lüscher (2010) says that theory and numerics "suggest" that the flowed field is "a smooth renormalized field", and Carosso–Hasenfratz–Neil (2018) used it numerically as a continuous real-space renormalisation group. Waldron (2019) showed that, for smooth initial data on a closed four-dimensional manifold, Yang–Mills flow

has no finite-time singularity. Known The relation between the two flows is at the level of suggestion and numerics.

06

Monotone quantities: c in two dimensions and a in four

We prepare two tools. The stress tensor (energy–momentum tensor) $T_{\mu\nu}$ is the field that describes the flow of energy and momentum. Its trace $\Theta = T^{\mu}{}_{\mu}$ (in two dimensions $T11 + T22$) measures how much the action changes when the scale is changed slightly. For a theory that does not change under a change of scale (a fixed point), $\Theta = 0$. The central charge c is a number carried by the theory at a fixed point, and roughly counts the massless degrees of freedom (1 for one free scalar field). In this chapter we use only the name, and see its value through the sum rule (10) below.

In two dimensions there is the c-theorem of Zamolodchikov (1986), which constructs a function that decreases along the flow and equals the central charge at fixed points. Physics As a form we can compute, we look at the sum rule for correlations of Θ, cut off at distance r_0.

$$c(r_0) = 3\pi \int_{|x|>r_0} |x|^2 \, \langle \Theta(x)\Theta(0)\rangle \, d^2x \qquad (10)$$

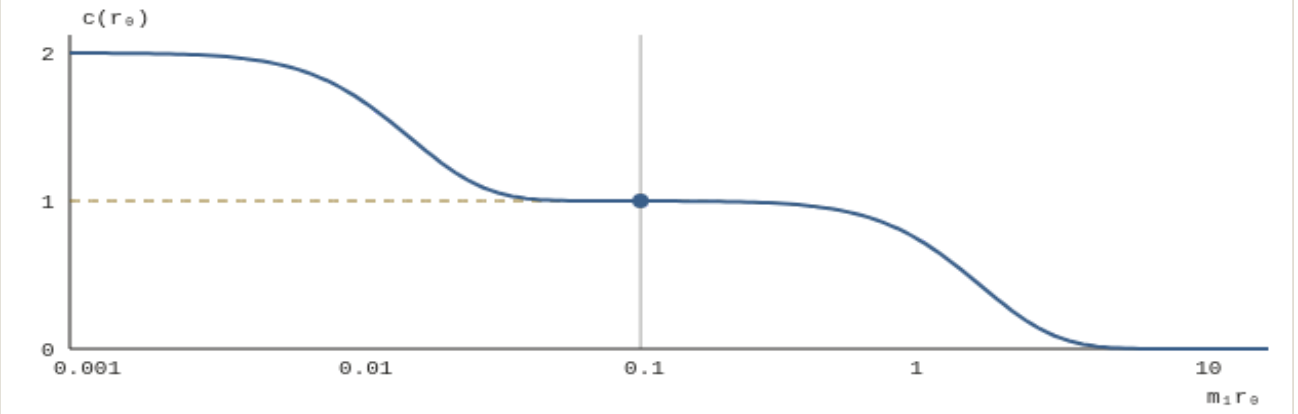
Here Θ is the trace of the stress tensor made directly from the action (in the normalisation $\Theta = 2\pi T^{\mu}{}_{\mu}$, the prefactor becomes $3/4\pi$). The content of the sum rule is that the value at $r_0 \to 0$ is the difference between the ultraviolet and infrared central charges. This sum rule is attributed to Cardy (1988). Physics

For a free scalar field of mass m, $\Theta = -m^2\phi^2$ and $\langle\Theta(x)\Theta(0)\rangle = 2m^4 G(x)^2$. $G(x) = K_0(m|x|)/2\pi$ is the propagator (1-11), and K_0 is a modified Bessel function (decaying like $e^{-m|x|}$ far away). Therefore

$$c(r_0) = 3\int_{mr_0}^{\infty} u^3 K_0(u)^2 \, du, \qquad c(0) = 1, \quad c(\infty) = 0 \qquad (11)$$

We checked $c(0) = 1$ by numerical integration as $1 - 8\times10^{-12}$. Computed Since the integrand is never negative, $c(r_0)$ decreases. In general, $\langle\Theta(x)\Theta(0)\rangle \geq 0$ for $x \neq 0$ follows from translation and rotation invariance and reflection positivity (4-10). A property that is easily lost under regularisation (7-11 the obstacle of positive regularisation) is where the monotonicity comes from. Known

Figure 2 Change the mass ratio m_2/m_1 and the scale r_0 with the knobs, and stretch r_0 with "Play". The solid line is $c(r_0)$ for two free fields, the dotted line for one



m₂/m₁ = 100 m₁r₀ = 0.10 c(r₀) = 0.999 (one field: 0.999)

Computed The curve is an interpolation of a table of 85 points from numerical integration of formula (11) on this machine (embedded with the trailing 0s omitted).

$mr0$	0.1	0.5	1	2	3	5
$c(r0)$	0.99946	0.93639	0.70823	0.25841	0.06861	0.00313

Table 2 $c(r_0)$ for one field. For two fields with mass ratio 100, at $m_1 r_0 = 10^{-3}, 10^{-2}, 0.1, 1$ it is 1.999, 1.708, 0.999, 0.708, staying on the step at 1 in between. Computed

The step shows that the flow passes near an intermediate fixed point (the scales at which only the light field looks massless); in an infrared with a gap, $c = 0$.

When a four-dimensional fixed point is placed on a curved background, the Euler density (a quadratic expression in the curvature whose integral is proportional to the Euler number of the manifold) appears with a coefficient in the expectation value of Θ. That coefficient is the Euler anomaly a (not the lattice spacing a; in this chapter only the name). The abstract of Komargodski–Schwimmer (2011) derives a monotonically decreasing function joining the ultraviolet and infrared a, "establishing the a-theorem". Physics The a of free fields is positive, and the contributions of a real scalar, a Weyl fermion and a gauge field are in the ratio $1 : \frac{11}{2} : 62$ (appendix A of the same paper). Known

The ultraviolet of pure Yang–Mills approaches free gluons, so $a > 0$. If there is a gap in the infrared, no massless degrees of freedom remain, so $a = 0$. Physics The two do not contradict each other, but $a_{\mathrm{UV}} > a_{\mathrm{IR}}$ does not force a gap. That there is a gap in the infrared is itself the unproved part of this book's subject. A separate "classification of infrared endpoints", corresponding to the classification of singularities, is needed (an analogy).

```
07
```

What plays the part of surgery: large fields and topological sectors

In four-dimensional Yang–Mills, the fact that the action does not change under changes of scale creates the same kind of difficulty as singularities in which curvature concentrates at a point. If $A_\lambda(x) = \lambda A(\lambda x)$, then $F_\lambda(x) = \lambda^2 F(\lambda x)$, and

$$\int_{\mathbb{R}^d} |F_\lambda|^2 \, d^d x = \lambda^{4-d} \int_{\mathbb{R}^d} |F|^2 \, d^d x \quad (12)$$

For $d = 4$ this does not depend on λ. Example: an instanton of size ρ has action $8\pi^2/g^2$ whatever ρ is (3-05), and as $\rho \to 0$ the action does not decrease even when the curvature concentrates at a point.

As a ruler for the size of the curvature we use $\|F\|_{L^p} = \left(\int |F|^p \, d^d x\right)^{1/p}$ ($p = 2$ is the L^2 of 1-10, and squared it is the action). The compactness of Uhlenbeck (1982) (from a sequence of connections whose curvature is bounded in L^p, one can extract, after changes of gauge, a subsequence converging in a weak sense) works with L^p estimates for $p > d/2$, and the L^2 of $d = 4$ (the action itself) lies exactly on the borderline. On the borderline, curvature can concentrate at finitely many points and small instantons can pinch off like bubbles (bubbling; in this chapter only the name). Known

On the quantum side, what could play the part of surgery are the large-field regions treated separately in Bałaban's method (7-05 § 04), small instantons, and topological sectors (7-11 Detour). None of them has reached the stage of "classify, then remove".

08

Another type: identification with an object in which the gap is visible

The Wiles type shows that two objects are the same, and brings in from one of them a property not visible in the other ($R = T$; a summary at the level of common knowledge). Jaffe–Witten § 6.6 writes that, since the gap is not visible classically, "a nonclassical change of variables or “duality transformation”" may be needed. Known

Examples where a gap was shown by this type start from an identity of Gaussian integrals. For a Gaussian field φ with covariance V,

$$\mathbb{E}\left[e^{\,i \sum_j q_j \varphi(x_j)}\right] = \exp\left(-\tfrac{1}{2} \sum_{j,k} q_j q_k \, V(x_j - x_k)\right) \quad (13)$$

The right-hand side is the weight of particles with charges q_j interacting through the potential V; the left-hand side is an expectation value of the field. Summing over the gas of charges, the left-hand side becomes a field theory containing $\cos\varphi$. This is called the sine-Gordon model (a field theory with a $\cos\varphi$ term in its action; in this chapter

only the name). Brydges–Federbush (1980) used this transformation to prove exponential decay of correlations (Debye screening) in the Coulomb gas at low density or high temperature. Known It is an abelian model of statistical mechanics.

Fragments for Yang–Mills itself are the gauge–string duality for $SO(N)$ at strong coupling and large N of Chatterjee (2019), the representation of Wilson loops as sums over surfaces of Cao–Park–Sheffield (17-04 § 09; the picture is in § 05), and "unbroken centre symmetry ⇒ confinement" of Chatterjee (2021) (an implication, not an equivalence). At the level of physics there are Seiberg–Witten (17-11) and holography (17-09). The problem asks for fixed N, so large N alone is not enough.

09

The candidates on one sheet

The proposal to give a symbol to $1/0$ is not included, since it carries little information (7-12 § 10).

First, how to read the table. The "Component" column says which of the three components of § 03 the candidate corresponds to. They divide into flow (i–iii), identification (v, vi) and surgery (vii); (iv) corresponds to none. "How far" is the range reached as a theorem; "Where it stops" is the first place not reached.

Lining up the places where they stop, they gather roughly in two. One is that small numbers disappear in the infrared, where the coupling becomes $O(1)$. (i) has no step there (the published construction, too, stops at the step with lattice spacing 1 just before it); the continuum limit obtained in (iii) is of a design that ties the coupling to 0; and (iv) is a power series, so it does not reach e^{-1/g^2}. The other is that they work only in a different limit, $N \to \infty$ or strong coupling: (v) and (vi) are of this kind. (i) tries to go from the ultraviolet side to the infrared and stops; (vi) has a picture of the infrared but stops without being able to return to finite N. They stop facing in opposite directions (this book's arrangement).

	Candidate	What it makes new	How far	Where it stops	Component
i	Constructive renormalisation group (Bałaban, MRS, BBS, the construction published in 2026)	Treat one step as a map on the space of theories	Published construction: the continuum limit in a periodic box and infinite volume along a subsequence, the Wightman axioms Assessment . Bałaban: ultraviolet stability on T^4 (with a hypothesis)	A step after the coupling has reached $O(1)$. The published construction stops at the step with lattice spacing 1 (where the coupling is large) (16-03)	Flow
ii	Stochastic quantisation and regularity structures (Hairer, CCHS)	The measure as the invariant measure of a dynamics, the space of orbits as the state space	The measure on T^2 is the unique invariant measure of the dynamics (Chevyrev–Shen). Local solutions for three-dimensional YMH	Subcritical $d < 4$ (7-09)	Flow
iii	New ways of taking limits (Chatterjee and others)	Decide first the space in which the limit lives	The gap of the strong-coupling lattice (in lattice units). The Gaussian limit of YMH (of a design that ties the coupling to 0)	A non-Gaussian limit	Flow
iv	Algebraic formulations (Connes–Kreimer, Costello)	Write renormalisation as an algebraic structure	A formulation within perturbation theory (at the level of formal power series)	Does not reach quantities invisible to perturbation theory, such as e^{-1/g^2}	—
v	Duality, change of variables (JW § 6.6)	Identify with an object in which the gap is visible	Debye screening (abelian). Fragments of gauge–string duality	No duality transformation that works for pure Yang–Mills was found, as far as we looked	Identification

	Candidate	What it makes new	How far	Where it stops	Component
vi	Large N and holography	See the gap in the geometry of extra dimensions	Level of physics Physics	$N \to \infty$, strong coupling	Identification
vii	Classical YM in geometric analysis (Uhlenbeck, Waldron)	Analysis in the critical dimension (bubbling, § 07)	The classical theory is within reach of existing methods (JW § 2)	Quantum configurations are expected not to be smooth	Surgery

This book's study treated in Part 23 (the diffusive-relaxation-time assumption, 23-01) is closest to type (i): it cuts out the physical premise "a single scale" as an inequality on the lattice (the judgement of closeness is this book's arrangement).

What this chapter can say

	Content
Said	What the setters asked new ideas for is the uniform gap and the infinite-volume limit. Perelman's monotonicity formula (5) (the formula when f is moved at the same time), and the statement that the gradient-like nature of the flow had been expected from the intuition of the renormalisation group (both from the original texts) Known
Said	The one-loop flow (8) of the $O(N)$ model agrees with the Ricci flow (4) of the sphere under $t = \ell/4\pi$, and the scale at which it shrinks away is the one-loop Λ (Table 1). From two loops it departs from Ricci flow Computed Physics
Said	For a free scalar field of mass m, $c(r_0)$ decreases monotonically from 1 to 0, and the monotonicity comes from reflection positivity Computed Known
Not said	Which candidate will work (the correspondences are analogies). The status as a theorem, after 2004, of the gap of the two-dimensional $O(N)$ model. Whether the infrared of pure Yang–Mills has a gap ($a = 0$ is under that condition). Whether a monotone quantity exists in four dimensions as a theorem. Exhaustive coverage from 2025 on

The list of open tasks — joining the open questions by arrows of "if this were known, what would move"

In this chapter, § 01– § 08 are a map of open questions and § 09 is guide material.

What this chapter shows — Twelve open tasks and the closest results there are now. The three strengths of the arrows that join the tasks (theorem, roadmap, physical expectation). Checking, with a figure and a count, which requirements of the problem statement move when a task is assumed known.

Prerequisite chapters — 16-05 Where the two ways of digging part. We use the vocabulary of 7-10 (what is reached at each stage in four dimensions), 7-11 (the six obstacles) and 16-01 (the board).

Said first — This chapter lines up and joins the tasks; it settles none of them. The choice of arrows and the way of counting are this book's arrangement, and only arrows checked in primary sources are used. This site shows neither the existence of the mass gap nor the construction of the continuum limit. The tasks touched by the construction published in 2026 are written in the "closest result" column of Table 1 and at the end of § 02 (the committee's assessment Assessment ; for the meaning of the label Assessment , see "Labels" in 6-00). The list of questions that remain after the published construction is in 16-02.

The order of this chapter

1. Writing the tasks with "if ... then" — requirements and arrows
2. Twelve tasks — continuum and lattice (Table 1)
3. Arrows joined by theorems — reflection positivity, the uniform gap, the centre
4. Roadmap arrows — the order the setters and surveys write
5. Suppose it were known — a map of the tasks (Figure 1, Table 2)
6. Counting the map — tasks needed on every road (Table 3, computed)
7. For every group — arrows that vanish when the group is changed
8. Tasks outside the problem statement — one-particle states, general manifolds
9. The book's coordinate system — dictionary, seams, tasks and walls in nine cells (Figure 2, Table 4)

01

Writing the tasks with "if … then"

A **task** in this chapter is a statement that has not yet become a theorem. What moves when a task becomes known can be written as an arrow "if A is known, B can be said", and we divide its strength into three. **Theorem** (a proved implication, or a definition), **roadmap** (a prospect that the problem statement or a survey writes as "once this is known, the next step should be possible"), and **expectation** (an implication at the level of physics). As a metaphor it is a table matching keys to doors; precisely, it is a list of rules of the form "if all the premises are in place, the conclusion follows".

$$X_1 \wedge X_2 \wedge \cdots \wedge X_k \overset{\ell}{\Longrightarrow} Y, \qquad \ell \in \{0\ (\text{theorem}),\ 1\ (\text{roadmap}),\ 2\ (\text{expectation})\} \tag{1}$$

The destination is the problem statement (Jaffe–Witten 2000, below JW; 0-03). Fix one group G, and divide the demand into four **requirements** Known (a summary of JW § 4; the division into four is this book's arrangement).

$$\mathsf{P} = \bigwedge_{G} \mathsf{P}_G, \qquad \mathsf{P}_G = \mathsf{E} \wedge \mathsf{A} \wedge \mathsf{N} \wedge \mathsf{M} \tag{2}$$

The requirement of existence (E) is the existence of the theory on $\mathbb{R}^4$; the requirement of the axioms (A) is the axioms (at least as strong as those of the book of Streater–Wightman [45] and the papers of Osterwalder–Schrader [35] cited by JW); the requirement of non-triviality (N) is non-triviality, local fields and agreement with asymptotic freedom at short distances (JW § 4); and the requirement of the gap (M) is the gap $\Delta > 0$ and $m < \infty$.

We add one more requirement, outside the problem statement: the requirement of the string tension (C). The requirement of the string tension is that the string tension d of the continuum theory is not 0. d is the constant of the continuum string-tension problem of Chatterjee 2018 (Chatterjee's Problem 5.2), written σ in 7-10 § 04. The physical expectation is that d is positive.

Example: the Theorem from Uniform Decay to the Area Law of Chatterjee (2021) (Theorem 2.4 of Chatterjee 2021) is a theorem arrow. If a lattice gauge theory has uniform exponential decay under arbitrary boundary conditions (the definition of strong decay (Definition 2.3 of Chatterjee 2021); the constants depend only on the group, β (the coefficient of the coupling in the lattice action; not an inverse temperature) and the dimension of the lattice, not on the box or the boundary conditions), then centre symmetry is not broken. Further, rectangular Wilson loops in an irreducible representation that acts non-trivially on the centre obey the area law in every Gibbs measure (a distribution on the infinite lattice that follows the lattice

weights inside any box once the outside is fixed)Known (16-08 § 06). An example of a roadmap is JW § 6.5's 'Such a result presumably would enable the study of the limit as T4 → R4' (from the uniform gap to the infinite-volume limit).

02

Twelve tasks — six in the continuum and six on the lattice

The upper six of Table 1 (from the task of the T⁴ construction to the task of local fields and short distances) are tasks for the continuum theory, corresponding to the ultraviolet-limit step through the uniform-gap step of the six steps of construction (7-01) and to the additional conditions of the problem statement. The lower six (from the lattice correlation-length problem to the task of the three-dimensional measure) are lattice tasks, and tasks that turn lower dimensions and physical premises into mathematics. In this chapter limits are required along the whole sequence (this book's arrangement). JW's weak-existence footnote (footnote 2 of Jaffe–Witten; 0-03 § 08) writes that weak existence by compactness alone is not accepted as a solution of the existence part unless the properties of the limit (the gap and the axioms) are shown by other methodsKnown . The first three (in order, the task of the T⁴ construction, the task toward infinite volume and the task of a uniform gap) have the following form (notation as in 7-10).

$$\lim_{a\to 0}\langle W_{\gamma a}\rangle^{\mathrm{ren}}_{a,L}\ \text{exists along the whole sequence},\qquad \lim_{L\to\infty}\mu_L\ \text{exists},\qquad \inf_L \Delta_L > 0 \tag{3}$$

$W_{\gamma a}$ is the Wilson loop of a lattice path, $\langle\cdot\rangle^{\mathrm{ren}}$ is the expectation with a term proportional to the perimeter removed from its logarithm (formula (5.2) of Chatterjee 2018; 7-10 § 04), μ_L is the measure on the box T^4 of side L, and Δ_L its gap. Requiring the limit along the whole sequence in the task of the T⁴ construction and the task toward infinite volume is this book's arrangement.

Known Table 1 Twelve tasks

	Task	Statement	Closest result	What moves if known
1	Task of the T⁴ construction	Expectation values of gauge-invariant quantities converge as $a \to 0$ along the whole sequence (the whole sequence is this book's arrangement)	For correlation functions of local fields, the construction published in 2026 showed convergence along the whole sequence of cutoffs in a periodic boxAssessment (8-05). Not in the form of this row's statement (renormalised Wilson loops) (16-02 § 05). Before that, ultraviolet stability with a hypothesis and subsequences (Bałaban), an outline (MRS)	The ultraviolet-limit step, half of the requirement of existence

	Task	Statement	Closest result	What moves if known
2	Task toward infinite volume	The limit $L \to \infty$ exists along the whole sequence (likewise this book's arrangement)	What the published construction has goes only as far as limits along subsequences and phase decomposition Assessment . Convergence of the whole sequence and uniqueness are open questions of the assessment report (16-02 § 02). At the time of the problem statement, 'Nor do present methods suggest how to obtain the existence of the infinite volume limit' (JW § 6), a stage at which § 6.5 writes that the task of a uniform gap would open the way. On the lattice it is shown at strong coupling	The infinite-volume step, the rest of the requirement of existence
3	Task of a uniform gap	$\inf_L \Delta_L > 0$	'New ideas are needed' (JW § 6.5). What the published construction has goes only as far as polynomial estimates uniform in the phase; there is no exponential decay (16-02 § 04)	The uniform-gap step; through the roadmap, the task toward infinite volume
4	Task of the remaining axioms	Recovery of rotation symmetry, and the regularity needed for reconstruction	In the published construction, the Wightman axioms (including Euclidean invariance) for each phase Assessment (12-06, 12-08). Reflection positivity survives from the lattice. Rotations: Driver's Corollary 6.7 in two dimensions	The axiom step, the seam of spacetime and space
5	Task of non-triviality	The limit is not Gaussian	The scaling limit of lattice-cut four-dimensional ϕ^4 (including the Ising type) is Gaussian (Aizenman–Duminil-Copin 2021; a result in the opposite direction from non-triviality). In the published construction, the short-distance law of the two-point function of the trace field excludes descriptions of the type "polynomials in free fields of finitely many masses" Assessment (13-02). It does not exclude every description built from Gaussian fields	Half of the requirement of non-triviality

	Task	Statement	Closest result	What moves if known
6	Task of local fields and short distances	Local fields such as $\mathrm{Tr}\, F_{ij}F_{kl}(x)$. Agreement with asymptotic freedom at short distances	The level of perturbation theory. There is no natural one-to-one correspondence (JW's local-field footnote). The published construction has labels for local fields (8-03), and at short distances checks the one-loop running and the trace coefficient. Agreement with perturbation theory at all orders is not shown Assessment (6-04 § 06)	The rest of the requirement of non-triviality
7	Lattice correlation-length problem (Chatterjee's Problem 5.1)	$\xi(\beta) \in (0, \infty)$ (all β), $\xi \to \infty$	At strong coupling exponential decay (an upper bound on ξ) has been shown. For finite groups, exponential decay even at weak coupling (Adhikari–Cao; outside the scope of the lattice correlation-length problem, and without $\xi \to \infty$)	Only cells of the lattice
8	Continuum string-tension problem (Chatterjee's Problem 5.2)	String tension d $/= 0$ in the continuum limit of Wilson loops	Not yet. Whether a perimeter term is needed is also open. The published construction has no continuum Wilson loops either (16-02 § 05)	The requirement of the string tension
9	Task of strong decay	Uniform exponential decay under arbitrary boundary conditions (all β)	For small β it can be shown by the method of Dobrushin–Shlosman, as Chatterjee 2021 remarks. Whether the strong version is expected at large β is not clear (ibid.)	The lattice area-law problem
10	Lattice area-law problem (Chatterjee's Problem 4.1)	The area law for all β	Small β for every group (Osterwalder–Seiler 1978). Three-dimensional $U(1)$ for all β (Göpfert–Mack 1982)	Only lattice confinement
11	Task of one scale	$c\,\sigma(\beta) \le m(\beta)^2 \le C\,\sigma(\beta)$ for $\beta \ge \beta_0$ (constants $c, C > 0$ independent of β; m, σ are the mass and string tension in lattice units, and neither $m > 0$ nor $\sigma > 0$ is assumed)	No theorem. The record of this book's study is at the stage of placing it as an assumption in the form of 17-12 formula (3) (the diffusive-relaxation-time assumption is a separate formula (6), 17-12 § 05)	Joins the requirement of the string tension and the requirement of the gap at the level of expectation

	Task	Statement	Closest result	What moves if known
12	Task of the three-dimensional measure	Construction of the measure on T^3	'remains open' (Chevyrev 2022)	Only the 3D ultraviolet-limit step

For details: the task of the T^4 construction is in 7-07 (the published construction in 6-01), the task of non-triviality in 7-08, the lattice correlation-length problem and the lattice area-law problem in 16-01 § 07, and the task of the three-dimensional measure in 7-06. Example: what moves the four-dimensional cells of the board (16-01 Table 3) is the upper four of Table 1 (from the task of the T^4 construction to the task of the remaining axioms) and the lattice correlation-length problem; the three-dimensional row is moved by the task of the three-dimensional measure. The continuum string-tension problem, the task of strong decay, the lattice area-law problem and the task of one scale have no cells; they are tasks on the side of the seams. In the ledger of conditions (27-02), the lattice side of the task of a uniform gap corresponds to the row of uniform decay of block observables (correlations of block observables decay at a rate uniform in L and the lattice spacing; the premises are ultraviolet control, the small-T^2 gap and the band comparison (in the language of the gap)) Paper . The ultraviolet-control row of the ledger was shown, as a continuum limit in a periodic cubic box, by the published construction, while the form of this book's road remains open (27-02 Table 1). What remains on this book's road is the seam that puts the ultraviolet result into a form the infrared arguments can use (16-03, 16-04) Inferred . The arrow from the area law (the lattice area-law problem) to the task of a uniform gap does not hold in general. The area law is about the gap in the charged sector (electric flux $e \neq 0$), the task of a uniform gap about the gap in the neutral sector ($e = 0$), and the transfer matrix preserves this decomposition Paper . The known theorem goes the other way (uniform exponential decay ⇒ the area law; the Theorem from Uniform Decay to the Area Law of Chatterjee 2021 in § 01) Known .

After the published construction. Of the upper six of Table 1, the construction published in 2026 meets the task of the T^4 construction for correlation functions of local fields and the task of the remaining axioms for each phase, and touches the task toward infinite volume in the form of subsequences, and the task of non-triviality and the task of local fields and short distances in the form of checks at short distances Assessment . In the words of this chapter, the requirement of existence is not met in the form that requires the limit along the whole sequence (the volume side is along a subsequence), and nothing is given towards the requirement of the gap (the mass gap) Inferred . The figure of § 05 and the count of § 06 are a map of the logic between the tasks, and the rules do not change because of the published construction. The list of which tasks remain is placed in 16-02, following the five open questions of the assessment report, and where the construction stops is in 16-03.

03

Arrows joined by theorems

Not many arrows have a proof. We look at three in turn.

Reflection positivity survives in the limit

The first is reflection positivity. It holds on Wilson's lattice (Osterwalder–Seiler 1978), and since it is an inequality, if the sequence of measures μ_n **converges weakly** it survives in the limit Known (4-10). Converging weakly means that the expectation values of all bounded continuous quantities converge (0-03 § 08).

$$\langle \Theta F\, F \rangle_{\mu} = \lim_{n\to\infty} \langle \Theta F\, F \rangle_{\mu_n} \;\geq\; 0 \quad (4)$$

Θ is time reflection, and F a bounded continuous quantity determined by the side of positive times alone. Together with the task of the remaining axioms, the Osterwalder–Schrader reconstruction sets up a Hilbert space and $H \geq 0$ (the rule of the axioms; JW also writes 'Establishing a quantum mechanical Hilbert space is part of the solution to this Millennium problem').

A uniform gap survives in the limit

The second is that a uniform gap survives in the limit (the rule of the gap). Let τ_t be the operation of shifting by t in the time direction, and write ν_F for the spectral measure of the vector made by F with its vacuum component subtracted. ν_F is the same thing as the μ_F of 4-11 § 02. In this chapter we use μ for the sequence of measures, so we change the symbol.

$$\langle \Theta F\, \tau_t F \rangle - \left|\langle F \rangle\right|^2 = \int_{[0,\infty)} e^{-tE}\, \mathrm{d}\nu_F(E) \quad (5)$$

That the left-hand side is at most a constant times $e^{-\Delta t}$ for every bounded F is the same as $H \geq \Delta$ in the directions orthogonal to the vacuum Known (4-11 § 02). The integral also includes the point $E = 0$, so uniqueness of the vacuum comes out at the same time.

In the estimate box by box (7-10 formula (7)), if the rate of decay $\Delta_L \geq \Delta_*$ does not depend on L, the estimate survives in the limit and becomes a gap (the standard argument). The prefactor $\|A^* \Omega_L\|\, \|B\, \Omega_L\|$ in (7) is at most 1 if $|F| \leq 1$. This argument needs three premises. (i) The expectation values of the F used converge along the sequence $L \to \infty$ (part of the requirement of existence). (ii) The vectors of those F are dense in the reconstructed Hilbert space. (iii) Since T^4 is also periodic in the time direction, the term $e^{-\Delta_L (L-t)}$ added to the correlations in the box vanishes as $L \to \infty$

(it does if $\Delta_L \geq \Delta_*$). What the rule of the gap gives is only $\Delta > 0$; $m < \infty$ comes separately from the theory not being the vacuum alone (7-10 § 06).

Example: the decay of a single F tells us only the lower end of the support of ν_F. The $\xi(\beta)$ of the lattice correlation-length problem is the decay of plaquette correlations. Chatterjee defines ξ by the limit $|x| \to \infty$ taken in every direction, but what connects to the spectrum of the transfer matrix (5-03) is the decay in the time direction. Read through the decay in the time direction, what is learned is the lower end of H on the subspace made by the plaquette (this chapter's reading).

From centre symmetry to the area law

The third is the Theorem from Uniform Decay to the Area Law of Chatterjee (2021) from § 01 (the rule from decay to the area law). Its introduction also cites Durhuus–Fröhlich (1980), which derives confinement in a gauge theory from exponential decay in a non-linear σ model one dimension lower, and Fröhlich (1979), which carries confinement from a $\mathbb{Z}_n$ theory to an $SU(n)$ theory Known (bibliographic data only). By the title of Fröhlich's paper the destination is the lattice Higgs theory of $SU(n)$; the introduction of Chatterjee 2021 presents it as "the $SU(n)$ theory".

04

Roadmap arrows — the order the setters and surveys write

JW writes prospects for the order of the tasks. For the task of the T[4] construction it says there are ample signs that extending known methods would reach it, writing 'One presumably needs to revisit known results at a deep level, simplify the methods, and extend them'. For the task of a uniform gap it writes 'New ideas are needed', and goes on that this would make the task toward infinite volume possible. § 5 also writes that a uniform gap 'may play a fundamental role' in the proof of the infinite-volume limit Known . This is the rule of the problem setters' route.

$$\text{task of a uniform gap} \overset{1}{\Longrightarrow} \text{task toward infinite volume}: \qquad \inf_L \Delta_L \geq \Delta_* > 0 \quad \rightsquigarrow \quad \text{correla}$$

Precisely, the right-hand side of (6) is not the existence of the limit but the material of a uniform estimate for taking the limit, and how to assemble it is not written ('presumably').

Example: the two things that the rule of the problem setters' route joins (uniform decay and the infinite-volume limit) were obtained together from the cluster expansion in models with a small parameter. Weak-coupling ϕ^4_2 and ϕ^4_3 are examples Known (7-04 § 08). They did not pass in the order of deriving the infinite-volume limit from a uniform gap. Four-dimensional Yang–Mills has no such parameter at long

distances (7-11 the obstacle of the infrared parameter). On the lattice side, Chatterjee (2018) places the continuum string-tension problem as 'the most basic question that needs to be solved before making any further progress' on the road through Wilson loops Known . This is a sentence in the direction of necessity, "needed first", and not an arrow of sufficiency from the continuum string-tension problem to the requirements.

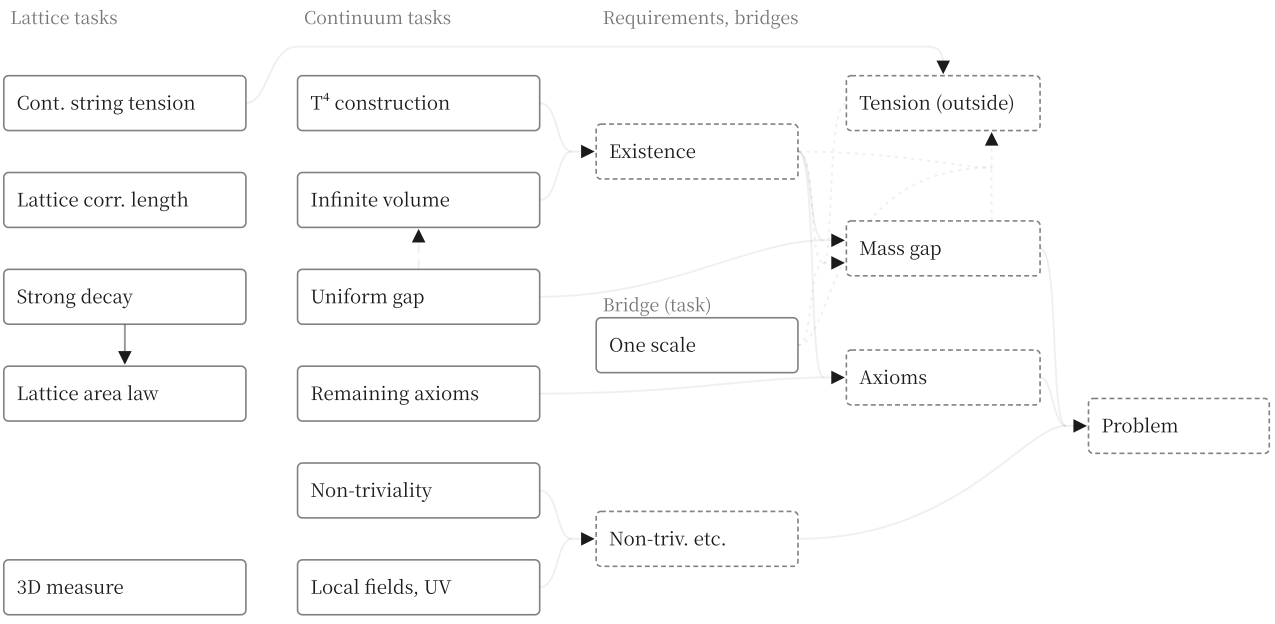
05

Suppose it were known — a map of the tasks

We put the rules of Table 2 into one figure. Pressing the box of a task makes that task "assumed known", and the conclusions of rules whose premises are all in place light up. What lights up is the smallest set that contains the conclusion whenever it contains all the premises (the closure).

$$\mathrm{cl}_\ell(S) = \bigcap \{ X \supseteq S : \text{ for every rule of level } \le \ell \text{, premises} \subseteq X \Rightarrow \text{conclusion} \in X \} \quad (7)$$

Figure 1 Pressing the box of a task makes it "assumed known", and the requirements that move and the cells of the board light up. The knob selects the strength of the arrows (theorems only / + roadmap / + expectation), and the button selects a group with trivial centre. Solid lines are theorems, dashed lines roadmaps, dotted lines expectations. G is fixed



Assumed known: none. To the problem statement: still T⁴ construction, Uniform gap, Remaining axioms, Non-triviality, Local fields, UV. Cells moved on the board: none (arrows: theorems, roadmaps, physical expectations)

Computed How this figure lights up is the closure (7) of the rules of Table 2, computed on the spot (the choice of arrows is this book's arrangement).

Known Table 2 Rules (if all the premises are in place, the conclusion). The upper seven (from the rule of existence to the rule of the string tension) are theorems or definitions, the rule of the problem setters' route is a roadmap, and the rule from the

string tension to the gap and the rule from the gap to the string tension are physical expectations Physics . The choice of rules is this book's arrangement. The requirement of the string tension is that of § 01: the continuum string tension d is not 0 (outside the problem statement)

Rule	Premises ⇒ conclusion	Strength	Grounds
Rule of existence	Task of the T^4 construction ∧ task toward infinite volume ⇒ requirement of existence	Definition	JW § 6.5
Rule of the axioms	Requirement of existence ∧ task of the remaining axioms ⇒ requirement of the axioms	Theorem	Formula (4) and OS reconstruction
Rule of the gap	Requirement of existence ∧ task of a uniform gap ⇒ requirement of the gap	Theorem	Formula (5) and 7-10 formula (7) (the standard argument; premises in § 03)
Rule of non-triviality	Task of non-triviality ∧ task of local fields and short distances ⇒ requirement of non-triviality	Definition	JW § 4
Rule of the problem statement	Requirement of the axioms ∧ requirement of non-triviality ∧ requirement of the gap ⇒ requirement of the problem statement (P_G)	Definition	Formula (2)
Rule from decay to the area law	Task of strong decay ⇒ lattice area-law problem	Theorem	Chatterjee 2021, Theorem from Uniform Decay to the Area Law
Rule of the string tension	Continuum string-tension problem ⇒ requirement of the string tension	Definition	Chatterjee 2018 § 5 (the requirement of the string tension is exactly the $d \neq 0$ of the continuum string-tension problem)
Rule of the problem setters' route	Task of a uniform gap ⇒ task toward infinite volume	Roadmap	JW § 5, § 6.5
Rule from the string tension to the gap	Requirement of existence ∧ requirement of the string tension ∧ task of one scale ⇒ requirement of the gap	Expectation	A single scale (17-12)
Rule from the gap to the string tension	Requirement of existence ∧ requirement of the gap ∧ task of one scale ⇒ requirement of the string tension	Expectation	The same sentence in the reverse direction

Example: even if the "Lattice tasks" button makes the lattice correlation-length problem, the continuum string-tension problem, the task of strong decay, the lattice area-law problem and the task of the three-dimensional measure assumed known,

only the requirement of the string tension lights up, and not a single requirement. This restates in the language of arrows the "showing it on the lattice is enough" of 16-08 § 08.

06

Counting the map — tasks needed on every road

Among the sets of tasks that reach the requirement of the problem statement, we call those that no longer reach it when any one task is removed **minimal sets**. We examined the 4096 subsets at three levels and counted all the minimal sets Computed .

$$\mathcal{S}\ell = \{ S : \ \mathsf{P}G \in \mathrm{cl}\ell(S), \quad S \text{ minus any one element gives } \mathsf{P}G \notin \mathrm{cl}\ell \} \tag{8}$$

With theorems only, there is one set, the upper six of Table 1 (from the task of the T^4 construction to the task of local fields and short distances); adding roadmaps, one set, {the task of the T^4 construction, the task of a uniform gap, the task of the remaining axioms, the task of non-triviality, the task of local fields and short distances}; adding physical expectations too, {the task of the T^4 construction, the task toward infinite volume, the task of the remaining axioms, the task of non-triviality, the task of local fields and short distances, the continuum string-tension problem, the task of one scale} is added, making two sets. The same held for groups with trivial centre.

Computed Table 3 For each task, whether it is in every minimal set for the requirement of the problem statement (required), in some, or in none

Task	Theorems only	+ Roadmap	+ Physical expectation	What it moves alone (up to physical
Task of the T^4 construction, task of the remaining axioms, task of non-triviality, task of local fields and short distances	Required	Required	Required	Nothing
Task toward infinite volume	Required	—	In some	Nothing
Task of a uniform gap	Required	Required	In some	Task toward infinite volume (roadr

Task	Theorems only	+ Roadmap	+ Physical expectation	What it moves alone (up to physical
Continuum string-tension problem	—	—	In some	Requirement of the string tension
Task of one scale	—	—	In some	Nothing
Lattice correlation-length problem, task of strong decay, lattice area-law problem, task of the three-dimensional measure	—	—	—	The task of strong decay alone give with non-trivial centre)

Example: (a) the task of the T^4 construction, the task of the remaining axioms, the task of non-triviality and the task of local fields and short distances are needed on every road. (b) At the level of physical expectation, instead of the task of a uniform gap, "the continuum string-tension problem and the task of one scale" reach the mass gap. The physical sentence that sees mass and string tension as two faces of one scale (formula (3) of 17-12) takes over the role of the task of a uniform gap. (c) The lattice correlation-length problem, the task of strong decay, the lattice area-law problem and the task of the three-dimensional measure are in no minimal set. The count uses only arrows checked in primary sources, so if an arrow from the lattice to a continuum requirement becomes a theorem, it must be redone.

07

For every group — arrows that vanish when the group is changed

The problem statement asks for the requirement of the problem statement for all compact simple groups G (formula (2)). The candidate Lie algebras are four series and five exceptions, and with each Lie algebra come groups in forms divided by the centre Known (1-04 Table 6). No general theorem carrying a result for one group to another was found in what this chapter read. Some arrows vanish depending on the group. The rule from decay to the area law uses that a finite-dimensional irreducible unitary representation π acts non-trivially on the centre, that is, that there is an element z of the centre with $\pi(z) \neq I$. An element of the centre commutes with every $\pi(g)$, so in an irreducible π it acts as a scalar by Schur's lemma (1-04 § 06).

$$\exists\, z \in Z(G): \qquad \pi(z) = \omega I, \quad \omega \neq 1 \qquad (\pi \text{ irreducible}) \ (9)$$

Example: in the fundamental representation of $SU(N)$, $z = e^{2\pi i/N} I$ and $\omega = e^{2\pi i/N}$ (1-04 § 07). For a group with trivial centre there is no representation satisfying (9). Besides the simply connected G_2, F_4 and E_8, this includes the forms divided by the centre $SO(3) = SU(2)/\mathbb{Z}_2$ and $PSU(N) = SU(N)/\mathbb{Z}_N$; every group divided by its centre has trivial centre Known . The reason in one line: for a connected Lie group, the centre is the kernel of the adjoint representation (1-04 § 06). $G/Z(G)$ is the same group as the image $\mathrm{Ad}(G) \subset GL(\mathfrak{g})$ of the adjoint representation, and its adjoint representation is $\mathrm{Ad}(g)$ itself on $\mathfrak{g}$ (for a simple Lie algebra ad is injective). The kernel is the elements with $\mathrm{Ad}(g) = I$, that is, the identity alone. The "group with trivial centre" of Figure 1 is this case, and the arrow from the task of strong decay to the lattice area-law problem vanishes. Chatterjee notes that for groups with trivial centre (for example $SO(3)$) it is believed they may not confine at weak coupling Physics . The problem statement asks for a gap for such groups too, so a road through confinement cannot be used for every group. On the other hand, the one-loop coefficient $16\pi^2 b_0 = \frac{11}{3} C_A$ is positive for every group (4-06 § 02), and perturbative asymptotic freedom does not depend on the group Known (0-03).

Replacing by SU(N). Moving the rows of this book's ledger of conditions (27-02) one by one to $SU(N)$, they fall into three kinds Paper . (i) Rows independent of the group: the uniform gap of the double well (the double well), the positivity of the 't Hooft tension and the reflection positivity of z (algebra), the uniform acceptance of insertion (an identity), and the limit to R^4. (ii) Rows that move as they are into the language of the centre $\mathbb{Z}_N$: in the twisted part of the small-T^2 gap, the Rigidity Lemma for Anticommuting Pairs of 25-01 (anticommuting pairs) is replaced by the uniqueness of the clock and shift pair (if the twist is primitive it is unique up to conjugation and its centraliser is $\mathbb{Z}_N$; González-Arroyo's review hep-th/9807108 § 4.2–4.3 Known), and the adjoint gap of the twisted T^2 becomes $4\sin^2(\pi/(NL))$ (for $SU(3)$, $L = 3$–6, it agrees with the computation of eigenvalues, and the value is determined by NL alone Computed). The source of the base point at small T^2 is for $SU(N)$, and the reflection positivity of z and frame decorrelation are in the general-group form of Osterwalder–Seiler. The one-loop $\beta - \beta'$ is $11N^2 \ln 2/(12\pi^2)$ (0.2575 for $N = 2$, 0.5794 for $N = 3$) Paper . The lemma of the colour average goes through with the $n = N^2 - 1$ colours of $\mathfrak{su}(N)$, and the constant 5 becomes $n(n+2)/3$ (including the existence of a weighted spherical 4-design, Lean: ColorAverageN (colorAverage, design_identity); the application to $\mathfrak{su}(N) \cong \mathbb{R}^n$ is Paper). The $SU(N)$ version of the Tomboulis–Yaffe inequality is Theorem 2 of Kanazawa arXiv:0808.3442 (unpublished) Known (its application to the slabs of this book is not done). (iii) Rows that need redoing: the ultraviolet parts that use properties of $SU(2) = S^3$ and $-1 \in$ the Weyl group (the

evenness of class functions) — that the conditional law of one link is one-parameter (15-07 (5)), the upper bound that drops the negative terms of the image sum of the heat kernel (the Heat-Kernel Fluctuation Rarity Lemma of 15-08), and the evenness step (in the hierarchical model, for $SU(3)$ it breaks through the cubic invariant $\operatorname{tr} X^3$) — and the numerics of the band (26-09 has only $SU(2)$ and $U(1)$). So to move this book's road to $SU(N)$, one must add, to the rows open for $SU(2)$ (the renormalisation comparison and others), the group versions of these three lemmas and the redoing of the numerics. Existence on the ultraviolet side is supplied by the published construction for any compact simple group Assessment . This book's ultraviolet parts are read not as parts for existence but as parts for the seam of this book's road Inferred (16-04). For groups with trivial centre (G_2, F_4, E_8 and groups divided by their centre) there is no tool of twists, and for $Sp(n)$ ($n \geq 2$) the centraliser of the pair that absorbs the twist is continuous, so a single twist of T^2 does not remove the zero modes Paper (one example). The road to all compact simple groups is open within the scope of this book.

08

Tasks outside the problem statement

JW § 5 lists 'natural extensions': isolated one-particle states (an upper gap in addition to the gap), confinement, other four-dimensional gauge theories with fields added that keep asymptotic freedom and their dynamics, and the extension from $\mathbb{R}^4$ to general four-dimensional manifolds Known . None of these is a requirement, and in Figure 1 only the requirement of the string tension was placed outside. Isolated one-particle states can be written through the spectrum of the mass operator $\sqrt{H^2 - \mathbf{P}^2}$ ($\mathbf{P}$ is the momentum) (16-05 the seam of the word "particle").

$$\operatorname{spec} \sqrt{H^2 - \mathbf{P}^2} \cap (0,\, m + \delta) = \{m\} \qquad (\text{some } \delta > 0) \ (10)$$

Example: for a free field of mass m, the one-particle states of Fock space (2-06) sit at m and two or more particles fill $[2m, \infty)$; the spectrum is $\{0\} \cup \{m\} \cup [2m, \infty)$, and the upper gap is m Known . JW § 5 also writes that the clustering that follows from the gap (7-10 § 08) may carry results on $\mathbb{R}^4$ to general four-dimensional manifolds ('may make it possible').

09

The book's coordinate system — dictionary, seams, tasks and walls on one grid

We use the two-column grades of the dictionary (18-01 § 05) as common coordinates, and plot four lists on nine cells. (a) is "if both exist, are they the same", (b) is "does it

exist in four dimensions". The grades of the dictionary rows are as in 18-01; the grades of seams, tasks and walls are this book's arrangement. The grounds are as follows.

Seams: take over the grade of the dictionary row corresponding to the pair of sentences in 16-05 Table 1 (1→1, 2→13, 3→9, 4→8, 5→2, 6→5, 7→14). Tasks: (a) is the strength of the rules leaving the task in Table 2 (theorem or definition = Settled, conditional on the group = Conditional, expectation = Unsettled; the lattice correlation-length problem, the lattice area-law problem and the task of the three-dimensional measure, which have no rule, are unrated), (b) is the "Closest result" of Table 1 (Conditional if there is a version with limited scope). Walls: the grade of the dictionary row named by the column of 23-02 Roads tried on the four-dimensional lattice, and walls (the relaxation-time upper-bound assumption, the relaxation-time lower-bound assumption, η, chain → 13; the physical-unit gap statement → 8; limit → 7. One step and the summability-of-shortfalls assumption have no row in the dictionary and are unrated).

Example. The thirteen walls that bear on the diffusive-relaxation-time assumption gather in the same "Unsettled, None" cell as dictionary row 13 (Λ, "a single scale"), the seam of "there is one scale" and the task of one scale. Although the types of wall (23-02 Roads tried on the four-dimensional lattice, and walls) divide into principle, structure, tool, assumption and measurement, on the dictionary they all bear on the same single pair. Only tasks enter "Settled, Conditional": those with a version of limited scope whose arrows to the requirements are theorems or definitions (the task of the T^4 construction, the task toward infinite volume, the task of the remaining axioms).

Figure 2 Choose a list with the buttons, and its rows are plotted on the nine cells of (a)×(b). "Overlay" plots all four at once. Below the frame: unrated

(a)	(b) Exists in four dimensions: Constructed	Cond.	None
Settled	#3 #10		#1 #2
Cond.	#12	#11	#4 #5 #6 #7 #8
Unsettled		#9	#13 #14

Unrated

```
Dictionary : Settled / Constructed 2, Settled / None 2, Conditional / Constructed 1, Conditional / Conditional 1, Conditional / None 5, Unsettled / Conditional 1, Unsettled / None 2
```

Computed The assignment of grades was made on this machine by the rules above from 18-01 Table 2, 16-05 Table 1 and Tables 1 and 2 of this chapter, and 23-02 Table 3, and the counts (14, 7, 12, 21) were checked.

Table 4 The rows that fall in each of the nine cells and in unrated (numbers are the rows of each table; walls are numbered as in 23-02 Table 3; in the figure, dictionary rows carry # and seams carry S).

(a) / (b)	Dictionary (18-01 Table 2)	Seams (16-05 Table 1)	Tasks (Table 1)	Walls (23-02 Table 3)
Settled / Constructed	3, 10			
Settled / Conditional			T^4 construction, infinite volume, remaining axioms	
Settled / None	1, 2	1, 5	uniform gap, non-triviality, local fields and short distances, continuum string tension	
Conditional / Constructed	12			
Conditional / Conditional	11		strong decay	
Conditional / None	4, 5, 6, 7, 8	4, 6		2, 9, 21
Unsettled / Constructed				
Unsettled / Conditional	9	3		
Unsettled / None	13, 14	2, 7	one scale	1, 3, 4, 5, 7, 10, 11, 12, 14, 16, 17, 18, 20
Unrated			lattice correlation length, lattice area law, three-dimensional measure	6, 8, 13, 15, 19

What this chapter can say

	Said	Not said
Known	The statements and current status of the tasks (within the primary sources). The implications of the rule of the axioms, the rule of the gap and the rule from decay to the area law (the rule of the gap is the standard argument, with the premises (i)–(iii) of § 03) and JW's roadmap sentences	That twelve exhausts them. The choice of arrows, and requiring limits along the whole sequence (this book's arrangement). Arrows not checked are not counted
Computed	The minimal sets under the rules of Table 2, and Table 3	Counts under other rules. Writing the rule of the gap out in detail for observables of four-dimensional Yang–Mills
Physics	That, if the rule from the string tension to the gap and the rule from the gap to the string tension are admitted, the continuum string-tension problem and the task of one scale take over the role of the task of a uniform gap	That the rule from the string tension to the gap and the rule from the gap to the string tension are theorems
Arrangement	The plots of Figure 2 and Table 4 come out mechanically from each table under the rules of § 09	The choice of rules itself (the grades of seams, tasks and walls are not theorems)
Overall	—	This site has settled none of the tasks. It does not show the existence of the mass gap. What the published construction reached, as written in Table 1, is at the level of the committee's assessment Assessment ; whether that proof is correct is outside this chapter

Next chapter to read: 16-08 Common misconceptions, which takes ways of speaking that mistake the tasks back to the words of the problem statement. The tasks on the side of the record of this book's study are in 23-15.

Common misconceptions — taking half-right ways of speaking back to the words of the problem statement

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — For nine commonly seen ways of speaking, the correct core and the slip. How the state of proof changes with group and dimension (Figure 1). That the decay of correlations does not go as far as saying whether there is a particle (Figure 2).

Prerequisite chapters — 0-03 (faster with 4-11, 5-02, 7-11 and 17-01; the words used are defined one line each at the end of §01).

Said first — What is corrected goes only as far as the level of ways of speaking. This chapter shows neither the existence of the mass gap nor the construction of the continuum limit. The ways of speaking that changed with the four-dimensional construction published in 2026 (the committee's assessment Assessment ; for the meaning of the labels see "Labels" in 6-00) are written in §02, §03 and §08.

The order of this chapter

1. How to read the misconceptions — taking them back to the one sentence of the problem statement, and the words used in this chapter
2. "The heart of the difficulty is infinity" — it remains even when the infinities are removed
3. "Two and three dimensions are already done" — for non-abelian groups, only two
4. "There is a gap because it is non-abelian" — the theorems divide by group and dimension (Figure 1)
5. "The mass gap is the mass of the lightest particle" — decay does not speak of particles (Figure 2)
6. "Show confinement and the gap follows" — different claims
7. "It has been confirmed by lattice numerics" — predictions that assume existence

8. "Showing it on the lattice is enough", "Build it in a finite box and the rest is technique" — the lattice correlation-length problem (Chatterjee's Problem 5.1) and T^4
9. "The mass gap comes from the uncertainty principle" — the theorem only converts a length into a mass
10. Detour: other ways of speaking one comes across — 1/0, holography, triviality, QCD

01

How to read the misconceptions

Many of the commonly seen ways of speaking are half right, and to that extent the slip is harder to see. This chapter divides each item into **the way of speaking**, **the correct core**, **the slip** and **a precise way of saying it**. The standard is the one sentence of the problem statement (0-03); lining up its conditions,

$$\forall G \;\; \exists \mathcal{T}_G : \quad \textbf{axioms} \;\wedge\; \textbf{non-trivial} \;\wedge\; \textbf{agrees with asymptotic freedom at short distances} \;\wedge$$

We read each word in one line Known .

- G: a compact simple group. All of them, from $SU(2)$ and $SU(3)$ to the exceptional group G_2 (0-03).
- $\mathcal{T}_G$: quantum Yang–Mills theory on $\mathbb{R}^4$. A theory not on a lattice, nor in a finite box, but on the infinitely extended continuous four dimensions (0-03).
- Axioms: the list of conditions a quantum field theory must satisfy (the Wightman axioms or the Osterwalder–Schrader axioms) (0-03).
- Non-trivial: not collapsed to a Gaussian theory without interaction (a free field) (0-03).
- Agrees with asymptotic freedom at short distances: the behaviour at short distances matches the prediction of perturbation theory (asymptotic freedom; (4) of § 04) (0-03).
- $\Delta_G > 0$: the spectrum of the Hamiltonian H has no points in the interval $(0, \Delta_G)$ above the vacuum energy 0 (0-03).

Most slips happen by replacing one word of (1) with a nearby word. Examples: "Δ" → "the mass of a particle" (§ 05), "existence" → "the numbers appear to converge" (§ 07), "$\mathbb{R}^4$" → "the lattice" (§ 08).

Words used in this chapter

We borrow words from Parts 4 and 5 in advance. Here we give only one-line definitions, and leave the details to the chapters on the right Known .

Word	Meaning in this chapter	Details
β (lattice coupling)	The number multiplying the lattice action (2), with $\beta \propto 1/g^2$. Small β is strong coupling, large β weak coupling, and the continuum limit lies on the side of large β	5-01
Exponential decay, correlation length	The correlation of two observables decreases with distance r like $e^{-r/\xi}$. ξ is called the correlation length. The gap measured in units of the lattice spacing corresponds to $1/\xi$	2-08, 4-11
Wilson loop	The quantity W_γ obtained by multiplying the group elements of the links along a closed path γ and taking the trace of the representation matrix	5-01
Area law	For large rectangular loops, $\langle W_\gamma \rangle$ decreases like $e^{-\sigma \times \text{area}}$. σ is called the string tension. The lattice sign of confinement	5-02
Perimeter law	$\langle W_\gamma \rangle$ decreases only to the extent of $e^{-c \times \text{perimeter}}$. Slower than the area law	5-02
Centre of a group	The set of elements that commute with every element of the group. For $SU(N)$ the N elements $e^{2\pi i k/N} I$; for $SO(3)$ and G_2 the identity alone	1-04
Casimir number C_A	A number determined by each group, entering the coefficient of (4). N for $SU(N)$, 0 for $U(1)$	1-04
Spectral measure	The ρ of (5). The weight of how much of the energy-E component the state $O\Omega$ has	1-10
Transfer matrix	The operator T that advances one step in the time direction of the lattice. With $T = e^{-H}$ it gives the Hamiltonian H on the lattice	5-03
Reflection positivity	Positivity with respect to a mirror that flips time. With it the transfer matrix is a positive operator, and the Hilbert space and the Hamiltonian come back	5-03
Boundary condition	A placement of group elements fixed in advance on the links at the edge of a finite box	(7) of § 06
Infinite-volume limit	The limit of the measures as the box is extended to the whole of $\mathbb{Z}^d$ (a subsequential limit is allowed). The limiting measure is called a Gibbs measure	5-04
Phase transition	A point at which, as β is varied, the properties of the infinite system change as if with a kink	2-08

02

"The heart of the difficulty is infinity"

The way of speaking: physics proceeds by handling the infinities along the way cleverly, but mathematics does not allow that. That is why it is hard.

The correct core: the continuum theory needs renormalisation (4-04) to control quantities that diverge as the lattice spacing $a \to 0$. Bałaban's work is aimed mainly at this ultraviolet control (7-07) Known .

The slip: having granted that a construction on T^4 can be expected from extensions of known methods, the setters write 'no present ideas point the direction to establish the existence of a mass gap that is uniform in the volume' (problem statement § 6) Known . On a finite periodic lattice with the lattice spacing fixed, the theory is a finite-dimensional integral and there are no infinities (7-11).

$$\langle F \rangle = \frac{1}{Z} \int F(U)\, e^{-\beta S_W(U)} \prod_{\ell} dU_\ell, \qquad 0 < Z \le 1 \tag{2}$$

dU_ℓ is the Haar measure of weight 1, and $S_W \ge 0$ the Wilson action (5-01). Example: for $SU(3)$ on a lattice of side 32 there are $4 \cdot 32^4$ links, each with 8 variables (the dimension of $SU(3)$), and the integral has $4 \cdot 32^4 \times 8 = 33{,}554{,}432$ variables Computed . Many, but finite.

What is hard is the theory with the box extended to $\mathbb{Z}^4$. Lecture material (Chatterjee 2020) wrote 'In 3D and 4D, mass gap has not been established at large β for any theory.' Known . Since then, for finite groups, Adhikari–Cao have shown exponential decay at large β (§ 04) Known . For continuous non-abelian groups, the gap at large β in three and four dimensions has still not been shown Known . What is missing is not the value of an infinity but an estimate uniform in the box and in β. The gap itself is also thought to have the form $e^{-1/(2b_0 g^2)}$, invisible to perturbation theory (0-02) Physics .

The ultraviolet side now: until 2025, "the ultraviolet is already settled" was also an overstatement. Bałaban's four-dimensional theorem (1989) comes with a hypothesis, and the theorem removing the hypothesis 'has not been published yet'. The limit of gauge-invariant observables, too, was at the level of taking subsequences by compactness (preface of Magnen–Rivasseau–Sénéor 1993; 7-07 § 05) Known . The construction published in 2026 takes the continuum limit along the whole sequence of cutoffs in a periodic box, passes to infinite volume along a subsequence, and builds a theory satisfying the Wightman axioms. The committee assesses this as "proved in Lean" Assessment (Part 6). Even so, one cannot go as far as saying "the ultraviolet is settled, so only the infrared remains". The uniqueness of the infinite-volume limit has not been shown, and the construction carries every step at weak coupling and stops at the step with lattice spacing 1. The seam that would put the result of that step into a

form the infrared arguments can use (the object of the limit, local estimates uniform in the volume, the image of observables) has not yet been made into a statement (16-03) Inferred .

A precise way of saying it

The ultraviolet side was supplied by the construction published in 2026, as a continuum limit in a periodic box (the committee's assessment). What the setters asked new ideas for is the gap uniform in the volume and the limit $T^4 \to \mathbb{R}^4$, that is, the infrared side, and that is still open. The seam connecting the two also remains.

03

"Two and three dimensions are already done"

The way of speaking: lower the dimension and it is done; only four dimensions remain.

The correct core: φ^4 has been constructed in two and three dimensions (problem statement § 6.2), and the two-dimensional abelian Higgs model has been shown up to the axioms. The problem statement calls it 'the only complete example of an interacting gauge theory satisfying the axioms' Known .

The slip: for non-abelian Yang–Mills the story is different. The two-dimensional construction (7-02) relies on an exactly solvable structure, the plaquettes becoming independent once the gauge is fixed, and there are no propagating degrees of freedom. In three dimensions, 'a construction of the 3D YM measure … even on T3, remains open' (Chevyrev 2022), and Bałaban (1985) goes as far as uniform estimates of the partition function on finite lattices (7-06) Known . The core of the difference is the dimension of the coupling constant.

$$[g^2] = (\text{mass})^{4-d} \quad (3)$$

Example: for $d = 3$, $g^2\ell$ (ℓ a length) is the dimensionless coupling, and it gets smaller at shorter distances. Interaction weakening at short distances is the foothold for the construction. For $d = 4$ this foothold survives only as a slow logarithmic change. Precisely, for $d = 4$, g^2 becomes dimensionless, and the dependence on scale is only the logarithm from the one-loop running ((4) of § 04) Known (a table by dimension is in 16-01).

A precise way of saying it

For non-abelian groups, two dimensions has been constructed (relying on an exactly solvable structure). In three dimensions the continuum measure has not been constructed even in finite volume. Four dimensions is the critical dimension, where the coupling constant becomes dimensionless, and the construction published in 2026 built a theory satisfying the Wightman axioms as a limit of Wilson's lattice (the committee's assessment). Even in four dimensions, the mass gap and the uniqueness of the infinite-volume limit have not been shown.

Even in two dimensions, for the continuum limit and mass gap of asymptotically free sigma models there was no claimed proof up to October 2026 (a manuscript with a claim made public on 2026-10-06 is unverified; 16-01 Table 5).

04

"There is a gap because it is non-abelian"

The way of speaking: the photon ($U(1)$) is massless, but gluons are non-abelian and interact with themselves, so there is a gap.

The correct core: in four-dimensional $U(1)$ lattice theory, the area law breaks down at large β (Guth 1980; the complete proof is Fröhlich–Spencer 1982), and the theory is in a massless phase (Fröhlich–Spencer 1982)Known . Both are said to be results mainly for Villain-type actions (actions of a different form from the Wilson action of (2)). The one-loop coefficient is also determined by the group.

$$\mu \frac{dg}{d\mu} = -b_0\, g^3 + \cdots, \qquad b_0 = \frac{11}{3} \cdot \frac{C_A}{16\pi^2} \quad (4)$$

The Casimir number C_A of the adjoint representation is N for $SU(N)$ and 0 for $U(1)$, and a theory without matter fields is asymptotically free only when non-abelian (4-06) Known .

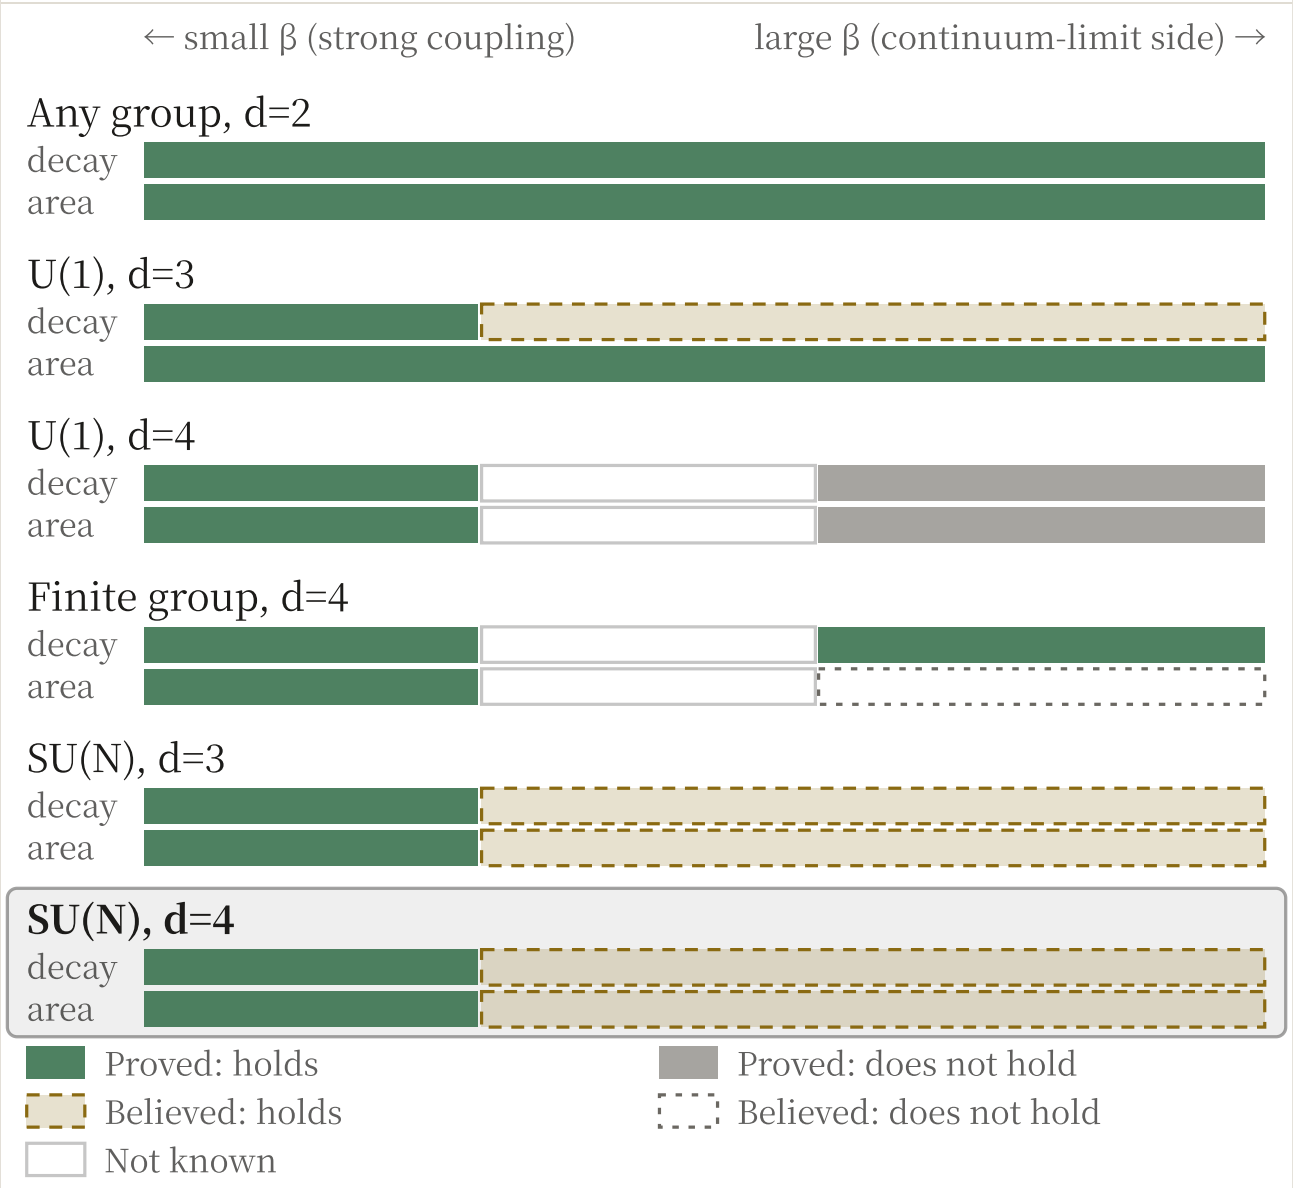
The slip: the lattice theorems divide by group and dimension (Figure 1, Table 1). At strong coupling (small β), exponential decay holds for every group, and the area law also holds for loops in representations that act non-trivially on the centre (Osterwalder–Seiler 1978)Known . For groups with trivial centre (G_2, $SO(3)$, finite groups with trivial centre), large loops are said to follow the perimeter law even at strong coupling, through screening by gluons Physics .

The area law at strong coupling is not evidence of confinement, because it holds at small β even for four-dimensional $U(1)$, which does not confine (Chatterjee 2018). Example: three-dimensional $U(1)$ is abelian, yet the area law holds for every β (Göpfert–Mack 1982; said to be for a Villain-type action)Known . Four-dimensional

finite groups (including non-abelian ones) have exponential decay even at large β (Adhikari–Cao) Known , but are believed not to confine Physics .

What matters is the following. For continuous non-abelian groups it is believed that there is no phase transition at finite β and that the correlation length diverges as $\beta \to \infty$ Physics . In that limit the gap measured in units of the lattice spacing, $1/\xi$, approaches 0, but physics holds that the gap in physical units (for example $m/\sqrt{\sigma}$) stays positive Physics . This is what needs to be shown (5-06, 5-10). An argument that does not distinguish groups would wrongly conclude that four-dimensional $U(1)$ also has a gap.

Figure 1 Choose a group and dimension with the buttons or a row of Table 1; that row is highlighted, and its content and sources appear below. In each row the upper band is exponential decay, the lower band the area law. Horizontal: β (the divisions are schematic)



SU(N), d=4: Theorems only on the strong-coupling side (Osterwalder–Seiler, Shen–Zhu–Zhu).

Known Table 1 The content of Figure 1 (theorems from primary sources and prospects that are "believed". The columns are for the side of large β). At small β, exponential decay is a theorem in every row, and the area law is a theorem for loops in representations that act non-trivially on the centre (in the row of finite groups, for groups and representations whose centre is non-trivial). Behaviour at intermediate β differs from group to group, and four-dimensional $\mathbb{Z}_N$ (for large N) is said to have a massless phase (note in the table of sources).

Group, dimension	Exponential decay (gap)	Area law (confinement)
Any group, $d = 2$	Yes	Yes (all β)
$U(1)$, $d = 3$	Said not to have been shown as of the lecture material (2020) (in physics it exists)	Yes (Göpfert–Mack; said to be for a Villain-type action)
$U(1)$, $d = 4$	No (massless phase; Fröhlich–Spencer)	No (the area law breaks down; Guth, Fröhlich–Spencer)
Finite group, $d = 4$	Yes (Adhikari–Cao)	Believed not to hold
$SU(N)$, $d = 3$	Unproved (believed to hold)	Same
$SU(N)$, $d = 4$	Unproved (believed to hold)	Same

A precise way of saying it

In four dimensions $U(1)$ is massless at weak coupling and non-abelian groups are asymptotically free; in that sense the group matters. But "there is a gap because it is non-abelian" is not a line of proof. For finite groups exponential decay has been shown even at weak coupling, and the weak-coupling side of continuous non-abelian groups is unproved in three and four dimensions.

05

"The mass gap is the mass of the lightest particle"

The way of speaking: the mass gap is the mass of the lightest glueball (a bound state of gluons), about 1.7 GeV.

The correct core: physics holds that there is an isolated one-particle state (the 0^{++} glueball) at the lower end of the gap, and measures it on the lattice. For pure $SU(3)$, $r_0 m = 4.21(11)(4)$ (Morningstar–Peardon 1999) (5-08) Physics .

There are three **slips**. First: what the problem statement asks for is a gap in the spectrum, and isolated one-particle states are one of the 'natural extensions' (0-03) Known . Second: what the lattice measures is the decay of correlations. Consider the

state $O\Omega$ obtained by applying a gauge-invariant operator O to the vacuum Ω. ρ is the weight (spectral measure) of how much of the energy-E component this state has. The connected correlation of O with itself separated by imaginary time τ can be written with ρ as follows (0-04 § 07, 4-11) Known .

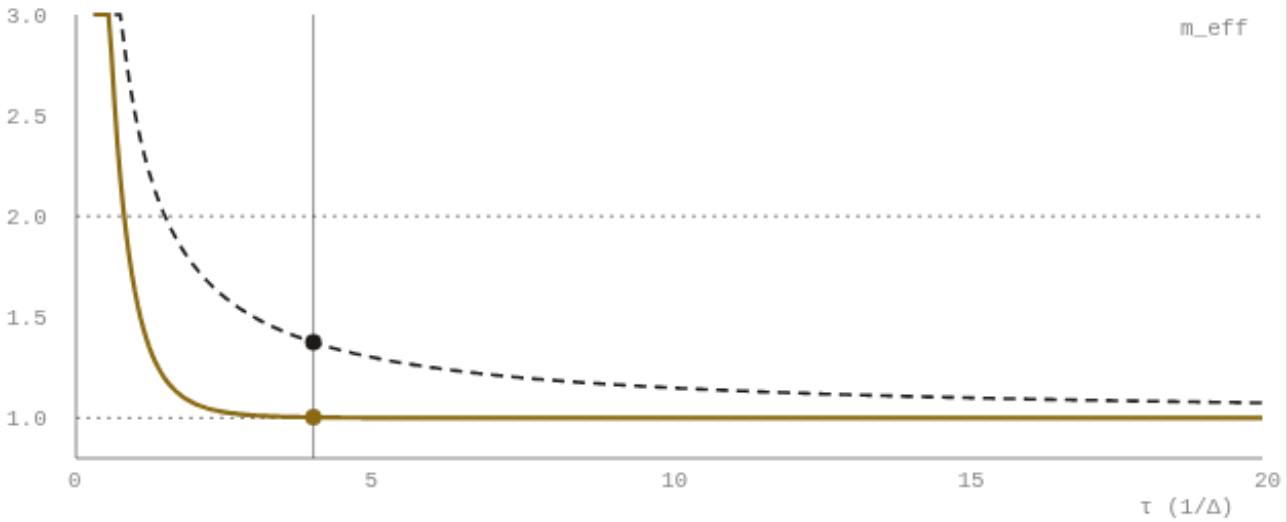
$$C(\tau) = \int_{[\Delta,\infty)} e^{-E\tau}\, d\rho(E), \qquad m_{\mathrm{eff}}(\tau) = -\frac{d}{d\tau}\log C(\tau) \quad (5)$$

m_{eff} approaches the lower end of the support of ρ as $\tau \to \infty$, but does not tell whether that lower end is an isolated point or the edge of a continuous spectrum. We compare two models ($\Delta = 1$).

A (with particle) : $d\rho = Z\,\delta(E-1)\,dE + c\,(E-2)_+^{1/2}\,dE$, B (no particle) : $d\rho = (E-1$

$(x)_+^{1/2}$ is $\sqrt{x}$ for $x > 0$ and 0 otherwise. From $\int_{E_0}^{\infty}(E-E_0)^{1/2}e^{-E\tau}dE = \Gamma(\tfrac{3}{2})e^{-E0\tau}\tau$ $^{-3/2}$, B has $m_{\mathrm{eff}} = 1 + \frac{3}{2\tau}$. Example: A comes within 1% at $\tau \approx 3.2$ ($c = 1$) to 4.2 ($c = 5$), while B only comes within it at $\tau = 150$ (Table 2). Fitting a single exponential in an intermediate window, B shows a "particle" heavier than Δ Computed . Reading the flat part as the mass of one particle is an interpretation at the level of physics Physics .

Figure 2 Changing the weight c of the continuous part of A (Z = 1) and the time τ changes the curves of the effective mass (solid A: with particle; dashed B: without particle) and the readings. Dotted lines are 1 and 2



c = 1.0, τ = 4.0: A 1.0028, B 1.3750 (Δ = 1)

Computed The numbers in this figure were computed on this machine (the closed form of (6) computed on the spot).

Computed Table 2 $m_{\mathrm{eff}}(\tau)$ ($\Delta = 1$, $Z = 1$). The last row is the first τ within 1%. The difference between the closed form and numerical integration is below 4×10^{-5} for $\tau \le 16$.

τ	A ($c=1$)	A ($c=5$)	B
1	1.6147	2.5495	2.5000
2	1.0712	1.3061	1.7500
4	1.0028	1.0138	1.3750
8	1.0000	1.0001	1.1875
16	1.0000	1.0000	1.0938
Within 1%	3.15	4.23	150

Third: the unit GeV does not come out of pure Yang–Mills itself; it borrows the scale r_0 of lattice QCD with quarks. The lattice papers also state that pure gauge theory and QCD are different theories (Athenodorou–Teper) Physics . "Gluons acquire a mass" is also a different matter: the mass term $m^2 \operatorname{tr} A_\mu A_\mu$ is not gauge-invariant Known .

A precise way of saying it

The mass gap is a gap in the spectrum. Physics holds that there is an isolated particle (a glueball) at its lower end, and measures its mass. What the decay of correlations tells is only the position of the lower end.

06

"Show confinement and the gap follows"

The way of speaking: confinement (that a quark cannot be taken out alone) and the gap are the same thing; show one and the other follows.

The correct core: physics sees the string tension σ and the gap m as two faces of one scale (17-01). Precisely, physics holds that the ratio $m/\sqrt{\sigma}$ approaches a finite positive number independent of β and the lattice spacing Physics . On the lattice there are also conditional theorems. Chatterjee (2021), for G a closed connected subgroup of $U(n)$, assumed decay in the following strong form Known .

$$\exists\, K_1, K_2 > 0 \;\; \forall B, \delta, f, g: \quad \left|\langle fg\rangle_{B,\delta} - \langle f\rangle_{B,\delta}\langle g\rangle_{B,\delta}\right| \le K_1 e^{-K_2 \operatorname{dist}(f,g)} \quad (7)$$

B is a cubic box, δ the boundary condition of the box, f, g local functions taking values in $[-1,1]$ (functions determined only by the variables near a single link), and $\operatorname{dist}(f,g)$ the distance between them. The constants K_1, K_2 do not depend on B, δ, f or g, and are determined by G, β and d alone. This order is the point: if the constants were allowed to differ from box to box and from boundary condition to boundary condition, the assumption would say almost nothing.

The Theorem from Uniform Decay to the Area Law (Theorem 2.4 of Chatterjee 2021) is that if (7) holds, centre symmetry is not broken, and the area law holds for rectangular loops in representations that act non-trivially on the centre Known . The author writes that at small β (7) can be shown for almost any lattice gauge theory, while also writing that it is not clear whether the decay believed in four dimensions includes this strong form.

The slip: (a) the problem statement does not ask for confinement; it only lists it among the 'natural extensions' Known . (b) "Any compact simple group" includes G_2 and others with trivial centre Known , and such groups are believed possibly not to confine at weak coupling (the remark on $SO(3)$ in the same paper) Physics . The problem statement asks for a gap there too. (c) Example: for three-dimensional $U(1)$ the area law has been shown (Göpfert–Mack; said to be for a Villain-type action). On the other hand, the gap at large β is said not to have been shown as of the lecture material (2020). For finite groups, exponential decay at large β is a theorem (Adhikari–Cao) Known , and they are believed not to confine Physics (Figure 1).

However, the author cautions that the "decay" spoken of for theories such as finite groups refers to the decay of two-point correlations under a particular boundary condition, which differs from the strong form of (7) (uniform under arbitrary boundary conditions) (the remark after Theorem 2.4 of Chatterjee 2021) Known . So the existence of theories that decay but do not confine does not contradict the Theorem from Uniform Decay to the Area Law.

A precise way of saying it

Confinement and the gap are different claims (17-02 § 02), and in the four-dimensional continuum theory neither implication is a theorem. On the lattice, for closed connected subgroups of $U(n)$, the area law for loops in representations that act non-trivially on the centre follows from the strong form of decay (7). What the problem statement asks for is the gap alone.

07

"It has been confirmed by lattice numerics"

The way of speaking: large-scale computations give glueball masses precisely, so the existence of the gap is known.

The correct core: example: for $SU(2)$, $m_{0^{++}}/\sqrt{\sigma}$ is 3.844(61) (Lucini–Teper 2001) and 3.781(23) (Athenodorou–Teper 2021), in good agreement Physics .

The slip: what is being confirmed is consistency under the assumption that it exists (17-13). In a finite box at finite β the gap is always positive (17-13) Known , so a positive number coming out does not test the claim. The value in the continuum is

$$\frac{m(a)}{\sqrt{\sigma(a)}} = \frac{m(0)}{\sqrt{\sigma(0)}} + c\,a^2\sigma \quad (8)$$

an extrapolation that assumes this form Physics , and the σ in the denominator passes through a correction that treats the flux tube as a Nambu–Goto string (17-13).

A precise way of saying it

Lattice numbers are precise predictions under the assumption that the theory exists, and strong physical evidence for the gap. They are not part of a mathematical proof, but they are a target the constructed theory must hit.

08

"Showing it on the lattice is enough", "Build it in a finite box and the rest is technique"

The way of speaking (lattice): show on the lattice that the correlation length is finite for every β, and that solves the prize problem.

The correct core: the lattice correlation-length problem of Chatterjee (2018) is a lattice version of the uniform gap: for any infinite-volume limit with a four-dimensional non-abelian compact Lie group $G \subseteq U(N)$ ($N \geq 2$), show the following about the length $\xi(\beta)$ over which plaquette correlations decay Known .

$$0 < \xi(\beta) < \infty \quad (\text{for all } \beta > 0), \qquad \lim_{\beta\to\infty} \xi(\beta) = \infty \quad (9)$$

The slip: the continuum limit, the axioms on $\mathbb{R}^4$, non-triviality and agreement at short distances are not in (9), and (9) alone does not solve the prize problem. The converse implication is not obvious either (5-09) Known .

The way of speaking (finite box): if it can be built on a finite box T^4 (the continuous four-dimensional torus), all that remains is to enlarge the box.

The slip: the problem statement says that construction on a compact space alone 'would represent a major breakthrough', and places the wall of the uniform gap beyond it Known . Example: even on a periodic lattice box (the lattice T^4), reflection positivity gives a transfer matrix, and the gap in a finite box is positive Known . The gap in a finite box is a quantity one naturally has. What is needed is $T^4 \to \mathbb{R}^4$ and a gap that does not collapse there (7-10). The construction published in 2026 gave a construction in a

periodic box and an infinite-volume theory along a subsequence Assessment , but what it has for correlations goes only as far as polynomial estimates uniform in the phase; there is no exponential decay (16-02 § 04). It is a current example of where "the rest is technique" in this way of speaking does not hold.

A precise way of saying it

(9) is a lattice version of the uniform gap, but it does not reach the requirements of the prize (continuum, $\mathbb{R}^4$, axioms, non-triviality). A construction on T^4 is also a big step, and beyond it remain the uniform gap and the infinite-volume limit.

09

"The mass gap comes from the uncertainty principle"

The way of speaking: squeeze a particle into a small region, and by the uncertainty principle its momentum spreads, so the energy does not go down. The mass gap is that lowest energy, and its origin is the uncertainty principle.

The correct core: the uncertainty relation is a theorem Known . For a state ψ in a Hilbert space and self-adjoint operators A, B,

$$\Delta_\psi A \, \Delta_\psi B \;\geq\; \tfrac{1}{2}\,\big|\langle \psi, [A,B]\psi\rangle\big| \qquad (10)$$

holds (Robertson 1929, Schrödinger 1930), and the proof is a single Cauchy–Schwarz inequality. Applied to $A = x,\ B = p$ it gives $\Delta x\,\Delta p \geq \hbar/2$ (Kennard 1927); equality holds for Gaussians, the ground state of the harmonic oscillator being an example (2-06 § 03). In the language of Fourier analysis, it is the theorem that a function and its transform cannot both be made narrow (1-11; there are also the strong forms of Hardy and Beurling). The kinetic energy of a state localised in a region of size R does not go below about $\hbar^2/(2mR^2)$, or, relativistically, about $\hbar c/R$. Physics In the picture of physics, a glueball is a lump of colour electric flux of size about $1/\Lambda$, and this count is why its mass is about Λ (17-01–17-03).

The slip: (a) what the theorem says is "given a length R, an energy $\hbar c/R$ is guaranteed"; it does not supply R itself. A free massless field (the photon, U(1)) also obeys (10), but its gap is 0. The gap of a free field of mass m is just the m put in by hand (2-06 § 08). The Yang–Mills action has neither a mass term nor a ruler of length (3-02). The length $1/\Lambda$ comes from a single scale being born out of a dimensionless coupling through a logarithmic flow (dimensional transmutation, 4-07), and the localisation comes from colour electric flux being squeezed into a closed tube (17-02, 26-03). Neither is a theorem in the four-dimensional continuum theory. (b) In the language of the Euclidean measure, uncertainty is not a principle but a duality. Exponential decay of

correlations and the absence of light modes are two faces of the same thing (4-11), and the content of (10) is already inside the definition of the gap. It is a restatement, not a cause. On this book's road the gap is the Poincaré constant of the vacuum measure (24-05), and uncertainty is dissolved inside that inequality. (c) In units with $\hbar = c = 1$, what (10) gives is $E \gtrsim 1/R$, and for the gap to be positive one needs R to be bounded, that is, that there is only one scale (17-12).

A precise way of saying it

The uncertainty relation is a theorem: given a length R, it guarantees an energy $1/R$. What the mass gap needs is the R side. That a single scale is born and that excitations are localised at that scale has not been shown for continuum non-abelian groups in four dimensions.

10

Detour: other ways of speaking one comes across

A section you may skip.

Four more commonly seen ways of speaking, corrected briefly.

- "Give infinity a symbol (1/0) and it is settled". The work of assigning values to divergences is already in order as mathematics inside perturbation theory, and the problem still remains (7-12).
- "Holography has shown the gap". What can be computed are models on the side of $N \to \infty$ and strong coupling, and the correspondence itself is a conjecture of physics (17-10) Physics .
- "φ^4_4 is trivial, so it collapses" / "It is asymptotically free, so non-triviality is automatic". Both are wrong; non-triviality is a condition to be shown separately (7-08).
- "It is a problem about QCD". The object is pure Yang–Mills (0-03).

What this chapter can say

Said	Not said
Known The separation of the correct core and the slip of nine ways of speaking, against the problem statement and theorems in primary sources	The existence of the mass gap. Unsolved, and this chapter shows nothing about it (the existence of the continuum limit was shown by the published construction and assessed by the committee Assessment ; whether that proof is correct is outside this chapter)

Said	Not said
Known That the lattice theorems divide by group and dimension (Figure 1, Table 1; the dates of the table are as in the table of sources)	Physics The gap and confinement at large β for continuous non-abelian groups in four dimensions. Unproved
Computed That the decay of correlations alone does not decide whether there is a particle (model (6), Table 2)	Physics That the continuum values of lattice numbers (values passed through the extrapolation (8)) are the values of the constructed theory
Known That the area law follows from decay in the strong form of (7) (closed connected subgroups of $U(n)$, representations acting non-trivially on the centre)	The current status of the gap of three-dimensional $U(1)$ at large β (according to the lecture material (2020)), and the phase of $\mathbb{Z}_N$ at intermediate β (unchecked)

Next chapter to read: 16-09 The stages a proof must contain. To read from the side of this book's study, 23-01 The line of construction and the diffusive-relaxation-time assumption.

The stages a proof must contain — the table of seven stages

> This chapter is a map of open questions. § 02, § 05 and § 06 are guide material.

What this chapter shows — The seven stages that a proof of the mass gap of four-dimensional Yang–Mills must contain, whichever road it starts from (the vessel, the ultraviolet, the gap on a small T^2, confinement on a small T^2, the crossover band, R^4, general groups). For each stage, what is known in the world, what this book has shown, and what has not yet been shown (within what we surveyed), set out with labels in one table. That the mass gap and confinement (the area law) are different statements. A figure of the two roads meeting at the band. An index of which cell of the table each chapter from Part 23 on fills, and the correspondence with the six continuum tasks of 16-07. The stages taken on by the construction published in 2026 (part of the vessel, existence on the ultraviolet side, existence and the axioms for R^4, existence for all groups), and the stages that remain.

Prerequisite chapters — 16-07 The list of open tasks (the twelve tasks and the three strengths of arrows) and 16-08 § 06 (confinement and the gap are different claims). The words for the stages follow 7-10 (what is reached at each stage in four dimensions). The questions that remain after the published construction are in 16-02, and where this book's holdings stand is in 16-04.

Said first — This chapter lays out stages; it settles none of them. The division into the seven stages a proof must contain is an arrangement often used in constructive field theory, cut again to fit the work of Parts 25 and 26 of this book. The marks ■◐□ in the table are marks of the state of the record, not a graduation of how much is proved (§ 02). This site shows neither the existence of the mass gap nor the construction of the continuum limit. The label Assessment means "according to the committee's assessment report" ("Labels" in 6-00).

The order of this chapter

1. The table of the seven stages a proof must contain — known, this book and unknown for each stage (Table 1)
2. How to read ■◐□ — marks of the state of the record, not a graduation

3. The mass gap and confinement are different statements — the road to each, and the missing arrow between them
4. The two roads meet at the band — the flow of the logic (Figure 1)
5. Which chapter fills which cell — an index of Parts 23–27 (Table 2)
6. Correspondence with the tasks of 16-07 — the six continuum tasks and the seven stages a proof must contain (Table 3)

01

The table of the seven stages a proof must contain — known, this book and unknown for each stage

We split the way from the lattice to the theory on $\mathbb{R}^4$ and the mass gap into seven stages. In order: (1) the vessel (the measure on the lattice, and the mechanism that assembles a quantum theory from it), (2) the ultraviolet (uniform control at all scales that does not break down as the lattice spacing a is sent to 0; as existence it was shown by the published construction, and what remains on this book's road is the seam), (3) the gap on a small T^2, (4) confinement on a small T^2, (5) the crossover band (the band for short), (6) the theory on R^4, (7) general groups.

The "small T^2" of the two small-T^2 stages (rows 3 and 4 of Table 1) is the case where four-dimensional space is written as $\mathbb{R}^2 \times T^2$ and the side L of the T^2 is taken much smaller than the physical length $1/\Lambda$ (Λ is the mass scale that the theory generates by itself, 4-07). Putting 't Hooft's twist (a boundary condition that glues opposite sides shifted by an element of the centre of the group) on the T^2 removes the zero modes (directions in which one can move without raising the action), and there is a prospect of keeping the coupling weak at scales up to L. It is a waypoint for splitting the problem into the stages up to there (the two small-T^2 stages) and the stage of widening the T^2 (the band stage). The content is treated in Part 25 (25-00).

The band of the band stage is the intermediate scale $L \sim 1/\Lambda$ at which the coupling passes from weak to strong. In four dimensions no tool has crossed this scale non-perturbatively (26-00). In the language of the space road, a statement that crosses the band takes the following form.

$$\ln \frac{1}{\theta(L,L)} \;\geq\; c\,L^2 \qquad (\text{for all } L, \text{ the same } c>0) \quad (1)$$

$\theta(L,L)$ is the sector bias when one vortex winding the T^2 is put into a container of side L (a quantity that moves away from 1 the "cheaper" the vortex is). (1) is an area law in the

form of 't Hooft's criterion; that "θ moves away from 1" alone is not enough is treated in 26-01.

After the construction published in 2026. The published construction takes on part of the vessel stage (reflection positivity of the original Wilson measure, the Chessboard Estimate, reconstruction; 12-01, 12-02, 12-08), existence for the ultraviolet stage (the continuum limit in a periodic box; Parts 8–11), existence and the axioms for the R^4 stage (infinite volume along a subsequence, phase decomposition, the Wightman axioms for each phase; 12-05, 12-07), and existence for the general-group stage (any compact simple group). The committee assesses this as "proved in Lean" Assessment . We have written what it takes on into the "known in the world" column of Table 1. What it does not take on is the two small-T^2 stages (twisted boundary conditions are not treated), the band stage, a uniform mass gap, and uniqueness of the infinite-volume limit (16-02). For the ultraviolet stage, even after existence has been shown, there remains the seam that puts the ultraviolet result into a form the infrared arguments can use (16-03) Inferred .

Table 1 The seven stages a proof must contain (to the right of the stage name is the mark: ■ closed in the record / ◐ partial / □ open. Labels are per claim within the row. "Chapters" is the same as the index of Table 2)

Stage and content	Known in the world	Shown in this book (with labels)	Unknown, and chapters that fill it
1 Vessel ◐ The lattice, reflection positivity, block observables, compactness. From decay on a dense set to a gap of the transfer matrix	Cited Reflection positivity and the transfer matrix (Osterwalder–Seiler 1978, 5-03), reconstruction (4-10). Assessment Shown by the published construction: reflection positivity of the original Wilson measure for planes through lattice points and planes through midpoints of edges, the Chessboard Estimate, reconstruction (Part 12)	Proved here Reflection positivity of z (positivity, under reflections through lattice points, of the ensemble summed over twists; the algebra of the kernel is in Lean: ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`), finite sums with non-negative weights). Lean: GapFromDecay (`GapFromDecay.gap_of_decay_dense`) (an abstract lemma for a bounded self-adjoint operator, with uniform decay on a dense set placed as a hypothesis)	Writing out the whole construction of the vessel (at present a strand) Chapters: 5-03, 26-04, 26-05

Stage and content	Known in the world	Shown in this book (with labels)	Unknown, and chapters that fill it
2 Ultraviolet ◐ Multiscale analysis uniform in a, from the lattice spacing a up to the scale L (locality of the effective action, rarity of large fields, flow of the coupling). Existence is from the published construction; what remains is the seam	Assessment Shown by the published construction: in a periodic box, the continuum limit along the whole sequence of cutoffs (Parts 8–11). It carries every step at weak coupling and stops at the step with lattice spacing 1 (16-03). Cited Before that, Bałaban's series (CMP, 1980s; parts remain at the central stage that the original sources call "unpublished", 7-07)	Proved here Only parts at the one-loop level (the perturbative level). The record so far placed the whole of ultraviolet control as an assumption, Assumption	The seam: fixing the theory at the step with spacing 1 as an object, local estimates uniform in the volume, the bridge for observables (writing continuum correlations as expectations at the step with spacing 1). On this book's road, in addition: the translation into quantities fixed by the measure, the construction with twisted boundary conditions and in elongated boxes, and how reflection positivity is carried Inferred Chapters: 16-03, 7-07, 25-00, 26-11, 27-02 ultraviolet control
3 Gap on a small T^2 ◐ The twist removes the zero modes, and the coupling stays weak up to the size L of the T^2. The gap of the transfer matrix $\geq c/L$ is uniform in a	Cited 't Hooft's twisted boundary conditions and flux (1979, 1981)	Proved here The twisted part: uniqueness of the vacuum that absorbs the twist, the gap $4\sin^2(\pi/2N)$ of the two-dimensional lattice Laplacian, and $S_{\min} > 0$ in the (1,1) sector (SU(2), lattice, N fixed). The form uniform in a holds only under the assumption of an ultraviolet construction in a box with twisted boundary conditions	A lower bound on the gap uniform in a, without that assumption. The published construction treats only periodic cubic boxes, so the construction in a twisted box becomes the first question of this book's road Inferred Chapters: 25-00, 25-01, 27-02 small-T^2 gap
4 Confinement on a small T^2 ◐ Bounds on containers and on insertions reduce confinement to "the insertion of one vortex" and "independence between regions"	Cited The container identity (Mack–Petkova 1980)	Proved here The reduction (on a finite configuration space, with positive weights and a bijection that flips the sector. Lean: Containers (`Containers.container_bound`), InsertionIdentity (`Insertion.mean_one`, `Insertion.mean_rho_sigma`), the algebra of finite sums). Proved here Slab confinement (with the lattice spacing and the T^2 fixed, an area law at every β. In the continuum limit the tension is 0)	Two inputs: uniform acceptance of insertions, and frame decorrelation Assumption Chapters: 25-03, 25-04, 25-05, 25-06

Stage and content	Known in the world	Shown in this book (with labels)	Unknown, and chapters that fill it
5 Band ☐ That (1) holds with the same c as the T^2 is widened. Crossing the intermediate scale $L \sim 1/\Lambda$ non-perturbatively	Cited 'New ideas are needed' (Jaffe–Witten § 6.5, the task of a uniform gap). The published construction gives no foothold inside the band (it carries every step at weak coupling) Inferred . The inequality of Tomboulis–Yaffe (1985) (from 't Hooft's criterion to the area law)	Proved here The correct form ($\theta \leq \theta_0$ is not enough). Proved here A conditional reduction to the lateral-widening inequality (assuming three things: the base point, frame decorrelation and lateral widening. The algebra of the iteration is in Lean: Doubling (`Doubling.iterate`)). Proved here The negative lemma that structural inputs alone cannot cross. Proved here The renormalisation comparison at the one-loop level ($\beta - \beta' = 0.258$). Reading Numerical signs (26-09)	The renormalisation comparison, non-perturbatively. The band itself. Stating the two ends of the band in the same quantity and the same class of actions (the strong side is β of the Wilson action in this book's Lean window; the weak side is the coefficients of the effective action at the entrance to the one-step estimate of the published construction) Inferred Chapters: 26-01–26-07, 26-09
6 R^4 ◐ The infinite-volume limit, the OS axioms, recovery of rotation invariance, non-triviality	Cited Reflection positivity survives weak limits; OS reconstruction (16-07 § 03). Assessment Shown by the published construction: the infinite-volume limit along a subsequence, phase decomposition, the Wightman axioms for each phase (Part 12). Checks at short distances (Part 13)	Assumption Only the strand that, under the band stage, most of it is the standard argument	Uniqueness of the infinite-volume limit (probably not needed for the mass gap of a single theory Inferred). If decay is obtained with twisted boundary conditions or in a pure phase, identifying the theory built from that state Inferred Chapters: 16-07, 27-01, 27-02 separate box
7 General groups ☐ SU(N), and groups without centre (G_2 and others)	Cited For groups with trivial centre, the arrows that use the centre disappear (16-07 § 07). Assessment Existence was shown by the published construction for any compact simple group	None (Parts 25 and 26 of this book are written for SU(2))	Everything on the side of the mass gap. The tools of vortices cannot be used for groups without centre Chapters: 16-07 § 07, 27-02 separate box

What to read from Table 1. (a) The "□" stages are the band and the general-group stage, which changes the group. The "◐" of the ultraviolet stage means that the continuum limit in a periodic cubic box was shown by the published construction, but there is no construction in twisted or elongated boxes and no statement of the seam (the same mark as 27-02 Table 1). What is open now at the ultraviolet stage is not existence but the seam; the band remains a long-standing open problem of the field. (b) The "◐" of the two small-T^2 stages is in both cases a "◐" under the assumption of an ultraviolet construction in a box with twisted boundary conditions. As long as that construction is missing, the marks of these two stages do not go up. (c) Of the claims written "Proved here" in this book, most of the chapters that place the paper proofs in the book are chapters still to be written (Parts 25 and 26). Until they are placed, the rows of the ledger (27-02) do not disappear.

02

How to read ■◖□ — marks of the state of the record, not a graduation

The marks of Table 1 mark how the record of this book's work treats each stage. ■ means closed in the record (there is a paper proof, and where there is a Lean entry its arithmetic is closed too), ◐ means part is closed and the rest stays a strand or a numerical sign, and □ means open.

These marks are not a graduation of how much is proved. There are three reasons. First, ■ says only that something is closed within the conditions written in the row, not the whole stage. Second, a ◐ stage does not necessarily have "less remaining" than a □ stage. The ◐ of the small-T^2 gap stage says that the twisted part is closed, but the rest depends on the seam of the ultraviolet stage (the construction in a twisted box; open). Third, the book's labels (proved here, cited, computer-assisted, reading, assumption) attach to each claim, while the marks attach to each stage. It is normal for "Proved here" and "Assumption" to stand side by side in the same stage. We do not add the marks up and read them as "so many of the seven stages a proof must contain".

Example. The reflection positivity of z in the vessel stage is closed in the record (a claim corresponding to ■). Even so, the mark of the vessel stage is ◐. This is because writing out the whole construction of the vessel (from block observables to the gap of the transfer matrix) remains a strand.

03

The mass gap and confinement are different statements — the road to each, and the missing arrow between them

What the problem statement asks for is the mass gap (that the spectrum of the Hamiltonian H of the quantum theory is separated by $\Delta > 0$ above the vacuum, 4-11); it does not ask for confinement (the area law of Wilson loops). As in 16-08 § 06,

confinement and the gap are different claims, and in the four-dimensional continuum theory neither implication is a theorem Cited . Physics sees the two as two faces of one scale (the ratio $m/\sqrt{\sigma}$ approaches a finite positive number), but that is a statement at the level of expectation Reading (physics). The implication from the area law to the mass gap does not hold as a general implication, because the area law is a statement about a gap in the charged sector, and the mass gap about a gap in the neutral sector (16-07 § 02).

The two roads of this book arrive at different statements.

- **The road to the gap** (the small-T^2 gap stage + the transfer matrix): carry the gap of the transfer matrix on a small T^2 (the small-T^2 gap stage) through the band to $\mathbb{R}^4$ with the same constant. If it can be carried, the gap survives in the limit (the rule of the gap of 16-07 § 03, with premises (i)–(iii)). The road of Part 23 (from the direction of time) also heads to the same statement of the gap, through the diffusive-relaxation-time assumption and the one-sided bridge.
- **The road to confinement** (the small-T^2 confinement stage, the band stage, the R^4 stage): make confinement on a small T^2 uniform in the size of the T^2 through the band, and turn it into an area law in the theory on $\mathbb{R}^4$ (the R^4 stage).

There is no known arrow joining the two roads, that is, no known road "from the area law to the mass gap". Even the statement of what must be added to get a gap from the area law is not yet settled (the last arrow of 27-01, the separate box of 27-02). So even if the road to confinement were closed entirely, that alone would not reach the requirement of the problem statement. This chapter sets the two roads side by side, but does not count the arrow from confinement to the gap as a "road that joins them".

A precise way of saying it

The mass gap and confinement (the area law) are different statements. The space road of this book heads separately to the two statements: from the small-T^2 gap stage through the transfer matrix to the gap, and through the small-T^2 confinement stage, the band stage and the R^4 stage to confinement. There is no general theorem that gives a gap from the area law, and this book does not show one either. This book's strong-coupling area law (20-06) is a statement inside the strong-coupling window with the lattice spacing fixed, and sits at the opposite end from the questions that remain.

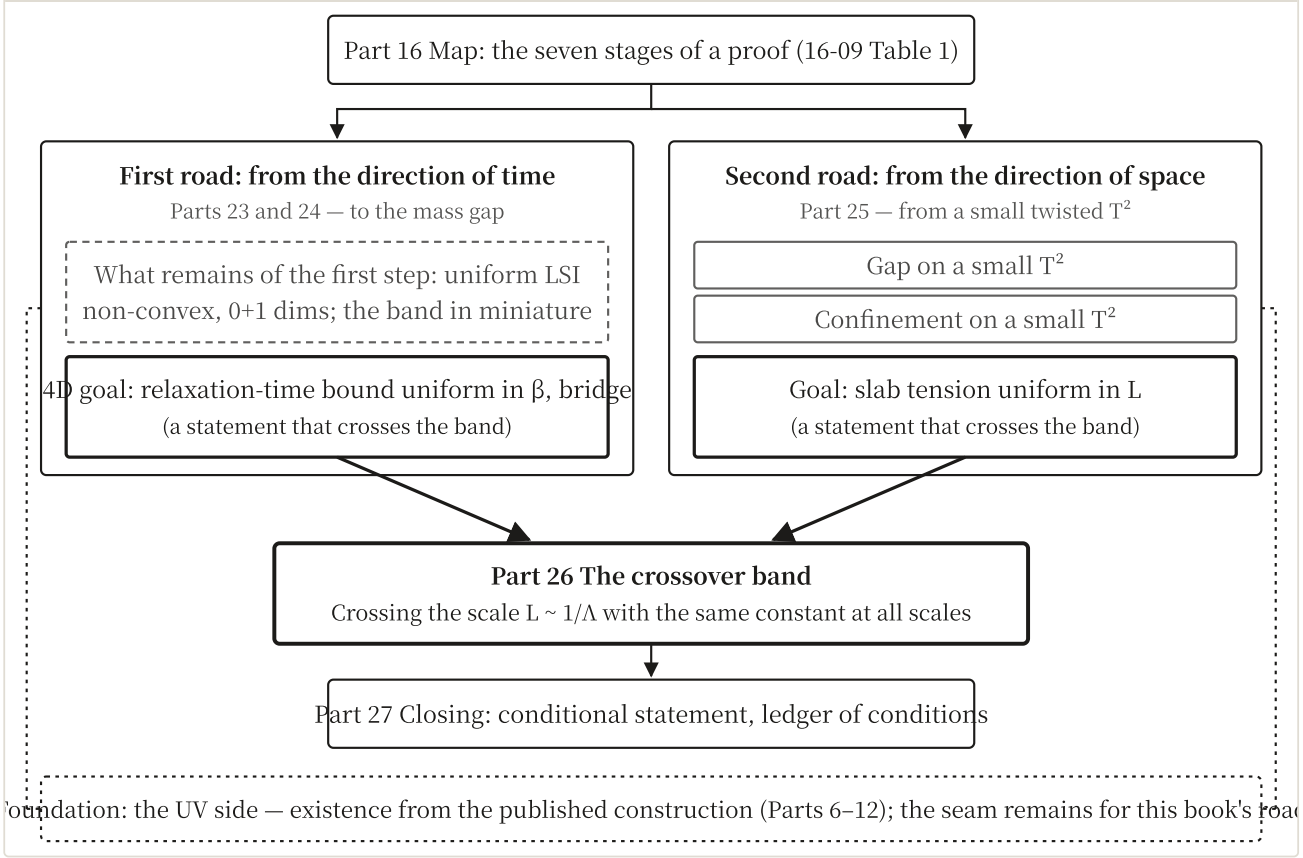
04

The two roads meet at the band — the flow of the logic

Figure 1 is the flow of the logic from Part 16 to Part 27. The first road comes from the direction of time (Parts 23 and 24), the second from the direction of space (Part 25), and at the level of the four-dimensional goal both arrive at a statement of one type: "the same

constant at all scales". That statement is the statement that crosses the band, and Part 26 treats it.

Figure 1 The two roads meet at the band. The column of the first road is split into two rows, and the arrow flowing into the band comes only from the "four-dimensional goal" row (what remains of the first step is a miniature of the band, not the band itself). The ultraviolet side at the bottom (existence from the published construction; what remains on this book's road is the seam) lies under both roads



What to read from Figure 1. (a) "What remains of the first step" on the first road (a uniform logarithmic Sobolev inequality for a measure that contains non-convex parts, the path measure of the 0+1-dimensional double well, 23-15 Table 1) is a wall of the same type as the band (there are different tools at the two ends, and the bound on the worst configuration stops in the middle), but it is not the band. The length of the crossover in the first step is fixed by a classical quantity, the first conjugate point of the Jacobi equation at the top; it does not depend on $\hbar$ and is finite in lattice units. The length of the crossover in four dimensions, $1/\Lambda$, is generated quantum mechanically (4-07) and diverges in lattice units. This difference is treated in 26-07 together with the proof of the computation of the conjugate point on the first-step side (until the proof is placed, Assumption). (b) What flows into the band is, on both roads, the "four-dimensional goal" row. On the first road it is the upper side of the diffusive-relaxation-time assumption uniform in $\beta \to \infty$ (the relaxation-time upper-bound assumption) and the one-sided bridge (the physical-unit target level of 23-15 § 07); on the second road it is the slab tension uniform in L. (c) The ultraviolet side lies outside the band. Existence was supplied by the published construction Assessment . This book's two roads proceed by

placing as an assumption the seam that puts the ultraviolet result into a form usable for their own objects (twisted boxes, slab tension, path measures)Inferred .

The meeting in Figure 1 means "arriving at a statement of the same type at the level of the goal"; it does not mean that the present walls of the two roads are in the same place. The "band" of the band part and the "windows" of Parts 23 and 24 (the site window, the window in $\hbar$, the time window) are different things (the note on words in 26-00).

05

Which chapter fills which cell — an index of Parts 23–27

Table 2 is an index of which cell of which stage of Table 1 the chapters from Part 23 on supply material to. The stages taken on by the published construction are read in Parts 6–13 of Volume 2, and this book's firm theorems are in Parts 19–22 (16-04 § 04). A "cell" is a column of Table 1 (known, this book, unknown). Parts 25–27 have chapters still being written, and the links are made by chapter number.

Table 2 The chapters of Parts 23–27, and the stages and cells of Table 1 (this book's arrangement)

Chapter	Stage	Cell	In a word
23-00–23-17	5 (time side)	This book, unknown	The first road. The statement of the four-dimensional goal (the physical-unit target level), and the list of rows of the first step (0+1 dimensions, a miniature of the band)
24-00–24-08	5 (time side), 6	This book, unknown	The first road (second half). Repairing the form of the assumption, and making time continuous. 24-07 is cited from the band part
25-00	2, 3	Known, unknown	Why go by way of a small twisted T^2
25-01	3	Known, this book	Twist and flux, and the three facts of the twisted part
25-02	4, 5	Known, this book	Vortices and fractional instantons, the form of the string tension
25-03, 25-04	4	Known, this book	The Container Identity and slab confinement
25-05, 25-06	4	This book	Insertion identities, driven insertion and the Flow Lemma
25-07	5	This book	Why fixed maps fail (at the one-loop level)
25-08	4	This book (Reading)	The measured record of the space road
25-09	5	Unknown	Where this road stops = widening the T^2
26-00–26-02	5	This book, unknown	Confluence, the correct form of the band, reduction to a single inequality
26-03, 26-04, 26-05	1, 5	This book	Where non-abelianness enters, structure alone cannot cross, the chessboard

Chapter	Stage	Cell	In a word
26-06, 26-07	5	This book, unknown	The renormalisation comparison, the band seen from the side of time
26-08, 26-09, 26-10	5	Known, this book (Reading), unknown	Roads tried and stopped, the measured record, candidate viewpoints
26-11	2	Known, this book, unknown	Ultraviolet control: what closing in one step means, the five stages of the series and where they stopped, a draft statement
27-00–27-04	All	Unknown (the column of conditions)	The conditional statement, the ledger of conditions, the index of questions and of what is not claimed
A-06, A-07	All	—	The index of names, the drafts of papers that came out of this book

06

Correspondence with the tasks of 16-07 — the six continuum tasks and the seven stages a proof must contain

The six continuum tasks of 16-07 Table 1 split the tasks needed for the continuum theory according to the requirements of the problem statement. The seven stages a proof must contain in Table 1 split the stages of one road that starts from the lattice. Since the axes of the splitting differ, they do not correspond one to one. Table 3 is the correspondence, and it is this book's arrangement.

Table 3 The seven stages a proof must contain and the tasks of 16-07 (this book's arrangement. The strengths of the arrows are as in 16-07)

Stage	Tasks of 16-07	Note
1 Vessel	Part of the task of the remaining axioms	Reflection positivity and the transfer matrix. The rest of the task of the remaining axioms (recovery of rotations) is in the R^4 stage. The published construction satisfied them for each phase Assessment
2 Ultraviolet	The task of the T^4 construction, the task of non-triviality, the task of local fields and short distances	Existence of the continuum limit, non-triviality, and agreement with asymptotic freedom at short distances are all tasks on the ultraviolet side. Existence, for local fields, was shown by the published construction; non-triviality and short distances are at the level of checks (Part 13) Assessment
3, 4 Small T^2	A partial problem of the task of the T^4 construction	Construction and bounds on a small volume. The task of the T^4 construction is a task on T^4, while the two small-T^2 stages are tasks on the small T^2 of $\mathbb{R}^2 \times T^2$, so they are not the same task
5 Band	The task of a uniform gap	The uniform gap $\inf_L \Delta_L > 0$. The task for which the setters write 'New ideas are needed'

Stage	Tasks of 16-07	Note
6 R^4	The task toward infinite volume, the task of the remaining axioms	The infinite-volume limit, and the remaining axioms
7 General groups	16-07 § 07	For groups with trivial centre, the arrows that use the centre disappear
(confinement side)	The continuum string-tension problem, the lattice area-law problem	The continuum string tension and the lattice area law. Outside the requirements of the problem statement (C of 16-07); it corresponds to where the small-T^2 confinement stage and the band stage arrive

What to read from Table 3. In the counting of 16-07 (16-07 § 06), if the arrows of the roadmap are admitted, the minimal set needed was one: {the task of the T^4 construction, the task of a uniform gap, the task of the remaining axioms, the task of non-triviality, the task of local fields and short distances}. In the language of the seven stages a proof must contain, it is the ultraviolet stage (the task of the T^4 construction, the task of non-triviality, the task of local fields and short distances), the band stage (the task of a uniform gap), and the axioms of the vessel stage and the R^4 stage (the task of the remaining axioms). After the published construction, the ultraviolet side has been filled as existence (for local fields), and the task of the remaining axioms has also been met for each phase Assessment . In either way of splitting, what remains is the band (the task of a uniform gap) and the seam that hands the ultraviolet result over to the infrared arguments Inferred (16-02, 16-03).

The list of premises is in 28-04 (a list written before the publication; the premises on the ultraviolet side have, as existence, been taken up by the published construction).

What this chapter can say

What is said	What is not said
Cited The "known in the world" column of each stage (the extent of the original sources is in each chapter's source table). That confinement and the gap are different claims	That the seven stages a proof must contain exhaust it. The division into stages is this book's arrangement
Proved here The claims in the "this book" column of Table 1 (within the conditions written in the row. The chapters that place the paper proofs are in Table 2)	Any of: the seam of the ultraviolet stage, the band stage, the mass gap of the general-group stage. The form of the two small-T^2 stages uniform in a (outside the assumption of an ultraviolet construction in a twisted box)
The arithmetic of the theorem names in the Lean entries (finite sums and lemmas on abstract operators. The physical measure is not formalised)	That the Lean entries checked the claims of the stages themselves
The meeting in Figure 1, in the sense of arriving at a statement of the same type at the level of the four-dimensional goal	That the present walls of the two roads are the same. The arrow from the area law to the gap

What is said	What is not said
Assessment The "shown by the published construction" entries of Table 1 are at the level of the committee's assessment	Whether the proof of the published construction is correct (outside this chapter)
Overall	This site shows neither the existence of the mass gap nor the construction of the continuum limit (the existence of the continuum limit belongs to the published construction)

Sources and reproduction

Item	Kind	Source / tools
Division into stages	This book	The stages of constructive field theory (7-01, 7-10), cut again to fit the material of Parts 25 and 26 (the table of stages, the list of tasks up to a proof, the list of assumptions)

Figure 1	This book	A hand-drawn figure (no numerical computation)

Words used in this chapter — the seven stages a proof must contain (vessel, ultraviolet, gap on a small T^2, confinement on a small T^2, band, R^4, general groups), the crossover band (the band), 't Hooft's twist, the sector bias θ, the marks of the state of the record (■◐□), the road to the gap and the road to confinement, the four-dimensional goal, a miniature of the band. Their meanings are in A-02 Glossary.

Next chapter to read: 16-10 A map of the tools. To read from the side of this book's study, 23-00 Entrance — the first road (from the direction of time). If you read from the list of conditions, 27-02 The ledger of conditions.

A map of the tools — where the known tools used by this book live

> This chapter is a guide (a map of the tools). It lists the homes of the known tools used by this book's study, and where each stops.

What this chapter shows — The twenty-two tools that the work from Part 23 on uses (the Poincaré inequality, Bakry–Émery, log-Sobolev, reflection positivity, the strong-coupling expansion, the renormalisation step, Migdal–Kadanoff, one-loop perturbation theory, interval arithmetic, Lean and others) in one table. For each tool, with labels: (1) its home — the chapter where its definition and known results are first set out (Parts 1–5 and Parts 7, 17 and 18), and the source; (2) how this book uses it — in which chapter from Part 23 on, and for what; (3) where it stopped when carried over to the group, and cautions. Also which chapter to read first when the same topic appears in two or more parts, three reading orders, the dependencies between the tools, and a list of the limits of the tools.

Prerequisite chapters — 16-09 The stages a proof must contain — the table of seven stages (the stages and the labels) and 0-01 § 03, the key to the labels.

Said first — This is a guide chapter and makes no new claims. The claims in each cell of the table are copied from the chapters listed there, with those chapters' labels (the conditions are in the text of each chapter). The column "where it stopped" is not a claim that the tool cannot be used; it records where the way this book used it did not reach, within this book's study. This site shows neither the existence of the mass gap nor the construction of the continuum limit. Where the tools used by the construction published in 2026 live is written in (6) (the label Assessment means "according to the committee's assessment report"; see "Labels" in 6-00).

The order of this chapter

1. The role of this chapter — in five lines
2. The table of tools — home, use, where it stopped (Table 1), and how topics found in two places are divided (Table 2)
3. Three reading orders — from the tools, from the results, from the map
4. Dependencies between the tools — tools needed first, and tools used later (Table 3)
5. What cannot be said — a list of the limits of the tools

00

The role of this chapter

(1) The chapters from Part 23 on take tools from Parts 1–5 and Parts 7, 17 and 18 into "lattice gauge theory on a group" and use them there. This chapter lets you look up, in one table, where the definition and the known results of each tool are.

(2) When the same tool appears in two or more parts (for example, Bakry–Émery in 5-11, 24-06 and Part 23; Migdal–Kadanoff in 18-04, 26-08 and 15-04), it divides them into "home" and "use", and fixes one chapter to read first.

(3) It lists, from the side of the tools, where they stopped when carried over to the group. In which part's chapter each stopped can be looked up in the third column.

(4) The labels are the same five classes as in 16-09. Proved here = this book has set out a proof on paper, Cited = known, checked in the source, Computer-assisted = computer-assisted (interval arithmetic), Reading = a reading of numbers or a physical picture, Assumption = an assumption. The correspondence with the labels of the chapters of Parts 1–5 and Parts 7, 17 and 18 (Lean, paper, computed, known, physics) is in 0-01 § 03.

(5) There are three ways to read (§ 02). Whether you enter from the tools, from the results or from the map, coming back to this table takes you to the home chapter.

(6) The construction published in 2026 assembled, from Table 1, reflection positivity (row 5), the renormalisation-group step (row 10), the one-loop coefficient (row 12) and Lean (row 21), together with tools not in the table (a coupling-dependent probability kernel, matching of the coupling by a shooting method, a multi-step ledger, Arzelà–Ascoli compactness, phase decomposition, reconstruction), and built a continuum limit in a periodic box and an infinite-volume theory along a subsequence. The committee assesses this as "proved in Lean" Assessment . Where those tools live is Volume 2: the kernel of one step in Part 9, the matching of the coupling in 10-04, the multi-step estimates in Part 11, and reflection positivity, the chessboard, compactness, phase decomposition and reconstruction in Part 12. The comparison with this book's tools is in Part 14.

01

The table of tools — home, use, where it stopped

Table 1 has one tool per row. The first column, "home", is the chapter where the definition and known results of the tool are first set out; it is the place a second-year student reads first. The second column gives the chapters from Part 23 on that use the tool, and what for. The third column gives where the tool stopped when carried over to a lattice on the group $SU(2)$, and cautions for reading. Numbers and conditions are written on the same row; the detailed conditions are in the chapters listed.

Table 1 The tools used by this book's work (home, use, where it stopped; labels are per claim within a cell)

Tool	Home (Parts 1–5 and Parts 7, 17 and 18, source)	Use in this book (Part 23 on)	Where it stopped on the group, cautions
1 The Poincaré inequality and the gap The constant C_P that bounds the variance by the squared gradient. The gap is $1/C_P$	1-10 § 08 (on the line, $V'' \geq \kappa > 0$ gives $C_P \leq 1/\kappa$) Cited . The reading as a relaxation time is in 2-10	23-06 (the condition of local Poincaré within a phase). 24-05 (on the lattice with continuous time, the gap $\Delta = \hbar^2/(2C_P(\nu))$, with ν the vacuum measure) Proved here	The gap in Langevin time and the gap of the transfer matrix are different quantities (18-03). The identity of 24-05 is a rewording; there is no tool that bounds C_P of the vacuum measure uniformly in the coupling
2 The Bakry–Émery criterion Curvature + second derivative of the potential $\geq K > 0$ gives a gap $\geq K$	5-11 § 02 (the criterion and the outline of its proof) Cited . 5-04 § 08 uses only the conclusion	5-11 § 05– § 07 (integrate a perfect family first; curvature lower bound $2 - 27\beta^2$) Proved here . 23-02 (families on the four-dimensional lattice). 24-06 § 02	On one link the criterion speaks only for $\kappa < 2$, while the true gap grows with κ Reading . On the whole lattice $\beta < 1/12$ Cited ; integrating first, $\beta < \sqrt{2/27} \approx 0.272$ (the strong-coupling side, lattice spacing fixed). The curvature of the group does not move with β, so the threshold cannot exceed $O(1)$. At weak-coupling scales convexity on the group itself fails (the lemma on the ceiling of convexity on the group, in 24-06 § 03) Proved here

Tool	Home (Parts 1–5 and Parts 7, 17 and 18, source)	Use in this book (Part 23 on)	Where it stopped on the group, cautions
3 The log-Sobolev inequality Bounds the entropy by the gradient. Stronger than Poincaré	5-11 § 02 (the criterion also gives log-Sobolev) Cited . The language of measures is in 1-08	24-06 § 06 (tools that pay with rarity instead of convexity; the entropy currency). 23-10 the type of mistaking the currency	The arrangement "Poincaré is the currency of exit speed, and only the entropy currency can pay for rarity" is a picture Reading . "The class of measures that pay with rarity" is a candidate rule and promises no prospect of closing the third step Assumption
4 Brascamp–Lieb and the hierarchical induction An induction whose entry is that the conditional measure at each scale is uniformly convex	No home in Parts 1–5 or Parts 7, 17 and 18. The definition and the conditions of the source are in 24-06 § 02 (Bauerschmidt–Bodineau) Cited	24-06 § 05 (carrying the induction over to the group: what applies, what changes, what does not)	The convexity assumption cannot hold, in principle, on the group at weak-coupling scales Proved here . The non-convex region is the reverse of flat ϕ^4 (on the group, the hemisphere far from the identity), and the wall is only pushed into a region of probability $e^{-c\beta}$ Proved here . Results for the hierarchical model imply nothing for four-dimensional Yang–Mills
5 Reflection positivity and the transfer matrix	5-03 (Osterwalder–Seiler), 4-10 (reconstruction) Cited . On the side of the published construction, 12-01 (two kinds of planes), 12-02 (the chessboard) Assessment	26-04 (positivity of the twist-summed ensemble z under reflections through lattice points) Proved here . 26-05 (input to the chessboard estimate). 16-09 the vessel stage	Transverse reflections break with the twist (the lemma on non-positivity of transverse reflections in 26-04) Proved here . The structural inputs (reflection positivity, duality, the transfer matrix, the centre identities) hold unchanged for $\mathbb{Z}_2$ and $U(1)$, and this set alone does not give the widening inequality (the negative lemma; its last step inherits the Reading of 26-03)
6 The Kogut–Susskind Hamiltonian lattice Only space is a lattice; time is continuous	5-03, 4-01 Cited	24-05 § 04 (a road that treats the gap directly). In the colour singlet the Poincaré constant of the vacuum measure halves at leading order Proved here	Local-to-global gap theorems do not apply as they stand on this lattice (reasons in 24-05 § 04). For the Kogut–Susskind form used in 24-05, read 5-03 first
7 The strong-coupling and cluster expansions Add weak couplings as corrections, and guarantee convergence by a criterion	5-02, 5-04, 7-04 (the Kotecký–Preiss, Dobrushin and Fernández–Procacci conditions) Cited	26-06 (the strong-coupling end). 15-04 § 05 (the exit of the chain in the hierarchical model = the strong-coupling decision region) Computer-assisted	They reach only the strong-coupling shore, with the lattice spacing fixed. They do not reach the band (intermediate coupling). How the strong-coupling ranges compare is in 5-11 § 07. This book's Lean theorems at strong coupling (the infinite-volume limit, the mass gap, the area law) are in 20-02–20-06, and are statements inside the strong-coupling window with the lattice spacing fixed. They sit at the opposite end from the questions that remain
8 The character expansion and class functions Expand a weight on the group in characters of irreducible representations. Conjugation-invariant functions = class functions	5-02 (the character expansion), 7-02 (the heat kernel in two dimensions), 1-04 Cited	15-04 § 01 (the one-link heat-kernel class is a semigroup and closes with one parameter) Proved here . 15-06 (couplings by loop shape and the attracting class)	It closes because in this model one weight returns to one weight in one step. Multi-link couplings, gauge re-fixing and large-field remainders are absent by construction, so nothing is implied for one step of the four-dimensional hypercubic lattice ("Said first" of 15-04)

Tool	Home (Parts 1–5 and Parts 7, 17 and 18, source)	Use in this book (Part 23 on)	Where it stopped on the group, cautions
9 Dobrushin's influence coefficient A criterion of the type: if the total influence of the neighbours on one site is below 1, correlations decay	7-04 (Dobrushin's condition, $4/27$ in the gas example) Cited	26-07 § 03 (one site at the top in the first step). 26-05 § 04. 26-10 mixing of the box fluxes	At the top in the first step, the conditional one-site measure is $\frac{15}{4}$-convex and the coupling to a neighbour is 2, so the influence from two neighbours is $\frac{16}{15} > 1$, back to the deficit $\frac{15}{4}$ versus 4 Proved here . With the frame fixed, the continuous field follows the boundary and the influence coefficient is close to 1 Reading (physics; the original papers not checked)
10 The renormalisation-group step (blocking) Integrate out the fine variables to make the action at the coarse scale	7-05 (the sequence of steps, blocking, small and large fields) Cited . What has been reached is in 7-07. The one step of the published construction (a coupling-dependent probability kernel) is in 9-01–9-07, and the many steps in Part 11 Assessment	15-03 (the decomposition statement, the ledger of transverse contraction). 15-05. 15-07 (background-dependent fluctuations η)	The numbers of 15-05 are for a step seen in the marginal of one coarse plaquette, not a true blocking step. The true two steps do not match two iterated steps (the contraction λ is 3.4–3.7 times larger) Reading . Fixing all coarse plaquettes at once makes the contraction a matrix, exceeding $1/16$ in coarse directions (Bundle Network Theorem; abelian configurations, tree level) Proved here . The multi-step induction for η has not been written Assumption
11 Migdal–Kadanoff and the hierarchical model A recursion that approximates blocking by a map on one weight	18-04 Figure 1 (the approximate recursion and its character) Cited	15-04 § 02– § 05 (pulled to an invariant curve at rate $1/16$ per step, its position set by the balance of source and contraction, $1/3600$: leading saddle-point term Proved here ; invariance of the tube for $\beta \in [2.46, 64]$ Computer-assisted). 26-08 road 30	The MK flow goes to strong coupling whether the group is abelian or not, and does not distinguish $U(1)$ from $SU(2)$ (Kanazawa) Cited . Tomboulis's interpolation relies on a common t^* for the untwisted and twisted sectors; this reduces to inequality (3.5) of Ito–Seiler, not shown outside strong coupling Cited . The hierarchical model confines even for $U(1)$ and is no test of non-abelianness
12 One-loop perturbation theory and the coefficient 11/3 Gaussian fluctuations around a background field. $\frac{11}{3} = 4 - \frac{1}{3}$	4-03, 4-06 (asymptotic freedom and the split of the coefficient) Cited	25-07 (isometric maps give only $\beta' \geq \beta + 0.023$; maps that reshape the fluctuations reproduce $\beta - \beta' = 0.258$) Proved here . 26-03, 26-06, 15-06	All are statements at the one-loop (Gaussian) level. Controlling the error of the reshaping maps at intermediate coupling and large fields is open. The $\frac{11}{3}$ at the head of those tables repeats 4-06; read 4-06 first for the split
13 Dimensional transmutation and Λ A mass scale Λ arises from a dimensionless coupling	4-07 Cited	24-07 (because it is four dimensions). 26-00, 26-07 (the position of the band, $L \sim 1/\Lambda$)	Placing the band at $L \sim 1/\Lambda$ is a physical reading of scales Reading . Most of 24-07 is an arrangement of known material and can be read with Parts 4 and 7 alone

Tool	Home (Parts 1–5 and Parts 7, 17 and 18, source)	Use in this book (Part 23 on)	Where it stopped on the group, cautions
14 The Gibbs variational principle and relative entropy Transporting a measure by a map, the remainder in the bound on the free-energy difference is a relative entropy. Crooks and Jarzynski are of this type	2-08 (free energy, relative entropy) Cited	25-06 (dynamically driven insertion). 25-07 the transport identity (the principle of direction) Proved here	In a sandwich by fixed maps, the remaining relative entropy grows with the area of the vortex sheet, and the form $e^{-\sigma A}$ does not come out Reading (physics; the stopped road "the deterministic sandwich" of 26-08). What can be used is the qualitative target $\Delta F(L,L)\to 0$
15 Twisted boundary conditions, the centre and 't Hooft flux	3-05 (topology), 5-01 (the lattice), 1-04 (the centre) Cited . The definition of the twist itself is in 25-01 Cited	25-01 (three facts, including uniqueness of the vacuum that absorbs the twist) Proved here . 25-04, 26-01, 26-04	For groups with trivial centre (G_2 and others) the arrows that use the centre disappear (16-09 the general-group stage) Cited . Parts 25 and 26 are written for $SU(2)$
16 Centre vortices and fractional instantons	17-02 (pictures of confinement), 3-05 (instantons) Cited	25-02 (definition and action, an upper bound on the minimal lattice action). 26-03 (a picture of where non-abelianness acts)	The dilute-gas count is a physical reading Reading . For the vortices of 26-03, read the definitions of 25-02 first
17 The container identity and the Tomboulis–Yaffe inequality Fixing the frame makes containers independent. From 't Hooft's criterion to the area law	The basis is 5-02, 5-04 (sums over surfaces). The identity is in 25-03 § 03 (Mack–Petkova), the inequality in 26-01 Cited	25-03–25-05 (rewriting in the sector-summed ensemble, nesting) Proved here . 26-02 (reduction to a single inequality)	Placing containers of fixed length independently gives, in four dimensions, only $V(R)\gtrsim R/\ln R$ (Kovács–Tomboulis) Cited . The area law needs one container of the size of the loop, which is the same condition as crossing the band. That the sector bias θ moves away from 1 is not enough (26-01) Proved here
18 The flux network — Thomson's principle, Kirchhoff's laws, orthogonal projection	1-01 (linear maps and projections) Cited . Standard facts of electrical circuits are in the source table of 15-05	15-05 Unit Bundle Theorem (the minimiser is fixed by a projection; contraction $\lambda\le \max f^2$, $1/(16d-8)\le\lambda\le 1/16$) Proved here	Statements at tree level (leading term as $\beta\to\infty$) restricted to abelian configurations. They do not include non-abelian configurations, the one-loop source, large fields or gauge re-fixing
19 The BCH formula and quaternions The commutator series of $\log(e^X e^Y)$. $SU(2)$ is the quaternions of length 1	1-03 (BCH up to third order), 1-02, 1-04 Cited	5-11 (the quaternion inner product and one-link integration). 15-06 (commutators as images under BCH). 15-07 (the group-geometry part = the third-order BCH coefficient $1/9$; leading Gaussian term, two links) Proved here	For $SU(2)$ the group-geometry part rides on the background itself and does not contract, and its budget diverges whatever threshold is chosen (arithmetic treating the one-loop flow as exact) Proved here . For $U(1)$ the third-order BCH term is identically 0

Tool	Home (Parts 1–5 and Parts 7, 17 and 18, source)	Use in this book (Part 23 on)	Where it stopped on the group, cautions
20 Computer assistance — interval arithmetic, certificates, the discipline of double precision Hold every number as an interval containing the true value, rounding outward	No home in Parts 1–5 or Parts 7, 17 and 18. The general theory is in 23-08 § 01– § 03 (rounding conventions, holding intervals, positive and negative controls) Cited	23-07, 23-08 (the chain condition $q < 1$ at every point of the $\hbar$ window) Computer-assisted . 15-04 § 05 (the tube of the hierarchical model) Computer-assisted . 23-15	Inequalities have been enclosed by interval arithmetic in the first-step window and in the hierarchical model, a map on one weight (plus the upper bounds on the action of explicit configurations in 25-02 Computer-assisted , upper bounds only). Even in the hierarchical model, $\beta > 64$ (the limit of zero lattice spacing) is not closed. The road of checking finitely many L by interval arithmetic is out of computational reach in four dimensions (26-08 road 3) Reading . Computer assistance says nothing outside the window (23-08 § 10)
21 Formalisation in Lean Statements as types, proofs as terms, checked by a small kernel	A-04 (kernel checking, the criterion of the three standard axioms) Cited . How to read the Lean of the published construction is in 6-00	5-11 (the curvature lower bound and the combinatorics of families). 23-13 (the bundles of the first step). The Lean column of Table 1 of 16-09	What is guaranteed is only the arrow from the stated hypotheses to the stated conclusion. Physical measures are not formalised. The interval-arithmetic layer lies outside Lean (23-13 § 04). The general theory is A-04; the list of bundles and examples is 23-13
22 Reading Monte Carlo Generate lattice configurations at random and measure averages	5-07, 5-08 Cited	25-08, 26-09 (the measured record) Reading . The numbers of 15-05 and 15-07 Reading	All measured numbers carry the "Reading" label and are not used as grounds for theorems. Lattice size, β, seeds and errors are on the same row in each chapter. There are examples where the numbers move when the way of measuring changes (the true two steps and two iterated steps in 15-05)

What to read from Table 1. (a) Two tools have no home in Parts 1–5 or Parts 7, 17 and 18 (the hierarchical induction and computer assistance). For both, chapters from Part 23 on (24-06 § 02, 23-08 § 01– § 03) double as the home. (b) The ways of stopping in the third column fall into types. The curvature and convexity tools (rows 2–4, 9) stop at the closed shape of the group and at the single site at the top; the renormalisation tools (rows 10, 11, 19) stop where one step is stacked into many; the structural tools (rows 5, 17) stop where they cannot be told apart from $U(1)$. (c) Computer assistance and Lean (rows 20, 21) both say nothing outside what was written.

How topics found in two or more places are divided

When the same tool appears in several parts, read the "home" of Table 2 first and the "use" after the home. The home chapter alone has the definitions and the known results.

Table 2 Topics found in two or more places (home = read first, use = read later)

Topic	Home	Use	Row of Table 1
The Bakry–Émery criterion	5-11 (the criterion and the one-link example)	24-06 § 02– § 03 (why it fails on the group at weak coupling), 23-02, 23-06	2
Migdal–Kadanoff	18-04 Figure 1 (the character of the approximation)	15-04 (invariant curve and interval arithmetic), 26-08 road 30 (Tomboulis's claim and its critiques)	11
The Kogut–Susskind lattice	5-03	24-05 (the gap and the vacuum measure)	6
Reflection positivity and the transfer matrix	5-03	26-04, 26-05 (checked for $\mathbb{Z}_2$ and $U(1)$)	5
The one-loop coefficient $\frac{11}{3}$	4-06	25-07, 26-03, 26-06	12

Topic	Home	Use	Row of Table 1
Dimensional transmutation	4-07	24-07, 26-00, 26-07	13
Vortices (centre vortices, fractional instantons)	The picture in 17-02; definition and action in 25-02	26-03 (a picture)	16
Renormalisation steps and Bałaban's series	7-05, 7-07 (what has been reached)	15-02 (inside the series and the BBS chain), 15-03	10
Interval arithmetic	23-08 § 01– § 03	23-07, 23-15, 15-04	20
Lean	A-04 (the general theory)	23-13 (the bundles of the first step and two examples of the types)	21

02

Three reading orders — from the tools, from the results, from the map

In all three, going back to Table 1 along the way to look up the home chapter lets you read without missing prerequisites. They can be used alongside the reading orders of 0-01 § 07.

Three reading orders (read in the order of the arrows; [ ] are rows of Table 1)

Way in	Reading order	What you know when you finish
From the tools readers from the mathematical side	1-10 → 5-03 → 5-11 → 7-04 → 7-05 → 18-04 → 23-08 § 01– § 03 → A-04 → 24-06 → 15-04 → 15-05 [1, 2, 5, 7, 10, 11, 20, 21, 3, 4, 18]	What each tool needs, and where on the lattice on the group it stopped. The three types of stopping ((b) after Table 1)
From the results from this book's conditional statement	16-09 → 27-01 → 27-02 → 25-04 → 26-02 → 15-03, going back from the "use" column of Table 1 to the home chapters as you read	Which tools each arrow of the conditional statement relies on. How the rows of the ledger of conditions correspond to the tools
From the map seeing the whole of what is open first	0-02 → 16-05 → 16-07 → 16-09 → this chapter → 26-08 → 15-08 → 27-04	Which of the seven stages are open, which tools stopped where, and what this book does not claim

03

Dependencies between the tools — tools needed first, and tools used later

Table 3 connects the tools of Table 1 by "tools needed first". The numbers are rows of Table 1. A tool needed first may have a later row number, but there are no cycles. Following this column from the left fixes the order in which to read the home chapters.

Table 3 Dependencies of the tools (this book's arrangement; "used together" is where they are combined from Part 23 on)

Tool (row of Table 1)	Tools needed first	Where used together
1 Poincaré inequality	— (linear algebra and spectra of 1-10)	The form of the conclusions of 2 and 3. The identity of 24-05
2 Bakry–Émery	1, 19 (the curvature of the group comes from $SU(2)$ being the three-sphere)	Gives 3. Entry to 4. Combined with 21 in 5-11
3 log-Sobolev	2	The tools of 24-06 that pay with rarity
4 Hierarchical induction	2, 10	Compared with 11 in 24-06 § 05
5 Reflection positivity	— (the axioms of 4-10)	The chessboard of 26-05. With 15 and 17, the negative lemma of 26-04
6 Kogut–Susskind lattice	5	Combined with 1 in 24-05
7 Strong-coupling expansion	8	The exit of the chain in 15-04. A criterion of the same type as 9

Tool (row of Table 1)	Tools needed first	Where used together
8 Character expansion and class functions	19	Combined with 10 and 11 in 15-04 and 15-06
9 Dobrushin's influence coefficient	7	Set beside 2 in 26-07 (back to the same deficit)
10 Renormalisation step	12	The frame for 11 and 18. The decomposition of 15-03
11 Migdal–Kadanoff	10, 8	Combined with 20 in 15-04. Road 30 of 26-08
12 One loop	— (perturbation theory of 4-03)	Combined with 14 in 25-07. 26-06, 15-06
13 Dimensional transmutation	12	The reading of the band's position (26-07)
14 Gibbs variational principle	— (2-08)	Combined with 12 in 25-06 and 25-07
15 Twist, centre, flux	— (3-05, 5-01)	The stage for 16 and 17. 26-04
16 Vortices	15	25-02, 26-03
17 Containers and Tomboulis–Yaffe	15, 7	25-03–25-05, 26-02
18 Flux network	10, 11 (comparison with $1/16$)	the Unit Bundle Theorem and the Bundle Network Theorem of 15-05
19 BCH and quaternions	— (1-03, 1-04)	The group-geometry part of 15-07
20 Interval arithmetic	— (23-08 § 01– § 03)	In 23-07, 23-08 and 15-04, encloses inequalities for maps such as 11
21 Lean	— (A-04)	Checks the algebraic steps of 2, 5, 17, 19 and others. The output of 20 is placed as a hypothesis
22 Monte Carlo	— (5-07)	The numbers of 25-08, 26-09, 15-05, 15-07 (Reading)

What to read from Table 3. The rows with no tool needed first (1, 5, 12, 14, 15, 19, 20, 21, 22) are the homes a second-year student can read first. Of these, 20 and 21 have their homes in Part 23 and the appendices, so read them first following the division of Table 2.

04

What cannot be said — a list of the limits of the tools

The limits of each tool, taken one line at a time from the third column of Table 1. What is not claimed, part by part, is in 27-04 What is not claimed (a cross-index); the limits of the ultraviolet tools of Part 15 are in 15-09 What cannot be said.

1. The curvature tools (Bakry–Émery, Brascamp–Lieb, Dobrushin) work only on the strong-coupling side with the lattice spacing fixed, and in the first-step window. At weak-coupling scales convexity on the group itself fails (24-06 § 03), and at the top in the first step they return to the same deficit $\frac{15}{4}$ versus 4 (26-07 § 03).
2. The strong-coupling and cluster expansions are tools of the strong-coupling shore and do not cross the band (intermediate coupling).
3. The statements about one renormalisation step (15-04, 15-05, 15-06) are each restricted to a map on one weight, the marginal of one coarse plaquette, or tree level on abelian configurations; none of them stacks a true step of the four-dimensional hypercubic lattice into many (15-09).
4. The Migdal–Kadanoff flow and the hierarchical model do not distinguish $U(1)$ from $SU(2)$. Closing there is no test of non-abelianness.
5. The structural inputs alone (reflection positivity, duality, the transfer matrix, the centre identities) do not give the widening inequality (the negative lemma of 26-04, in the form "this set of inputs alone").

6. Comparisons by one-loop tools and by the Gibbs variational principle are statements at the one-loop (Gaussian) level, not non-perturbative bounds.
7. Interval arithmetic says nothing outside the intervals written. Lean guarantees only the arrow from the stated hypotheses to the stated conclusion, and physical measures are not formalised (23-13, A-04).
8. Monte Carlo numbers are readings and are not used as grounds for theorems.
9. Whatever tools in this table are combined, this book's study shows neither the existence of the mass gap nor the construction of the continuum limit (27-04). The existence of the continuum limit was shown by the published construction, with the set of tools in (6)Assessment . The existence of the mass gap is in neither (16-02).

What this chapter can say

Can say	Cannot say
Cited The known results in the "home" column of Table 1 (the extent of the sources is in each chapter's source table)	That the twenty-two of Table 1 exhaust the tools of this book. The division into tools is this book's arrangement
Proved here Computer-assisted Reading Assumption The claims in the second and third columns of Table 1 (with the labels and conditions of the chapters listed)	That "where it stopped" in the third column is a limit of the tool in principle (it records the range of this book's use)
The division of Table 2 and the dependencies of Table 3 (this book's arrangement)	That the dependency table exhausts all logical implications
Overall	This site shows neither the existence of the mass gap nor the construction of the continuum limit

Sources and reproduction

Item	Kind	Source, tools
The claims and numbers in each row of Table 1	As labelled in each chapter	The text and source tables of the chapters listed on the row (this chapter copies them and does no new computation)
The Bakry–Émery criterion	Cited	D. Bakry, M. Émery, Diffusions hypercontractives, Séminaire de Probabilités XIX (1985) 177–206 (bibliographic data in the source table of 5-11)
The whole-lattice threshold $1/12$	Cited	H. Shen, R. Zhu, X. Zhu, Commun. Math. Phys. 400 (2023) 805–851 (the source table of 5-11)
The assumption of the hierarchical induction	Cited	Bauerschmidt–Bodineau (the source table of 24-06)
Tomboulis's interpolation and its critiques	Cited	E. T. Tomboulis, arXiv:0707.2179. K. R. Ito, E. Seiler, arXiv:0711.4930 ((3.5)). T. Kanazawa, arXiv:0805.2742 (the source table of 26-08)
The container identity and $R/\ln R$	Cited	Mack–Petkova (1980), Kovács–Tomboulis hep-lat/0108017 (the source table of 25-03)
Thomson's principle, Kirchhoff's laws	Cited	Standard facts of electrical circuits (the source table of 15-05)
Dobrushin's condition	Cited	The source table of 7-04. The original papers of the criteria in 26-05 are not checked
Table 2, Table 3, the three reading orders	This book	Arranged from the prerequisite paragraphs and the cross-references in the text of the chapters (no numerical computation)

Words used in this chapter — home (the chapter where a tool's definition and known results are first set out), use, where it stopped, the Bakry–Émery criterion, the log-Sobolev inequality, the hierarchical model, reflection positivity, class function, influence coefficient, blocking, Migdal–Kadanoff, the flux network, BCH, interval arithmetic, certificate. Their meanings are in A-02 Glossary.

Next chapter to read: 16-11 A map of ideas for crossing the band — living ideas, broken ideas, mathematics that seems to be needed. To read alongside it, 23-00 Entrance — the first road (from the direction of time). If you read from the tools, 5-11 Detour: Bakry–Émery and one-link integration.

A map of ideas for crossing the band — living ideas, broken ideas, mathematics that seems to be needed

> This chapter is a map of what is unsolved. The derivations of § 02 and § 03 are this book's own study.

What this chapter shows — The ideas that this book's study tried for crossing the crossover band (26-00), on a single map. First we set out the two ends of the band and a rough order of magnitude for the distance between them, and split the core into two jobs (extending the control of the published construction, keeping the sum of errors finite, to where the coupling is of order a number; and a statement for the last stretch from there to strong coupling). Next we derive why a chain of lossy inequalities cannot give a conclusion uniform in the cutoff. Then we see that the facts specific to SU(2) in this book's Lean are all facts about the action of configurations (facts on the side of energy), that what the band needs is a bound that counts fluctuations and the number of arrangements from below, uniformly in scale (the shortfall on the side of entropy), and which direction the bounds that can be written in variational form go. On that basis we sort the ideas into three tables, living, broken and undecidable, put the smallest next step in the form of questions, and list by name the mathematics that seems to be needed. Widening the test opponents to seven, and the small-lattice computations, are in 26-12.

Prerequisite chapters — 16-03 The infrared edge of the published construction, 16-04 Where this book stands, 26-00 Entrance — confluence, 26-06 The renormalisation comparison, A-08 § 05 The infrared side.

Said first — This chapter does not give a road across the band. There is no proof. What there is: a map of ideas, facts checked by hand counts and small-lattice computations, and a sketch of "this type of argument cannot cross". The observations written here (the two-way split of the core, the lossy chain, the shortfall on the side of entropy) may be known to specialists. This book writes them not as new results but as a sketch map used by this book's study. The numbers for the distance (the number of doublings, the ratio of scales) are rough orders of magnitude, not quantitative claims.

The order of this chapter

1. The two ends of the band, and the core split in two — a rough order of magnitude for the distance; the ultraviolet extension and the statement for the last stretch to strong coupling
2. A lossy chain gives no conclusion uniform in the cutoff — the rate is uniform, the prefactor grows
3. Facts on the side of energy, and the shortfall on the side of entropy — the direction of variational bounds — the facts specific to SU(2) in this book, what the vortex floors count, what is missing
4. The list of ideas — living (Table 1), broken (Table 2), undecidable (Table 3)
5. The smallest next step — in the form of questions
6. Mathematics that seems to be needed — seven items
7. What this chapter does not say

Labels — Proved here = a hand count whose derivation is placed in this chapter / Cited = a fact from the literature, checked at the relevant place in the original or a review / Reading = a reading of this book's small-lattice numbers (lattice, sweeps and seeds given) / Assumption = a conjecture or an expectation / Lean = a theorem in this book's Lean (only inside the strong-coupling window, with the lattice spacing fixed). For details, see "Labels" in 6-00. Statements in the literature that we have not checked are written as "a statement in the literature (not checked by this book)", and are not used as grounds for claims.

Notation follows this book's conventions. The one-loop slope is $s = 11C_g/(24\pi^2)$, for SU(2) $s = 11/(3\pi^2) \approx 0.3715$ (in Parts 25 and 26 the same quantity is written $8b_0$; the $s(N)$ of 26-06 is a different quantity). We write $\bar{\beta}$ for the reference coupling of the published construction (a coefficient of the effective action), and $\beta = 4/g^2$ for the coupling of the SU(2) Wilson action.

01

The two ends of the band, and the core split in two

The two ends. The strong end is this book's Lean window: the infinite-volume limit and the mass gap for $|\beta| < 1/19$ (an explicit sufficient condition for $18 \tanh |\beta| < 1$; the window itself is $|\beta| < 0.0556$; 20-03), and the area law for $\beta < 1.1 \times 10^{-3}$ in a finite box and $\beta < 1.2 \times 10^{-4}$ in infinite volume Lean (20-06; lattice spacing fixed, Wilson action

only). The weak end is the threshold required by the one-step estimate of the published construction; it is a lower bound on a coefficient of the effective action, not a Wilson β. The value of the threshold itself is not written as a number in the source; from just one of the conditions imposed on it, the threshold comes out as at least 9×10^5 ($e^{13.7065}$) (16-03 § 01). The two ends are stated in different quantities and in different classes of actions.

A rough order of magnitude for the distance. In the one-loop formula, each doubling of the lattice spacing lowers the coupling by $s \ln 2 \approx 0.2575$. If this one-step pace is extended straight into the region where it cannot be trusted (coupling of order 1), and moreover the coefficient of the effective action and the Wilson β are put on the same axis, the number of doublings from 9×10^5 to $1/19$ is

$$k \;\approx\; \frac{9 \times 10^5 - 1/19}{0.2575} \;\approx\; 3.5 \times 10^6, \qquad 2^k \;\approx\; 10^{1.05 \times 10^6} \quad (1)$$

Proved here (the division and the computation of $k \log_{10} 2$). This is a **rough order of magnitude**. The one-loop formula cannot be used where the coupling is of order 1, and the two axes are coefficients of different actions, so (1) is not a quantitative claim. What can be said goes only as far as the expectation that the weak end and the strong end are separated by an astronomical ratio of scales in units of step 0 Assumption .

Splitting the core in two. We view the core of the band as split into the following two jobs Assumption .

1. **The ultraviolet extension.** The job of extending the control of the published construction from the present threshold (at least 9×10^5) down to the value β_* where the coupling is of order a number, while keeping the sum of the errors over the steps finite. It is the same kind of job as the published construction, but the whole amount remains (the order of magnitude of (1)).
2. **The statement for the last stretch to strong coupling.** A statement with few steps, from β_* to the strong-coupling window. It is a non-perturbative statement where the coupling is of order 1 (it is different from the "Corollary Crossing the Band in Finitely Many Steps" of 26-06).

Where the boundary β_* is placed changes how the difficulty is divided. If the threshold is left at its present value, the "box of physical size of order $1/\Lambda$" that the second statement treats has a side of the order of (1) in units of step 0, and is no longer a statement about a small box. The second becomes a statement about a small box only when the first job has brought the threshold down to order a number Assumption . Note that in a periodic box, the published construction has the result that, with the volume fixed, the effective density at step 0 converges along the whole sequence of cutoffs (16-

03 § 02; the limiting measure itself is not defined as an object). There is no quantitative information at the size $1/\Lambda$.

This view comes with another reading. On a line of fixed physical size (fixed ratio of the side of the box to the correlation length), one step of the renormalisation comparison (26-06) is a statement that "compares boxes of the same physical size with the lattice spacing halved". So the sequence of doubling steps is at the same time a sequence of steps running into the infrared and a sequence of statements of ultraviolet uniformity (control of the continuum limit) Assumption . The conclusion of § 02 agrees with this reading.

02

A lossy chain gives no conclusion uniform in the cutoff

Consider the renormalisation comparison (26-06) in a form that allows a loss of a factor $K \geq 1$ at each step. With $\Delta F(N, M, \beta)$ the vortex free energy of a slab of width N and length M (19-02) and $f(\beta) = \beta - c$ ($c > 0$), suppose that

$$\Delta F(2N, 2M, \beta) \;\leq\; K\, \Delta F(N, M, f(\beta)) \qquad (N \geq N_1,\; M \geq M_0,\; \beta_s \leq \beta \leq \beta_0) \quad (2)$$

holds at every β the chain passes through (from the edge β_s of the strong-coupling window up to the starting β_0) (an assumption; it has not been shown). Here β_s is the edge of the window in which the estimate exponential in the area, with prefactor the transverse area, can be used (the finite-box window of 20-06, $\beta < 1.1 \times 10^{-3}$). It is a different window from the $1/19$ of § 01 (the window for the infinite-volume limit and the mass gap).

Derivation Proved here . Chain (2) k_0 times. k_0 is the number of steps, starting from β, until the coupling reaches the edge β_s of the strong-coupling window, and $k_0 \approx (\beta - \beta_s)/c$. For any $N' \geq N_1$, $M' \geq M_0$,

$$\Delta F(2^{k_0} N',\, 2^{k_0} M',\, \beta) \;\leq\; K^{k_0}\, \Delta F(N', M', \beta_s).$$

Insert the area-exponential estimate at the edge of the window, $\Delta F(N', M', \beta_s) \leq C\, N'^2 e^{-\sigma_s M'^2}$ (of the type of 20-06; the prefactor is the transverse area and σ_s the rate at the edge of the window), and set $L := 2^{k_0} M'$, $\xi := 2^{k_0}$. Then

$$\Delta F(\xi N',\, L,\, \beta) \;\leq\; C\, N'^2\, K^{k_0}\, \exp\!\Big(-\sigma_s \frac{L^2}{\xi^2}\Big) \quad (3)$$

Three things can be read from this.

- **The rate is uniform.** The rate per unit area is σ_s/ξ^2 and does not depend on K. If ξ is read as "the ratio of scales between the lattice at β and the lattice at the edge of the window" (of the order of the correlation length), the rate in physical units is σ_s and does not depend on the cutoff.
- **The prefactor grows.** $K^{k0} = \xi^{\log_2 K}$ (an equality), so the prefactor diverges as a power of the correlation length (the cutoff seen in lattice units). The right-hand side of (3) becomes smaller than 1 only from $\sigma_s (L/\xi)^2 \gtrsim k_0 \ln K + \ln(CN'^2)$, which in physical length L/ξ is of order $\sqrt{k_0 \ln K/\sigma_s}$; since k_0 is proportional to β, this stretches like $\sqrt{\beta}$ (of order $\sqrt{\ln \xi}$).
- **The condition for a uniform statement.** For the prefactor not to depend on the cutoff, the product of the per-step losses K_i must be bounded, that is, $\sum_i \ln K_i < \infty$ ($K_i = 1 + \varepsilon_i$, $\sum_i \varepsilon_i < \infty$).

Reading. A chain whose loss is a constant $K > 1$ uniform over the steps can carry **confinement at each** β (exponential in the area at fixed lattice spacing), but cannot carry **constants uniform in the cutoff** Proved here . A uniform statement needs the sum of the losses to be finite, and this is not a matter of cleverness with inequalities but a job of the kind of controlling the continuum limit (the first job of § 01) Assumption .

Seen additively, the distinction lies in the leading term. On the weak-coupling side, the vortex free energy is semiclassically of the type $\Delta F \approx \pi^2 \beta_{\text{eff}}(L)$ (π^2 is the lower bound of the sector action of the continuum theory; 25-02). If at one loop β_{eff} decreases by $s \ln 2$ per doubling, the change per doubling is

$$\Delta F(2L) - \Delta F(L) \;\approx\; -\pi^2 s \ln 2 \;=\; -\tfrac{11}{3} \ln 2 \;\approx\; -2.54 \quad (4)$$

Proved here ($\pi^2 \cdot 11/(3\pi^2) = 11/3$; at the one-loop level). In the Coulomb phase of U(1), the quantity of the same type does not run. So "the difference on the weak side is small, $O(1/\beta)$" is a relative way of speaking; on an additive ruler, the distinction is $O(1)$ per step. Subtracting values in this book's measured record (Tables 8 and 10 of 26-09, 1–3 seeds), SU(2) $4^4 \to 8^4$ gives 1.61, 1.88, 1.80 at $\beta = 2.7, 2.9, 3.0$ Reading (with a scatter of ± 0.3–0.7 on each value). The recorded values are $\Delta F(L) - \Delta F(2L)$ (the decrease), and compared with the size 2.54 of (4) they are of the same order.

However, the K-fold loss of (2) multiplies $\Delta F \approx \pi^2 \beta$, so $(K-1)\pi^2\beta$ eats up the 2.54 of (4) in a single step. Looking at the approximate formula, the lossless additive comparison $\Delta F(2L, \beta) \le \Delta F(L, \beta - c')$ is false in small boxes because of lattice artefacts: the minimal sector action $S(L)$ seen by cooling increases with L (7.84 at 2×2, 9.80 at 4×4, approaching the continuum $\pi^2 \approx 9.87$ from below; 25-02 Table 1) Reading , and the first term of $\Delta F(2L) - \Delta F(L) \approx \beta\,(S(2L) - S(L)) - 2.54$ is positive, so

the lossless form can only be written with a lower bound of order $\sqrt{\beta}$ on the side of the box Proved here . That the recorded decrease $2^4 \to 4^4$ moves away from 2.54 as $1.83,\ 0.85,\ 0.55$ at $\beta = 2.5,\ 2.75,\ 3.0$ agrees with the direction of this artefact Reading .

03

Facts on the side of energy, and the shortfall on the side of entropy — the direction of variational bounds

1. The facts specific to SU(2) in this book Assumption (within what we read of this book's Lean theorems (A-04 Table 4g and the pages 21-05, 21-07, 20-06); we have not checked by carrying the proof of each theorem over to U(1)). The ones that can clearly be read as depending on the non-commutativity of SU(2) and not carrying over to U(1) as they stand are the following four.

- With a twist in one direction only as background, there is a configuration of action 0 (the twisted vacuum) Lean (`ThetaLimit.flat_exists_10`, 21-07). This is because the quaternions **i** and **j** anticommute. In an abelian group, a single twist cannot be satisfied with action 0 Proved here (multiplying the products over the faces of a closed surface leaves only the sign of the twist).
- The gauge transformations that fix the twisted vacuum are only ± 1 Lean (`TwistBlocks.stab_vacT`, `TwistBlocks.rigidT_all`, the detour of 21-05).
- A box with twists in two directions at once has no configuration of action 0 (`TwistFlat.no_flat_twist11`, 21-07), and the minimal action of a vortex is positive, $S_N > 0$ (`VortexPos.SN_pos`, 21-05) Lean .
- For $N = 2, 3, 4$, a thick vortex is cheaper than a thin one: $S_N < 2N^2$ Lean (computer certificates; `VortexCert.SN_two_lt` and others, 21-05).

All of these are **facts about the action of configurations (facts on the side of energy)**. They point both ways: the first and fourth say "the twist goes in for free" and "a vortex can be made cheap", while the third says "a vortex is not free".

2. What this book's vortex floors count. The thin-vortex floor and the thick-vortex floor (21-02, 21-03) are upper bounds on the vortex ratio θ, that is, bounds in the direction of confinement, with rate $-\ln\tanh(N^2\beta)$ for the thin vortex and $e^{-\beta(S_N+\varepsilon)}$ for the thick vortex Lean (the thick-vortex floor is a statement for sufficiently large β and, for each β, sufficiently large M; the threshold is not explicit). This rate can be read as coming from the action of a single vortex (its classical value) and the number of positions at which the vortex pierces the longitudinal face (the factor M^2) Assumption . It is a value with the transverse size N fixed, not uniform in N, and the decrease at large β stays the exponential of the classical action. The upper-bound certificate $S_N <$

$2N^2$ is used in the direction of improving this rate (`TwistBlocks.thick_vortex_floor_two` and others, 21-05).

3. What is missing Assumption . What the band needs is that the rate is preserved when the transverse size is widened beyond the physical length (26-01, 26-02). In the picture of physics, what acts there is that the fluctuations of vortices and the number of their arrangements (entropy) run with scale (the reading of the margin $5/3 = 11/3 - 2$ in 26-00 Figure 2). In U(1) there is no such running. The vortex floors count positions too, but that count is with the transverse size fixed. However many facts about the action of configurations are piled up, this running is not expected to come out. What is needed is a bound that counts fluctuations and the number of arrangements from below, uniformly in scale. This book calls this **the shortfall on the side of entropy**.

4. The direction of variational bounds Proved here . Written with the partition functions Y_0, Y_1 of electric flux $e \in \{0, 1\}$, the untwisted and twisted partition functions are $Z_{n34=0} = Y_0 + Y_1$ and $Z_{n34=1} = Y_0 - Y_1$, and the vortex ratio is $\theta = Y_1/Y_0$ (26-06 § 02, 26-04). Confinement needs an upper bound on θ, that is, a **lower bound** on the energy of the flux sector. What a trial state (a variational bound) gives is an **upper bound** on the energy, that is, a lower bound on Y_1 and a lower bound on θ, the opposite of the direction confinement needs. On the magnetic side, a lower bound on the twisted partition function $Z_{n34=1}$ (an ensemble of trial configurations and Jensen's inequality) gives an upper bound on θ, which is the direction of confinement. Only on the magnetic side can the direction of confinement be written in variational form. We do not, however, say that a proof for the band is limited to this type alone.

04

The list of ideas

Each row gives the reason and the range checked. The seven test opponents, and the type of argument each one knocks out, are collected in 26-12; here we give only names and conclusions. Three terms first: a **mixed action** is the SU(2) action made by adding an adjoint-representation term to the Wilson action (the fundamental-representation term); a **first-order transition** is a transition in which the plaquette average or the like jumps as a function of the coupling; a **critical endpoint** is the point where a line of first-order transitions ends. A **flat connection** (a flat configuration, as 21-07 calls it) is a configuration in which the holonomy of every face equals the identity (or the sign of the twist when there is a twist), and a **frozen phase** is the phase of a gauge theory with a finite group, on the large-β side, that clings to the neighbourhood of flat connections.

Table 1 Living ideas (none of them crosses the band. "Living" means that there is not yet a reason to break it)

Name	Content	Reason and range checked
Seven test opponents	Test arguments about the band not only against weak-coupling U(1) but against seven opponents	With U(1) alone, the types of argument that can be knocked out are coarse. Finite non-abelian groups, the limit of the adjoint Higgs model, and the mixed action of SU(2) itself knock out arguments of other types. The counts and the traces of the first-order line are in 26-12 § 05 Reading ; the properties of the opponents checked in the literature are in the source table of 26-12 Cited
Splitting the core in two	The ultraviolet extension (bringing the threshold down to β_* while keeping the sum of errors finite), and the statement for the last stretch to strong coupling	§ 01, § 02. The count of the prefactor Proved here . Where the boundary is placed is Assumption
Mixing statement for a box of physical size	With the side of the box taken at a physical length C/Λ, the total variation of the law of gauge-invariant observables inside, when the frame (the links on the boundary of the box) is changed, is below a threshold, uniformly in β	Can be written independently of the group, the centre and the class of action, and is a form that should fail both in the Coulomb phase of U(1) and at a point of the endpoint type of the mixed action (if the gap closes at the endpoint; for SU(2) not checked by this book) Assumption . But it is a restatement of the mass gap (in a strong form), not a road. The direction of the input on the strong side (finite-box mixing ⇒ uniform exponential decay) is a combination of theorems of known types Assumption (not written out in the form for gauge theory)
Looking at the side of energy and the side of entropy separately	The facts specific to SU(2) in this book are facts about the action of configurations (the side of energy), and they point both ways. What the band needs is a bound that counts fluctuations and the number of arrangements from below, uniformly in scale (named by the picture of § 03: the shortfall on the side of entropy)	§ 03. Within the list we read Assumption ; the direction of variational bounds Proved here
Three classes by level of value	The quantity for a symmetric box with one twist: at weak coupling, proportional to β for U(1), constant in the frozen phase of finite non-abelian groups, of the type $\frac{3}{2}\ln\beta$ for SU(2)	Counts for finite groups Reading ; the power for SU(2) on 1^4 Proved here Reading (26-12 § 05). A distinction at the level of values; it does not cross the band

Name	Content	Reason and range checked
Stating the quantifiers explicitly	In the renormalisation comparison, where U(1) fails changes depending on whether the aspect ratio is fixed, or the width is fixed and the length extended	The form with fixed aspect ratio holds with a uniform constant even for U(1) on the weak side Proved here Reading ; extending the aspect ratio makes the constant grow (26-12 § 02)

Table 2 Broken ideas ("this type of argument does not go through, because ...")

Idea	Why it does not go through
Setting a measure-defined coupling by the ratio of the twisted to the untwisted partition function	The untwisted periodic box has a continuous family of flat connections, whose contribution acts logarithmically near the centre, so the denominator of the ratio is contaminated (the power on 1^4 in 26-12 § 05) Proved here Reading . This book's ΔF, a ratio of two twisted sectors, suffices
Crossing the band by an open-and-closed dichotomy ("if the vortex ratio in some box is below a threshold, it decays exponentially in the area from then on", plus connectedness of the set of β with decay)	Showing "the closed side is empty" takes in the whole of the running (the steps of the order of (1)), and the open-and-closed form returns to a restatement of "there is no transition" Proved here (logic)
Getting a conclusion uniform in the cutoff from a chain with a loss $K > 1$ uniform over the steps	The prefactor grows like $\xi^{\log 2\, K}$ (§ 02) Proved here . No harm as far as confinement at each β
Using "no transition on the β axis / no fixed point of the step map" in a class of effective actions	Within the class of SU(2) fundamental + adjoint mixed actions there is a line of first-order transitions and a critical endpoint (26-12 § 02) Cited Reading . That both sides of the line are confining phases is an inference from the line ending at the endpoint and connecting smoothly to the confining phase on the Wilson axis Assumption . It is a fact specific to the Wilson axis, and does not extend to the class of effective actions at step 0 of the published construction
Arguments whose only input is "non-commutative as an algebra", or only "the group is continuous and non-abelian, centre symmetry, positivity of the weights"	The former fails for finite non-abelian groups. The latter fails for the adjoint Higgs family: these are the same for every J in the family, and $J = \infty$ becomes the U(1) Wilson action Proved here , which has a non-confining phase Cited (Fröhlich–Spencer; shown mainly in the Villain approximation, with the text stating that all the results can be extended to the Wilson action; the extension relies on techniques of other papers) (26-12 § 03)
Using convexity at a single scale (of the Bakry–Émery type) at weak coupling	The curvature of the Haar measure is $O(1)$ and the Hessian of the action is $O(\beta)$, so the input at a single scale is relatively $O(1/\beta)$ and vanishes at weak coupling Proved here (a count of orders). The form that accumulates step by step is in Table 3

Idea	Why it does not go through
Getting the direction of confinement from a variational bound on the electric side (trial states)	What a trial state gives is an upper bound on the energy of the flux sector, the wrong direction (§ 03) Proved here
Taking a global log-Sobolev inequality on the torus as a gap quantity that works for every group	If the statement in the literature (not checked by this book) that the weak-coupling phase of Z_2 has a gap is right, then there the mixing between the holonomy sectors is slow and the global form is expected to fail, so it would not work as a gap quantity Assumption . Recast as local mixing with boundary conditions (spatial mixing) and kept in Table 1
Taking reflection positivity of the push-forward measure and a fixed block map as non-abelian-specific parts usable for the band	The push-forward identities hold just the same when the U(1) Wilson measure is pushed forward by the same map. It is a vessel, not an input that distinguishes groups Proved here
Convexity of the slab tension in the logarithm of the scale	For twisted slabs, in the semiclassical dilute region the logarithmic slope of $N^2\sigma_N$ is expected to be $11/3$, and 2 at large N, so the slope decreases Assumption (based on the picture of 26-00 Figure 2)
Using the a-theorem or trace-anomaly sum rules on the continuum side to say that the infrared is not a free photon	The value of a is consistent with decreasing from the ultraviolet (three gluons) to the infrared (one photon), so it does not exclude a free photon Assumption

Table 3 Undecidable ideas

Idea	Present state
Termwise sign inequalities in the twisted sector ($\partial\Delta F/\partial\beta_p \geq 0$ for the per-face couplings β_p)	All 48 positive for SU(2) on 1^4 Reading (26-12 § 05). For the finite group Q_8 there are points where a similar monotonicity breaks (21-01: monotonicity in β, three dimensions, no background) Reading . The lattice is a single point, so we cannot say it "holds"
A finite-box criterion for the total variation under a change of frame (on gauge-invariant observables)	The proofs of this book's Lean strong-coupling window use Dobrushin's condition on all links without fixing a gauge (a reading of the proofs of 20-02 and 20-03). A criterion that captures, outside the window, decay present only in the gauge-invariant part has no precedent in this book. In an inner region that does not touch the frame, this distinction may not be needed (item 5 of § 05, not checked by computation)
Filling the gap between physical strong coupling ($\beta \lesssim 2.2$) and the proof window ($1/19$) with finite-box criteria and certificates from the loop equations	There is a method that gets upper and lower bounds on lattice plaquette averages from the loop equations and positivity (in the large-N limit) Cited . The scale needed for small boxes of SU(2) is unknown

Idea	Present state
Seeing the generator of the heat bath as a sum of projections, and borrowing the criterion from quantum spin systems "if the gap of a finite chain exceeds a threshold, there is a gap in infinite size too"	The criterion itself exists for one-dimensional translation-invariant systems (and the two-dimensional square lattice) Cited . Whether the form of the threshold fits for projections on links in four dimensions has not been checked
Using the binary icosahedral group for a finite version of the band	There is a count of flat connections Reading . The value of β at which it freezes, and whether it imitates the behaviour of SU(2), are statements in the literature (not checked by this book)
Curvature that accumulates step by step	In the hierarchical model the one-step pace $(1-b^{-2})/3$ (0.25 for $b=2$) comes from the curvature factor of the group Proved here (note below). Most of the $11/3$ in four dimensions is not expected to come from curvature, so this is not expected to be the core Assumption
From tension to gap, by soft arguments within a class of actions	For SU(3) there is a report that the scalar mass in lattice units drops as the endpoint of the first-order line of the mixed action is approached Cited . For SU(2) not checked by this book, and the position of the endpoint also varies in the literature (an apparent endpoint on small lattices, and a revision on large lattices; 26-12 § 02). It concerns fixed lattice spacing and says nothing about the gap of the continuum theory
Using "the rate is uniformly positive" in a class of effective actions	Across a first-order line the tension may only jump and stay positive, so the first-order line of the mixed action does not break this. What would break it is the gap closing at the endpoint, which for SU(2) is not checked by this book
With pure gauge fields and a local action, the 't Hooft loop cannot have an area law (so for SU(2) the gap and confinement are hard to separate)	A conjecture Assumption
The trajectory of renormalised actions passes far from the endpoint of the mixed action	A statement in the literature (not checked by this book)
Vortex insertions adapted to the configuration, with relative entropy tending to 0 (a lower bound on the side of entropy)	Only a draft of the form. The first hurdle is to reproduce the one-loop $11/3$ Assumption
A monotonicity formula with the trace anomaly as its deficit	Only a draft of the form Assumption

Note (one step of curvature accumulating step by step) Proved here . Approximating the SU(2) plaquette weight by the heat kernel $K_t(\theta)$ (θ the angle of the plaquette holonomy), for small t one has $K_t(\theta) \propto \frac{\theta}{\sin\theta}\, e^{-\theta^2/(4t)}$. Bundling n plaquettes (the n-th power of the weight) gives $K_t^n \propto (\theta/\sin\theta)^{n-1} K_{t/n}$, and putting $\ln(\theta/\sin\theta) \approx \theta^2/6$ into the exponent, the Wilson β ($\beta = 1/(2t)$ from $1-\cos\theta \approx \theta^2/2$) becomes $n\beta - (n-1)/3$.

In the four-dimensional hierarchy with $b = 2$ (bundling $n = b^2 = 4$ plaquettes, and convolving b^2 plaquettes within a face, $t \to b^2 t$), one step gives $\beta \mapsto \beta - (1 - b^{-2})/3 = \beta - 0.25$. We read its closeness to the one-loop step $s \ln 2 \approx 0.2575$ as a coincidence Assumption .

05

The smallest next step

We write it in the form of questions. None of them has been answered.

1. **Filling in the sieve table.** For each "—" cell of 26-12 Table 2: in that opponent model, is the statement true, false, or undefined? Can the candidates for the core be re-selected by the criterion of keeping only statements that are false for weak-coupling U(1) and also false at a point of the endpoint type of the mixed action (if the gap closes at the endpoint; for SU(2) not checked by this book)?
2. **The minimal form of the ultraviolet extension.** In a box with background twist $n_{12} = 1$, does $\Delta F(N, M, \beta)$ with the ratio of the side of the box to the correlation length fixed converge as $\beta \to \infty$? The first step is reading: in the published construction's proof of convergence of the whole sequence in a periodic box, where does it depend on the boundary conditions?
3. **Testing the sign inequality.** For SU(2), background $n_{12} = 1$ and non-negative per-face couplings, is $\partial \Delta F / \partial \beta_p \geq 0$? After 1^4, elongated boxes (because the breaking for finite groups appears in geometries long in the transverse direction), then the closed formula in two dimensions and 2^4. Lift the smallest example that breaks for Q_8 to SU(2), and see where the breaking disappears.
4. **The additive comparison on the weak side.** Can $\Delta F(2L, \beta) \leq \Delta F(L, \beta - c')$ $(0 < c' < 0.2575)$ for $\beta \geq \beta_0$, $L \geq N_1(\beta)$ (N_1 of order $\sqrt{\beta}$) be written as a proposition at the one-loop level? The margin per doubling is the 2.54 of (4).
5. **A model case of a finite-box criterion on the strong side** Assumption (not checked by computation). In a two-dimensional SU(2) box, is the total variation, under a change of frame, of the law of an inner region not touching the frame bounded for all β by $C(\beta)\,(I_2(\beta)/I_1(\beta))^n$, with n the number of plaquettes in between (I_ν the modified Bessel functions)? And when the law of the inner links is invariant under gauge transformations at the inner points, is its total variation the same whether measured on all links or on the gauge-invariant part? Both are proposals not checked within this book's study; if checked, they would likely give the smallest model case of "the box criterion works even at β where the single-link criterion fails".

6. **A single-plaquette ruler** Assumption (not checked by computation). Measuring disorder by the ratio of fundamental-representation coefficients of a single plaquette, SU(2)'s $I_2(\beta)/I_1(\beta)$ matches U(1)'s value at its transition point, $I_1(1.01)/I_0(1.01) \approx 0.450$, at $\beta \approx 2.105$ (a numerical value of a ratio of Bessel functions, recomputed with this book's script). Whether it is meaningful to compare the two groups with this ruler, and whether its closeness to where SU(2) crosses over is not a coincidence, has not been checked.

06

Mathematics that seems to be needed

All of these are this book's conjectures Assumption . The names were chosen to describe the content.

- **Control of the continuum limit in twisted boxes.** Comparisons of scales, with a finite sum of errors, for quantities fixed by the measure and in twisted (framed) boxes. An extension of the type of the published construction, and the tool for the first job of § 01.
- **Coupling the laws of gauge-invariant observables.** A way of coupling conditional laws of gauge-invariant functions rather than link by link, and a finite-box criterion of Dobrushin–Shlosman type on top of it.
- **A method for computing lower bounds on the side of entropy.** Insertions adapted to the configuration, with relative entropy tending to 0. The first hurdle is to reproduce the one-loop $11/3$. A tool to fill the shortfall on the side of entropy of § 03.
- **Orderings of actions in the twisted sector.** A non-abelian inequality of Ginibre type saying that ΔF increases with the per-face couplings, or an ordering between actions that would take its place.
- **Expansion-free tools where the coupling is of order 1.** The combination of finite-box criteria and computational certificates.
- **A monotonicity formula with the trace anomaly as its deficit.** A quantum version of the classical monotonicity that becomes exactly trivial in four dimensions.
- **A stand-in for the vortex free energy for groups without centre.** The response to boundary fields and the like. For G_2 the tools of vortices cannot be used (26-12 § 02).

07

What this chapter does not say

- It does not give a road across the band. None of the ideas crosses the band. There is no proof.
- The number of doublings and the ratio of scales in (1) are rough orders of magnitude, not quantitative claims. They were computed from the lower bound that the threshold is at least 9×10^5.
- It does not say that "the remaining question is a question about the lattice theory at lattice spacing 1" (16-03 § 05).
- The discussion of the endpoint of the mixed action concerns fixed lattice spacing; it does not mean that the continuum SU(2) theory has no mass gap.
- The enumeration of the facts specific to SU(2) in this book (§ 03) is within what we read of the list of Lean theorems; it was not checked by carrying the proofs over to U(1).
- "Broken" means that arguments of that type do not go through; it does not mean that the goal itself is false.
- It does not say that the observations written here are new.

What this chapter has established

Established	Not established
Lean The strong end: the infinite-volume limit, the mass gap and the area law in the strong-coupling window (20-06). Facts specific to SU(2): the vacuum with a twist in one direction, its stabiliser ± 1, no configuration of action 0 in a box with two twists, $S_N > 0$, $S_N < 2N^2$ ($N = 2, 3, 4$) (21-05, 21-07)	Outside the window. The same statements in a class of effective actions. A rate uniform in the transverse size
Proved here The division of (1) (as a rough order of magnitude). (3): the prefactor is exactly $K^{k0} = \xi^{\log 2\, K}$, the rate σ_s/ξ^2 does not depend on K, and uniformity needs $\sum \ln K_i < \infty$. The one-loop 2.54 per doubling of (4). The direction of variational bounds. The hierarchical step 0.25	The quantitative meaning of (1). That (2) holds. The existence of a comparison with a finite sum of losses
Reading The recorded decrease $4^4 \to 8^4$: 1.61, 1.88, 1.80. The minimal sector action 7.84, 9.80. Cited The literature rows of Tables 2 and 3 (the source table of 26-12)	Conclusions about large lattices from values on small lattices
Assumption The two-way split of the core, the shortfall on the side of entropy, the division into Tables 1–3, § 05 and § 06	A road across the band

Item	Kind	Source, tool
Statements in the literature in Tables 1–3 that have not been checked (the gap in the weak-coupling phase of Z_2, the freezing β of the binary icosahedral group, the position of the renormalised trajectory, the scalar mass at the SU(2) endpoint, the equivalence of Stroock–Zegarlinski type)	—	Statements in the literature (not checked by this book). Not used as grounds for claims in the text

Words used in this chapter — the crossover band, the two-way split of the core, the ultraviolet extension, the statement for the last stretch to strong coupling, the lossy chain, the prefactor, facts on the side of energy, the shortfall on the side of entropy, the mixing statement for a box of physical size, the seven test opponents, the three classes by level of value, mixed action, first-order transition, critical endpoint, flat connection, frozen phase, control of the continuum limit in twisted boxes, coupling the laws of gauge-invariant observables. Their meanings are in A-02 Glossary.

Next chapter to read: 17-01 How physics sees it. The table of opponents against which arguments about the band are tested is in 26-12 (after reading Part 26).

2026-10-01 · chapter Yang–Mills and the mass gap Part 17 From the side of physics asymptotic freedom, dimensional transmutation, confinement

How physics sees it — freedom at short distances, a single scale, the tube of confinement, and the premise that "the theory exists"

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — We split the picture physics draws of pure Yang–Mills theory into three parts, asymptotic freedom, dimensional transmutation and confinement, and look at each with formulas and numbers. We read how the ratios of the lattice glueball masses connect with "there is a single scale". We check that the whole picture rests on the premise that "the theory exists", and that confinement and the mass gap are different claims in mathematics.

Prerequisite chapters — 4-07 Dimensional transmutation and Λ (and 4-06 before it). Easier with: 3-02 (gauge fields), 5-01 (the lattice and β), 4-11 (the definition of the gap). The vocabulary of Wilson loops and the lattice is defined on the spot as far as needed. Within Volume 3, this chapter is read after Part 16 (where things stand, and the questions that remain).

Said first — This is a chapter of pictures at the level of physics. "Confinement", "a single scale" and "the glueball mass" are not theorems of the four-dimensional continuum theory (label Physics). This book does not itself show either the mass gap or the construction of the continuum limit. For the construction of the continuum limit, Volume 2 reads the one published on 2026-11-10 (a theory satisfying the Wightman axioms; it does not show the mass gap). The lattice numbers are values from primary sources; only the ratios and conversions were recomputed on this terminal.

The order of this chapter

1. The question of physics and the question of mathematics — how it is, rather than whether it exists
2. Short distances: the coupling becomes weak — the minus sign of the β function

3. A single scale is born: dimensional transmutation — every mass is a constant multiple of Λ
4. Long distances: Wilson loops and the area law — the definition of confinement, and its linear case
5. The flux tube and the Lüscher term — the picture of the tube, and the correction at long distances
6. The physical face of the gap: glueballs — the lattice ratios $m/\sqrt{\sigma}$
7. Detour: where the unit MeV comes from — borrowing a unit
8. The premise that "the theory exists" — at which stage of the numbers it enters
9. Confinement and the gap are different claims — examples with only one of them, and the implication on the lattice
10. The tools of physics, and the shore of each — a map of Part 17
11. Detour: why the gap has a minimum — the picture of being squeezed from both sides — on the large side anti-screening, on the small side uncertainty

---

01

The question of physics and the question of mathematics

The prize problem asks "does the theory exist, and is there a gap in the spectrum?" (0-03). The questions of physics are "what is the mass of the lightest particle?" and "how does the force change as a pair of quarks is pulled apart?". Physics takes the theory as already existing and asks about its contents.

Jaffe and Witten list three properties that QCD (Yang–Mills theory with quarks) must have at the quantum level Known . (1) The mass gap: 'every excitation of the vacuum has energy at least Δ'. This is why the nuclear force is strong yet reaches only short distances. (2) Quark confinement: physical particle states are invariant under SU(3) transformations, and a single quark is not seen. (3) Chiral symmetry breaking.

Pure Yang–Mills has no quarks, so (3) does not arise. (1) is the body of the prize problem, and (2) is set apart in § 5 of the problem statement as a "natural extension". The picture of physics tries to explain (1) and (2) in one sheet, and is made of three parts: the coupling weakens at short distances (§ 02), a single scale is born (§ 03), and at long distances the flux is confined to a tube (§ 04, § 05).

02

Short distances: the coupling becomes weak

Under renormalisation, the coupling g changes its value with the scale μ at which we look (an energy; as a distance, roughly $1/\mu$) (4-04). The β function that fixes how it changes has the following form in the one-loop computation for pure SU(N) Known .

$$\beta(g) = \mu\frac{dg}{d\mu} = -b_0\, g^3 + O(g^5), \qquad b_0 = \frac{11N}{48\pi^2} \quad (1)$$

Because of the minus sign, raising μ (looking at shorter distances) makes g smaller. This is **asymptotic freedom** (4-06). The PDG review writes, with $\alpha = g^2/4\pi$, $\mu^2 d\alpha/d\mu^2 = -b'_0\alpha^2 - \cdots$ and $b'_0 = 11N/(12\pi)$ (the same thing Computed), and says 'The minus sign in Eq. (9.3) is the origin of "asymptotic freedom"'. With the first term alone, $d(1/g^2)/d\ln\mu = 2b_0$ is constant, so

$$\frac{1}{g^2(\mu)} = \frac{1}{g^2(\mu_0)} + 2b_0 \ln\frac{\mu}{\mu_0} \quad (2)$$

With SU(3) and $g^2(\mu_0) = 1$, we get $g^2 = 0.757$ at $\mu = 10\mu_0$, and still 0.342 at $10^6\mu_0$ Computed . The weakening is logarithmic. In the words of the problem statement, 'at short distances the field displays quantum behavior very similar to its classical behavior'. But (1) is a perturbative computation. That the continuum theory really behaves like this at short distances is one of the properties the problem statement requires of a solution.

03

A single scale is born: dimensional transmutation

Reading (2) in the direction of lowering μ, $1/g^2$ becomes 0 at a certain scale Λ.

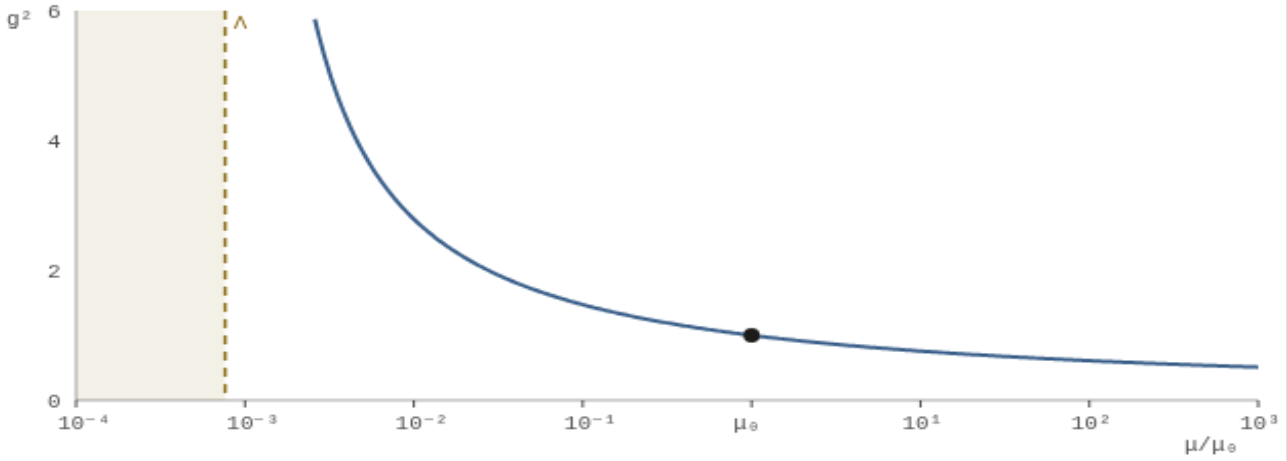
$$\Lambda = \mu\, \exp\!\Big(-\frac{1}{2b_0\, g^2(\mu)}\Big) \quad (3)$$

Substituting (2), the $\ln(\mu/\mu_0)$ cancels and Λ does not depend on μ (at three points along the flow it agrees up to double-precision rounding Computed). Classical four-dimensional Yang–Mills has no constant with the dimension of mass (g is dimensionless, 1-12). Even so, in the quantum theory a scale Λ appears. This is **dimensional transmutation** (4-07). The PDG explains Λ as 'a constant of integration, which corresponds to the scale where the perturbatively-defined coupling would diverge'. What breaks at $\mu = \Lambda$ is the one-loop formula, not the theory. From here physics concludes that every quantity with a dimension is a constant multiple of Λ Physics .

$$m_0{}^{++} = c_1\Lambda, \qquad \sqrt{\sigma} = c_2\Lambda, \qquad \Delta = c_3\Lambda \quad (4)$$

$m_0{}^{++}$ is the mass of the lightest glueball (§ 06), σ the string tension (§ 04), and c_i pure numbers fixed by N. This "single scale" looks obvious in physics as dimensional analysis, and is not proved in mathematics ("the diffusive-relaxation-time assumption" in the record of this book's study; 17-12, 23-01). Also, $\exp(-1/(2b_0 g^2))$ has all Taylor coefficients 0 at $g = 0$. If (4) is granted, Δ too appears at no order of the perturbation series. This runs the same way as the problem statement's 'the mass gap is not classically visible' (4-12).

Figure 1 Changing, with the knobs, the coupling $g^2(\mu_0)$ at the reference scale μ_0 and N moves the running coupling $g^2(\mu)$ (solid line) and the scale Λ where it diverges (dashed line). For SU(3), changing $g^2(\mu_0)$ from 0.5 to 1 moves Λ/μ_0 by a factor of about 1300 (three orders of magnitude)



```
SU(3), g²(μ₀) = 1.00 → Λ/μ₀ = 7.63×10⁻⁴ | increasing g² by 1% multiplies Λ by 1.074
```

Table 1 The one-loop Λ/μ_0, and the factor by which Λ changes when g^2 is increased by 1%

Group	$g^2(\mu_0)$	Λ/μ_0	Factor
SU(2)	0.5	4.45×10^{-10}	1.238
SU(2)	1.5	7.63×10^{-4}	1.074
SU(3)	1.0	7.63×10^{-4}	1.074
SU(3)	3.0	9.14×10^{-2}	1.024

Computed The numbers in this figure were computed on this machine. The curves are drawn on the spot from formulas (2) (3), and Table 1 evaluates the same formulas in Python 3 (for SU(3) at $g^2 = 0.5$, $\Lambda/\mu 0 = 5.83 \times 10^{-7}$).

The smaller the coupling, the exponentially smaller Λ is, and the more sensitive to changes. SU(2) at $g^2 = 1.5$ and SU(3) at $g^2 = 1.0$ give the same value because at one loop only Ng^2 (the 't Hooft coupling, 17-04) matters. The numerical value of Λ changes by a fixed factor depending on how g is defined, but the form of (4) is kept.

04

Long distances: Wilson loops and the area law

To measure the force in a theory without quarks, we place a pair of static colour charges from outside (a colour charge is a charge that acts as a source of the gauge field; 3-02). In Euclidean spacetime (4-02, One sign is different) take a rectangle of width R and length T; the trace of the matrix obtained by parallel transport once around it along the gauge field (the holonomy, 1-07) we call the **Wilson loop** $W_{R,T}$. The rectangle is the process "create the pair, leave it for a time T, annihilate it", and the expectation value decreases roughly as $e^{-V(R)T}$, so we define the potential by the following (Wilson 1974; the notation follows Chatterjee 2018 § 4) Known .

$$V(R) = -\lim_{T\to\infty} \frac{1}{T} \log\langle W_{R,T}\rangle \quad (5)$$

If $V(R) \to \infty$ as $R \to \infty$, the pair cannot move apart beyond a fixed distance. This is **confinement** (the definition in Chatterjee 2018 § 4). In particular, if $\langle W_{R,T}\rangle$ decreases as $e^{-\sigma RT}$ in the area RT (the **area law**), then $V(R) \approx \sigma R$ grows linearly. The coefficient σ in this linear case is the **string tension**. That it grows linearly in four-dimensional non-abelian Yang–Mills stands at the level of 'it is believed that V(R) grows like a multiple of R' (ibid. § 4) Physics .

On the lattice, which replaces spacetime by a mesh of points (5-01), the strength of the coupling is expressed by the **lattice inverse coupling** β (for the standard Wilson action $\beta = 2N/g^2$; a large β is weak coupling; this is not the β function of § 02). On the side where β is small (strong coupling) the area law is proved, but it holds for every group including `U(1)`, so it is no evidence of non-abelian confinement. The weak-coupling side for non-abelian groups in four dimensions 'remains elusive' (Chatterjee 2018; 5-02, 5-06) Known .

05

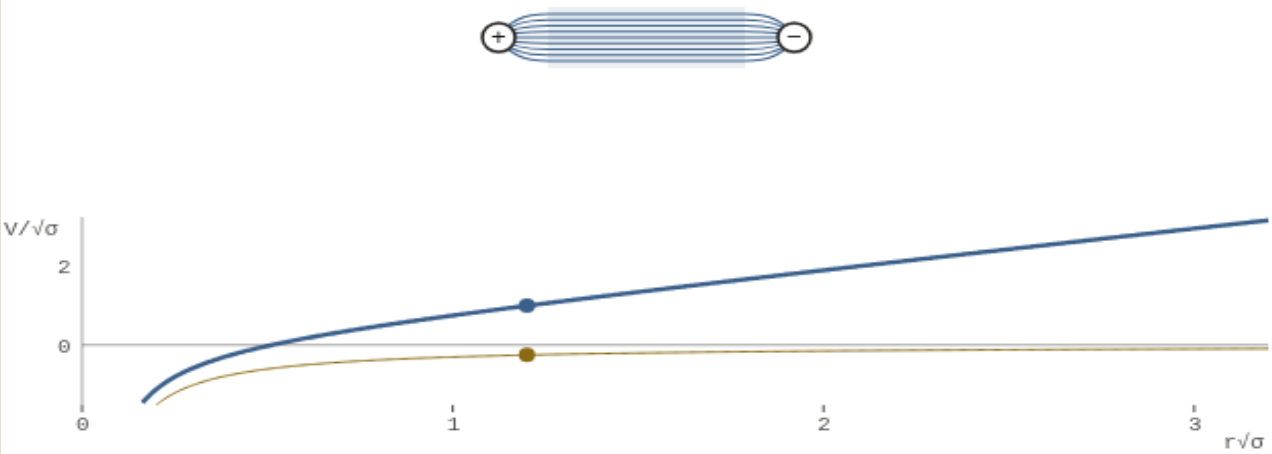
The flux tube and the Lüscher term

The picture of physics is the **flux tube**. The lines of force of electromagnetism spread out, and pulling the charges apart the energy approaches a constant value ($V \sim -c/R$). Under confinement the lines of force are squeezed into a tube of fixed thickness, and the energy is proportional to the length. As a metaphor, it is a string whose tension does not change as it is stretched. More precisely, the tube is not a fact derived from the theory but a picture that fits the lattice numbers; the effective theory of the fluctuations of the tube (17-03) takes the existence of the tube as its starting point and gives the correction at long distances as follows Physics .

$$V(r) = \sigma r + c_0 - \frac{\pi}{12\,r} + \cdots \quad (6)$$

$-\pi/(12r)$ is the Lüscher term, and its coefficient is held not to depend on the details of the theory ($-\pi(d-2)/24$ in d dimensions). c_0 is a non-universal constant. Putting (6) into the lattice length standard r_0 ($r_0^2 F(r_0) = 1.65$ for $F = dV/dr$, Sommer 1994) gives $r_0\sqrt{\sigma} = \sqrt{1.65 - \pi/12} = 1.178$, which differs by 1.6% from the lattice continuum value $1.160(6)$ (Athenodorou–Teper 2020) Computed . At r_0 the tube is still at short distance, so this is a rough guide that extends formula (6) to that distance. It agrees in outline, but the difference is about 3 times the lattice error, and it does not agree in detail.

Figure 2 Changing the distance r between the charges with the knob moves the lines of force above and the point on the energy V(r) below. The buttons switch between "electromagnetism (spreading)" and "confinement (tube)"



r√σ = 1.20 (about 0.49 fm), confinement: V/√σ = 0.98, electromagnetic sample: −0.25

r√σ	r (fm)	Confinement V/√σ	Electromagnetic sample V/√σ
0.3	0.12	−0.57	−1.00
0.51	0.21	0.00	−0.59
3.0	1.22	2.91	−0.10

Computed The numbers in this figure were computed on this machine. Confinement is $\sigma r - \pi/(12r)$ of (6) (without c_0), electromagnetism is the sample $-0.3/r$, and fm is converted with $\sqrt{\sigma} = 485$ MeV (§07). 0.51 is $\sqrt{\pi/12}$, where the two terms balance.

In QCD with quarks, signs that a long tube breaks have been reported on the lattice (SESAM 2005) Physics . Pure Yang–Mills has no quarks to create a pair midway and break the tube.

06

The physical face of the gap: glueballs

The particles of pure Yang–Mills are thought to be **glueballs**, colourless bound states made only of gluons. States are classified by J^{PC} (spin, parity, charge conjugation). 0^{++} is a state of spin 0 that changes sign neither under spatial inversion (parity) nor under the exchange of particle and antiparticle (charge conjugation). In physics the mass of the lightest 0^{++} is often called "the mass gap" Physics . Chatterjee 2018 explains the correlation length (2-08) as 'the reciprocal of the mass of the lightest glueball', and writes that the existence 'has not yet been experimentally verified'.

The gap of the problem statement is defined as a gap in the spectrum of the Hamiltonian (the problem statement calls its supremum 'the mass'), and does not presuppose the existence of particles. If the lowest excitation is an isolated one-particle state, the gap coincides with the mass of the lightest glueball (4-11). A proof that an isolated one-particle state exists is counted by the problem statement on the side of the "natural extensions".

Lattice computations replace spacetime by a mesh with lattice spacing a (the distance between lattice points) and produce the dimensionless ratio $m/\sqrt{\sigma}$.

Table 2 Glueball masses (continuum limit), and the ratios computed on this machine

J^{PC}	SU(2) $m/\sqrt{\sigma}$	SU(3) $m/\sqrt{\sigma}$	SU(∞) $m/\sqrt{\sigma}$	$m/m_{0^{++}}$: SU(2), SU(3), SU(∞)
0^{++}	3.781(23)	3.405(21)	3.072(14)	1, 1, 1
2^{++}	5.349(20)	4.894(22)	4.582(14)	1.415(10), 1.437(11), 1.492(8)
0^{-+}	6.017(61)	5.276(45)	4.711(25)	1.591(19), 1.549(16), 1.534(11)
0^{++*}	6.126(38)	5.855(41)	–	1.620(14), 1.720(16), –

Computed The errors of the ratios are a naive propagation treating them as independent, a rough guide that ignores correlations. SU(∞) is the value extrapolated in $1/N^2$. On the lattice rotation symmetry is reduced to the rotations of a cube, and spin 2 splits into two sets (E, T_2) that are measured separately. The 2^{++} of SU(∞) is the E value (4.578(11) for T_2; 5-08). 0^{++*} is an excited state.

For every N, 0^{++} is the lightest, and the ratios change only slowly with N (17-04). On the other hand, $m_{0^{++}}/\sqrt{\sigma}$ for SU(3) is 3.347(68) (Meyer 2005), 3.405(21) (Athenodorou–Teper 2020) and 3.607(87) (Lucini–Teper 2001), scattered more widely than the quoted errors. σ is obtained by subtracting the fluctuation correction from the mass of a closed tube. Formula (4) of Lucini–Teper is $am_l = a^2\sigma L - \pi/(3L)$, where m_l is the mass of a flux tube closed once around a periodic box, and L is the side of the box counted in lattice points. The authors note: 'in using eqn(4) we are assuming that we have linear confinement'. The continuum limit is an extrapolation assuming $m(a)/\sqrt{\sigma(a)} = m(0)/\sqrt{\sigma(0)} + c\,a^2\sigma$ (5-08).

07

Detour: where the unit MeV comes from

A section you may skip.

When we say "the lightest glueball is about 1.7 GeV", where does the MeV come from? Pure Yang–Mills has only one scale, Λ, and the unit is borrowed from outside. Athenodorou–Teper 2020 take $r_0\sqrt{\sigma} = 1.160(6)$ from pure Yang–Mills and $r_0 = 0.472(5)$ fm from lattice QCD with quarks, obtain $\sqrt{\sigma} = 485(6)$ MeV, and give 0^{++} as 1653(26) MeV. The recomputation on this machine gives $\sqrt{\sigma} = 484.96 \pm 5.7$ MeV and $0^{++} = 3.405 \times 485 = 1651 \pm 22$ MeV Computed . The paper states that the errors of its Table 18 are statistical only, while our ± 22 is a rough guide that includes the error of $\sqrt{\sigma}$; the meanings differ. The authors add: 'Strictly speaking this is of course not possible: the pure gauge theory and QCD … are two different theories'. What has meaning within pure Yang–Mills is the ratio 3.405.

08

The premise that "the theory exists"

The parts and numbers so far rest on the premise that four-dimensional pure Yang–Mills theory really does exist, as one theory. We list the stages of a lattice computation at which the premise enters.

Stage	What is done	Premise
Finite lattice	A finite-dimensional integral evaluated by the Monte Carlo method (5-07)	None (a well-defined probability measure)
Extracting σ	Subtracting the fluctuation correction of the tube	Linear confinement and the universality of the fluctuations
Infinite volume	Using only boxes with side at least $3/\sqrt{\sigma}$ (Lucini–Teper)	That the values do not change beyond that
Continuum limit	Extrapolating to $a \to 0$ in the form $c\,a^2\sigma$	That the limit exists, is unique, and is approached in this form

For physics this premise is natural, and the problem statement too writes that experiment and computers 'have given strong encouragement'. But the same paragraph continues 'there does not exist a convincing, whether or not mathematically complete, theoretical computation demonstrating any of the three properties in QCD', and the mathematical side is at the stage of 'nor even a precise definition' Known .

Put as a metaphor, physics draws a detailed map of land it is convinced exists, and mathematics is asked to show that the land exists. Precisely, the task is, for every compact simple group, to construct a non-trivial quantum Yang–Mills theory on $\mathbb{R}^4$ (with axioms at least as strong as those of Wightman or Osterwalder–Schrader; 4-09, 4-10) and to show $\Delta > 0$. A commonly taken road is to construct a Euclidean probability

measure with a regularisation and take the limit. A footnote of the problem statement says that weak existence, where only a subsequence converges, is not accepted unless the properties of the limit are shown separately. The numbers of physics, however precise, are "predictions made on the assumption of existence" (5-09, 7-10).

For the construction published on 2026-11-10, the committee's assessment is that it is proved in Lean that a theory satisfying the Wightman axioms can be constructed as a limit of Wilson's lattice gauge theory (Volume 2, 6-01). However, the infinite-volume limit is taken along a subsequence, and its uniqueness and the mass gap are not shown (6-04). The premise of the "continuum limit" row in the table above (that the limit exists and is unique) is still not fully met.

09

Confinement and the gap are different claims

In the picture of physics σ and m are two faces of the same Λ (formula (4)), and confinement and the gap are spoken of together. In mathematics they are separate claims.

There are examples where only one of them holds. For lattice gauge theory with finite groups, exponential decay of correlations at weak coupling is proved, while the absence of confinement is at the level of 'believed' (5-10). For compact `U(1)` in three dimensions the area law is proved at every coupling, and the continuum limit is a free scalar field (abstract of Göpfert–Mack 1982). In the converse direction, exponential decay under arbitrary boundary conditions on the lattice gives the area law for Wilson loops in representations on which the centre of the group acts non-trivially (Chatterjee 2021) `Known` . The table and the precise statements are in 17-02 § 02 (the master copy in this book).

This converse implication has a form close to "gap ⇒ confinement", but its hypothesis is a strong form of decay on the lattice. There is no theorem deriving confinement from a gap in the sense of the problem statement ($\Delta > 0$ in the continuum and in infinite volume). The variables physics mainly looks at (the tube and σ) and the target of the problem statement (Δ) are slightly offset.

10

The tools of physics, and the shore of each

Each tool of physics has a "shore" where its computations are under control. More precisely, a shore is a region near some limit ($g \to 0$, lattice $\beta \to 0$, $N \to \infty$ and so on) in which the errors of the computation can be controlled. The remaining chapters of Part 17 dig into the rows of the table.

Tool	Shore where the computation works	Level	Chapter
Perturbation theory	$g \to 0$. The gap does not show (granting (4))	Known	4-03–4-07
Strong-coupling expansion	The lattice inverse coupling β is small (strong coupling). Area law for every group including U(1)	Known	5-02
Lattice numerics	Finite a and boxes, and their extrapolation	Physics	5-08
Mechanisms of confinement, strings	Gauge-fixed variables / a long tube (confinement assumed)	Physics	17-02, 17-03
Large N, holography	$N \to \infty$ (holography also $g^2N \to \infty$)	Physics	17-04, 17-08–17-10
Supersymmetry	Supersymmetric theories with matter fields	Physics	17-11

The theory of the problem statement — any compact simple group, finite N, no matter, the continuum $\mathbb{R}^4$ — is on none of the shores. The pictures of physics fill the space between the shores with the premise that "one theory connects them" (§ 08). The places where that premise leaves mathematics are gathered in 17-13 and 16-05.

11

Detour: why the gap has a minimum — the picture of being squeezed from both sides

This section may be skipped. It reassembles three parts of this chapter (§ 02 asymptotic freedom, § 03 dimensional transmutation, § 04 confinement) towards a single question: "why does the lightest excitation have a non-zero mass?" Physics This is a picture, not a proof. None of its steps is a theorem in the four-dimensional continuum theory (27-02).

In one sentence. Because the field binds itself with its own charge, it cannot become a long wave, only a short lump. The minimum appears where the size of an excitation is squeezed from both sides.

The large side is closed off. A massless free field (light) has no gap because a wave can be made however long the wavelength, and its energy $E = |p|$ goes to zero. A long wave needs the field to keep its direction aligned over long distances. In Yang–Mills the mediating field itself carries colour charge, so the fluctuations of the vacuum do not screen the field but anti-screen it, and the coupling grows stronger as the distance grows (§ 02, 4-06). Beyond the distance $1/\Lambda$ where the coupling becomes of order one, the field cannot keep its direction and falls apart. So waves with wavelength longer than $1/\Lambda$ cannot survive as states. The colour electric flux cannot spread out, and is bundled into a closed tube (§ 05).

The small side is closed off too. In a region smaller than $1/\Lambda$ the coupling is weak and the field is nearly free, but an excitation localised to size R cannot, by the uncertainty relation, have energy below about $\hbar c/R$ (2-05, 16-08 § 09). If $R < 1/\Lambda$ then $E > \Lambda$.

Squeezed from both sides. What keeps it from growing large is anti-screening, and what keeps it from becoming small is uncertainty, so the lightest excitation is a closed ring of electric flux of size about $1/\Lambda$. Its mass is of order Λ, and that is the gap (the glueball of § 06). In one word, the origin is self-interaction; in one word, the reason for the minimum is the squeeze from both sides.

The difference from U(1). The photon carries no charge, so the vacuum only screens, and the coupling stays weak at long distances. The electric flux spreads out, long waves are allowed, and the gap is zero (5-06). Non-commutativity takes effect at a single point, "whether the field acts on itself", and the one-loop $11/3 = -1/3 + 4$ is its face (26-03).

In the language of the strong-coupling lattice. On the Hamiltonian lattice (Kogut–Susskind), the Hamiltonian is the sum of an electric term $\frac{g^2}{2}\sum E^2$ and a magnetic term $\frac{1}{g^2}\sum(1-\operatorname{tr}U_\square)$, and at strong coupling the electric term wins. Electric flux sits on single links, and each link costs of order g^2. The smallest gauge-invariant excitation is a ring of electric flux going round one face, and its cost is a finite positive number. This is the gap at strong coupling, and at strong coupling with the lattice spacing fixed it is a theorem (5-02, 5-04). What asymptotic freedom says is that "at the distance $1/\Lambda$ the effective coupling is strong", so this picture becomes, as it is, the picture at long distances. The question that remains is that this picture does not break down as the lattice spacing goes to zero; that is the ultraviolet control row of the ledger (as existence, shown by the published construction; the form of this book's road is open) and the renormalisation comparison row (27-02, A-08).

What this chapter can say

What is said	What is not said
Known The one-loop b_0, the solution (2), and within it that Λ does not depend on μ (as a perturbative computation). The definition of the gap in the problem statement, and that the gap coincides with the mass of an isolated one-particle state if there is one. Physics A single scale, the area law and the tube, the Lüscher term, the values of Table 2.	None is a theorem of the four-dimensional continuum theory (the construction published on 2026-11-10 gives the existence of the theory, but does not show confinement or the mass gap; 6-04). Table 2 is an extrapolation presupposing that the limit exists, and σ passes through the tube correction.
Known The area law at strong coupling (every group), the decay of correlations at weak coupling for finite groups, centre symmetry and its implication for confinement on the lattice, the area law at every coupling for U(1) in three dimensions.	The area law on the weak-coupling side for non-abelian groups in four dimensions. Deriving confinement from a gap in the sense of the problem statement. That finite groups do not confine (the level at which Chatterjee 2021 writes 'believed').
Computed The ratios of Tables 1 and 2, Figures 1 and 2, the estimate 1.178 of $r_0\sqrt{\sigma}$, the recomputation in MeV.	Ratios and conversions of primary-source values and evaluations of one-loop formulas, not measurements. The errors of the ratios are rough guides ignoring correlations. 1.178 is a rough guide extending a long-distance formula to short distances.

What is said	What is not said
Physics The squeeze picture of § 11 (on the large side anti-screening, on the small side uncertainty, the minimum a ring of size $1/\Lambda$). That on the strong-coupling lattice the cost of a ring round one face is positive.	No step of the picture is a theorem in the four-dimensional continuum. That anti-screening removes long waves, that the ring is the smallest excitation, that the picture survives as the lattice spacing goes to zero.

Next chapter to read: 17-02 Mechanisms of confinement — on to the explanations from physics of why the tube of § 05 forms (dual superconductivity, monopoles, centre vortices, Gribov–Zwanziger).

Mechanisms of confinement — reading four pictures by what each casts in the leading role, and where each is cut off from mathematics

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — The leading roles and the support of the four pictures of confinement (dual superconductivity, abelian projection, centre vortices, Gribov–Zwanziger), and where each is cut off as a mathematical statement. That confinement and the gap are different sentences.

Prerequisite chapters — 17-01. Also 5-02 (Wilson loops), 4-08 (Gribov copies), 1-04 (the centre of a group).

Said first — All four pictures are physical pictures, and there is no theorem deriving confinement in the four-dimensional non-abelian theory. This chapter shows neither confinement nor the gap. The model of Figure 2 is a toy.

The order of this chapter

1. What we want to explain — the area law
2. Confinement and the gap are different sentences — the area law and exponential decay, a conditional implication
3. Dual superconductivity — turning the magnetic flux tube inside out (Figure 1)
4. Abelian projection and monopoles — singularities of diagonalisation / Detour: Elitzur's theorem
5. Centre vortices — membranes that multiply by a centre element
6. A model of a vortex gas — the area law and the perimeter law (Figure 2)
7. The Gribov region and the horizon — from the gauge-fixed side
8. The propagator and positivity — a correlation that would not go negative for a particle (Figure 3)
9. Setting the four pictures side by side — leading roles, support, what is missing

01

What we want to explain

"Confinement" is a word that comes from the observation that quarks cannot be extracted on their own. Pure Yang–Mills theory has no quarks, so we place two infinitely heavy test charges and ask about the energy of pulling them apart (17-01). On the lattice, the expectation of the trace of the matrix obtained by multiplying link variables along a closed path C is the Wilson loop (5-01); for an $R \times T$ rectangle $W \approx e^{-V(R)T}$, where $V(R)$ is the energy of the pair of charges.

$$W(C) = \left\langle \frac{1}{N} \operatorname{tr} \prod_{\ell \in C} U_\ell \right\rangle, \qquad V(R) = -\lim_{T\to\infty} \frac{1}{T} \ln W(R,T) \quad (1)$$

There are two ways a large loop can decrease.

$$W(R,T) \approx e^{-\sigma RT} \ \text{(area law)}, \qquad W(R,T) \approx e^{-c\,(2R+2T)} \ \text{(perimeter law)} \quad (2)$$

Under the area law $V(R) \approx \sigma R$, and the energy grows in proportion to the distance. σ is the **string tension**. Under the perimeter law V is bounded. Example: with $\sigma = c = 0.05$ and $R = T = 10$, $-\ln W$ is 5 and 2; with sides of 20 it is 20 and 4. To tell them apart we use the Creutz ratio, which is σ for a pure area law and 0 for the perimeter law Known .

$$\chi(R) = -\ln \frac{W(R,R)\,W(R-1,R-1)}{W(R,R-1)\,W(R-1,R)} \quad (3)$$

To ask about the "mechanism" is to ask **what in the vacuum** produces the area law. The area law at small β (the lattice inverse coupling; for $SU(N)$, $\beta = 2N/g^2$, smaller meaning stronger coupling) is a theorem (5-02), but it holds for every group including `U(1)`, so it is no explanation for the non-abelian case Known . The question remains on the side of large β, heading towards the continuum limit.

02

Confinement and the gap are different sentences

The mass gap is exponential decay of correlations (4-11), confinement is the area law, and as logic they are different claims. What the Clay problem statement requires is $\Delta > 0$; confinement is set apart as a "natural extension" Known .

Table 1 Presence of confinement (area law) and of the gap (exponential decay), and the level

Model	Area law	Exponential decay	Level

Model	Area law	Exponential decay	Level
Any group, small β	Yes	Yes	Theorem (5-02)
4-dimensional `U(1)`, large β	No	No (photon)	Theorem (5-06)
Finite group, large β	Believed not	Yes (in a weak sense)	Decay is a theorem (5-10)
3-dimensional compact `U(1)`	Yes	In physics the photon acquires a mass	Area law is a theorem (§ 03)
4-dimensional `SU(N)`, continuum limit	Expected	Expected	Unproved

On the lattice there is an implication in one direction. Chatterjee (2021) showed the following Known . If the representation forming the Wilson loop acts non-trivially on the centre of the group (§ 05) (the fundamental representation of `SU(N)` does), and centre symmetry is unbroken (that is, in slab-shaped regions of finite thickness, the measure is invariant under centre transformations whatever boundary condition is taken; Definition 2.1 of that paper), then for any measure on the infinite-volume lattice $\mathbb{Z}^d$ the following holds for some function V with $V(R) \to \infty$ as $R \to \infty$.

$$|\langle W(R \times T) \rangle| \leq e^{-V(R)\,T} \tag{4}$$

This means that V is unbounded, not that $\sigma > 0$. Assuming a strong form of the gap, exponential decay under arbitrary boundary conditions, yields even the area law (the Theorem from Uniform Decay to the Area Law; Theorem 2.4 of the same paper). The decay shown for finite groups is decay of two-point correlations under a specific boundary condition, weaker than the "decay under arbitrary boundary conditions" that this theorem assumes. So it does not contradict the finite-group row of Table 1 (§ 2.4 of the same paper). There is no theorem deriving confinement from a gap in the Clay sense.

03

Dual superconductivity: turning the magnetic flux tube inside out

A superconductor expels magnetic fields (the Meissner effect), and a magnetic field entering from the surface decays over the penetration depth λ_L. If forced through, it is bundled into thin tubes (Abrikosov vortices), and the flux of one tube is an integer multiple of $h/2e$ Known .

$$\nabla^2 \mathbf{B} = \mathbf{B}/\lambda_L^2, \qquad B(x) = B_0\, e^{-x/\lambda L} \tag{5}$$

A tube with energy density $B^2/2$, cross-section S and flux $\Phi = BS$ carries $E/\ell = \Phi^2/(2S)$ per unit length. In vacuum S can be widened to bring this close to 0, but in a

superconductor widening costs something, and E/ℓ stays at a positive constant. If a pair of monopoles were embedded, the energy should be proportional to the distance (a schematic estimate).

Maxwell's equations with a magnetic current j^m added are symmetric under exchanging electric and magnetic ($\tilde{F}$ is the dual; only here do we use real-time notation)Known .

$$\partial^\mu F_{\mu\nu} = j^e_\nu, \quad \partial^\mu \tilde{F}_{\mu\nu} = j^m_\nu; \qquad \mathbf{E} \to \mathbf{B},\ \mathbf{B} \to -\mathbf{E},\ j^e \to j^m,\ j^m \to -j^e \tag{6}$$

If the vacuum is a **condensate of colour-magnetic monopoles**, what is expelled is the colour electric field, the colour electric flux forms a tube, and quarks are confined. This is the picture of dual superconductivity, said to have been proposed independently by 't Hooft (a 1975 talk) and Mandelstam (1976)Physics . Nambu (1974) is regarded as its forerunner. More precisely, the monopoles are not fields appearing in the action but objects defined only once a gauge is chosen (§ 04), and there is as yet no way to write "condensation" as a statement about the measure.

Figure 1 Left: in vacuum the lines of force spread out. Right: in a vacuum where monopoles have condensed, the electric flux forms a tube (schematic).

Vacuum (E/ℓ → 0) Condensed vacuum (E/ℓ = σ)

Di Giacomo et al. (2000, SU(2)) measured an order parameter for monopole condensation on the lattice and reported that "confinement appears as a transition to a dual superconductor"Physics . The context is the deconfinement transition at finite temperature, and the mechanism was not shown. Neither step of "condensation ⇒ area law ⇒ gap" is proved for the four-dimensional non-abelian case.

Examples where the mechanism can be computed in an abelian model

In three-dimensional compact U(1) monopoles act as instantons; Polyakov (1977) obtained the area law semiclassically, and Göpfert–Mack proved $\sigma > 0$ at every coupling (on the lattice with the Villain action)Known . But the abstract of the same work also states that the continuum limit is a free scalar field and that the string tension in physical units goes to ∞ (text not read). From this mechanism "the masses and the string tension are fixed by a single scale" (17-12) does not follow. In four dimensions, for an $\mathcal{N} = 2$ supersymmetric theory broken to $\mathcal{N} = 1$ by a mass term,

Seiberg–Witten (1994) described confinement by monopole condensation (17-11) Physics .

04

Abelian projection and monopoles

't Hooft (1981) found monopoles, absent from the action, as **singularities of the choice of gauge**. Choose a quantity $X(x)$ that transforms as $X \mapsto gXg^{-1}$ (for example F_{12}) and diagonalise it at each point.

$$g(x)\,X(x)\,g(x)^{-1} = \operatorname{diag}\big(\varepsilon_1(x),\dots,\varepsilon_N(x)\big) \tag{7}$$

ε_i are the eigenvalues. The remaining symmetry is $U(1)^{N-1}$, and the diagonal gluons are the "photons". At points where eigenvalues coincide the diagonalisation is not determined, and these are the monopoles Physics . Example: in `SU(2)` with $X = \sum_a X^a \sigma^a/2$ the eigenvalues are $\pm|\boldsymbol{X}|/2$, and they coincide at $\boldsymbol{X}=0$, which is 3 real conditions. In three dimensions this is a point, in four a line (a world line) (the same for general N, the detour of 1-01). If $\boldsymbol{X} \approx \underline{x}$ near the zero, then $\boldsymbol{X}/|\boldsymbol{X}|$ covers the sphere surrounding the zero once, and that number of times is the magnetic charge Known .

On the lattice, the maximal abelian gauge (MAG, Kronfeld et al. 1987) brings the links close to diagonal.

$$R[U] = \sum_{x,\mu} \operatorname{tr}\left[\,U_\mu(x)\,\sigma^3\,U_\mu(x)^\dagger\,\sigma^3\,\right] \;\to\; \max \tag{8}$$

No method is known for reliably finding the global maximum, and in practice local maxima (Gribov copies) are used. Suzuki–Yotsuyanagi (1990) reported that the string tension of the projected links accounts for most of the original (abelian dominance), and Greensite's review (2003), citing $(92 \pm 4)\%$ for `SU(2)` (Bali et al. 1996), writes that "abelian dominance is not yet a proof of confinement by monopoles" Physics .

Detour: Elitzur's theorem

A subsection you may skip.

A gauge transformation g at the starting point of a link U_ℓ alone gives $U_\ell \to gU_\ell$ (the other links touching that point change too, but the action and the measure are invariant). So $\langle U_\ell\rangle = g\langle U_\ell\rangle$ holds for every g, and averaging over the Haar measure (5-01) gives

$$\langle U_\ell\rangle = \Big(\int_{SU(N)} g\,dg\Big)\langle U_\ell\rangle = 0 \tag{9}$$

Elitzur's theorem (1975) states that, even in infinite volume, the expectation of a local quantity that is not gauge invariant stays 0 Known . Unlike a global symmetry (2-09), a gauge transformation at one point meets no barrier. A monopole defined by fixing a gauge is a function of the configuration once the gauge-fixing procedure is included. But since the maximum is not unique (Gribov copies), it is not determined as a single function, nor is it a local quantity.

05

Centre vortices: membranes that multiply a loop by a centre element

The **centre** of SU(N) is $Z_N = \{e^{2\pi i k/N} I\}$, which commutes with every element. A centre element z acts in each representation as z^k, and this $k \pmod N$ is the **N-ality**. The fundamental representation has 1 and the adjoint 0 Known .

The starting point is the lattice observation that the string tension of large loops is fixed by the N-ality alone, and is 0 for the adjoint (screened by the gluons themselves) (Greensite's review § 4.3) Physics . A centre vortex is a line in three dimensions and a surface in four, and multiplies a loop linked with it by one centre element (-1 for SU(2)). Adjoint loops do not notice the vortex. More precisely, the thinnest vortex on the lattice is a configuration in which the links piercing some region are all multiplied by a centre element, and only the plaquettes on the rim of the region change (inside, the centre elements cancel). This rim is the vortex, and only loops linked with the rim pick up the centre element. Divide the plane into squares of area $\Sigma_{\min}$; if the $Z(C_i)$ picked up by the loops of the squares are nearly independent, a large loop splits into a product and obeys the area law (formulas (94)–(96) of the same review).

$$\langle W_k(C)\rangle \approx e^{-\sigma(k)\,\Sigma}, \qquad \sigma(k) = -\ln\langle Z(C_i)^k\rangle / \Sigma_{\min} \quad (10)$$

Confinement becomes the question of whether the vortex surfaces spread through the volume (percolate). Numerically, Del Debbio–Faber–Greensite–Olejník (1997) reported that projected vortices carry most of the string tension (centre dominance), and de Forcrand–D'Elia (1999) that removing the vortices removes confinement Physics . As a theorem, Tomboulis–Yaffe (1985, SU(2)) bounded the Wilson loop from above by a function of the vortex free energy Known . The vortex free energy is $-\ln$ of the ratio of the partition function $\mathcal{Z}_{\mathrm{tw}}$ with a centre twist put into the boundary condition in one direction to the partition function $\mathcal{Z}$ without it, that is $F_v = -\ln(\mathcal{Z}_{\mathrm{tw}}/\mathcal{Z})$, and it is gauge invariant. In the same family of gauge-invariant quantities is the 't Hooft loop (an operator inserting a centre vortex along a loop). Formula (4) is also a theorem bounding Wilson loops from centre symmetry. Tomboulis (2007) claimed a proof at every coupling for SU(2), and Ito–Seiler point out a gap in the argument.

Vortices defined by projection depend on the gauge. The hypotheses of the conditional theorems concentrate on a single point, that vortices condense at weak coupling in four dimensions (gauge-invariantly, decay of the vortex free energy), and this is not proved.

For how this book uses this, see 26-08 § 03 (where the average over vortex containers and the Migdal–Kadanoff interpolation stopped in the literature).

06

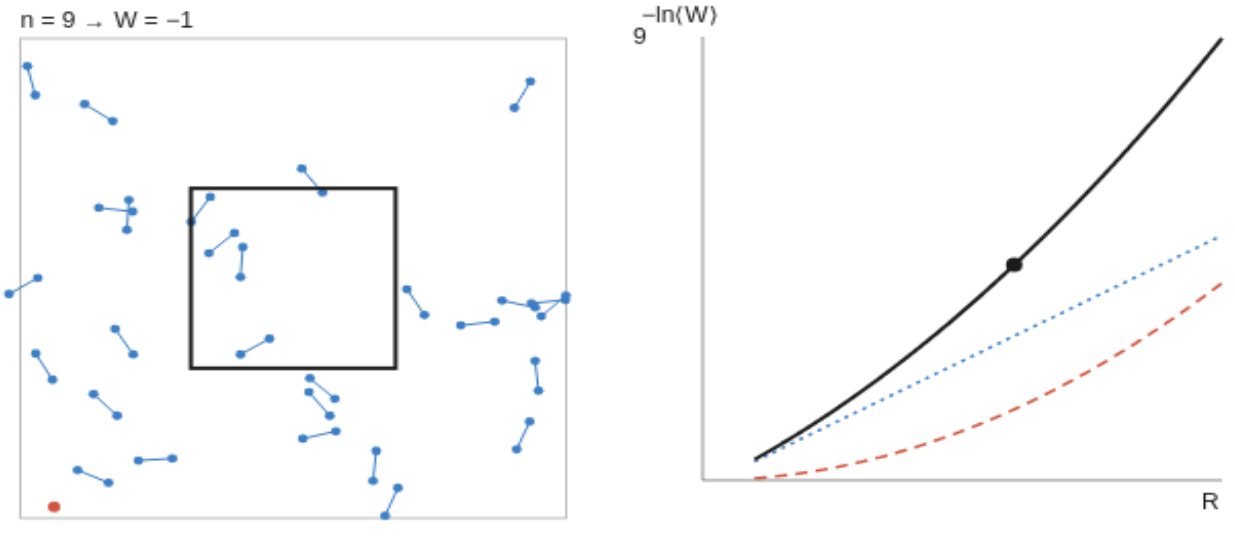
A model of a vortex gas: counting the area law and the perimeter law

Scatter over a plane the points where `SU(2)` vortices pierce it, and with n the number of points inside the loop set $W = (-1)^n$. There are two kinds of points. (a) Independent points of density ρ_f (cross-sections of extended vortices). (b) Pairs of points at distance d, with point density ρ_p (small vortices piercing the plane twice). A pair changes the sign only when it straddles the edge. For an $I \times J$ rectangle the following holds exactly (averaging over directions the area of the symmetric difference of two translated rectangles) Computed .

$$-\ln\langle W(I,J)\rangle = 2\rho_f\, IJ + 2\rho_p\Big[\frac{2d}{\pi}(I+J) - \frac{d^2}{\pi}\Big] \qquad (I,J \geq d) \quad (11)$$

The first term comes from the number n of independent points following a Poisson distribution with mean $\mu = \rho_f IJ$, so that $\mathbb{E}[(-1)^n] = \sum_n e^{-\mu}\mu^n(-1)^n/n! = e^{-2\mu}$ (1-08). The first term is the area law and the second the perimeter law, and the Creutz ratio is $2\rho_f$. However many small vortices there are, they contribute nothing to the string tension.

Figure 2 Changing R, ρ_f and ρ_p changes the sample sheet on the left (red = independent, blue = pairs) and, on the right, −ln⟨W⟩ (solid line, formula (11)), the area term (red dashed) and the perimeter term (blue dotted).



```
R = 6、ρf = 0.020、ρp = 0.20 : −ln⟨W⟩ = 1.44 (area) + 2.93 (perimeter) = 4.37. Creutz ratio = 0.040.
This sheet has n = 9
```

Computed The curves are computed on the spot from formula (11), and the points on the left are one random sample. Formula (11) was checked on this machine against a Monte Carlo (MC) of one million samples (Table 2).

Table 2 −ln⟨W(R,R)⟩: formula (11) and MC (lattice spacing 1, d = 1; in brackets the MC standard error in the last digit; "—" means it cannot be measured)

R	Independent 0.05	MC	Pairs 0.2	MC	Mixed	MC
2	0.400	0.399(1)	0.891	0.890(2)	1.051	1.052(3)
4	1.600	1.596(5)	1.910	1.920(7)	2.550	2.546(13)
6	3.600	3.574(36)	2.929	2.929(19)	4.369	4.255(70)
8	6.400	—	3.947	3.921(50)	6.507	—
Creutz ratio	0.100		0.000		0.040	

Mixed means $\rho_f = 0.02$, $\rho_p = 0.2$. The MC standard error grows as $-\ln W$ grows, and is at most 0.02 for $-\ln W \le 3$. Mixed at $R = 6$ has error 0.070, and its difference 0.11 from the exact formula is about 1.6 standard errors. $e^{-6.4} \approx 0.0017$ is about the size of the noise 10^{-3} of an average of ± 1, and cannot be measured. This difficulty is the same as in real lattice computations (5-07). For `SU(3)`, multiplying by $e^{\pm 2\pi i/3}$ at each piercing gives the string tension $1.5\rho_f$ for $k = 1, 2$ and 0 for the adjoint Computed .

For how this book uses this, see 25-03 § 03 (the identity by which fixing the frame makes the container signs independent).

07

The Gribov region and the horizon: from the gauge-fixed side

The fourth picture reads confinement from the shape of the gauge-fixed propagator. The Landau gauge surface $\partial_\mu A_\mu = 0$ can meet a single orbit more than once (4-08), so Gribov (1978) restricted the integral to the region Ω where the Faddeev–Popov operator $\mathcal{M}$ is positive. Its boundary is the Gribov horizon.

$$\mathcal{M}^{ab} = -\partial_\mu\left(\partial_\mu \delta^{ab} + g f^{acb} A^c_\mu\right), \qquad \Omega = \{A : \ \partial_\mu A^a_\mu = 0,\ \mathcal{M} > 0\} \quad (12)$$

"$\mathcal{M} > 0$" means that the eigenvalues of $\mathcal{M}$ (the spectrum of a self-adjoint operator, 1-10) are all positive. At $A = 0$, $\mathcal{M} = -\partial^2$, which is positive apart from constants. As A grows the smallest eigenvalue goes down, and where it reaches 0 is the horizon. On the horizon an infinitesimal gauge transformation in the direction of the zero eigenvalue preserves the gauge condition, so copies arbitrarily close appear.

What is certain as mathematics goes only as far as Dell'Antonio–Zwanziger (1991): "every orbit passes inside the horizon" Known . Copies remain inside Ω too, and no method is known for handling a copy-free region analytically (Zwanziger claims that the copies inside do not affect expectation values Physics).

08

The propagator and positivity

Zwanziger (1989) wrote the restriction to Ω as a local action. The propagator of its tree approximation (lowest order, without loop contributions, 4-03) is on the left below, and the version with condensates added (RGZ, Dudal et al. 2008) on the right Physics .

$$D_{\mathrm{GZ}}=\frac{p^2}{p^4+\lambda^4},\qquad D_{\mathrm{RGZ}}=\frac{p^2+M^2}{p^4+(M^2+m^2)\,p^2+\lambda^4+M^2m^2} \tag{13}$$

$\lambda^4=2g^2N\gamma^4$, and γ is fixed by the horizon condition. Here λ is a mass scale, different both from the penetration depth λ_L of § 03 and from the large-N $\lambda=g^2N$. M^2 and m^2 are mass parameters added in RGZ. The GZ form is 0 at $p=0$ and its poles are complex, $p^2=\pm i\lambda^2$, quite unlike $1/(p^2+m_0^2)$ for a free particle of mass m_0.

If the gluon were a physical particle, the propagator could be written as a superposition with positive density ρ (the Källén–Lehmann representation), and the correlation in the time direction $C(t)$ could not be negative (formulas (159)(160) of Dudal et al. 2008, 4-10). ω is the mass being superposed.

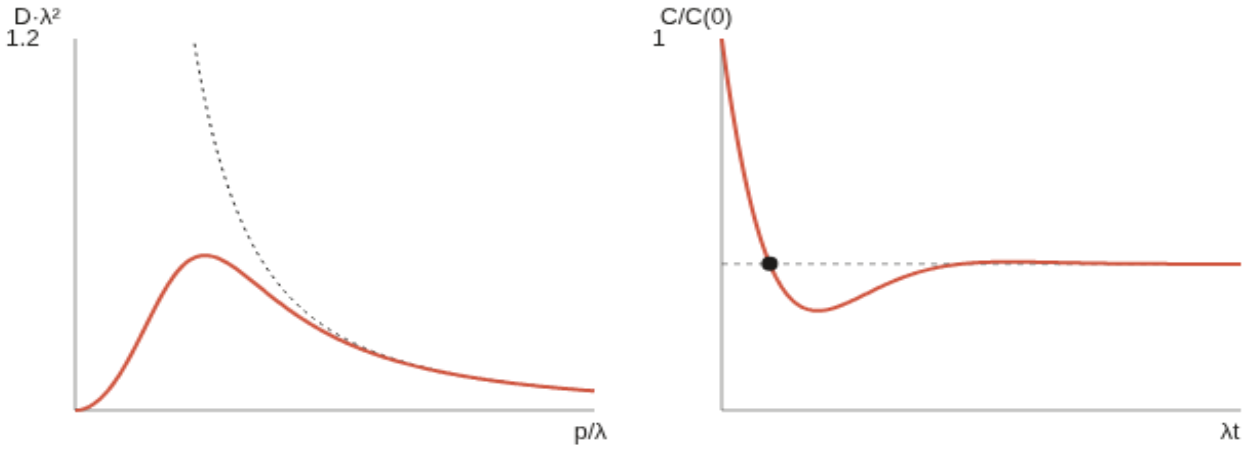
$$D(p^2)=\int_0^\infty d\omega^2\,\frac{\rho(\omega^2)}{p^2+\omega^2},\qquad C(t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}e^{-ipt}D(p^2)\,dp=\int_0^\infty d\omega\,\rho(\omega^2)\,e^{-\omega t} \tag{14}$$

At $m=0$, computing by complex integration (residues) gives a closed form (it can also be checked by numerical integration; bottom of Figure 3). For $M^2<2\lambda^2$, setting $\cos\varphi=M^2/(2\lambda^2)$ Computed

$$C(t)=\frac{e^{-\lambda t\cos(\varphi/2)}}{2\lambda\sin\varphi}\,\sin\!\left(\frac{3\varphi}{2}+\lambda t\sin\frac{\varphi}{2}\right) \tag{15}$$

and it first becomes negative at $t_*=(\pi-3\varphi/2)/(\lambda\sin\frac{\varphi}{2})$. For GZ, $t_*=\pi/(2\sqrt{2}\,\lambda)\approx 1.111/\lambda$. For $M^2>2\lambda^2$ it splits into real poles, $D=A/(p^2+r_1)+B/(p^2+r_2)$ $(0<r_1<r_2)$, and although B is negative (ρ is not positive), $C(t)\geq e^{-\sqrt{r_2}\,t}C(0)>0$ and it does not become negative. This test works in one direction only.

Figure 3 Changing M^2/λ^2 (m = 0) changes $D(p^2)$ on the left (dotted line $1/p^2$) and $C(t)/C(0)$ on the right. 0 is GZ; the black dot is the first zero.



M²/λ² = 0.0 (GZ) : D(0)·λ² = 0.0。The poles are complex conjugates. Negative from t* = 1.111/λ.

Computed The curves are computed on the spot from formulas (13)(15) and the partial fractions for real roots. The closed formula was checked on this machine against numerical integration, with differences at most 2×10^{-11}.

Table 3 Tree approximation of RGZ at m = 0 (λ = 1)

M²	D(0)	Poles	C(0)	Zero t*
0 (GZ)	0	Complex conjugate	0.354	1.111
1.0	1.0	Complex conjugate	0.577	3.142
1.9	1.9	Complex conjugate	0.734	16.86
2.5	2.5	Real (B = −0.333)	0.825	No
4.0	4.0	Real (B = −0.077)	1.021	No

The lattice did not agree with the original prediction $D(0) = 0$. Cucchieri–Mendes (SU(2), 128^4, about $(27\ \text{fm})^4$; 1 fm = 10^{-15} m) report in their abstract that at zero momentum it "seems to show a finite non-zero value", and Bogolubsky et al. (SU(3)) point the same way Physics . RGZ is built to reproduce this Physics . BRST symmetry (the symmetry that remains after gauge fixing, 4-08) is softly broken in GZ. Soft breaking means that the breaking term has low dimension and has no effect at short distances. This breaking is not a price paid by RGZ but a property of the horizon term of GZ itself Physics .

Seam

The propagator depends on the gauge. The target of the problem statement is correlations of gauge-invariant local fields such as $\mathrm{tr}\, F_{\mu\nu}F_{\rho\sigma}$, and there is no theorem deriving their gap from the infrared shape of the propagator. Nor can a continuous global gauge fixing be made (Singer, 3-04).

09

Setting the four pictures side by side

Table 4 The leading role, support and what is missing in the four pictures

Picture	Leading role	Gauge dependence	Support	What mathematics can say	What
Dual superconductivity	Monopole condensation	Through the definition of monopoles	Numbers for the order parameter	Area law for 3-dimensional compact `U(1)`	Cond ⇒ ar gap
Abelian projection	MAG monopoles	Strong	Abelian dominance	— (Elitzur's theorem constrains it)	A def a uni deter gaug invar quan
Centre vortices	Vortices / their free energy	The former only	Centre dominance, vortex removal	Tomboulis–Yaffe, formula (4)	Vorte cond at we coup dime
GZ	Propagator	By definition	Lattice propagators	Orbits pass inside the horizon	A bri gaug invar corre

Every leading variable becomes visible only once a gauge is chosen, and the gauge-invariant core is only the vortex free energy and the inequalities around it. What every picture explains is σ; Δ is merely expected as a consequence (§ 02). None of the pictures yields "a single scale". The seams are sorted out in 16-05, obstacles other than divergence in 7-11.

What this chapter can say

What is said	What is not said
Known The area law at small β. On the lattice, a strong form of the gap ⇒ the area law	The area law in the continuum limit of the four-dimensional non-abelian theory. An implication between the Clay gap and confinement
Computed Agreement of the exact formula (11) for the vortex gas with MC, Creutz ratio $= 2\rho_f$	That this model describes the Yang–Mills vacuum (the distribution of vortices is assumed)
Computed The closed form (15) of $C(t)$ in the tree approximation of RGZ ($m = 0$)	Deriving the gap of gauge-invariant correlations from the propagator

What is said	What is not said
Physics Lattice numbers for monopole condensation, abelian dominance, centre dominance, vortex removal and $D(0) \not= 0$	Deciding which mechanism is right (the numbers depend on the gauge)

Next chapter to read: 17-03 The string picture — treating the squeezed tube as a single string and looking at its fluctuations.

The string picture — treating the tube of confinement as a single string, a universal correction and a shape come out of its fluctuations

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — We follow how the Lüscher term $-\pi(d-2)/(24R)$ comes out of the zero-point energy of the transverse fluctuations of the tube, and why its coefficient does not depend on the details of the theory. With formulas, moving figures and computations we look at the thickness of the tube, the Nambu–Goto levels, the "rigid side" and the "rough side" of the lattice string, and the shape selected by a tension that depends on direction (the Wulff shape).

Prerequisite chapters — 17-01 How physics sees it (Wilson loops, the area law, the string tension σ). The zero-point energy (2-06) and the strong-coupling expansion (5-02) are written on the spot as far as needed.

Said first — This is a chapter at the level of physics Physics . The string picture takes as its starting point that a long tube exists (confinement), and in four-dimensional non-abelian Yang–Mills that is not a theorem. This book does not itself show confinement, the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. Treating the tube as a single string — the weight of the area
2. The Nambu–Goto action — expanding the fluctuations
3. The zero-point energy and the Lüscher term — open strings and closed strings
4. Detour: 1+2+3+… and −1/12 — the part that does not depend on how we cut off
5. The tube thickens logarithmically — a fluctuating string
6. The Nambu–Goto levels and short tubes — the range of universality
7. The lattice string is rigid, and roughens somewhere — the side with theorems
8. The Wulff shape — a tension depending on direction, and the shape

9. The droplet of the two-dimensional Ising model — an exactly known tension, and from a square to a circle
10. What the string picture hands to mathematics, and what it does not — what is fixed under an assumption, and the assumption itself

---

01

Treating the tube as a single string

The flux tube of 17-01 § 05, if its thickness is much smaller than the distance R of the pair, is from afar a single line. Extended in the direction of Euclidean time, the line sweeps out a surface (the **world sheet**). The string picture is an effective theory that describes long distances by the fluctuations of this surface Physics . To a surface S bounded by the rectangle $R \times T$ of the Wilson loop we give a weight fixed by its area $A(S)$.

$$\langle W_{R,T} \rangle \approx \sum_{S:\ \partial S = \text{rectangle}} e^{-\sigma A(S)} \quad (1)$$

With the minimal surface alone this is $e^{-\sigma RT}$, the area law. The question is what the fluctuations add. As a metaphor, it is the trembling of a stretched membrane. More precisely, (1) is not a formula derived from Yang–Mills but a starting point under the assumption that "a long tube exists, and its low excitations are only transverse fluctuations" (Athenodorou–Bringoltz–Teper 2011 § 2; ABT below).

At strong coupling on the lattice (5-02) a formula close to (1) holds, and the weight u of one plaquette plays the role of $e^{-\sigma 0}$ Known . But the area law also comes out for `U(1)`, so it is no evidence of non-abelian confinement (Chatterjee 2018 § 4, 5-06).

02

The Nambu–Goto action

An action proportional to the area is called the **Nambu–Goto action** (the name is said to be after Nambu and Goto). We describe the surface by coordinates t, x and a perpendicular displacement $h(t,x) \in \mathbb{R}^{d-2}$ (static gauge; d is the dimension of spacetime). The area of a surface $X(t,x)$ is given by the surface-area formula learnt in multivariable calculus, $\iint \sqrt{|X_t|^2 |X_x|^2 - (X_t \cdot X_x)^2}\, dt\, dx$ ($X_t = \partial_t X$, $X_x = \partial_x X$). Putting in $X = (t, x, h)$ gives the following.

$$A = \int_0^T dt \int_0^R dx \, \sqrt{1 + |\partial_t h|^2 + |\partial_x h|^2 + |\partial_t h|^2 |\partial_x h|^2 - (\partial_t h \cdot \partial_x h)^2} \tag{2}$$

If the fluctuations are gentle, expanding with $\sqrt{1+z} \approx 1 + z/2$ gives

$$\sigma A = \sigma R T + \frac{\sigma}{2} \iint \left(|\partial_t h|^2 + |\partial_x h|^2 \right) dt \, dx + O\big((\partial h)^4\big) \tag{3}$$

The second term is a massless free field with $d-2$ components, of the same form as the vibrating string of 2-02 (with $h = 0$ at the ends). For a long string the higher terms are suppressed by powers of $1/(\sigma R^2)$ (ABT § 2.1).

Example: the increase in length of a ripple $h = A_0 \sin(\pi x/R)$ is $\pi^2 A_0^2/(4R)$ in the quadratic approximation. With $R = 1$ fm and $A_0 = 0.2$ fm this is 0.099 fm (0.092 fm exactly). Multiplying by $\sigma = 1192$ MeV/fm ($\sqrt{\sigma} = 485$ MeV, 17-01 § 07) gives about 110 MeV Computed .

03

The zero-point energy and the Lüscher term

The second term of (3) is the action of a Euclideanised free field. When T is long, $\langle W_{R,T} \rangle \approx e^{-V(R)T}$, so the ground-state energy of the Hamiltonian of the same field gives $V(R)$ (4-02). The modes of this field are $k_n = n\pi/R$ ($n = 1, 2, \ldots$). Each mode is a harmonic oscillator of frequency k_n, and even in its lowest state it has the zero-point energy $k_n/2$ (2-06; $\hbar = c = 1$). Summing over the $d-2$ components gives the following.

$$E_0(R) = \sigma R + \frac{d-2}{2} \sum_{n=1}^{\infty} \frac{n\pi}{R} \tag{4}$$

The sum diverges. Fluctuations finer than a length a are outside the effective theory, so we cut off with $e^{-k_n a}$.

$$\sum_{n \geq 1} n \, e^{-\varepsilon n} = \frac{e^{-\varepsilon}}{(1 - e^{-\varepsilon})^2} = \frac{1}{\varepsilon^2} - \frac{1}{12} + \frac{\varepsilon^2}{240} - \cdots, \qquad \varepsilon = \frac{\pi a}{R} \tag{5}$$

Putting (5) into (4), the first term is $(d-2)R/(2\pi a^2)$, proportional to R, and is absorbed into the tension. What remains is the static potential.

$$V(R) = \sigma R + c_0 - \frac{\pi (d-2)}{24 R} + \cdots \tag{6}$$

c_0 is a non-universal constant. At $d = 4$ this is $-\pi/(12R)$, the **Lüscher term** of 17-01 formula (6) (Lüscher–Symanzik–Weisz 1980, Lüscher 1981). It is a coefficient derived

within the effective theory of long tubes, not a mathematical theorem Physics . The $1/R$ term is a finite part that does not diverge, so its coefficient does not depend on a. With $R = 1$ and $a = 0.2,\ 0.1,\ 0.05$, the remainder is $-0.2567,\ -0.2605,\ -0.2615$, approaching $-\pi/12$ Computed .

Closed strings and the Casimir energy of a cylinder

For a tube wound around a direction of period L (flux going round a periodic boundary), $k_n = 2\pi n/L$ occurs in both directions, positive and negative, and the same computation gives the following (ABT formula (9)).

$$E_0(L) = \sigma L - \frac{\pi(d-2)}{6L} + \cdots \quad (7)$$

This is the Casimir energy of a free field on a cylinder. Lucini–Teper 2001 extract the lattice σ with formula (4) of their paper, $am_l = a^2\sigma L - \pi/(3L)$, and note: 'in using eqn(4) we are assuming that we have linear confinement' (5-08). A rough guide: at $R = 1$ fm, $\pi/(12R) \approx 52$ MeV is 4.3% of σR, and at $L\sqrt{\sigma} = 3$ (the lower limit of Lucini–Teper; about 1.22 fm converting with $\sqrt{\sigma} = 485$ MeV, while Lucini–Teper themselves write $\simeq$1.3 fm) the correction in (7) is 11.6% of the leading term Computed .

04

Detour: 1+2+3+… and −1/12

A section you may skip.

The sum in the slogan "$1 + 2 + 3 + \cdots = -1/12$" diverges. The precise content is the following formula. For a smooth cutoff f ($f(0) = 1$, decreasing fast), as $\varepsilon \to 0$,

$$\sum_{n \geq 1} n\, f(\varepsilon n) = \frac{C_f}{\varepsilon^2} - \frac{1}{12} + O(\varepsilon^2), \qquad C_f = \int_0^\infty x f(x)\, dx \quad (8)$$

The coefficient C_f of the divergent term changes with the cutoff, and $-1/12$ does not. The reason is the **Euler–Maclaurin formula**. It writes the difference between a sum and an integral in terms of derivatives at the end point, and when g and its derivatives decrease fast at infinity it takes the following form ($B_2 = 1/6$ is a Bernoulli number).

$$\sum_{n \geq 0} g(n) = \int_0^\infty g(x)\, dx + \tfrac{1}{2} g(0) - \tfrac{B_2}{2!}\, g'(0) - \cdots$$

For $g(x) = x f(\varepsilon x)$ we have $g(0) = 0$, $g'(0) = f(0) = 1$, and the integral is C_f/ε^2, so the constant term is $-B_2/2 = -1/12$. The remaining terms are powers ε^2 and higher. The analytic continuation of the zeta function, $\zeta(-1) = -1/12$, is the same number Known .

Computed Table 1 The sum minus C_f/ε^2 (exponential $f=e^{-x}$, $C_f=1$; Gaussian $f=e^{-x^2}$, $C_f=1/2$)

ε	Exponential	Gaussian
0.1	−0.0832917	−0.0834169
0.01	−0.0833329	−0.0833342
→ 0	−0.0833333	−0.0833333

The part that changes with the cutoff is absorbed into the tension, and only $-1/12$ remains in the coefficient of $1/R$ (for divergent series see also 4-12, 7-12).

05

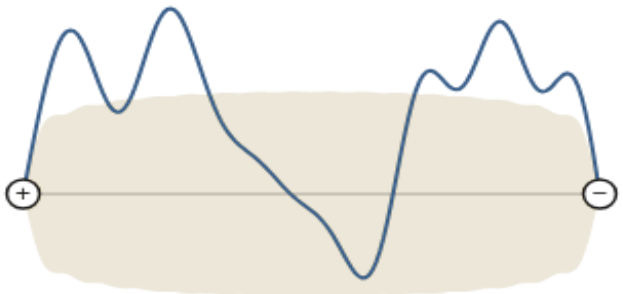
The tube thickens logarithmically

The modes q_n of (3) are oscillators with mass σ and frequency k_n, and the variance in the ground state is $1/(2\sigma k_n)$. At the midpoint of $h=\sum_n \sqrt{2/R}\, q_n \sin k_n x$ only odd n survive, and $\langle h^2\rangle = \sum_{n\ \mathrm{odd}} 1/(\sigma\pi n)$. Summing up to $n \lesssim R/a$ gives a logarithm (Lüscher–Münster–Weisz 1981; Gliozzi–Pepe–Wiese 2010 formula (3)). It is a formula derived within the effective theory of long tubes Physics .

$$w^2\left(\frac{R}{2}\right) = \left\langle |h(R/2)|^2 \right\rangle \approx \frac{d-2}{2\pi\sigma}\ln\frac{R}{R_0} \quad (9)$$

What is universal is the coefficient of $\ln R$; R_0 is not universal. The thickness grows without bound, but $w/R \to 0$, so from afar it stays a thin line.

Figure 1 Changing the distance R with the knob changes the number of modes on the string and the width of the fluctuation (the band). "Play" makes each mode oscillate with its zero-point size



1/√σ

R√σ = 4.00 (1.63 fm), modes: 16, midpoint w²σ = 0.644 (ln N+γ+ln2)/(2π) = 0.643

Computed The numbers in this figure were computed on this machine. Cutoff $a = 0.25/\sqrt{\sigma}$, the band is $\pm w$, one transverse component. The oscillation is a classical picture, not the quantum fluctuation itself.

Table 2 Variance of the free field at the midpoint of a lattice strip (width R, h=0 at both ends, infinite time)

(one component, in units of $1/\sigma$)

R (lattice spacings)	$\sigma\langle h^2\rangle$	Increase when R is doubled
8	0.516070	0.111626
1024	1.288650	0.110318
Prediction of (9)	—	ln2/(2π) = 0.110318

Computed Summed exactly with the closed form $1/\sqrt{m^2(m^2+4)}$ for each mode. The increase agrees with (9) to 6 digits.

At $d=4$ the coefficient $1/(\pi\sigma)$ is 0.053 fm^2, and doubling R increases w^2 by only 0.037 fm^2 Computed . The logarithmic growth has been confirmed on the lattice for `SU(2)` in (2+1) dimensions (Gliozzi–Pepe–Wiese 2010) Physics .

06

The Nambu–Goto levels and short tubes

The levels of a closed string with no longitudinal momentum can be written in closed form in Nambu–Goto (with the sums of the left- and right-moving excitations both equal to n; ABT formula (21)). It is a formula that comes from naive light-cone quantisation (Aharony–Komargodski cite, as the source of this method, Arvis 1983, which treated a string with fixed ends).

$$E_n(L)=\sqrt{\sigma^2L^2+8\pi\sigma\left(n-\frac{d-2}{24}\right)} \quad (10)$$

Expanding gives $\sigma L+\frac{4\pi}{L}\left(n-\frac{d-2}{24}\right)+\cdots$, and $n=0$ returns to (7). The ground state becomes imaginary at $\sigma L^2<\pi(d-2)/3$, which in $d=4$ is $L_H\sqrt{\sigma}=\sqrt{2\pi/3}=1.447$. If the periodic direction is regarded as time, $1/L$ is the temperature (4-02). The number of string states grows exponentially with energy, so above some temperature the sum of the partition function stops converging. This point is called the **Hagedorn transition** (for the growth of the states, see the detour of 17-05) Physics . ABT write that L_H can be regarded as 'the Hagedorn/deconfining transition in the Nambu-Goto model', and go on to say that pure gauge theories at large N do not reach this length. As the length shrinks, a first-order deconfinement transition occurs before it, at $l_c\sqrt{\sigma}=\sqrt{\sigma}/T_c\simeq 1.65$ (the l_c below Table 3).

Table 3 Energies of the closed string ($d=4$, in units of $\sqrt{\sigma}$)

L√σ	σL−π/(3L)	Ground state of (10)	Error of the approximation	n=1 of (10)	E_1-E_0
1.6	0.9455	0.6824	+38.6%	5.0595	4.377
3.0	2.6509	2.6279	+0.88%	5.6602	3.032
6.0	5.8255	5.8229	+0.04%	7.6836	1.861

Computed By formula (10). The length $l_c\sqrt{\sigma}$ at which the tube disappears on the lattice is the product of $a\sqrt{\sigma}$ and l_c/a in Table 3 of ABT: SU(3) 1.544, 1.559, SU(5) 1.636, SU(6) 1.676. All are slightly longer than L_H, and the two at larger N lie on either side of ABT's 1.65.

How far does universality go? According to Aharony–Komargodski 2013 'all the terms up to (and including) order 1/L^5 are universal': the ground state agrees with (10) up to $1/L^5$, the excitations for $d > 3$ deviate universally at $1/L^5$, and theory-specific terms enter from $1/L^7$. These are results derived within the effective theory of long tubes Physics . Of the quantisation in (10) they also write 'There is no rigorous derivation'. ABT measured about 20 levels of closed tubes on the lattice for four-dimensional SU(N), and reported that many are well described by (10) down to short lengths where the $1/L$ expansion does not converge. Some states with $J^P = 0^-$ (J is the angular momentum about the axis of the tube, P the sign under reflection) deviate strongly Physics .

In the last column of Table 3, the first excitation $3.03\sqrt{\sigma}$ of the string at $L\sqrt{\sigma} = 3$ is of the same order as the 0^{++} glueball of SU(3), $3.405\sqrt{\sigma}$ (17-01 Table 2) Computed (this does not imply a correspondence). Turning "there is a single scale" into a mathematical sentence is the subject of 17-12.

07

The lattice string is rigid, and roughens somewhere

On the strong-coupling side of the lattice, shifting part of the surface by one lattice step adds plaquettes, each carrying a small weight u. Transverse fluctuations are suppressed exponentially, and the surface stays **rigid** (flat). In the world of (9) the variance diverges logarithmically, and the surface is **rough**.

For crystal surfaces there is a **roughening transition** between the two. Itzykson–Peskin–Zuber 1980 argued that in four-dimensional lattice gauge theory too, roughening occurs at a finite coupling without any phase transition of the vacuum, and that $\sigma(\beta)$ has an essential singularity there. An essential singularity here is a singularity of the kind where the function and all its derivatives stay finite, but the Taylor expansion no longer represents the function at that point. An example is the function set to e^{-1/x^2} for $x > 0$ and 0 for $x \le 0$; its Taylor series at $x = 0$ has all coefficients 0. However far the series is extended, this point cannot be seen. IPZ write 'The roughening transition is a natural barrier to the extrapolation of strong-coupling series for the string tension'. For SU(2), β_r is about 2 (with a large error), and the authors note that their four-dimensional argument is 'for the most part, intuitive' Physics .

The three-dimensional Z(2) gauge theory is **dual** to the three-dimensional Ising model. Dual means that under a change of variables the partition functions of the two

models agree (up to simple factors) (the detour of 2-09; IPZ cite Wegner 1971). Under this correspondence the surface of a Wilson loop becomes an interface of the Ising model (IPZ formula (8)) Known . Measuring the gauge coupling by $t = \tanh\beta$ (in terms of the temperature of the dual Ising model, $t = e^{-2J/T}$; IPZ formula (7)), the phase transition is at $t_c = 0.6418$. The roughening point, by the series estimate IPZ cite, is $t_r \approx 0.46$, before the phase transition Physics . The effective string theory applies only on the rough side (Gliozzi–Pepe–Wiese 2010) Physics .

Key point

Physics The theorem on the area law at strong coupling (Osterwalder–Seiler 1978, 5-04) is about the rigid side; the Lüscher term and the logarithmic thickness are about the rough side. Physics holds that between them lies a singularity of $\sigma(\beta)$ beyond which the strong-coupling series cannot be extended.

08

The Wulff shape

On the rigid side of § 07, the tension also depends on direction. The edge of a Wilson loop at angle θ to the lattice axes becomes a staircase, and the minimal surface has $RT(|\cos\theta| + |\sin\theta|)$ plaquettes. At leading order in strong coupling this gives the following.

$$\sigma(\theta) = \sigma_0\big(|\cos\theta| + |\sin\theta|\big) \quad (11)$$

At 45° it is $\sqrt{2}$ times larger Computed . In the continuum limit rotation symmetry is expected to return and the tension to become constant Physics .

What shape does a region of fixed area (a two-dimensional droplet) take when it is enclosed by a line whose tension depends on direction? With the tension $\tau(\mathbf{n})$ for each normal $\mathbf{n}$, we minimise $\oint \tau\, ds$ with the enclosed area fixed. The answer is given by the construction of Wulff 1901 (bibliographic data for the proof that the construction gives the minimum is in the table of sources) Known .

$$\mathcal{W}_\tau = \bigcap_{|\mathbf{n}|=1} \{\mathbf{x} : \ \mathbf{x}\cdot\mathbf{n} \le \tau(\mathbf{n})\}, \qquad \min_{\text{area}=A} \oint \tau\, ds = 2\sqrt{|\mathcal{W}_\tau|\, A} \quad (12)$$

If the tension is constant the answer is a circle; for $\tau = |n1| + |n2|$ of (11) it is the square $\{\max(|x|,|y|) \le 1\}$. The total at area 1 is 4 for the square and $8/\sqrt{\pi} = 4.51$ for a circle Computed .

09

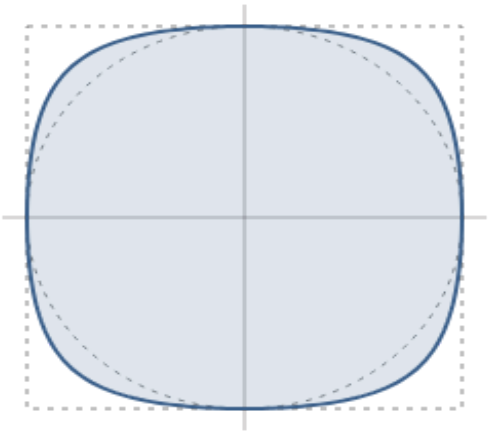
The droplet of the two-dimensional Ising model

An example where the direction-dependent tension is known exactly is the Ising model on the square lattice (coupling J, 2-09). The $\beta = 1/T$ of this section is the inverse temperature ($k_B = 1$; not the β of lattice gauge theory). The equilibrium shape of an island of the minority (a droplet) in the low-temperature phase is the following curve (the first exact analysis is attributed to Rottman–Wortis 1981) Known .

$$\cosh(\beta x) + \cosh(\beta y) = \sinh(2\beta J) + \frac{1}{\sinh(2\beta J)} \quad (13)$$

(13) is the boundary of $\mathcal{W}_\tau$ in (12) itself. Its size too is as in (12): the extent $\max \mathbf{x}\cdot\mathbf{n}$ in the direction $\mathbf{n}$ equals the tension $\tau(\mathbf{n})$ (in units of J). So x, y are not positions but coordinates measured in units of energy. The intercept with the x axis (the tension in the axis direction) agrees to 5 digits with $2J + \beta^{-1}\ln\tanh\beta J$ from Onsager's exact solution Computed . As $T \to 0$, (13) becomes a square, and the tension is the same staircase count as in (11). As $T \to T_c$ the right-hand side approaches 2, and for $u = \beta x$, $v = \beta y$ we have $\cosh u + \cosh v \approx 2 + (u^2 + v^2)/2$, so it becomes a circle.

Figure 2 Changing the temperature T/T_c with the knob changes the equilibrium shape of the two-dimensional Ising droplet (filled) from a square to a circle. The tension along the axis is normalised to 1; the dotted lines are the square and the circle



```
T/T_c = 0.30  τ(0°) = 1.9278 J (Onsager's formula 1.9278)  τ(45°)/τ(0°) = 1.1196 (square 1.4142, circle 1)
```

Table 4 Equilibrium shapes of the two-dimensional Ising model. The isoperimetric ratio is $4\pi\,\text{area}/\text{perimeter}^2$; the last column is the ratio of the total tension to that of a circular droplet of the same area

T/T_c	τ(45°)/τ(0°)	Isoperimetric ratio	Wulff/circle
→ 0	1.4142	0.7854	0.8862
0.2	1.1984	0.9406	0.9698
0.4	1.0690	0.9917	0.9958

T/T_c	τ(45°)/τ(0°)	Isoperimetric ratio	Wulff/circle
0.8	1.0035	1.0000	1.0000

Computed The numbers in this figure and table were computed on this machine ((13) solved by bisection for each angle).

At low temperature the diagonal tension falls first. A stepped edge has a number of arrangements (entropy), and the corners round off from there. Approaching T_c the correlation length becomes much longer than the lattice spacing, the orientation of the lattice is forgotten, and the shape becomes a circle. This is how the expectation that rotation symmetry returns in the continuum limit (5-05) looks in an exactly tractable model.

That the droplet takes the Wulff shape in the low-temperature two-dimensional Ising model has been shown from the microscopic model (Dobrushin–Kotecký–Shlosman 1992, 1993) Known .

The Wulff problem applies directly to droplets of a two-dimensional phase with fixed area like this one. A closed ring of flux in Yang–Mills has no constraint fixing its area, and left alone it shrinks. Still, a closed tube on the lattice must turn corners, so its energy depends on its shape through $\sigma(\theta)$ Physics . How it is used in the record of this book's study is in 23-02.

10

What the string picture hands to mathematics, and what it does not

What it hands over

Physics If a long tube is assumed to exist, the Lüscher coefficient, the coefficient of $\ln R$ in the thickness, and the form of the levels up to $1/L^5$ are fixed independently of the details.

Known For the low-temperature two-dimensional Ising model, the relation between the direction-dependent tension and the shape of the droplet is a theorem.

What it does not hand over

That a tube exists (the area law at large β) 'remains elusive' for the four-dimensional non-abelian theory (Chatterjee 2018). The lattice σ is extracted by subtracting the string correction, and Lucini–Teper, fitting only two points, note: 'we cannot claim to have evidence for both the 1/L functional form and for its coefficient'.

The string picture is about massless transverse fluctuations, and the glueball masses do not come out of it directly. ABT examine the possibility that the $J^P = 0^-$ levels that deviate from (10) represent 'the massive modes associated with the internal structure

of the flux tube' Physics . Since the only length scale is $1/\sqrt{\sigma}$, $m \sim \sqrt{\sigma}$ looks natural, but it is not derived (17-01 § 09, 17-12). The view as a sum over surfaces appears in the next chapter, 17-04, as the $1/N$ expansion.

What this chapter can say

What is said	What is not said
Physics The universality, derived within the effective theory that assumes a long tube exists, of the Lüscher coefficient, the coefficient of $\ln R$ in the thickness, and the levels up to $1/L^5$	That a long tube exists in four-dimensional non-abelian Yang–Mills (the area law at large β)
Computed That differences of regularisation enter only the term proportional to R (Table 1). The increase in thickness of the lattice free field (Table 2)	A theorem on the thickness of the Yang–Mills tube
Computed The difference between (10) and the Lüscher approximation, L_H, l_c (Table 3)	That (10) is exact for Yang–Mills
Known The Wulff construction and its justification for the low-temperature two-dimensional Ising model. Computed Table 4	That $\sigma(\theta)$ becomes constant in the four-dimensional continuum limit
Known The area law at strong coupling (Osterwalder–Seiler). The duality between the three-dimensional `Z(2)` gauge theory and the Ising model. $-1/12$ by Euler–Maclaurin	Extending the strong-coupling series beyond the roughening point
Physics The roughening transition of four-dimensional lattice gauge theory (the argument of IPZ), and the series estimate of t_r for three-dimensional `Z(2)`	A proof of the existence and location of the roughening transition

Next chapter to read: 17-04 Large N — a view that organises the sum over surfaces by $1/N$.

Large N — sending the number of colours to infinity sorts Feynman diagrams by surfaces

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — That as N grows, diagrams are sorted by genus into powers of N, and only planar diagrams survive ('t Hooft 1974). That the sum of diagrams becomes a sum over random surfaces, and fluctuations disappear. A phase transition that appears only at N=∞ on the two-dimensional lattice, and the N-dependence on the four-dimensional lattice.

Prerequisite chapters — 4-03 Perturbation theory and Feynman diagrams. 3-02, 7-02 and 17-01 are written on the spot as far as needed.

Said first — Large N is an expansion at the level of physics. The prize problem requires finite N, and no road back from N→∞ is known. Mathematically established results are limited to the strong-coupling lattice or to two dimensions. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. The idea of varying N — 1/N in place of a small number
2. The double-line notation — a line is two indices
3. 't Hooft's counting — the power of N is fixed by the genus
4. The genus expansion of a Gaussian matrix — actually counting (Detour: Catalan numbers and the semicircle)
5. Random surfaces — towards the string picture
6. The master field — fluctuations disappear as 1/N
7. The Gross–Witten transition — a kink only at N=∞
8. The four-dimensional lattice — ratios move slowly with N
9. What can be said, and what cannot — the shores of strong coupling and two dimensions

01

The idea of varying N

Four-dimensional pure Yang–Mills has no small number to expand in. The mass scale Λ has the form $e^{-1/(2b_0 g^2)}$ ($b_0 = 11N/(48\pi^2)$, formula (1) of 17-01) and shows up at no power of g (17-01 § 03). 't Hooft (1974) treated the size N of the group as a knob and considered the following limit (the group in the original paper is U(N)) Known .

$$N \to \infty, \qquad \lambda = g^2 N \ \text{ fixed} \quad (1)$$

According to the abstract, 'only planar diagrams with the quarks at the edges dominate', and 1/N corresponds to the coupling of the string models of the time. As a metaphor, the idea is to see $N = 3$ as "$N = \infty$ with a correction of order $1/9$"; more precisely, how small the correction is has to be checked with lattice numbers (§ 08). The problem statement calls the duality conjecture, that through the 1/N expansion a gauge theory might be equivalent to a string theory with coupling $1/N$, 'A prominent speculation', and writes that such a description could be 'perhaps a good starting point for a rigorous proof (for sufficiently large N)' Known . But the requirement is finite N (0-03).

02

The gauge field is a matrix: the double-line notation

The gauge field A_μ is an $N \times N$ Hermitian matrix at each point (3-02), and we regard the two indices of a component ${A_\mu}^i{}_j$ as the two ends of colour lines. The action is (Euclidean)

$$S = \frac{1}{2g^2}\int \operatorname{tr} F_{\mu\nu}F_{\mu\nu}\, d^4x = \frac{N}{2\lambda}\int \operatorname{tr} F_{\mu\nu}F_{\mu\nu}\, d^4x, \qquad F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - i[A_\mu, A_\nu].$$

The trace of a product joins indices into a ring, as in $\operatorname{tr}(ABC) = A^i{}_j B^j{}_k C^k{}_i$, and the three-point and four-point vertices of (2) are all of this form. The colour part of the propagator (4-03) for U(N) is

$$\langle A^i{}_j\, A^k{}_l \rangle \ \propto\ \frac{\lambda}{N}\,\delta^i{}_l\,\delta^k{}_j. \quad (3)$$

One delta is one index line, so a gluon line is two lines of opposite orientation, a thin ribbon. This is the **double-line notation**. In the continuum action (at the level of the Lie algebra) the direction of the identity matrix drops out of the commutators, and its cross terms with the traceless part vanish too, so the U(N) of pure gauge theory is

SU(N) plus one **free U(1) field that does not interact** Known . As groups, U(N) does not split into SU(N)×U(1) (the identity matrix times $e^{2\pi ik/N}$ lies in both), and on the lattice U(N) (§ 07) this separation does not hold.

03

't Hooft's counting: the power of N is fixed by the genus of a surface

From (2)(3), each vertex carries N/λ, each propagator λ/N, and each closed index ring $\sum_i \delta^i{}_i = N$. A vacuum diagram with V vertices, E propagators and F index rings is proportional to

$$\left(\frac{N}{\lambda}\right)^{V}\left(\frac{\lambda}{N}\right)^{E} N^{F} = N^{\,V-E+F}\,\lambda^{\,E-V} \tag{4}$$

Gluing a disc to each index ring gives an oriented closed surface, and $V - E + F$ becomes the **Euler characteristic** $\chi = 2 - 2h$, fixed by the surface alone (h is the number of handles = the **genus**; for a tetrahedron on a sphere $4 - 6 + 4 = 2$). Therefore

$$\ln Z = \sum_{h\geq 0} N^{\,2-2h}\, f_h(\lambda) \tag{5}$$

where f_0 is the sum of diagrams that can be drawn in the plane (**planar diagrams**), and the corrections go in steps of $1/N^2$ Known . A quark line is a single index line, and opens a boundary in the surface, multiplying by $1/N$. (5) is a rearrangement of the perturbation series; convergence is a separate question (4-12). The reason for fixing λ lies in the β function (the formula describing how the coupling constant changes with the scale μ at which we look; 17-01 § 02). Writing it in terms of λ with the b_0 of § 01, N disappears Computed .

$$\mu\frac{d\lambda}{d\mu} = -\frac{11}{24\pi^2}\,\lambda^2, \qquad \Lambda = \mu\,\exp\!\left(-\frac{24\pi^2}{11\,\lambda(\mu)}\right) \tag{6}$$

The left-hand side is how λ changes when the scale μ is changed slightly, and since the right-hand side is negative, λ is smaller at shorter distances (larger μ). Fixing λ fixes Λ too, and on the lattice this choice gives a smooth limit (Lucini–Teper) Physics .

04

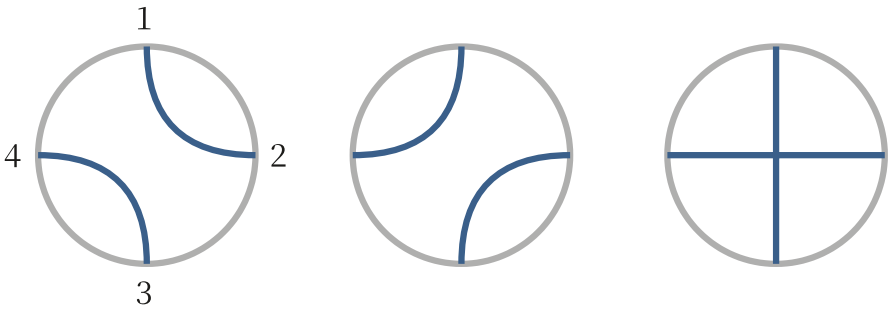
Counting: the genus expansion of a Gaussian matrix

The counting (4) can be checked in a model where spacetime is shrunk to a single point. Take one Hermitian matrix M distributed according to a Gaussian (1-08) (dM is the Lebesgue measure on the real components).

$$d\mu(M) \;\propto\; e^{-\frac{N}{2}\operatorname{tr} M^2}\,dM, \qquad \langle M_{ij}M_{kl}\rangle = \frac{1}{N}\,\delta_{il}\,\delta_{jk} \tag{7}$$

The expectation of a product of Gaussian variables is the sum over ways of pairing them (Wick's theorem, 2-07). The pairings of $\frac{1}{N}\operatorname{tr} M^4$ are the three of Figure 0: (a)(b) give $\frac{1}{N}\cdot N^3\cdot N^{-2}=1$ and (c) gives N^{-2}.

Figure 0 The three ways of joining legs 1–4 of $\operatorname{tr} M^4$ in pairs. (a)(b), where the strings do not cross, have 3 index rings; (c), where they cross, has 1 (it cannot be drawn on a sphere and needs a torus)



(a) 3 rings: 1 (b) 3 rings: 1 (c) 1 ring: $1/N^2$

In general

$$\left\langle \tfrac{1}{N}\operatorname{tr} M^4 \right\rangle = 2 + \frac{1}{N^2}, \qquad \left\langle \tfrac{1}{N}\operatorname{tr} M^{2k} \right\rangle = \sum_{g\ge 0} \varepsilon_g(k)\, N^{-2g} \tag{8}$$

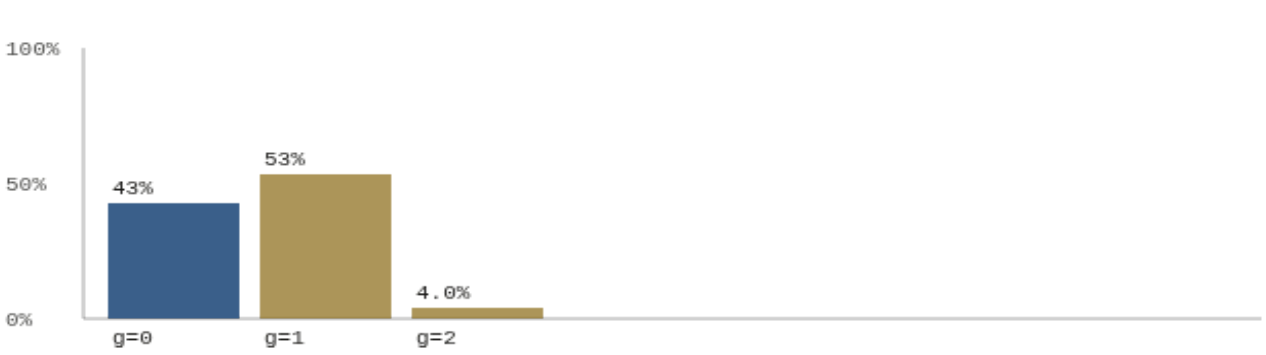
where $\varepsilon_g(k)$ is the number, among the $(2k-1)!!$ pairings, of those of genus g (with $k+1-2g$ index rings). The coefficients can be obtained from the recursion of Harer–Zagier (1986).

$$(k+1)\,\varepsilon_g(k) = (4k-2)\,\varepsilon_g(k-1) + (k-1)(2k-1)(2k-3)\,\varepsilon_{g-1}(k-2) \tag{9}$$

Table 1 $\varepsilon_g(k)$ (full enumeration of pairings; agrees with recursion (9))

k	g=0	g=1	g=2	g=3	Total
4	14	70	21		105
5	42	420	483		945
6	132	2310	6468	1485	10395
7	429	12012	66066	56628	135135

Figure 1 Varying N and k changes the share of genus-g diagrams in $\langle \frac{1}{N}\operatorname{tr} M^{2k}\rangle$. Raising N leaves only the planar diagrams (g=0)



k = 4 N = 2.00 ⟨(1/N)tr M^8⟩ = 32.81, planar part 14 (42.7%)

Computed The numbers of Table 1 and Figure 1 were computed on this machine (for $k \le 7$, full enumeration checked against the recursion). If JavaScript is disabled, see Table 1.

The total $(2k-1)!!$ grows much faster than the number of planar diagrams, and at $k = 9$, $N = 1$ planar diagrams are under 0.02%. The large-N limit is the limit that keeps only the few diagrams.

Detour: Catalan numbers and the semicircle

A subsection you may skip.

The $g = 0$ column of Table 1 is the Catalan numbers $\frac{1}{k+1}\binom{2k}{k}$. As $N \to \infty$ the distribution of the eigenvalues of M approaches the semicircle $\rho(x) = \frac{1}{2\pi}\sqrt{4 - x^2}$ ($|x| \le 2$) (Wigner's semicircle law) Known . Integrating numerically the $2k$-th moment $\int x^{2k}\rho(x)\,dx$ of this density agrees with the Catalan numbers to 10 digits for $k \le 6$ Computed . Counting planar diagrams is the same as finding the large-N limit, and Brézin–Itzykson–Parisi–Zuber (1978) used this as a way of counting Known .

05

The sum of diagrams becomes a sum over random surfaces

We read the ribbon diagrams inside out. Replace four-point vertices by squares, three-point vertices by triangles, and propagators by the gluing of two edges, and each diagram becomes one closed surface glued from polygons. (5) is

$$\ln Z = \sum_{\Sigma} N^{\chi(\Sigma)}\, w_{\lambda}(\Sigma) \qquad (10)$$

a sum over **random surfaces**, where N counts the topology and λ the number of polygons (w_λ is a weight that includes the momentum integrals). As a metaphor it is a sum over shapes of a membrane; more precisely, (10) is a rearrangement of a series, and convergence as a sum over surfaces has to be shown separately.

Physics reads this membrane as the world sheet of the string swept out by the tube of confinement (17-03). N^{2-2h} has the form of the perturbative expansion of a string with string coupling $1/N$; in the problem statement, 'may be equivalent to a string theory with 1/N as the string coupling constant' Physics . In two-dimensional QCD, the coefficients of the $1/N$ expansion are fixed by sums over maps of surfaces, and it can be read as a theory of closed strings (Gross–Taylor 1993) Known .

06

Fluctuations disappear: factorisation and the master field

One more thing follows from the counting (4): the covariance of quantities normalised with $\frac{1}{N}\operatorname{tr}$ is smaller by $1/N^2$ Known .

$$\left\langle \tfrac{1}{N}\operatorname{tr} A \cdot \tfrac{1}{N}\operatorname{tr} B \right\rangle = \left\langle \tfrac{1}{N}\operatorname{tr} A \right\rangle \left\langle \tfrac{1}{N}\operatorname{tr} B \right\rangle + O\left(N^{-2}\right) \quad (11)$$

This is **factorisation**, and for $A = B$ the standard deviation shrinks as $1/N$.

Table 2 $\frac{1}{N}\operatorname{tr} M^4$ from random samples of the matrix (7) Computed

N	Mean	$2 + 1/N^2$	N × standard deviation
2	2.2541(80)	2.2500	7.19
8	2.0152(38)	2.0156	6.09
128	2.0003(15)	2.0001	6.06

At $N = \infty$, quantities made from traces (for the matrix model (7), quantities unchanged under conjugation $M \to UMU^\dagger$; for gauge theory, gauge-invariant quantities) stop being random, and the measure behaves as though concentrated on a single configuration. By custom, where it concentrates is called the **master field**. As a metaphor it is the picture of a heaving sea freezing; more precisely, what freezes is the distribution of quantities made from traces, while the components of the matrix keep fluctuating.

The representative case in gauge theory where factorisation works is the **Wilson loop**. It is the $\frac{1}{N}\operatorname{tr}$ of the matrix (an $N \times N$ unitary matrix) obtained by parallel transport with the gauge field along a closed path C, defined in 17-01 § 04. The **Schwinger–Dyson equations** are relations among expectation values that come from the integral not changing when the integration variable is shifted. Putting factorisation into these equations for Wilson loops gives equations closed in the expectations of loops alone (Makeenko–Migdal 1979) Physics . In the plane $\mathbb{R}^2$, Lévy constructed the large-N limit of the Yang–Mills measure (7-02) and showed that each Wilson loop converges in probability to a deterministic limit, and that these equations hold both at finite N and in the limit Known .

07

Large N seen on the two-dimensional lattice: the Gross–Witten transition

We write as much lattice vocabulary as needed (for details see 5-01). Replace spacetime by a mesh of lattice points, and on each edge ℓ joining two neighbouring points place a group element $U_\ell \in U(N)$. Write U_p for the product of the elements on the four sides of the smallest square of the lattice (a **plaquette**) p, taken in order around it; the action is made from $\operatorname{tr} U_p$. The $\frac{1}{N}\operatorname{tr}$ of the product of edge elements along a closed path is the lattice **Wilson loop**. Each U_ℓ follows the **Haar measure** (the uniform probability measure on the group, 1-08 § 03) multiplied by the weight of the action.

On the two-dimensional lattice, the **tree gauge**, which sets some of the edge elements to 1, makes the plaquettes independent, and a Wilson loop enclosing n faces is exactly w^n (7-02 § 02, § 03). Large N can be studied with the integral over a single plaquette. Weighting the Haar measure of U(N), set

$$d\mu(U) \;\propto\; \exp\Big(\frac{N}{\lambda}\operatorname{tr}(U+U^\dagger)\Big)\,dU, \qquad w_N(\lambda) = \Big\langle \tfrac{1}{N}\operatorname{Re}\operatorname{tr} U \Big\rangle \tag{12}$$

(in terms of the β of 7-02, $\beta = 2N/\lambda$). At finite N, Weyl's integration formula (which turns the Haar integral of a function depending only on traces into an integral over the eigenvalues $e^{i\theta 1},\dots,e^{i\theta N}$) and Heine's identity (which turns that eigenvalue integral into a determinant) give a determinant whose entries are the modified Bessel functions

$$I_n(x) = \frac{1}{2\pi}\int_0^{2\pi} e^{x\cos\theta}\cos n\theta\, d\theta$$

Known .

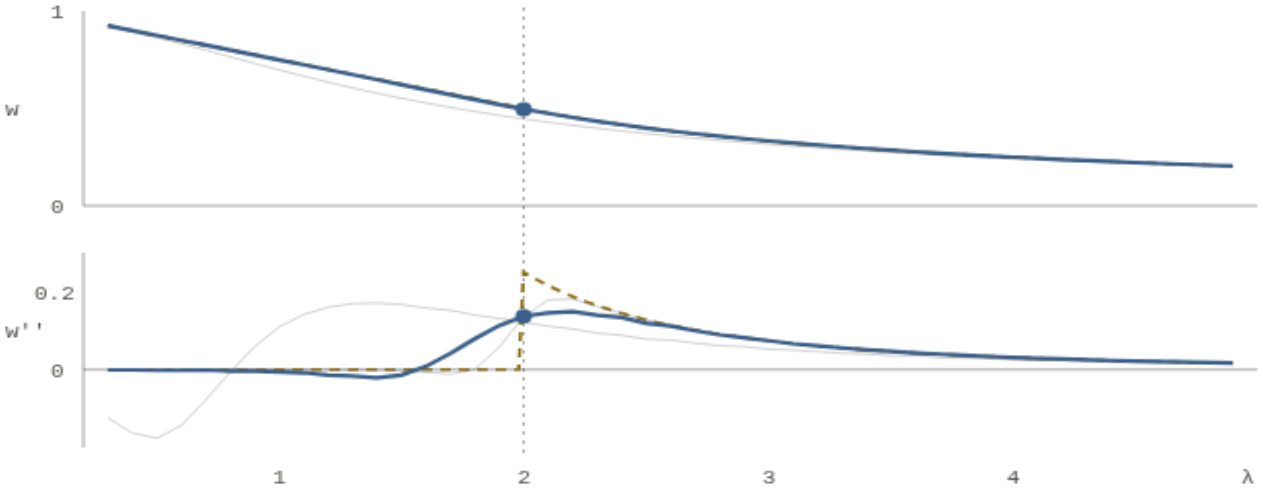
$$Z_N = \det\big[I_{j-k}(2N/\lambda)\big]_{j,k=1}^{N}, \qquad w_N = \frac{1}{2N}\frac{d\ln Z_N}{d(N/\lambda)} \tag{13}$$

Gross–Witten (1980) evaluated $N\to\infty$ by the **saddle-point method** (a method that approximates $\int e^{Nf(x)}dx$, containing a large parameter N, around the point where f is maximal) and found a third-order phase transition at $\lambda = 2$. The same transition appears in Wadia's 1979 preprint Known . In this normalisation the limit has the following form, and the finite-N values approach it as in Table 3 Computed .

$$w_\infty(\lambda) = \begin{cases} 1-\lambda/4 & (\lambda \le 2) \\ 1/\lambda & (\lambda \ge 2) \end{cases} \tag{14}$$

At $\lambda = 2$ both the value 1/2 and the slope −1/4 join up, and the second derivative jumps from 0 to 1/4 (the third derivative, for the free energy). The string tension is $\sigma = -\ln w$.

Figure 2 Choosing N draws $w_N(\lambda)$ in the upper panel and w''_N in the lower panel as thick lines (dashed is N=∞). Raising N brings the lower panel closer to the step at λ=2



N = 10 λ = 2.0 w = 0.49634 (N=∞ : 0.50000) σ = 0.700 w" ≈ 0.14 (N=∞ : step 0→0.25)

Table 3 $w_N(\lambda)$. The last column is formula (14)

λ	N=1	N=10	N=40	N=∞
1	0.69777	0.74937	0.74996	0.75000
2	0.44639	0.49634	0.49939	0.50000
4	0.24250	0.25000	0.25000	0.25000

Computed The numbers in this figure and table were computed on this machine ((13) evaluated to 300 digits; N=1,2 agree with direct integration to 10 digits; the second derivative in the figure is a difference with step 0.1). If JavaScript is disabled, see Table 3.

Three things can be read off Computed . (i) At finite N, Z_N is an entire function of N/λ and positive, so w_N is smooth, and the kink appears only at $N = \infty$. (ii) The manner of approach differs between the phases. The deviation is nearly $-1/(16N^2)$ at $\lambda = 1$; at $\lambda = 4$ it is exponentially small, 2×10^{-12} at $N = 20$; at $\lambda = 2$ doubling N only reduces it by about 1/2.5. (iii) Extending the strong-coupling formula $1/\lambda$ to $\lambda = 1$ gives 1, away from the correct 0.75. This is an example of the strong-coupling expansion not reaching beyond the transition (5-02).

Wadia's preprint (reprinted on arXiv) writes of this transition that it 'seems to be a pathology of the infinite N limit', and holds that in this model it is unrelated to the physical continuum limit (the $\lambda \to 0$ side). Still, $N \to \infty$ can create singularities that finite N does not have, so exchanging $N \to \infty$ and $a \to 0$ needs a reason.

08

The four-dimensional lattice: ratios move slowly with N

In four dimensions we rely on lattice numbers. Lucini–Teper (2001) fitted the continuum limits of $m_{0^{++}}/\sqrt{\sigma}$ (the lightest glueball and the string tension, 17-01) for SU(2) to SU(5) with a linear function of $1/N^2$, and summarised: 'all SU(N) gauge theories are close to SU(∞), at least as far as the low-lying mass spectrum is concerned' Physics .

$$\left.\frac{m_{0^{++}}}{\sqrt{\sigma}}\right|_N = a + \frac{b}{N^2} \quad (15)$$

Refitting (15) to the four points of the paper with error weights gives $a = 3.366 \pm 0.106$, $b = 1.93 \pm 0.54$, $\chi^2 = 0.26$ (2 degrees of freedom), with central values the same as the paper's $3.37(15) + 1.93(85)/N^2$. A constant alone gives $\chi^2 = 12.9$ (3 degrees of freedom) and does not fit Computed .

Table 4 Continuum-limit values of $m_{0^{++}}/\sqrt{\sigma}$ and the line (15) (in the Athenodorou–Teper column, SU(3) is from the 2020 paper, SU(2) and SU(∞) from the 2021 paper)

N	Lucini–Teper	Line (15)	Athenodorou–Teper
2	3.844(61)	3.848	3.781(23)
3	3.607(87)	3.580	3.405(21)
4	3.49(14)	3.487	
5	3.38(16)	3.443	
∞	3.37(15)	3.366	3.072(14)

Physics Extrapolated values from primary sources. Computed "Line (15)" is the fit on this machine (correlations and systematic errors ignored).

From SU(2) to SU(∞) the ratio changes by about 12.5% on the line (15), and by about 19% in the Athenodorou–Teper values Computed . The SU(∞) values of the two primary sources differ by about 2.0σ Computed . All are extrapolations presupposing that the continuum limit exists, and σ is extracted through the string picture. "N=3 is close to N=∞" is an observation within that premise.

09

What can be said as mathematics, and what cannot

Large-N results that have become theorems lie on the following shores Known .

- **Theories of planar diagrams**: 't Hooft (1983) treated a theory of planar diagrams alone in four-dimensional Euclidean space, and showed that 'if all particles involved have non-vanishing masses' and the couplings are small enough, an absolutely convergent procedure gives Green functions (expectations of products of fields; the

propagator is one of them) that uniquely solve the Dyson–Schwinger equations (the same as the Schwinger–Dyson equations of § 06) (abstract: 'an absolutely convergent procedure exists to obtain Green functions that uniquely solve the Dyson-Schwinger equations'). The gap is an assumption.

- **The strong-coupling lattice**: Chatterjee (2015) computed the expectations of large-N Wilson loops for SO(N) at strong coupling as absolutely convergent sums over trajectories of strings on the lattice, and Chatterjee–Jafarov, for the same strong-coupling SO(N), proved the $1/N$ expansion of Wilson loops as an asymptotic expansion (the first term is genus 0, higher orders surfaces of higher genus).
- **All N and β**: Cao–Park–Sheffield expressed the expectations of Wilson loops, for any matrix size $N \geq 1$, $\beta > 0$ and dimension $d \geq 2$, as sums over **embedded maps** (graphs drawn on a surface, mapped onto the lattice). For U(N) the weight of one map is proportional to the product of N^{χ} and the weights of the lattice edges (Weingarten functions, which themselves depend on N).
- **Two dimensions**: the planar master field (§ 06) and the area law at all couplings (7-02).

Seam

(1) The sum over surfaces holds for all β, but there is no estimate producing the area law or the gap on the continuum-limit side (large β). (2) Exchanging $N \to \infty$ and $a \to 0$ is not justified. (3) Even if something can be shown at $N = \infty$, the prize problem requires finite N, and the $1/N$ expansion has no guarantee of convergence. The problem statement too, about four dimensions, only goes as far as writing 'there might some day be an asymptotic solution in a large N limit'.

Large N is used again for strings (17-05) and for holography, which also takes $\lambda \to \infty$ (17-08). The distance to finite N is in 17-10.

What this chapter can say

What is said	What is not said
Known (4)(5) (as rearrangements of series), the difference between U(N) and SU(N).	Convergence of f_h. That the $1/N$ expansion approximates the theory in four dimensions.
Computed (6), Tables 1–3, Figures 1 and 2, the moments of the semicircle density, the check of (13) at N=1,2, the fit of Table 4.	Table 4 is a refit of extrapolated values from primary sources.

What is said	What is not said
Known Large N and the $1/N$ expansion for strong-coupling SO(N), sums over surfaces, the planar master field, the theory of planar diagrams assuming positive masses.	The area law and the gap on the weak-coupling side. Exchanging $N \to \infty$ and $a \to 0$. The return to finite N.
Physics The dominance of planar diagrams, the string coupling $1/N$, the loop equations, the smallness of the N-dependence of the ratios.	Not theorems of the four-dimensional continuum theory. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit: Volume 2).

Next chapter to read: 17-05 String theory and extra dimensions — what is needed to read the sum over surfaces as a theory of strings.

String theory and extra dimensions — 26, 10 and 11 are numbers that come from conditions of consistency

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — That quantising a string as a fundamental object takes away the free choice of the dimension of spacetime. How 26 for the bosonic string is derived in two ways (the first excited state / the central charge), and 10 for the superstring by the same balance. That 11 is a number that comes from supergravity.

Prerequisite chapters — 17-04 Large N. We use the zero-point energy and $-1/12$ of 17-03. Group representations (1-02), Lorentz transformations (2-04) and the harmonic oscillator (2-06) are written on the spot as far as needed.

Said first — The derivations are at the level of physics. The two-dimensional computations on the world sheet are exact, but string theory has no non-perturbative definition, and the existence of M-theory is a hypothesis. The story of extra dimensions shows nothing about the construction of four-dimensional Yang–Mills or about the mass gap. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. Making the string a fundamental object — how it differs from the string of the tube
2. Counting the transverse oscillations — the mass formula
3. Why 26 (I) — the first excited state is massless
4. Counting the levels — the tachyon and the growth (Detour: partition numbers and Hardy–Ramanujan, Detour: the growth of states and the Hagedorn temperature)
5. Why 26 (II) — the balance of the central charge

6. Why 10 — world-sheet supersymmetry (Detour: 26 − 10 = 16 and the heterotic string)
7. Why 11 — the number of supergravity
8. The "critical dimension" is a critical central charge — it need not be geometry
9. Back to Yang–Mills — the string of the tube, and holography

---

01

Making the string a fundamental object

17-03 treated the tube of confinement as a single string, and in 17-04 § 05 $1/N$ played the role of the string coupling. String theory too is said to have begun from models of mesons (**dual resonance models**). The scattering amplitude of Veneziano (1968) is often cited as the starting point; for example, the abstract of Neveu–Schwarz (1971) opens with 'A new dual-resonance model of mesons is constructed ...' Known . For mesons, spin J and the square of the mass line up on a straight line (Regge trajectories). If a string of tension T and length $2R$ rotates with angular velocity $1/R$, its ends move at the speed of light, and integrating the energy and the angular momentum (2-04) gives $E = \pi T R$ and $J = \pi T R^2/2$, that is

$$J = \alpha' E^2, \qquad \alpha' = \frac{1}{2\pi T}. \ (1)$$

For the quantised open string, the maximum spin at level N is $J_{\max} = \alpha' M^2 + 1$ (Tong § 3.1.3). Putting the $\sqrt{\sigma} = 485$ MeV of 17-01 into T gives $\alpha' = 0.677\ \text{GeV}^{-2}$, $\sqrt{\alpha'} \approx 0.16$ fm Computed . The **fundamental string** of this chapter is not the effective theory of a tube; it is required to be quantisable without contradiction at however short a distance. Then the dimension D of spacetime stops being a free input. In this chapter, following the string literature, we write D for the dimension of spacetime. It is the same as the d of 17-03 and of the table of notation in the appendix, not the dimension of space alone.

02

Counting the transverse oscillations: the mass formula

A string sweeps out a surface (the **world sheet**) in spacetime $\mathbb{R}^{1,D-1}$. In **light-cone gauge** we use the light-cone coordinates $X^{\pm} = (X^0 \pm X^{D-1})/\sqrt{2}$, recombining time X^0 and one longitudinal direction X^{D-1}, and make X^+ proportional to the world-sheet time τ ($X^+ = x^+ + \alpha' p^+ \tau$; x^+ and p^+ are the $+$ components of the position and

momentum of the centre of mass of the string; Tong (2.13)). The oscillations of X^- do not vanish, but they are fixed by the transverse oscillations through the constraint equations. Only the $D-2$ transverse directions oscillate independently (Goddard–Goldstone–Rebbi–Thorn 1973) Known . This is the same counting as the transverse displacement $h \in \mathbb{R}^{d-2}$ of 17-03 ($d = D$). The n-th oscillation in direction i is a harmonic oscillator (2-06), and each application of the creation operator α^i_{-n} raises the **level** N by n. The mass of the open string is

$$\alpha' M^2 = N - a \tag{2}$$

where $-a$ is the zero-point energy (the sum of $\frac{1}{2}n$ over all oscillators). Its finite part is the $-1/12$ of 17-03 (17-03 § 04), so

$$a = -\frac{D-2}{2}\sum_{n\geq 1} n \;\longrightarrow\; -\frac{D-2}{2}\cdot\Big(-\frac{1}{12}\Big) = \frac{D-2}{24}. \tag{3}$$

The Lüscher term $-\pi(D-2)/(24R)$ of 17-03 and the $(D-2)/24$ of the Nambu–Goto levels (17-03 § 06) are this same number Known . Tong admits that this treatment of the sum is 'famously unconvincing', and derives it again by the central-charge method, the same as § 05 of this chapter (Tong § 4.4.1). The closed string has right-moving oscillations α and left-moving oscillations $\tilde{\alpha}$, and its levels satisfy $N = \tilde{N}$ (Tong (2.26)).

03

Why 26 (I): the first excited state must be massless

The internal states of a particle form a representation of the rotations that leave its momentum unchanged (the **little group**) (1-02; Wigner 1939). For mass $M > 0$ we can go to the rest frame and the little group is $SO(D-1)$; for zero mass it is the $SO(D-2)$ that preserves the momentum $(p, 0, \ldots, 0, p)$ (precisely, it is the group $ISO(D-2)$ of rotations and translations in $D-2$ dimensions, but what acts on finitely many states is the rotation part $SO(D-2)$). A photon in four dimensions has 2 polarisations, a massive spin-1 particle 3 Known . The level-1 states $\alpha^i_{-1}|0\rangle$ of the open string are a transverse vector with $D-2$ states, one short of the $D-1$ components a massive vector needs. To keep Lorentz symmetry it must be massless, and

$$\alpha' M^2 = 1 - a = 0 \implies a = 1 \overset{(3)}{\implies} \frac{D-2}{24} = 1 \implies D = 26. \tag{4}$$

Tong makes the same argument for the first excited state of the closed string ($(D-2)^2$ states) and writes 'these states will have to be massless. And this is only the case if the dimension of spacetime is D = 26' Physics .

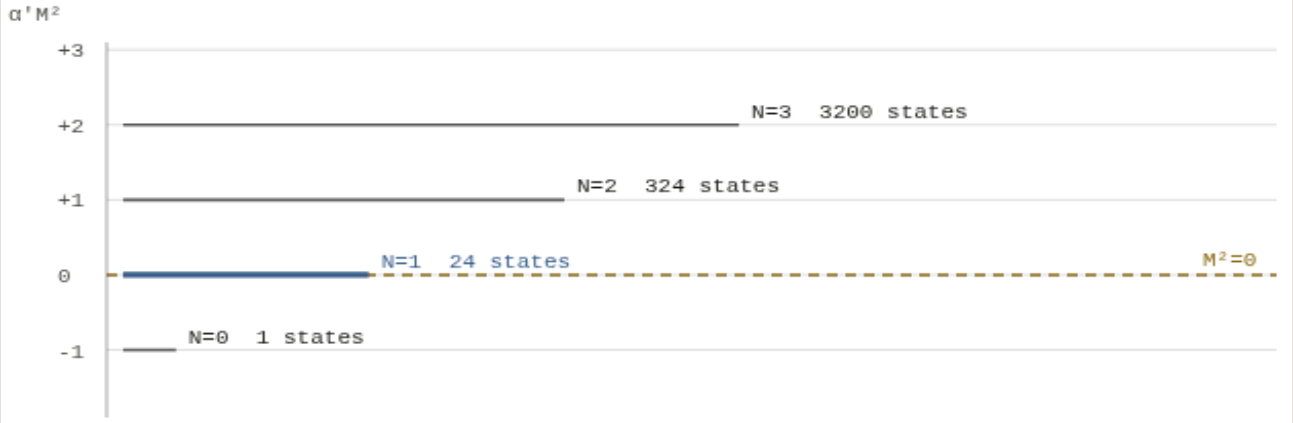
Checking with the Lorentz algebra

More carefully, we check whether the conserved quantities $M^{\mu\nu}$ that generate Lorentz transformations (rotations and boosts) satisfy the relations of the Lorentz algebra in light-cone gauge too. $M^{\mu\nu}$ includes the angular momentum carried by the oscillations of the string. The crux is $[M^{i-}, M^{j-}] = 0$, where i, j are transverse directions and $-$ is the light-cone direction X^- (Tong § 2.4). Since the oscillations of X^- are fixed by the transverse oscillations, this commutator can be written with the transverse oscillators.

$$[M^{i-}, M^{j-}] \propto \sum_{n>0} \left[\left(\frac{D-2}{24} - 1\right)n + \frac{1}{n}\left(a - \frac{D-2}{24}\right)\right](\alpha^i_{-n}\alpha^j_n - \alpha^j_{-n}\alpha^i_n) + (\alpha \leftrightarrow \tilde{\alpha}) \quad (5)$$

The proportionality factor $2/(p^+)^2$ is omitted. This is the formula for the closed string, and $(\alpha \leftrightarrow \tilde{\alpha})$ is a term of the same form for the left-moving oscillations. It vanishes for every n only when $D = 26$ and $a = 1$ Known . The original source is Goddard–Goldstone–Rebbi–Thorn (1973), whose abstract also states that the angular momentum operators generate the Lorentz group $O(D-1,1)$ 'only when the first excited state is a photon, i.e., a spin-one massless state, and when D = 26'. The first excited state of the closed string has $24^2 = 576 = 299 + 276 + 1$ states Computed , and Tong assigns these to the symmetric traceless, antisymmetric and trace fields $G_{\mu\nu}, B_{\mu\nu}, \Phi$ of $SO(24)$, reading the first as a massless spin 2, that is, the graviton Physics .

Figure 1 Varying D moves the levels $\alpha' M^2 = N - a$ up and down (the length of a line is the logarithm of the number of states). The thick level 1 (1/2 for the superstring) sits on $M^2 = 0$ only for D=26 for the bosonic string and D=10 for the superstring



D = 26, a = (D−2)/24 = 1, level 1: 24 states, α'M² = 0 → consistent as a massless vector (SO(24))

Computed The numbers in this figure were computed on this machine. If JavaScript is disabled, see (4) and Table 2.

Counting the levels: the tachyon and the growth of the number of states

$N = 0$ of the open string at $D = 26$ has $\alpha' M^2 = -1$: a **tachyon**, with negative squared mass (Tong § 3.1.1). It is a field whose mass term has the opposite sign (2-02), meaning that we are expanding around a maximum of the potential Physics . The number of states d_N at level N is the number of ways of splitting N into a sum of "positive integers in 24 colours".

$$\sum_{N \geq 0} d_N \, q^N = \prod_{n \geq 1} (1 - q^n)^{-24} \tag{6}$$

The 324 at level 2 is the dimension of the symmetric traceless rank-2 tensor of $SO(25)$, and the 3200 at level 3 is $2900 + 300$ (symmetric traceless rank 3 and antisymmetric rank 2) Computed . According to Tong all excitations fit into representations of $SO(D-1)$, and the condition is on level 1 alone. That the numbers at levels 2 and 3 match sums of dimensions of representations of $SO(D-1)$ we checked for $D = 4$–39 Computed . Both are polynomials in D of degree at most three, so this makes them identities valid for any D.

Table 2 Levels of the open bosonic string ($D = 26$). The ratio is to the Bessel form of the detour ($n = N - 1$)

N	$\alpha' M^2$	d_N	Ratio
0	−1	1	
1	0	24	
2	1	324	1.000009
3	2	3200	0.999998
10	9	6.392×10^{8}	1.00000000
400	399	1.446×10^{91}	1.00000000

Computed The numbers in this table were computed on this machine.

Detour: partition numbers and Hardy–Ramanujan

A subsection you may skip.

With one colour the coefficients of (6) are the partition numbers $p(N)$ ($p(4) = 5$ from $4 = 3+1 = 2+2 = 2+1+1 = 1+1+1+1$), and Hardy and Ramanujan (1918) gave $p(N) \sim \frac{1}{4\sqrt{3}\,N} e^{\pi\sqrt{2N/3}}$ Known . For (6) with 24 colours, setting $n = N - 1$ gives $d_N \approx \frac{1}{\sqrt{2}} n^{-27/4} e^{4\pi\sqrt{n}}$, but the approach is slow, and the ratio is still 0.71 at $N = 400$. What fits well is the form $2\pi n^{-13/2} I_{13}(4\pi\sqrt{n})$ using the modified Bessel function I_{13}, which already agrees to 5 digits at $N = 2$ (Table 2) Computed . $I_\nu(x)$ is a function that behaves like $e^x/\sqrt{2\pi x}$ when x is large. Putting this

in gives $2\pi n^{-13/2}\, e^{4\pi\sqrt{n}}/\sqrt{8\pi^2\sqrt{n}} = \frac{1}{\sqrt{2}} n^{-27/4} e^{4\pi\sqrt{n}}$, and the two formulas agree at large n. The ratio 0.71 is the error from replacing I_{13} by this approximation.

Detour: the growth of states and the Hagedorn temperature

A subsection you may skip.

An open string at level N has $\alpha' M^2 = N - 1$, so setting $n = N - 1$ as in the detour above gives $\alpha' M^2 = n$, that is $M = \sqrt{n/\alpha'}$. From the asymptotic form of the detour above, the number of states grows at the rate $e^{4\pi\sqrt{n}} = e^{4\pi\sqrt{\alpha'}M}$ (the power of n in front changes slowly compared with the exponential). Write Θ for the temperature (to distinguish it from the tension T; in units with Boltzmann's constant 1). The weight of a state of mass M is the Boltzmann factor $e^{-M/\Theta}$ (2-08), so the product of number and weight has the form $e^{(4\pi\sqrt{\alpha'} - 1/\Theta)M}$, and for $\Theta > \Theta_H = 1/(4\pi\sqrt{\alpha'})$ it grows with M and the sum diverges. This Θ_H is the **Hagedorn temperature** Physics . Putting $d = D = 26$ and $\sigma = 1/(2\pi\alpha')$ into the Hagedorn length L_H of 17-03 § 06 ($\sigma L_H^2 = \pi(d-2)/3$, where σ is the tension, the T of this chapter) gives $L_H = 4\pi\sqrt{\alpha'}$, and its reciprocal $1/L_H$ coincides with Θ_H Computed . It is the same reading as in 17-03, where $1/L$ became the temperature when the periodic direction was regarded as time.

05

Why 26 (II): the balance of the central charge

The second derivation looks at the D fields X^μ on the world sheet as two-dimensional free scalar fields (2-02). A two-dimensional theory whose form does not change under a change of scale (a **conformal field theory**) has a **central charge** c, and one free scalar has $c = 1$. More precisely, a conformal field theory is a theory invariant under angle-preserving maps (**conformal transformations**), of which changes of scale are a part. In two dimensions there are infinitely many such maps, and this constrains the theory strongly. c appears in the ground-state energy on a cylinder of circumference L (when the left and right c are equal).

$$E_0(L) = -\frac{\pi c}{6L} \quad (7)$$

(Blöte–Cardy–Nightingale 1986, Affleck 1986; Tong § 4.4.1) Known . The $-\pi(D-2)/(6L)$ of the closed tube of 17-03 is the case $c = D - 2$, and about the $-\pi c/(24R)$ of a tube with ends Tong writes 'c counts the number of degrees of freedom of the QCD flux tube'. The Lüscher coefficient measures the central charge of the tube.

In Polyakov's formulation the metric of the world sheet is also a field to be integrated, and changes of coordinates and changes of scale of the metric (Weyl transformations) are gauge symmetries. Fixing the gauge brings in auxiliary fields (ghosts; the same

mechanism as Faddeev–Popov in 4-08), with central charge -26. A quantum breaking of a gauge symmetry (an anomaly) is not allowed, so the total must be 0 (Tong § 5.3) Physics .

$$c_{\text{matter}} + c_{\text{ghost}} = D \cdot 1 + (-26) = 0 \implies D = 26 \quad (8)$$

The $D - 2$ fields and $-1/12$ in light cone, and the D fields of the covariant form with the ghosts' -26, select the same 26. More precisely, (8) is a condition only as long as the scale of the metric (Weyl) is kept as a gauge symmetry. For $D \neq 26$ the scale degree of freedom does not disappear but remains, and behaves as a new field called the Liouville field (the non-critical string of Tong § 5.3.2). The abstract of Polyakov (1981) too writes 'At D = 26 the string dynamics is that of harmonic oscillators ..., otherwise it is described by the nonlinear integrable theory', treating the $D \neq 26$ side as a different theory.

06

Why 10: world-sheet supersymmetry

The bosonic string has no fermions (relatives of the electron and the quarks), and has a tachyon. Add to the world sheet fermions ψ^μ as partners of X^μ ($c = 1/2$ each), make the **world-sheet supersymmetry** that exchanges the two a gauge symmetry, and the ghosts add central charge $+11$.

$$D\left(1 + \frac{1}{2}\right) + (-26 + 11) = 0 \implies D = 10 \quad (9)$$

In Tong § 5.3.1, 'c = 26 − 11 = 15' and 'D(1 + 1/2) = 15' Physics . We check it in light cone too. Depending on the boundary condition, the fermion oscillations take half-integer labels $r = \frac{1}{2}, \frac{3}{2}, \ldots$ (Neveu–Schwarz, NS) or integer ones (Ramond, R), and their zero-point energy has the opposite sign, $-\frac{1}{2}\sum r$. The finite parts are in Table 1.

Table 1 The sum minus $1/\varepsilon^2$ (cutoff $e^{-\varepsilon r}$)

ε	Integer $\sum n e^{-\varepsilon n}$	Half-integer $\sum r e^{-\varepsilon r}$
0.1	-0.0832917	0.0416302
0.001	-0.0833333	0.0416667
→ 0	-1/12	+1/24

Computed The numbers in this table were computed on this machine (closed forms checked against direct sums).

The zero-point energy per transverse direction is $-\frac{1}{24} - \frac{1}{48} = -\frac{1}{16}$ for NS and $-\frac{1}{24} + \frac{1}{24} = 0$ for R Computed . The NS levels are $\alpha' M^2 = N - \frac{D-2}{16}$ (N also takes half-integers), and the first excited state $\psi^i_{-1/2}|0\rangle$ is again a vector with $D - 2$ components. The

massless condition $\frac{1}{2} - \frac{D-2}{16} = 0$ gives $D = 10$, agreeing with (9) ("Superstring" in Figure 1). The tachyon of the NS ground state, $\alpha' M^2 = -\frac{1}{2}$, is said to be removed by a rule that discards part of the states (attributed to Gliozzi–Scherk–Olive 1977) Physics .

Detour: 26 − 10 = 16 and the heterotic string

A subsection you may skip.

Green–Schwarz (1984) named $SO(32)$ and $E_8 \times E_8$ as the groups for which the gauge and gravitational anomalies in 10 dimensions cancel, and Gross–Harvey–Martinec–Rohm (1985) built the heterotic string as 'a chiral combination of the closed D=26 bosonic and D=10 fermionic strings' Known . The difference between 26 and 10 is 16, and $SO(32)$ and $E_8 \times E_8$ both have rank 16 and dimension 496 (E_8 has 240 roots and rank 8, giving 248; 1-04) Computed . How this 16 becomes a gauge group is in 17-07.

07

Why 11: a number of supergravity, not of strings

11 is not a critical dimension of strings. The abstract of Cremmer–Julia–Scherk (1978) reads 'We present the action and transformation laws of supergravity in 11 dimensions' Known . **Supergravity** is a field theory containing the graviton and its supersymmetric partner (the gravitino), and that 11 is its upper limit is said to follow from the classification of Nahm (1978).

The skeleton is this Physics . **Supercharges** are the generators of the symmetry that exchanges bosons and fermions (supersymmetry), and Q is the number of their real components. With Q supercharges, the range of helicities (the amount of rotation about the direction of motion) of a massless multiplet is $Q/8$, and for spin at most 2 (range at most 4) $Q \leq 32$. 11 dimensions is said to be the last dimension that fits within this.

The fields of 11-dimensional supergravity are the graviton, a **3-form** and the gravitino. A 3-form is an antisymmetric field with three indices, the electromagnetic potential A_μ (2-03) with three indices instead of one. Counting the degrees of freedom with the little group $SO(9)$ (the $SO(D-2)$ of $D = 11$), the 128 bosons, graviton $45 - 1 = 44$ and 3-form $\binom{9}{3} = 84$, balance the gravitino's $9 \cdot 16 - 16 = 128$ Computed . In counting the gravitino we used, only as a number, that a **spinor** of $SO(9)$ (the quantity carrying the internal degrees of freedom of a fermion) has 16 components.

Witten (1995) argued in the abstract 'It is argued ... that eleven-dimensional supergravity arises as a low energy limit of the ten-dimensional Type IIA superstring'.

The **IIA string** is a kind of closed superstring in 10 dimensions in which the supersymmetries carried by the right- and left-moving oscillations have opposite handedness (chirality). With λ the coupling of the IIA string, the radius of the 11th circle in 11-dimensional units is

$$r(\lambda) = \lambda^{2/3} \quad (10)$$

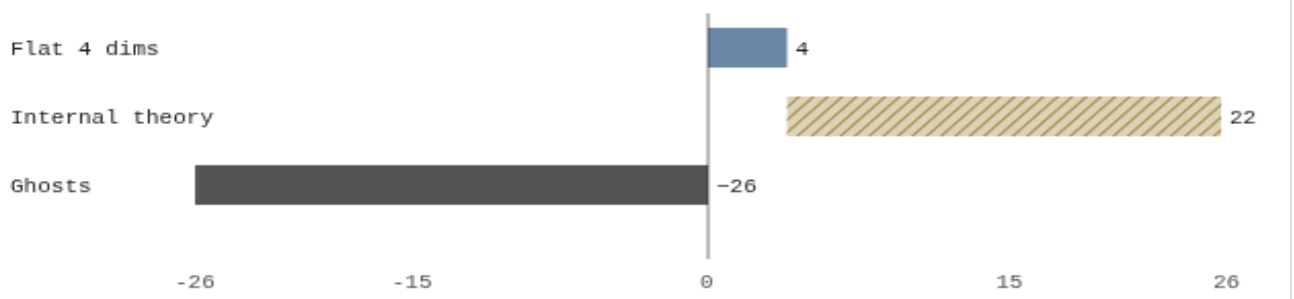
(formula (2.13) of that paper) Physics . At weak coupling the circle shrinks, and states with momentum n around the circle have mass $\sim |n|/\lambda$ in the string metric (formula (2.14)): heavy and not seen. As a metaphor, the 10 dimensions of the string are how a thin 11-dimensional tube looks from afar. More precisely, this is a conjecture from low-energy arguments, and the IIA string at strong coupling has no independent definition. Hořava–Witten (manuscript 1995, published 1996) **proposed** a link between the heterotic string and 11 dimensions in the form 'We propose'. The following paper (1996) argued that the gauge group is fixed to one E_8 for each boundary, wrote that this gives new material testing 'the hypothesis that there is a consistent quantum M-theory', and treated the existence of M-theory as a hypothesis. This 11-dimensional theory (M-theory) has no complete definition.

08

The "critical dimension" is a critical central charge: extra dimensions need not be geometry

What (8)(9) require is not a dimension but a central charge. Tong writes 'the "critical dimension" of string theory is something of a misnomer: it is really a "critical central charge"' Known . For flat four-dimensional spacetime, for the bosonic string it suffices to add **any conformal field theory with** $c = 22$ to the $c = 4$ of $X^0, \dots, X^3$, and Tong continues 'It is what we really mean when we talk about the "extra hidden dimensions of string theory"'. For the superstring flat four dimensions give $c = 6$ and the rest is $c = 9$ Computed . As a metaphor, only the total of the ledger is fixed and the items are free. More precisely, the internal theory must also satisfy other conditions (world-sheet supersymmetry and so on), and it can be read as geometry, as a manifold, only in special cases. How the extra dimensions then become invisible is in 17-06, and how gauge fields come out in 17-07.

Figure 2 Varying the number of flat dimensions d_{flat} changes the breakdown of the central-charge ledger. The internal theory (hatched) takes up what is removed, and the total stays 0



Bosonic string, flat 4 dims c = 4, internal c = 22, ghosts c = −26, total 0

Computed The arithmetic of this figure was checked on this machine. If JavaScript is disabled, read it as $d_{\text{flat}} + c_{\text{int}} = 26$ (for the superstring $\frac{3}{2}d_{\text{flat}} + c_{\text{int}} = 15$).

09

Back to Yang–Mills: the four-dimensional tube, and the dimensions of holography

Then is the string of the four-dimensional tube of 17-03, not being 26-dimensional, inconsistent? The abstract of Polchinski–Strominger (1991) states that the long-distance effective theory of four-dimensional strings such as 'QCD strings' is 'an interacting Poincaré-invariant conformal field theory with four bosons and c=26', and showed the compatibility to second order in perturbation Physics . The 4 bosons, which would have $c = 4$ if free, carry $c = 26$ through their interaction. What the critical dimension constrains is the fundamental string; the effective theory of a long tube is consistent as it is, in four dimensions. But the effective theory breaks down at short distances, and there is no mathematical derivation either (17-03 § 06).

The extra dimensions of the fundamental string return to Yang–Mills through holography (17-08), and the breakdown differs from model to model. Maldacena's $AdS_5 \times S^5$ (AdS_5 is a five-dimensional spacetime of constant negative curvature, with the four-dimensional directions and a radial direction; S^5 is the five-sphere) is 10 = 4 + radial + S^5; Witten 1998 § 4 is 11 = 4 + two circles + radial + S^4 (one circle fewer, 10, on reducing to IIA); the improved holographic QCD of Gürsoy–Kiritsis is 5 = 4 + radial. The dimensions that make the gap also differ by model: in Witten's type, a two-dimensional cigar formed by the radial direction and a shrinking circle; in the bottom-up type, a single radial direction and an infrared singularity (17-09) Physics . These extra dimensions are tools of a dual description, not claimed to be real dimensions, and are a separate matter from the experimental lower bounds (17-06).

Seam

(1) String theory has no non-perturbative definition, and the very existence of M-theory is a hypothesis. (2) Holographic computations work on the side of $N \to \infty$ and 't Hooft coupling $\to \infty$, the opposite direction to the limit that returns to four-dimensional pure Yang–Mills (17-10). (3) The problem statement (Jaffe–Witten,

2000) writes 'at present we do not know' of a non-trivial relativistic field theory in four dimensions satisfying axioms such as Wightman's (4-09). The four-dimensional theory was constructed by the construction published in 2026, as a limit of Wilson's lattice (the committee's assessment; Volume 2). The road of extra dimensions does not construct a four-dimensional theory in this sense.

What this chapter can say

What is said	What is not said
Known The counting of (3)(5) (as a two-dimensional world-sheet computation in light cone).	A non-perturbative definition of string theory. The existence of M-theory.
Physics The reading of (4) (reading the first excited state as massless) and the balance of (8)(9) (the central charge of the ghosts and the anomaly argument).	The treatment of the non-critical string (the Liouville field) for $D \neq 26$.
Computed Tables 1 and 2, Figures 1 and 2, 576, 496, 128, the Hagedorn temperature (the $1/L_H$ of 17-03), α'.	Why the Bessel form of Table 2 fits so well.
Physics The readings of the graviton and the tachyon, the relation between 11 dimensions and IIA, Hořava–Witten (a proposal).	Checking "11 is the upper limit" in the original source.
Physics That the effective theory of the four-dimensional tube is consistent with $c = 26$ (to second order in perturbation). The breakdown of the dimensions of the models.	Consistency of the effective string at all orders. That a tube exists in four-dimensional Yang–Mills. Constructing a four-dimensional theory from extra dimensions. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit: Volume 2).

Next chapter to read: 17-06 How extra dimensions become invisible — why extra dimensions that can be read as geometry do not show up in four-dimensional experiments.

How extra dimensions become invisible — waves on a small circle look like a tower of heavy particles

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — That extra dimensions being invisible means that fluctuations in those directions become a sequence of heavy particles (the KK tower), which cannot be produced at low energy. That the lowest rung of the tower is the first eigenvalue of the Laplacian, bounded by the diameter when the curvature is non-negative (Zhong–Yang). Two ways of hiding, Calabi–Yau and branes, and the experimental lower bounds.

Prerequisite chapters — 17-05 String theory and extra dimensions. We use 2-02 § 06, 2-05 § 08 and 1-10 § 07. Fourier series and the Rayleigh quotient are written on the spot, and the metric, the Laplacian, Ricci curvature and the Einstein equations are defined on the spot as far as they are used.

Said first — Whether the real world has extra dimensions is not known, and the experimental numbers are lower bounds. The gap of the KK tower comes from the internal space being small, and is a different thing from the mass gap of Yang–Mills (which arises from interaction on $\mathbb{R}^4$). This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. What "seeing" means — the resolution is ħc/E
2. A field on a circle — one field becomes a tower
3. The lowest rung of the tower — the first eigenvalue and the diameter (the minimum of metric, Laplacian and Ricci curvature)
4. Kaluza and Klein — charge is momentum
5. The six dimensions of strings — Calabi–Yau
6. Confining to a brane — ADD and RS (Detour: extra dimensions without a gap)
7. Experimental lower bounds — Newton's law and colliders

8. Back to Yang–Mills — the KK gap is not the mass gap

01

What "seeing" means — the resolution is ħc/E

To see, in physics, is to collide particles and examine how they bounce off. To resolve a structure of size ℓ needs a probe with wavelength shorter than ℓ, that is, high energy (2-05).

$$\ell \approx \frac{\hbar c}{E}, \qquad \hbar c = 197.327\ \text{MeV}\cdot\text{fm} \quad (1)$$

1 TeV gives 2.0×10^{-19} m, the LHC collision energy of 13.6 TeV gives 1.5×10^{-20} m, and the Planck mass 1.22×10^{19} GeV gives 1.6×10^{-35} m Computed . From here on we set $\hbar = c = 1$ (2-04 § 08). As a metaphor, a garden hose seen from afar is a line, but up close the direction going around it becomes visible. More precisely, what this chapter says is that "fluctuations along a small circle need high energy".

02

A field on a circle — one field becomes a tower

Consider the five-dimensional spacetime $\mathbb{R}^{1,3} \times S^1$ with a circle of radius R attached to each point of space (the circle coordinate y identified with $y + 2\pi R$). A massless scalar field $\Phi(x, y)$ obeys the wave equation (2-02), and since it is periodic in y it can be expanded in a Fourier series (1-11).

$$(\partial_t^2 - \nabla^2 - \partial_y^2)\Phi = 0, \qquad \Phi(x,y) = \frac{1}{\sqrt{2\pi R}} \sum_{n\in\mathbb{Z}} \phi_n(x)\, e^{iny/R} \quad (2)$$

Substituting, ∂_y^2 is replaced by $-n^2/R^2$, and the equation splits coefficient by coefficient.

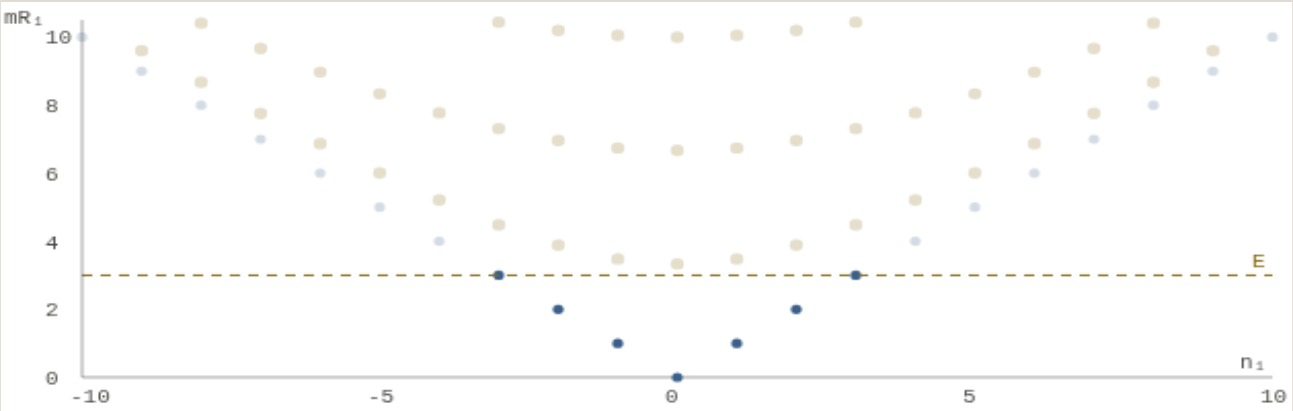
$$\left(\partial_t^2 - \nabla^2 + \frac{n^2}{R^2}\right)\phi_n = 0, \qquad m_n = \frac{|n|}{R} \quad (3)$$

This is the Klein–Gordon equation of mass m_n (2-02 § 06). One five-dimensional field looks, in four dimensions, like a massless **zero mode** ϕ_0 and an infinite sequence of fields of mass $1/R, 2/R, \ldots$. This is the **Kaluza–Klein tower** (KK tower) Known . The PDG writes 'At energies smaller than 1/R, the KK modes can be neglected, leaving the zero-mode action'. The couplings of the zero mode are diluted; for a quartic interaction

$\lambda_4 = \lambda_5/(2\pi R M_5)$ (PDG formula 84.6), weaker the larger the circle. M_5 is the fundamental mass scale of the five-dimensional theory, put in to make λ_5 dimensionless.

For a product of δ circles (a torus T^δ with radii R_i), each tuple of integers n_i gives a field with $m^2 = \sum_i n_i^2/R_i^2$. Figure 1 is the case of two circles.

Figure 1 The KK tower of two circles ($R_1 \geq R_2$). Each point is a four-dimensional field (horizontal n_1, vertical the mass). Varying E (dashed) and the ratio of radii changes the fields below E



E·R₁ = 3.00, R₂/R₁ = 0.30, fields below E: 7 (Weyl estimate 8.5), the thin direction is not yet visible

Table 1 The number of four-dimensional fields of mass at most E (including the zero mode). In brackets the Weyl estimate $\pi R_1 R_2 E^2$ (the area $4\pi^2 R_1 R_2$ times $E^2/4\pi$; the detour of 1-10)

R_2/R_1	$ER_1 = 2$	**5**	**10**	**30**
1	13 (12.6)	81 (78.5)	317 (314.2)	2821 (2827.4)
0.1	5 (1.3)	11 (7.9)	23 (31.4)	267 (282.7)
One circle	5	11	21	61

Computed The numbers of Table 1 and Figure 1 were computed on this machine (the figure is drawn on the spot from formula (3)). If JavaScript is disabled, see Table 1.

The row $R_2/R_1 = 0.1$ is the same as one circle for $ER_1 \leq 5$, and the thin direction first appears at $E \gtrsim 1/R_2$. The count grows as E to the power of (the number of visible extra dimensions).

03 The lowest rung of the tower — the first eigenvalue and the diameter

The lowest rung $1/R$ can be restated as an inequality. For a periodic function with mean 0, $f = \sum_{n\neq 0} c_n e^{iny/R}$, Parseval's identity gives (Wirtinger's inequality) Known

$$\int_0^{2\pi R} |f'|^2\,dy = 2\pi R \sum_{n\neq 0} \frac{n^2}{R^2}|c_n|^2 \;\geq\; \frac{1}{R^2}\int_0^{2\pi R} |f|^2\,dy \qquad (4)$$

This is the simplest example of the Poincaré inequality of 2-05 § 08 and 1-10 § 07, and the best constant R^2 is the reciprocal of the gap $1/R^2$ (the square of the lowest rung of the tower).

Measuring lengths — metric, diameter, Laplacian

To replace the circle by a general compact manifold K (1-05) we need a way of measuring lengths. An inner product given on each tangent space (1-05 § 06), varying smoothly from point to point, is called a **metric**. It is a way of measuring lengths and angles. With a metric we can measure the lengths of curves, and the length of the shortest path joining two points is their distance. The maximum of that distance over all pairs of points is the **diameter** d (for a circle of circumference $2\pi R$, $d = \pi R$; the d of this chapter is the diameter, not the spacetime dimension d of other chapters). The size of the gradient of a function, $|\nabla f|$, is also fixed by the metric, and the operator $-\Delta_K$ with $\int_K |\nabla f|^2 = \int_K \bar{f}\,(-\Delta_K f)$ is called the **Laplacian** (the Laplace–Beltrami operator). On a flat torus, in coordinates y_i measured by length, $-\Delta_K = -\sum_i \partial^2/\partial y_i^2$.

If spacetime is the unwarped product $\mathbb{R}^{1,3} \times K$ and the field is a scalar, expanding in the eigenfunctions of $-\Delta_K$ (eigenvalues $0 = \lambda_0 < \lambda_1 \le \cdots$) gives $m_j^2 = \lambda_j$. The first KK mass is the minimum of the Rayleigh quotient (1-10 § 06).

$$m_1^2 = \lambda_1(K) = \inf\left\{ \frac{\int_K |\nabla f|^2}{\int_K |f|^2} \;:\; \int_K f = 0,\ f \not= 0 \right\} \tag{5}$$

For form or spinor fields, or in warped backgrounds, it becomes the eigenvalue of another operator (the Hodge Laplacian, the Dirac operator and so on). In this chapter we restate "extra dimensions are invisible" as the Poincaré inequality on the part without the zero mode, $\int |\nabla f|^2 \ge \lambda_1 \int |f|^2$.

When the diameter suffices — Ricci curvature

Multiplying the metric by s^2 (multiplying all lengths by s) multiplies λ_1 by s^{-2}, so shrinking raises the tower. That "small" may be measured by the diameter d alone is a theorem when the Ricci curvature is non-negative.

Ricci curvature, as a metaphor, is the average of how much a bundle of geodesics (locally shortest paths) leaving a point around one direction gathers together as it goes. On a sphere it is positive (meridians gather at the poles), on a flat torus 0, on a saddle-shaped surface negative (they spread). More precisely, for a direction v of length 1, it is the sum $\mathrm{Ric}(v,v) = \sum_i K(v, e_i)$ of the bending (sectional curvature) of the $n-1$ sections spanned by v and the directions e_i orthogonal to v, which is $n-1$ times the average. In two dimensions there is a single section, so it is the same as the Gauss curvature. The bending itself is the curvature in the sense of 1-07 § 05 (the

discrepancy after going round a small loop) when the bundle of tangent spaces is given the connection fixed by the metric. $\mathrm{Ric}_K \geq 0$ is the condition that this sum is at least 0 at every point in every direction Known .

$$\mathrm{Ric}_K \geq 0 \implies \lambda_1(K) \geq \frac{\pi^2}{d^2} \qquad \text{(Zhong–Yang; equality only for the circle: Hang–Wang)} \,($$

Table 2 The ratio $\lambda_1 d^2/\pi^2$. (6) says it is at least 1 Computed

K	Ratio	K	Ratio
Circle	1	Square torus	2
Rectangular torus 1×0.2	1.04	Hexagonal torus	1.7778
Rectangular torus 1×0.05	1.0025	Spheres S^2, S^3, S^6	2, 3, 6

The tori were computed numerically and agree to 5 digits with the closed forms (rectangle $1+\rho^2$, hexagon $16/9$). The spheres are known values.

For thin tori the ratio approaches 1 but does not reach it. The curvature condition cannot be dropped. Join two spheres by a thin neck and put into (5) a function that is $+1$ on one and -1 on the other: the numerator comes only from the neck, so making the neck thinner leaves the diameter nearly unchanged while the Rayleigh quotient becomes as small as we like. At the base of the neck the curvature becomes strongly negative, and $\mathrm{Ric} \geq 0$ fails. This is a well-known example Known .

04

Kaluza and Klein — charge is momentum around the circle

The idea of extra dimensions goes back to Kaluza and Klein in the 1920s (the introduction of the PDG). Five-dimensional spacetime also has a metric in the sense of § 03 (in spacetime, what corresponds to the inner product at each point has, like the $\eta = \mathrm{diag}(-1,1,1,1)$ of 2-04, exactly one negative sign, and it may vary from point to point). Its 15 components split into 10 for the four-dimensional metric $g_{\mu\nu}$, 4 for a vector A_μ and 1 for a scalar ϕ. Rewriting formulas 5 and 8 of the review by Overduin–Wesson with signature $(-,+,+,+,+)$ gives[Note 1]

$$ds^2 = g_{\mu\nu}dx^\mu dx^\nu + \phi^2\left(dy + \kappa A_\mu dx^\mu\right)^2, \qquad \kappa = \sqrt{16\pi G} \quad (7)$$

The **Einstein equations** are the equations of gravity that tie the bending (curvature) of the metric to the energy of matter. Here we do not go into their content and use only the counting of components. If no component depends on y, the five-dimensional Einstein equations split into 10+4+1=15 four-dimensional equations (ibid. formula 6). Setting ϕ constant, among the 15 the equations for the metric and vector components become the four-dimensional Einstein equations and Maxwell's equations (ibid.

formula 7) Known . But the remaining scalar equation is compatible with $\phi =$ constant only when $F_{\mu\nu}F^{\mu\nu} = 0$ (pointed out by Jordan and Thiry, ibid. § 3.4). The change of coordinates $y \mapsto y + \kappa\lambda(x)$ induces $A_\mu \mapsto A_\mu - \partial_\mu\lambda$, and the gauge transformation (2-03) appears as a re-choice of the coordinate in the direction of the circle.

Klein (1926) connected Kaluza's theory with wave mechanics (abstract) and made the circle small. The momentum n/R of the n-th component in (2) becomes, under (7), a charge (ibid. formula 25, $\phi = 1$).

$$q_n = \frac{n\sqrt{16\pi G}}{R}, \qquad n \in \mathbb{Z} \quad (8)$$

Charge is restricted to integer multiples of q_1 (the title of Klein's short communication of the same year is 'The Atomicity of Electricity as a Quantum Theory Law'). As a metaphor, charge is momentum around an invisible circle; more precisely, it is the momentum n/R times a constant κ fixed by convention.

Setting $q_1 = e$ ($e^2/4\pi = \alpha \approx 1/137.036$) gives $R = 2\ell_P/\sqrt{\alpha} \approx 3.8 \times 10^{-34}$ m (about 23 times the Planck length), and the first rung of the tower is $1/R \approx 5.2 \times 10^{17}$ GeV, about 10^{21} times the electron mass Computed . Overduin–Wesson, taking the radius as the Planck length, estimate the discrepancy at about 22 orders of magnitude, and write that it 'played a large role in the abandonment of five-dimensional Kaluza-Klein theory'. If the internal space has a non-abelian symmetry, non-abelian gauge fields can come out (17-07) Physics .

05

The six dimensions of strings — curling up into Calabi–Yau

Spacetime in superstring theory is ten-dimensional (17-05 § 06), so to make it look four-dimensional a six-dimensional internal space K is needed. Candelas–Horowitz–Strominger–Witten (1985) studied vacua leaving one supersymmetry in four dimensions, and wrote in the abstract 'This condition permits only a few possibilities'. The K satisfying the condition is said to be a Kähler manifold with Ricci curvature 0 (a complex manifold whose metric and complex structure mesh) whose holonomy (1-07) lies in SU(3): a **Calabi–Yau manifold** Physics .

That such metrics exist is a mathematical theorem. Yau announced in 1977 'We announce a proof of Calabi's conjectures on the Ricci curvature of a compact Kähler manifold' (the paper is from 1978). As a consequence, a compact Kähler manifold with vanishing first Chern class has a Ricci-flat Kähler metric Known . If it is Ricci-flat, (6) applies, so the scalar KK tower on a Calabi–Yau of diameter d starts above π/d.

On the size, the introduction of the PDG writes 'The extra dimensions were supposed to be compactified at a scale close to the Planck scale, and thus not testable experimentally in the near future'. The shape affects the particle content (the model of CHSW has 'an E6 gauge group with four standard generations of fermions').

06

Confining to a brane — ADD and RS

In 1998, Arkani-Hamed–Dimopoulos–Dvali (ADD) proposed a way of hiding in which the fields of the Standard Model are confined to a three-dimensional membrane (a 3-brane) and only gravity spreads into $4+\delta$ dimensions. Since they can be probed only by gravity, the extra dimensions may be large. The abstract reads 'The observed weakness of gravity on distances $\gtrsim 1$ mm is due to the existence of n ≥ 2 new compact spatial dimensions large compared to the weak scale' Physics . The weakness of gravity is the same dilution as the λ_4 of § 02, and the fundamental scale M_D and the reduced Planck mass $M_P \approx 2.4 \times 10^{18}$ GeV are related by (PDG formula 84.10)

$$M_P^2 = R^{\delta} M_D^{2+\delta} \quad (9)$$

Table 3 R fixed by (9) (reproducing the "10^9 km, 0.5 mm, ..., 0.1 MeV^{-1}" of PDG formula 84.11) Computed

δ	$M_D = 1$ TeV	$M_D = 4$ TeV
1	1.2×10^{12} m	1.8×10^{10} m
2	4.8×10^{-4} m	3.0×10^{-5} m
6	2.6×10^{-14} m	4.2×10^{-15} m

$\delta = 1$ is the size of the solar system, 'clearly ruled out' (PDG), and $\delta = 2$ gives 0.5 mm. The next year, 1999, Randall–Sundrum (RS) used a slice of five-dimensional anti-de Sitter space (PDG formula 84.16).

$$ds^2 = e^{-2ky}\eta_{\mu\nu}dx^{\mu}dx^{\nu} + dy^2, \qquad 0 \leq y \leq \pi R \quad (10)$$

Anti-de Sitter space is a spacetime of constant negative curvature (17-08). The metric (10) is the slice $0 \leq y \leq \pi R$ of that spacetime with curvature radius $1/k$. Scales at the end $y = \pi R$ are redshifted by a factor $e^{-k\pi R}$. The PDG writes that $k \sim M_P$ and $R \simeq 11/k$ give the TeV; at $kR = 11$, $ke^{-k\pi R} \approx 2.4$ TeV, and changing kR from 10 to 12 moves it from 55 TeV to 0.1 TeV Computed . Making a large ratio with an exponential resembles dimensional transmutation (17-01). More precisely, in RS the exponent comes from geometry (kR), in dimensional transmutation from the running of the coupling ($1/g^2$). The view that connects warped extra dimensions with strongly coupled four-dimensional theories is AdS/CFT (17-08), at the level of a conjecture Physics .

Detour: extra dimensions without a gap

A subsection you may skip.

The paper of RS from the same year argued that four-dimensional gravity can be reproduced even if the extra dimension is infinitely long: 'even without a gap in the Kaluza-Klein spectrum, four-dimensional Newtonian and general relativistic gravity is reproduced to more than adequate precision' Physics . A gap in the tower is not essential for invisibility.

07

Experimental lower bounds — Newton's law and colliders

Deviations from Newton's law are by custom expressed in Yukawa form (PDG formula 84.12).

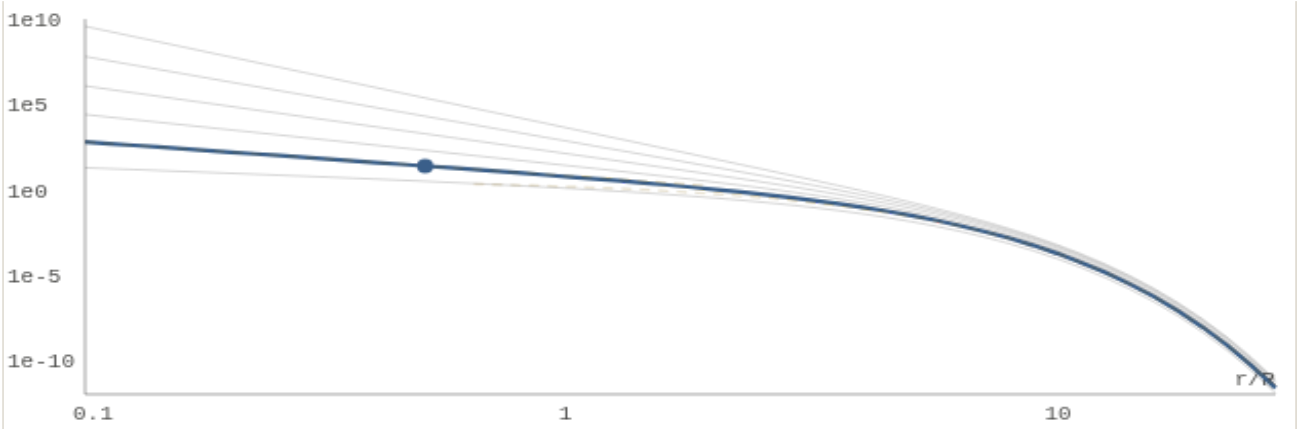
$$V(r) = -G_N \frac{m_1 m_2}{r}\left(1 + \alpha\, e^{-r/\lambda}\right) \quad (11)$$

The exchange of a field of mass m gives a Yukawa potential e^{-mr}/r, and one term is added for each KK mode. In a scalar (Newtonian) model, summing the whole tower of T^δ (radius R) gives

$$\frac{V(r)}{V_{\mathrm{N}}(r)} = \sum_{k \in \mathbb{Z}^\delta} e^{-|k|\, r/R} \xrightarrow{\;r \gg R\;} 1 + 2\delta\, e^{-r/R} \quad (12)$$

2δ is the number of fields on the first rung; for $\delta = 1$ the sum is $\coth(r/2R)$. For $r \ll R$, $V \propto r^{-1-\delta}$: the law of a space of $3+\delta$ dimensions. For the graviton the coefficient changes. The KK modes of the graviton are massive spin-2 fields, and the contribution of their polarisations is said to multiply the coefficient of the first rung by 4/3; the PDG takes, for a two-dimensional torus, $\alpha = 16/3$ (4/3 of the 4 in (12)) and $\lambda = R$ Physics . (12) is not the formula for gravity itself but a model for seeing how summing the tower produces a Yukawa-type deviation.

Figure 2 $V/V_{\mathrm{N}} - 1$ of (12) (log scale). Varying δ and r/R changes the deviation and the dimension of space that can be read off. The dashed lines are two approximations



```
δ = 2  r/R = 0.501  V/V_N = 25.13, readable dimension of space ≈ 5.0 (3 far away, 5)
```

Table 4 The ratio V/V_{N} of (12)

δ	$r/R = 0.1$	**1**	**10**
1	20.02	2.164	1.000091
2	628.3	6.507	1.000184
6	3.72×10^{9}	3721	1.000593

Computed The numbers of Figure 2 and Table 4 were computed on this machine (sums over $|k| \le 420$; $\delta = 1$ agrees with $\coth$ to 12 digits, and $r \to 0$ with the integral approximation to 5 digits). If JavaScript is disabled, see Table 4.

That the deviation vanishes as $e^{-r/R}$ for $r \gg R$ is the quantitative content of "invisible".

Table 5 Lower bounds from PDG 2025 (lengths converted with (1) Computed)

What was searched for	Lower bound
Inverse-square law (torsion balance)	For $\delta = 2$, $R < 30$ μm, $M_D > 4.0$ TeV
Supernova SN1987A / neutron stars	For $\delta = 2$, $M_D > 27$ / 1700 TeV
Graviton emission at the LHC (ATLAS / CMS)	$M_D > 5.9$–11.2 / 5.5–10.7 TeV ($\delta = 2$–6)
The lightest KK graviton of RS	ATLAS 4.5 TeV ($k/M_P = 0.1$), CMS 2.2–5.6 TeV
Gauge fields propagating in flat extra dimensions	$1/R > 4.16$ TeV (a reinterpretation by ATLAS; 4.7×10^{-20} m), $\gtrsim 6$ TeV from LEP2
All fields propagate (UED)	$1/R > 1.4$–1.5 TeV. The minimal model is excluded together with dark matter

One of the inverse-square-law experiments (Tan et al. 2016) confirms $|\alpha| \le 1$ down to $\lambda = 59$ μm (abstract). The observed gauge fields are four-dimensional down to about 5×10^{-20} m, and gravity follows the inverse-square law down to some tens of μm. Extra dimensions have not been found, but neither has it been shown that there are none.

08
```

Back to Yang–Mills — the KK gap is not the mass gap

The KK gap is not the mass gap. The lowest rung of the tower is a gap that comes only from the internal space being compact; free fields have it too, and the zero mode has no gap. It is the same computation as the gap of a free field in a box (2-02 § 06, 2-05 § 06). What the prize problem asks for is a gap arising from interaction on $\mathbb{R}^4$, which has no compact directions (4-11), and Jaffe–Witten write 'no present ideas point the direction to establish the existence of a mass gap that is uniform in the volume'.

Do not mix the two kinds of extra dimensions. The lower bounds of § 07 concern real extra dimensions. The extra dimensions of holographic models (17-08, 17-09) (the radial direction of anti-de Sitter space, S^5, the auxiliary circle of Witten's model) are tools of a dual description or of regularisation, and are not claimed to be real dimensions.

Within the models the tower is visible. In models that read the gap from geometry, the KK tower of the extra dimensions comes at the same height as the glueballs (in the Maldacena–Núñez model of $\mathcal{N} = 1$ supersymmetric Yang–Mills, if the gravity approximation is valid, 'comparable to the masses of Kaluza Klein states'; the authors also write that quantising the string on this background might allow the KK states to be separated) Physics . Removing the tower requires shrinking the extra dimensions, and then the coupling becomes weak (in four dimensions, because of asymptotic freedom), which is the opposite side from the region where the computation works (Csáki et al., of Witten's three-dimensional model: 'This is the opposite of the limit that is required for the supergravity description to be valid'). The order of limits is treated in 17-10.

Seam

What can be said as a theorem about "invisible" is only about linear fluctuations on a fixed internal space ((4)–(6)). Within the range we searched we found no result justifying that the tower separates in an interacting theory, in particular in the limit that returns to four dimensions.

Note 1 Overduin–Wesson take the four-dimensional signature $(+,-,-,-)$ and set $\kappa \equiv 4\sqrt{\pi G}$ (formula 8). (7) is aligned with this book's signature $(-,+,+,+)$, and $\kappa = \sqrt{16\pi G}$ is the same value. Back to text

What this chapter can say

What is said	What is not said
Known (2)–(8), Yau's theorem.	General lower bounds for towers in warped backgrounds or of forms and spinors. The consistency of keeping ϕ constant (the scalar equation requires $F_{\mu\nu}F^{\mu\nu} = 0$).
Computed Tables 1–5, Figures 1 and 2, Klein's radius, reproducing the numbers of the PDG with (9).	(12) is a scalar model. The 16/3 for the graviton is quoted from the PDG; the origin of the factor 4/3 is not derived in this chapter.
Physics The Calabi–Yau condition, ADD and RS, non-abelian gauge fields, the height of the towers in the models.	Whether real extra dimensions exist. That the towers of the models separate in the limit returning to four dimensions. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit: Volume 2).

Next chapter to read: 17-07 Where gauge fields come from — extracting gauge groups from branes and geometry.

Where gauge fields come from — the group is read off from the number of branes, a lattice, the shape of a singularity

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — Four mechanisms by which, on the side of extra dimensions, the gauge group becomes an output (symmetries of the internal space, stacked branes, an internal lattice of the string, collapsing spheres). That the positions of branes become eigenvalues of matrices, and that ADE comes out of the linear algebra of "negative definite". The road down to pure Yang–Mills, and the expectations it relies on.

Prerequisite chapters — 17-06 How extra dimensions become invisible. We use roots (1-04), holonomy (1-07) and the central charge (17-05). Intersection numbers and lattices are defined on the spot.

Said first — All the mechanisms are at the level of physics, and neither string theory nor M-theory has a mathematical definition. That a group comes out of geometry and that the four-dimensional quantum Yang–Mills theory exists and has a mass gap are different questions. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. Is the group an input or an output? — four sources
2. Symmetries of the internal space — non-abelian Kaluza–Klein
3. Strings on branes — N branes give U(N)
4. Positions become matrices — eigenvalues are brane positions
5. The heterotic string — a 16-dimensional lattice (Detour: the same tower, different groups)
6. Compactifying on Calabi–Yau — the commuting part

7. Collapsing spheres and ADE — negative definiteness
8. Folding and geometric engineering
9. From eleven dimensions to pure Yang–Mills — two circles and an expectation
10. Back to Yang–Mills — the group is not where the difficulty lies

01

Is the group an input or an output? — four sources

In four-dimensional Yang–Mills theory the gauge group G is an input chosen by hand. The text of the prize problem (Jaffe–Witten) too says 'for any compact simple gauge group G', allowing any of the list in 1-04 (0-03). In theories with extra dimensions the group becomes an output, read off from something else Physics .

Symmetry	Number of branes	Lattice	Singularity
Isometries of the internal space § 02	N D-branes give U(N) § 03–04	The 16 left-over dimensions of the heterotic string § 05–06	The arrangement of collapsing spheres gives ADE § 07–08

What any of these roads fixes is the set of fields and the group seen at low energy, not the existence of a four-dimensional quantum theory. Of the four, three (branes, lattice, singularity) are stories within supersymmetric settings (theories with a symmetry exchanging bosons and fermions), and what that means for pure Yang–Mills we look back on in § 10.

02

Symmetries of the internal space — non-abelian Kaluza–Klein

In 17-06 § 04 the rotation of the circle became U(1). If the group $\mathrm{Isom}(K)$ of transformations of the internal space K that do not change distances (isometries) is large, each of its infinitesimal generators (Killing vector fields) gives one gauge field, and the commutators of the generators become the structure constants (1-03) Physics . For the generators of rotations of a sphere, $L_a = \varepsilon_{abc} x_b \partial_c$,

$$[L_a, L_b] = -\varepsilon_{abc}\, L_c, \qquad \dim SO(n+1) = \frac{n(n+1)}{2} \quad (1)$$

(the left formula was checked numerically Computed); S^n gives $n(n+1)/2$ gauge fields, and $\mathbb{CP}^2$ (the set of all complex lines through the origin of $\mathbb{C}^3$; real dimension 4) gives the 8 gauge fields of SU(3) Known . An example of a seven-dimensional space whose isometry group is locally (as a Lie algebra) SU(3)×SU(2)×U(1) (3-07) is $\mathbb{CP}^2 \times S^2 \times S^1$ ($4+2+1=7$ dimensions), and together with four dimensions the whole is $4+7=11$-dimensional.

Witten (1981) studied the road of compactifying eleven-dimensional supergravity on seven-dimensional spaces, and wrote in the abstract 'It is possible to obtain an SU(3) × SU(2) × U(1) gauge group, but the proper fermion quantum numbers are difficult to achieve'. The seven-dimensional spaces Witten studied are not necessarily the same as the example above.

03

Strings on branes — stacking N gives U(N)

Impose on open strings a boundary condition attaching their ends to a subspace, and that subspace is a **D-brane** (Polchinski 1995: 'extended objects defined by mixed Dirichlet-Neumann boundary conditions in string theory') Physics . One with p spatial dimensions is called a Dp-brane. Labelling the two ends of a string with brane numbers $1,\dots,N$, the states have $N\times N$ matrices as coefficients, and the massless vectors form the adjoint representation of U(N) (1-04) (Polchinski's lectures of 1996: 'this global symmetry of the world-sheet theory is elevated to a gauge symmetry in spacetime'). There are N^2 kinds of strings, and $\dim U(N) = N^2$.

Separating the branes makes the strings between them heavy (Witten 1995b § 3; T is the string tension, a_i the positions of the branes).

$$m_{ij} = T\,|a_i - a_j| \quad (2)$$

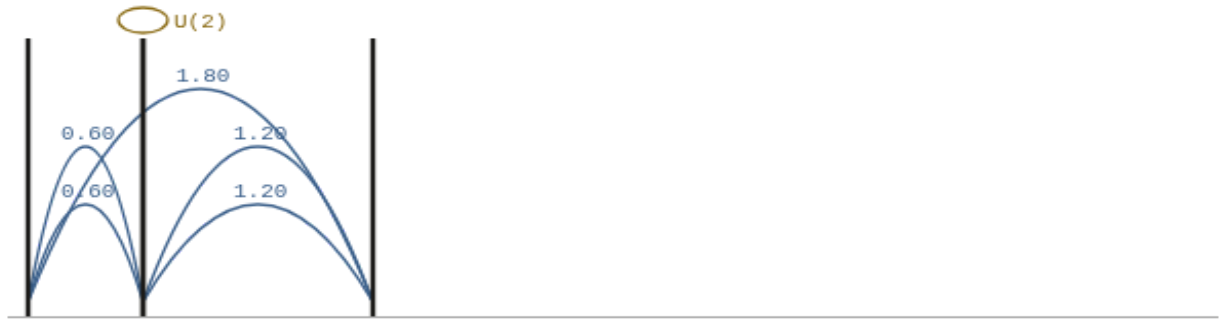
If they are stacked $n_1, n_2, \dots$ at a time, the remaining group is $U(n_1)\times U(n_2)\times\cdots$, and

$$\#\{\text{massless vectors}\} = \sum_k n_k^2, \qquad \#\{\text{heavy W}\} = N^2 - \sum_k n_k^2 \quad (3)$$

(the same count appears in Polchinski's lectures). Separating branes is the Higgs mechanism seen from the side of geometry. More precisely, when the adjoint scalars X^i of § 04 take diagonal values $\mathrm{diag}(a_1,\dots,a_N)$, the off-diagonal gauge fields acquire the masses (2). This mechanism, in which the values of scalars make gauge fields heavy, is called the Higgs mechanism (3-07) Physics .

Figure 1 Varying the spacings d_1, d_2, d_3 of four branes (vertical lines) changes the remaining group and the W masses. Arcs are heavy strings (numbers are mass/T); the loops at the top are strings between stacked branes. A

heavy string has two orientations ($i \to j$ and $j \to i$), so each arc, each mass, counts as 2



```
Group U(2)×U(1)², massless 6, heavy 10, W masses/T (2 each): 0.60, 0.60, 1.20, 1.20, 1.80
```

Table 1 How four branes are stacked, and the numbers in (3) (a heavy string has two orientations, so 2 for each W mass)

Stacking	4	3+1	2+2	2+1+1	1+1+1+1
Remaining group	U(4)	U(3)×U(1)	U(2)×U(2)	U(2)×U(1)²	U(1)⁴
Massless / heavy	16 / 0	10 / 6	8 / 8	6 / 10	4 / 12

Computed Table 1 was counted on this machine, and Figure 1 is drawn on the spot from (2)(3). If JavaScript is disabled, see Table 1.

The W masses of four separated branes are d_1, d_2, d_3 and their consecutive sums, 6 in all: the relation between the 3 simple roots and the 6 positive roots of SU(4) (A_3). In § 07 the same structure appears as the areas of spheres.

04

Positions become matrices — the theory on the branes

The theory on stacked branes is 'the dimensional reduction of ten-dimensional supersymmetric Yang-Mills theory with gauge group U(n) from ten to p+1 dimensions' (Witten 1995b § 3) Physics . Splitting the components of the ten-dimensional gauge field into directions along the branes and perpendicular to them gives

$$A_M = (A_0, \dots, A_p;\, X^{p+1}, \dots, X^9), \qquad V = -\frac{T^2}{2} \sum_{i,j} \operatorname{tr}\left([X^i, X^j]^2\right) \;\geq 0 \quad (4)$$

where X^i are the $9-p$ scalars in the adjoint representation ($N \times N$ Hermitian matrices), and V is their potential. Since X is Hermitian, $[X^i, X^j]$ is anti-Hermitian and $\operatorname{tr}[X^i, X^j]^2 \leq 0$. Therefore $V \geq 0$. If $V = 0$, the matrices can be diagonalised simultaneously, and Witten reads the diagonal entries as the positions of the branes. The off-diagonal entries are the strings between branes, and the eigenvalues of the map $\delta \mapsto \sum_k [X^k, [X^k, \delta]]$ are $|a_\lambda - a_\mu|^2$ (times T^2, the square of (2)). We checked agreement within 4×10^{-15} on an example of two directions conjugated by a unitary matrix Computed .

On D3-branes the theory is four-dimensional $\mathcal{N} = 4$ U(N) supersymmetric Yang–Mills with 6 scalars and fermions (the starting point of 17-08), not pure Yang–Mills. The matrix indices have the same structure as the double lines of 17-04.

05

The heterotic string — a 16-dimensional lattice becomes a group

The heterotic string is a closed string whose right-movers follow the ledger of the superstring (central charge 15) and whose left-movers follow that of the bosonic string (26) (17-05 § 06, Gross–Harvey–Martinec–Rohm 1985). The left-movers are 16 short of the 10 of flat ten dimensions; Polchinski's lectures (1994), on the supersymmetric heterotic string, write 'an additional (0, 16) is needed from another unitary CFT', and go on to say that the only solutions are $E_8 \times E_8$ or SO(32) Physics .

A 16-dimensional lattice

In the lattice picture this 16 is seen as a torus $\mathbb{R}^{16}/\Gamma$ on which 16 left-moving bosons are wound Physics . The momentum P lies on the lattice Γ, and the states with $P \cdot P = 2$ become massless vectors. On the heterotic string wound on a torus, Witten (1995 § 4.6) writes 'The gauge symmetry is extended precisely when $V^\perp$ contains some P of $d_P = 1$'. Witten's $V^\perp$ is the space of left-moving charges. Witten takes the sign of the inner product opposite to this chapter and writes $d_P = -(P,P)/2$, so $d_P = 1$ corresponds to $P \cdot P = 2$ in this chapter's sign. Γ must be **even** (every $P \cdot P$ even) and **self-dual** (the points having integer inner product with all points are exactly Γ). This condition is said to come from the requirement that the one-loop amplitude, whose world sheet is a torus, not depend on how the shape of the torus is chosen (modular invariance), and Polchinski's lectures also write 'The constraints of modular invariance are strong'.

$$\dim G = 16 + \#\{P \in \Gamma : \ P \cdot P = 2\} \quad (5)$$

There are only two even self-dual lattices in 16 dimensions Known . Both can be written as "$x \in \mathbb{Z}^n \cup (\mathbb{Z} + \frac{1}{2})^n$ with $\sum x_i$ even": two copies of $n = 8$ side by side give $E_8 \oplus E_8$, and $n = 16$ gives D_{16}^+. Both have 480 roots, and (5) is 496, but joining roots with non-zero inner product, the former splits into two sets of 240 ($E_8 \times E_8$) and the latter is connected ($\mathfrak{so}(32)$) Computed . The ten-dimensional group is written precisely as $\mathrm{Spin}(32)/\mathbb{Z}_2$. $\mathrm{Spin}(32)$ is the double cover of SO(32), the same relation as SU(2)→SO(3) in 1-02 (the $\mathbb{Z}_2$ divided out is a different element from the one that returns to SO(32)). The lattice spanned by the roots of D_{16}^+ is a sublattice of index 2 in D_{16}^+, and this $/\mathbb{Z}_2$ is said to correspond to that difference.

Seen from eleven dimensions, Hořava–Witten **proposed** that the two E_8 sit one on each of the walls at the two ends of the segment $S^1/\mathbb{Z}_2$ (the 1995 abstract says 'We propose'; the 1996 abstract writes that the group is fixed to 'a copy of E8 for each boundary component', explicitly presupposing 'the hypothesis that there is a consistent quantum M-theory') Physics .

Detour: the same tower, different groups

A subsection you may skip.

The eigenvalues of the Laplacian on a flat torus $\mathbb{R}^n/\Gamma$ are $4\pi^2\, v\cdot v$ for each point v of the dual lattice (the n-dimensional version of 17-06 § 02) Known ; if the lattice is self-dual, the number on each rung of the KK tower is the number of points of squared length $2k$. Counting, $E_8 \oplus E_8$ and D_{16}^{+} both give 480, 61920 and 1050240 for $k = 1, 2, 3$, agree on every rung with $k \le 6$, and also agree with $480\,\sigma_7(k)$ (σ_7 is the sum of the 7th powers of the divisors) Computed .

It is known that they agree on every rung, and Milnor (1964) is said to have given these two tori as an example of being non-isometric although their eigenvalues agree including multiplicities Known . The tower is the same, but the groups carried by the heterotic string differ.

06

Compactifying on Calabi–Yau — holonomy and the commuting part

To bring $E_8 \times E_8$ down to four dimensions, compactify on a six-dimensional Calabi–Yau manifold K (17-06 § 05). The holonomy of K (1-07) lies in SU(3), and in the standard construction the holonomy of the gauge field is said to be aligned with an SU(3) inside E_8 too Physics . A gauge transformation visible in four dimensions is a g constant over all of K that is unchanged by parallel transport along every closed path, that is, it must commute with every element of the holonomy Known .

$$G_4 = \{\, g \in E_8 :\ gh = hg \ \text{ for all } h \in SU(3) \,\} \quad (6)$$

Of the 240 roots of E_8, 72 are orthogonal to the roots of SU(3), giving E_6 (dimension 78) Computed . The abstract of Candelas–Horowitz–Strominger–Witten (1985) writes 'a model that in four dimensions has an E6 gauge group with four standard generations of fermions'.

Table 3 The part of E_8 that commutes with SU(n) (248 = remaining group + SU(n) + remainder)

Holonomy	SU(2) (K3)	SU(3) (Calabi–Yau)	SU(4)	SU(5)
Remaining group	E_7	E_6	SO(10)	SU(5)
Breakdown	133+3+112	78+8+162	45+15+188	24+24+200

Computed Table 3 was counted by building the 240 roots of E_8 in coordinates; the types were fixed by rank, number of roots and the determinant of the Cartan matrix.

The remaining 162 are $\mathbf{2}\times\mathbf{27}\times\mathbf{3}$ (pairs of the 27-dimensional representation of E_6 and the 3-dimensional one of SU(3), and their conjugates), and the four-dimensional fermions are said to come from here.

07

Collapsing spheres and ADE — the linear algebra of negative definiteness

A **K3 surface** is a Calabi–Yau manifold of complex dimension two (real dimension four), with holonomy SU(2) (the left end of Table 3) Known . Witten (1995 § 4.6), on the correspondence between the heterotic string wound on a torus and the IIA string wound on a K3 surface, writes 'Whenever the heterotic string on a four-torus gets an enhanced gauge group G, the corresponding K3 gets an orbifold singularity of type G' Physics . Then 'a configuration of r two-spheres S_i (with an intersection matrix given by the Dynkin diagram of G) collapses to a point' (Dynkin diagrams are defined later in this section), and each sphere gives one U(1). The W bosons are two-dimensional membranes wrapped on the collapsing spheres (as described in Bershadsky–Sadov–Vafa 1996 § 1). Their mass is said to be the tension of the membrane times the area of the sphere, the same form as the $T|a|$ of § 03.

Intersection numbers and negative definiteness

Why only ADE? Look at the **intersection numbers** $M_{ij}=S_i\cdot S_j$ of the spheres. For two spheres this is the sum over intersection points counted with orientation signs ±1. The intersection number of a sphere with itself (the self-intersection number) counts in the same way the intersection points with a slightly shifted copy, and for spheres in K3 it is -2 Known . Defining the "inner product" of classes of spheres by this intersection number, on K3 the inner product is positive in three directions and negative in nineteen (signature $(3,19)$) Known . According to Witten, in the collapsing limit the classes of the spheres lie in the subspace $V^{\perp}$ on which this inner product is negative definite, so M is negative definite ($x^{\mathsf T}Mx<0$ for every $x\neq0$). The collapsing spheres S_i can be taken to be **holomorphic curves** (curves of complex dimension one, locally the zero sets of holomorphic functions of complex coordinates), and intersection points of distinct holomorphic curves all count as positive because of the complex structure, so $M_{ij}\geq0$ Known . With $x=e_i+e_j$, $-4+2M_{ij}<0$ gives $M_{ij}\leq1$. Hence $M=-(2I-A)$, where A is the adjacency matrix of the graph whose vertices are the spheres and whose edges are the intersections. This graph is called the **Dynkin diagram** (those that appear here are of "simply laced" type, all edges single). We need the following.

$$x^{\mathsf{T}}(2I - A)\,x = 2\sum_i x_i^2 - 2\sum_{\text{edges } ij} x_i x_j \;>\; 0 \qquad (x \;/= 0) \quad (7)$$

If the graph is not connected we consider each component (the group is a product over components). If a connected graph has a cycle, the vector equal to 1 on the cycle makes the left-hand side at most 0, so it must be a tree. Examining the 201 trees with at most 10 vertices, only types A (a straight line), D (forked at one end) and E_6, E_7, E_8 remained (Table 4) Computed . That these are the only ones for any number of vertices is known as part of the classification of simple Lie algebras (1-04) Known .

Figure 2 Choosing a type changes the arrangement of collapsing spheres (circles are spheres, lines are intersections), the smallest eigenvalue of (7) and the dimension of the group. "Fold" shows by colour the orbits of the permutations of § 08

E₈: 8 spheres, 240 roots, group dimension 248, smallest eigenvalue 0.010956 (positive definite)

Table 4 The number of trees with n vertices, and the types satisfying (7) (for $n \le 3$ only the straight line)

n	4	5	6	7	8	9	10
Number of trees	2	3	6	11	23	47	106
Types satisfying it	A D	A D	A D E	A D E	A D E	A D	A D

Computed The numbers of Table 4 and Figure 2 were computed on this machine. The smallest eigenvalue agrees to 6 digits with $2 - 2\cos(\pi/h)$ (h is the number of roots ÷ the rank), and the figure is drawn with this formula. One beyond E_8 there is an integer vector making (7) 0 (centre 6, arms 3 / 4, 2 / 5, 4, 3, 2, 1). If JavaScript is disabled, see Tables 4 and 5.

08

Folding and geometric engineering — A to G are all there

ADE are only the types whose roots have equal lengths. B, C, F and G come out when the singularities are further bundled in another direction. Bershadsky et al. (1996 § 3) write that going once around over another parameter can permute the collapsing spheres by an automorphism of the Dynkin diagram (a permutation of vertices preserving edges), and that then 'the actual gauge group will be smaller', listing the following (the last is the cyclic permutation of three legs) Physics .

$$A_{2n-1} \to C_n, \qquad D_n \to B_{n-1}, \qquad E_6 \to F_4, \qquad D_4 \to G_2 \quad (8)$$

With this every type from A to G comes out of geometry. The number of orbits into which the permutation bundles the positive roots agrees with the number of positive

roots of the folded algebra (Table 5) Computed .

Table 5 Folding: number of orbits of positive roots = number of positive roots of the algebra after

Before → after	$A_5 \to C_3$	$D_5 \to B_4$	$E_6 \to F_4$	$D_4 \to G_2$
Dimension	35 → 21	45 → 36	78 → 52	28 → 14
Positive roots (fixed) → orbits	15 (3) → 9	20 (12) → 16	36 (12) → 24	12 (3) → 6

Computed Table 5 was counted by generating roots from the Cartan matrices ($A_3 \to C_2$, $A_7 \to C_4$ and $D_6 \to B_5$ also agree).

But the same paper notes that 'a given A-D-E singularity may *not* correspond to an enhanced gauge symmetry'. Computing field theories by this mechanism is **geometric engineering**; Katz–Klemm–Vafa (1997) reduced the mathematically established results of four-dimensional $\mathcal{N} = 2$ (17-11) to the T-duality of strings (strings wound on a circle of radius R and on a circle of radius α'/R give the same theory; α' is from (1) of 17-05), and write 'This construction is not based on any duality conjecture' Physics . What it can handle is supersymmetric theories with at least 8 supercharges (17-05 § 07) (corresponding to four-dimensional $\mathcal{N} = 2$ or more); within the range we searched we found no example handling the mass gap of non-supersymmetric pure Yang–Mills by geometric engineering.

09

From eleven dimensions to pure Yang–Mills — two circles

Witten (1998 § 4) describes a road from eleven dimensions down to four-dimensional **pure** Yang–Mills Physics . The starting point is the six-dimensional (2,0) theory on M5-branes (membranes of M-theory extending in five spatial dimensions) ((2,0) is the name of a type of six-dimensional supersymmetry; Witten calls it 'exotic'), which 'can apparently be interpreted' as M-theory on $AdS7 \times S^4$ ($AdS7$ is a seven-dimensional spacetime of constant negative curvature, treated in 17-08) (according to Maldacena's conjecture). No description by a Lagrangian is said to be known, and there is no mathematical definition either. This is wrapped on two circles.

$$(2,0) \xrightarrow{C_1(R_1)} \text{5-dim. } SU(N),\ g_5^2 = R_1 \xrightarrow{C_2(R_2)} \text{4-dim. } SU(N),\ g_4^2 = \frac{R_1}{R_2} \quad (9)$$

Making the fermions antiperiodic (changing sign once around) on C_2, the fermions acquire masses of order $1/R_2$, the scalars too 'very plausibly' become heavy at one loop, and 'If this is so, the low energy theory will be the pure SU(N) theory without supersymmetry'. In terms of the IIA string this is N D4-branes wrapped on $\mathbb{R}^4 \times S^1$, and the theory on the branes of § 03–04 comes down to four dimensions.

Witten writes that he would like to keep $\eta = g_4^2 N$ small, so that the coupling is weak at the scale of the circles and strong at much longer distances. A one-loop rough guide:

putting $b_0 = 11N/(48\pi^2)$ (formula (1) of 17-01), $\mu = 1/R_2$ and $g^2(\mu) = g_4^2 = \eta/N$ into (3) of 17-01 gives

$$\Lambda R_2 \;\sim\; \exp\!\Big(-\frac{24\pi^2}{11\,\eta}\Big) \quad (10)$$

which is 4×10^{-10} for $\eta = 1$ and 0.12 for $\eta = 10$ Computed . The coefficient changes with the convention for the coupling and the choice of $\mu = 1/R_2$, so this is a guide to the order of magnitude. But supergravity can compute only 'at least if η is large', and Witten writes of connecting to small η 'This looks like a tall order'. The order of limits is in 17-10, and how the gap appears as geometry in 17-09.

10

Back to Yang–Mills — the group is not where the difficulty lies

On every road the group comes with extra fields or supersymmetry (the $9-p$ scalars on the branes, the fields of mass $1/R_2$ from the two circles, and so on) Physics . And for the prize problem, the group is not where the difficulty lies. The problem statement allows any compact simple group; what is asked is that its quantum Yang–Mills theory exists on $\mathbb{R}^4$ satisfying the axioms (4-10) and has a mass gap (4-11). Geometry can produce all the names from A to G, but within supersymmetric settings, and the road to pure Yang–Mills (§ 09) relies on expectations and on the order of limits.

Seam

(1) Every construction stands on string theory or M-theory, neither of which has a non-perturbative mathematical definition. (2) Trying to define a four-dimensional theory from the side of extra dimensions makes the definition of the starting point ((2,0) theory and so on) the harder part. (3) Within the range we searched we found no result connecting the group coming out of geometry with the existence of a four-dimensional quantum theory with a gap.

What this chapter can say

What is said	What is not said
Known (1), the commutation of (6), that the diagrams satisfying (7) are limited to ADE, the signature and positivity of the intersection numbers of K3, the classification of 16-dimensional lattices and Milnor's example (the last two: bibliographic data only).	Proofs of the classification and of the properties of intersection numbers are not written.
Computed Tables 1–5, Figures 1 and 2, the eigenvalues around (4), the numbers of (10).	Lattice point counts up to $k \leq 6$. (10) is a one-loop rough guide, and its coefficient may change with convention.
Physics The U(N) of D-branes, the groups of the heterotic string, E_6, the proposal of Hořava–Witten, ADE and folding, geometric engineering, the pure SU(N) of (9).	None is a mathematical theorem. The existence of string theory, M-theory and the (2,0) theory. That the scalars become heavy at one loop. This book does not itself show either the mass gap or the construction of the continuum limit (the published construction of the continuum limit: Volume 2).

Next chapter to read: 17-08 Holography — the $\mathcal{N} = 4$ theory on branes, and the correspondence in which the radial direction becomes scale.

Holography — reading a four-dimensional field theory through the geometry of gravity in one more dimension

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — AdS/CFT is the conjecture that a four-dimensional field theory and a theory of gravity in five dimensions (times a sphere) are the same. That depth from the boundary measures scale, the dictionary linking mass and dimension, Wilson loops computed with a hanging string, and where the line falls for the correspondences that can be written exactly.

Prerequisite chapters — 17-05. We also use the 't Hooft coupling λ of 17-04 and the Nambu–Goto action of 17-03. For D-branes see 17-07. Tools not in the prerequisite chapters, such as the metric, geodesics and sources, are defined on the spot, one line each.

Said first — AdS/CFT is a conjecture, not a theorem. The representative example, $\mathcal{N} = 4$ supersymmetric Yang–Mills theory, is conformal and has no mass gap; it is not pure Yang–Mills theory. There is no example in which holography has shown the mass gap as a mathematical theorem (models with a gap at the level of physics are in 17-09), and this book itself shows nothing about the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. What is claimed (Detour: why "hologram")
2. The two faces of D3-branes
3. Anti-de Sitter space
4. Radial direction = scale — depth measures size (Figure 1)
5. The dictionary — mass and dimension
6. Hanging a string — Wilson loops (Figure 2)

7. Putting in a single scale — a model of the area law
8. Correspondences that can be written exactly — theorems and proposals
9. The distance to Yang–Mills

01

What is claimed — the boundary theory and gravity in the interior

The claim of holography is this. **A field theory without gravity in d dimensions describes, in other words, the same physics as a theory with gravity in $d+1$ dimensions.** The extra dimension is "depth" from the boundary; the former is called the boundary theory and the latter the interior (bulk) theory. The representative example is Maldacena (1997, ATMP 1998; the first year is when it appeared on arXiv, the second the year of the journal).

$$\mathcal{N}=4 \text{ SYM } \left(U(N),\, g_{\mathrm{YM}}\right) \quad \overset{\text{conjecture}}{\Longleftrightarrow} \quad \text{type IIB string theory on } AdS_5\times S^5 \ \left(N,\, g_s\right) \ (1)$$

On the left is four-dimensional $\mathcal{N}=4$ supersymmetric Yang–Mills theory (SYM below), on the right ten-dimensional string theory. **Type IIB** is one of the ten-dimensional superstring theories, differing from the type IIA of 17-05 in the combination of handedness (chirality) of its supersymmetries. The dimensions are 10 = 4 (boundary) + 1 (depth) + 5 (S^5) (17-05 § 09). The original paper writes 'We are led to the conjecture', and (1) is still a conjecture Physics . This chapter deals with the entrance; models in which the mass gap turns into geometry are left to 17-09.

Detour: why "hologram" — counting by area

A subsection you may skip.

The entropy of a black hole is proportional not to its volume but to the area A of its horizon (Bekenstein 1973, Hawking 1975) Known .

$$S/k_B = A/(4\ell_P^2), \qquad \ell_P^2 = G\hbar/c^3 \ (2)$$

For a solar mass the radius is 2953 m and $S/k_B = 1.05\times 10^{77}$, far less than the 2.6×10^{115} obtained by dividing the volume by the cube of the Planck length Computed . From here 't Hooft (1993) and Susskind (1994, J. Math. Phys. 1995) set up the idea of counting degrees of freedom by area, and Susskind wrote 'much like a holographic image' Physics . As a metaphor, it is a hologram recording a three-dimensional image on a flat plate. More precisely, (1) is a claim that two quantum theories are equivalent, and the "plate" is at the infinity of spacetime.

02

The two faces of D3-branes — where the conjecture came from

Open strings ending on N stacked D3-branes (membranes with three spatial dimensions on which the ends of open strings sit) become $U(N)$ gauge fields at low energy (17-07). Seen from gravity, the same branes curve spacetime. Maldacena read that in the low-energy limit the theory on the branes and the spacetime just near the branes describe the same thing Physics . The **metric** (line element) ds^2 is the formula giving the squared distance when the coordinates shift slightly, and the length of a curve is $\int ds$ (for flat space $ds^2 = dx_1^2 + dx_2^2 + \cdots$). The metric made by the branes is

$$ds^2 = f^{-1/2} dx_{\parallel}^2 + f^{1/2}\left(dr^2 + r^2 d\Omega_5^2\right), \qquad f = 1 + \frac{4\pi g_s N \alpha'^2}{r^4} \quad (3)$$

Here $x_{\parallel}$ are the four coordinates along the branes (in $dx_{\parallel}^2$ only the time direction has the opposite sign; 2-04), r is the distance from the branes, $\alpha' = \ell_s^2$ is the square of the string length, and g_s is the string coupling. As $r \to 0$, $f \approx R^4/r^4$ ($R^4 = 4\pi g_s N \alpha'^2$), and setting $z = R^2/r$ gives

$$ds^2 = \frac{R^2}{z^2}\left(dx_{\parallel}^2 + dz^2\right) + R^2 d\Omega_5^2 \quad (4)$$

the product of AdS_5 of radius R and S^5 Known . There are two ways of writing the correspondence of couplings. In the convention widely used today $g_{\mathrm{YM}}^2 = 4\pi g_s$ and $R^4/\alpha'^2 = 4\pi g_s N = \lambda$ ($\lambda = g_{\mathrm{YM}}^2 N$); in the convention of the original paper, $g_{\mathrm{YM}}^2 = 2\pi g_s$, $R^4/\alpha'^2 = 2\lambda$ Known . The difference is only in the normalisation of the action; today's convention is the normalisation in which the instanton action is $8\pi^2/g_{\mathrm{YM}}^2$ (the review of Aharony–Gubser–Maldacena–Ooguri–Oz (3.8), § 4.2). (2) of 17-04 ($\frac{1}{2g^2}\int \mathrm{tr}\, F^2$ with matrix traces, $\lambda = g^2 N$) has the same normalisation, so with the λ of 17-04, $R^4/\alpha'^2 = \lambda$. In this chapter we do not use λ directly and write $R^2/\alpha' = \sqrt{4\pi g_s N}$.

Supergravity (the field theory with gravity that remains at low energy in string theory) is reliable when $R \gg \ell_s$, that is $g_s N \gg 1$, and quantum effects in the interior correspond to the $1/N$ corrections of the gauge theory (original paper) Physics . Making this compatible with $g_s \ll 1$ requires $N \gg g_s N \gg 1$.

Table 1 The string coupling $g_s = (R/\ell_s)^4/(4\pi N)$ needed for radius R

R/ℓ_s	$N = 3$	$N = 100$
2	0.424	0.0127
3	2.15	0.0645
5	16.6	0.497

R/ℓ_s	$N=3$	$N=100$
10	265	7.96

Example: taking the curvature radius to be 5 times the string length, $N=3$ gives $g_s=16.6$, a strong string coupling, and only at $N=100$ does it come down to 0.5 Computed .

03

Anti-de Sitter space — the boundary is infinitely far away

Anti-de Sitter space AdS_{d+1} is, in a flat space whose metric (§ 02) has signature $(-,-,+,\dots,+)$, the hyperboloid

$$-X_{-1}^2-X_0^2+X_1^2+\cdots+X_d^2=-R^2 \quad (5)$$

and the group $SO(2,d)$ preserving (5) is its symmetry as it stands (appendix of Maldacena). Choosing coordinates again gives the form of the first half of (4) (Poincaré coordinates). Below we consider the Euclidean version, moved to imaginary time (2-04). Writing the boundary coordinates as $x=(x_1,\dots,x_d)$,

$$ds^2=R^2\,\frac{\sum_{i=1}^{d}dx_i^2+dz^2}{z^2}\qquad (z>0)\quad (6)$$

For $d=1$ it is the upper half-plane, and Figure 1 draws this case. Example: the length going up along $x=0$ from $z=1$ to $z=\varepsilon$ is $\int_\varepsilon^1 R\,dz/z=R\ln(1/\varepsilon)$, infinite as $\varepsilon\to 0$. The boundary $z=0$ is infinitely far away Known . The dimension of the symmetry is $6\cdot 5/2=15$ for $SO(2,4)$ (in the Euclidean version $SO(1,5)$, of the same dimension 15; 1-03), and the four-dimensional conformal transformations number 15 (translations 4, Lorentz 6, dilatation 1, special conformal 4); in the words of Witten (1998a), 'SO(2, d) ... acts on M_d as the conformal group' Known .

04

Radial direction = scale — depth measures size

In (6), under $(x,z)\mapsto(sx,sz)$ both numerator and denominator are multiplied by s^2, and ds^2 does not change. This **isometry** of the interior (a transformation preserving length) is, on the boundary, the dilatation $x\mapsto sx$: "looking at something s times larger on the boundary" and "looking s times deeper" become the same operation. In the words of Susskind–Witten (1998), 'scale size gets transmuted into a spatial dimension' Known .

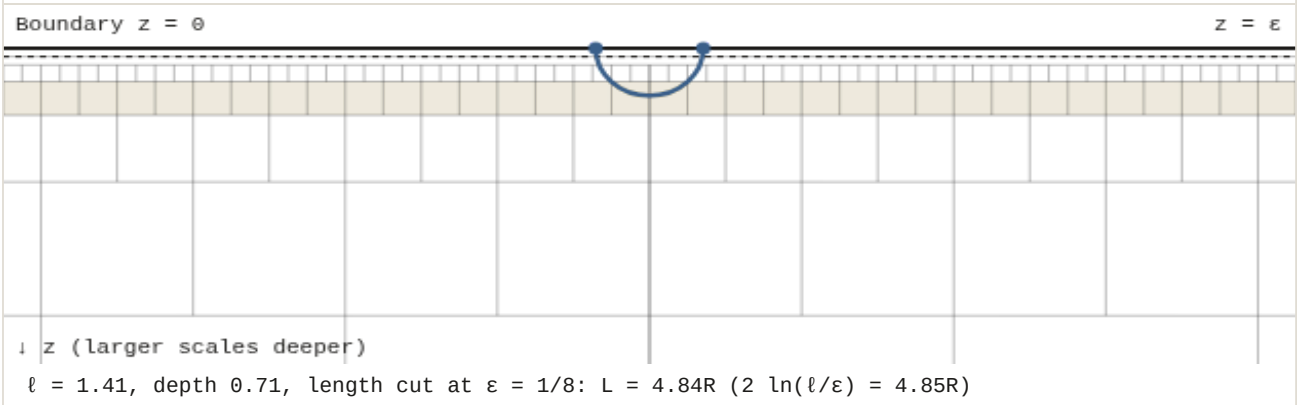
The **geodesics** of (6) (the shortest curves joining two points) are semicircles orthogonal to the boundary, and the semicircle hanging from the boundary interval

$[-\ell/2, \ell/2]$ goes down to depth $\ell/2$. The length cut off at depth ε is logarithmic in ℓ.

$$L(\ell) = 2R \ln \frac{\ell + \sqrt{\ell^2 - 4\varepsilon^2}}{2\varepsilon} \approx 2R \ln \frac{\ell}{\varepsilon}, \qquad e^{-mL} \approx \left(\frac{\varepsilon}{\ell}\right)^{2mR} \tag{7}$$

The amplitude for a particle of mass m to propagate through the interior is roughly e^{-mL}, so exponential decay turns into a power law on the boundary. Susskind–Witten (2.5) follow the same idea, writing it on a model of the sphere in a form without coefficients, $\delta^m / |X_1 - X_2|^m$. The exponent $2mR$ is an approximation for large mR; exactly it is (9) Physics .

Figure 1 The upper half-plane (6) and a dyadic tiling (every tile has area $R^2/2$). Changing the interval ℓ with the knob changes the depth of the semicircle and the L of (7). The coloured band is the level where the bottom lies



Computed The numbers in this figure were computed on this machine.

Table 2 L of (7) ($R = 1$; agrees with numerical integration along the semicircle). Each doubling of ℓ increases L by $2\ln 2 = 1.386$

ℓ/ε	L	$2\ln(\ell/\varepsilon)$
10	4.584863	4.605170
100	9.210140	9.210340
1000	13.815509	13.815511

Cutting near the boundary at $z = \varepsilon$ is an ultraviolet cutoff of the boundary theory. Susskind–Witten write 'the infrared regulator δ in the bulk theory also plays the role of an ultraviolet regulator in the boundary super Yang Mills theory' (δ corresponds to the ε of this chapter). They then divided the cut sphere into a lattice of size δ, assumed one degree of freedom per field per lattice cell, and counted the degrees of freedom as N^2/δ^3 (ibid. (3.1)) Physics . In Figure 1 the width of the tiles doubles at each level down, which recalls one step of the renormalisation group, grouping blocks in pairs (7-05). More precisely, it stands at the level where de Boer–Verlinde–Verlinde (1999, JHEP 2000) derived the form of the Callan–Symanzik equation (the formula describing how correlation functions change when the scale is changed; 4-04) from the Hamilton–Jacobi equation describing radial evolution in classical supergravity (an equation set

up by regarding the action as a function of the values at the end), and proposed 'We propose a direct correspondence' Physics .

05

The dictionary — fields in the interior and operators on the boundary

In the prescription of Gubser–Klebanov–Polyakov (1998) and Witten (1998a), the boundary value ϕ_0 of an interior field ϕ is read as the **source** of a boundary operator $\mathcal{O}$ (an external field added to the action in the form $\int \phi_0 \mathcal{O}\, d^d x$), and the following are set equal. The right end is the action I of the classical solution in the limit where supergravity can be used ($N, \lambda \to \infty$). The abstract of GKP begins 'We suggest'; it is a proposal Physics .

$$\left\langle \exp \int \phi_0\, \mathcal{O}\, d^d x \right\rangle_{\text{boundary}} = Z_{\text{interior}}\left[\phi \to \phi_0\right] \approx e^{-I[\phi_0]} \tag{8}$$

One consequence is the relation between mass and dimension. For solutions independent of x, the equation of a field of mass m is $z^{d+1}(z^{1-d}\phi')' = m^2 R^2 \phi$ (Witten 1998a (2.37)), and putting in $\phi = z^\alpha$ gives $\alpha(\alpha - d) = m^2 R^2$. We write the larger root as Δ (the letter customary in the literature, distinct from the Δ of the mass gap).

$$\Delta(\Delta - d) = m^2 R^2, \qquad \Delta = \frac{d}{2} + \sqrt{\frac{d^2}{4} + m^2 R^2} \tag{9}$$

A solution with $\phi \approx \phi_0 z^{d-\Delta}$ near the boundary extends smoothly into the interior. Under the dilatation $(x, z) \mapsto (sx, sz)$, ϕ_0 is multiplied by $s^{\Delta - d}$, so for $\int \phi_0 \mathcal{O}$ to be invariant the **scaling dimension** of $\mathcal{O}$ (the Δ such that the operator is multiplied by $s^{-\Delta}$ under the dilatation $x \mapsto sx$) must be Δ, and the two-point function is proportional to $|x|^{-2\Delta}$ Physics . The condition for real roots, $m^2 R^2 \geq -d^2/4$, is the Breitenlohner–Freedman bound, which allows negative squared masses down to this point Known .

Table 3 Δ of (9) ($d = 4$). The right end is the power read off by solving the equation numerically from $z = 1$ to e^{-25} (agrees with $d - \Delta$)

$m^2 R^2$	−3	0	5	12
Δ	3	4	5	6
Numerical power	1.000000	0.000000	−1.000000	−2.000000

Example: if massless, $\Delta = 4 = d$, and the ϕ_0 in $\int \phi_0 \mathcal{O}\, d^4 x$ is a dimensionless number, that is, it plays the role of a coupling. The dilaton (the scalar whose expectation value fixes the string coupling) corresponds to $\operatorname{tr} F^2$. For the $\mathcal{N} = 4$ theory, Witten (1998a § 2.6) states that the operator obtained by differentiating the Lagrangian density with respect to the coupling (which includes $\operatorname{tr} F^2$) corresponds to the dilaton with $m^2 = 0$, and Csáki–Ooguri–Oz–Terning, citing earlier literature, write 'the operator tr F^2 in four

dimensions corresponds to the dilaton field ...' Physics . $\mathrm{tr}\, F^2$ creates the 0^{++} glueball (17-01), so in 17-09 we read glueball masses from the dilaton equation.

06

Hanging a string — computing the Wilson loop

The energy $E(L)$ of a heavy quark pair at distance L is read from the Wilson loop (5-01). In the prescription put forward at about the same time by Maldacena (1998) and Rey–Yee (1998, EPJC 2001), the quarks are the endpoints of a string ending on the boundary, and the area (Nambu–Goto) of the string hanging into the interior gives E Physics . In (4) the tension $1/(2\pi\alpha')$ is multiplied by R^2/z^2.

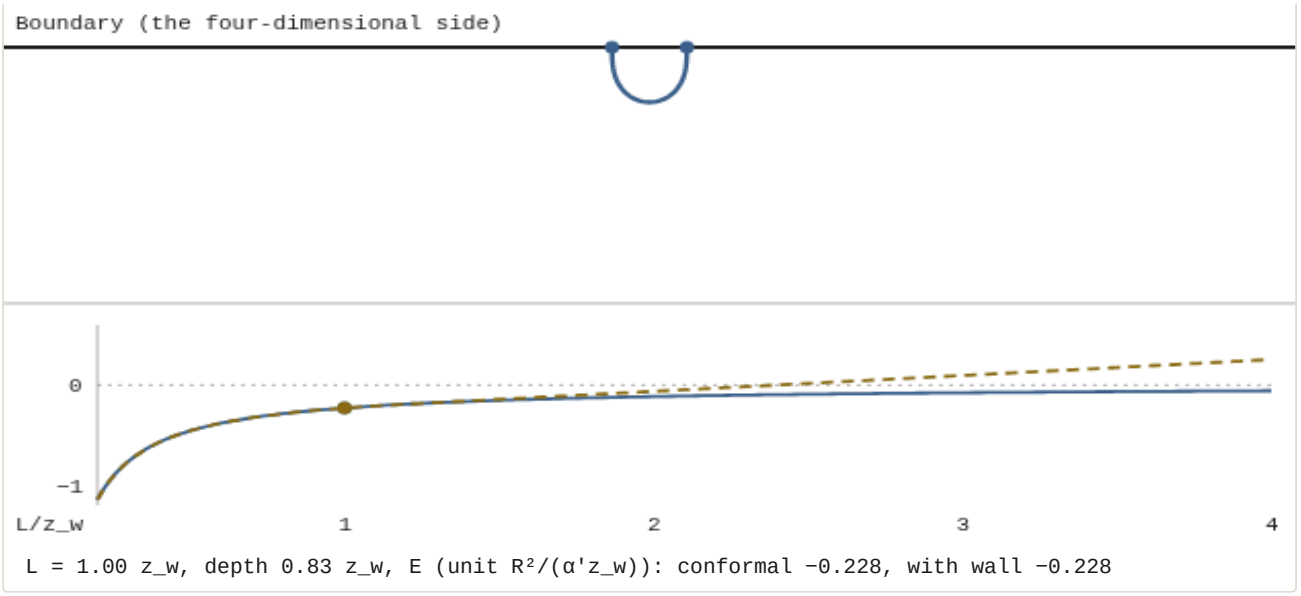
$$E = \frac{1}{2\pi\alpha'}\int_{-L/2}^{L/2} \frac{R^2}{z^2}\sqrt{1+z'^2}\,dx, \qquad L = 2z_0\int_0^1 \frac{y^2\,dy}{\sqrt{1-y^4}} = \frac{2\sqrt{2}\,\pi^{3/2}}{\Gamma(1/4)^2}z_0 = 1.19814\,z_0 \quad (10$$

The integrand does not contain x, so $z^2\sqrt{1+z'^2} = z_0^2$ (z_0 is the depth of the bottom) is conserved, giving the right-hand formula. The string goes down to a depth $z_0 = 0.8346L$ proportional to L. Subtracting the divergence at the boundary (the self-energy of point charges) by the amount for two straight strings gives

$$E(L) = -\frac{4\pi^2}{\Gamma(1/4)^4}\,\frac{R^2}{\alpha'}\,\frac{1}{L} = -0.22847\,\frac{\sqrt{4\pi g_s N}}{L} \quad (11)$$

where the constant agrees between numerical integration and the closed form to 8 digits, and is the same as (4.6)(4.8) of the original paper Computed . The original paper writes 'the energy goes as 1/L, a fact which is determined by conformal invariance. Notice that the energy goes as $(\mathrm{gN})^{1/2}$ as opposed to gN which is the perturbative result' Physics .

Figure 2 Top: a string with both ends on the boundary. Bottom: $E(L)$ (solid line (11); dashed line (12), with a wall). Changing L changes the depth and E, and with "Put a wall" the string lies down along the wall



Computed The numbers in this figure were computed on this machine (the shape of the string from a table of the integral (10), E from (11)(12)).

Table 4 E (unit $R^2/(\alpha' z_w)$) and the depth without a wall. $L_c = 1.19814\, z_w$

L/z_w	Conformal (11)	With wall (12)	$z0/z_w$
0.5	−0.45695	−0.45695	0.4173
1.19814	−0.19069	−0.19069	1.0000
2	−0.11424	−0.06307	1.6693
4	−0.05712	0.25524	3.3385
8	−0.02856	0.89186	6.6770

07

Putting in a single scale — cutting the geometry gives an area law

The $1/L$ of (11) is a consequence of conformality, so confinement ($E \approx \sigma L$, 17-01) needs a scale. The crudest model is to cut the interior at depth z_w. Polchinski–Strassler (2001, PRL 2002) stated that if there is a gap 'the gravitational redshift has a nonzero lower bound' and used the approximation of cutting the geometry Physics . Minimising (10) in this model, for $L \le L_c = 1.19814 z_w$ the conformal solution (bottom depth $0.8346 L \le z_w$) can be used as it is. For $L > L_c$ the bottom of the string reaches the wall. Where it touches the wall the string is tangent to it (slope 0), so the conserved quantity $z^2\sqrt{1+z'^2}$ becomes z_w^2, and the descending part is half of the conformal solution with $z_0 = z_w$. The halves on the two sides use up a width L_c, and the remaining $L - L_c$ is joined by a straight line along the wall.

$$E(L) = -0.19069\,\frac{R^2}{\alpha' z_w} + \sigma(L - L_c), \qquad \sigma = \frac{\sqrt{4\pi g_s N}}{2\pi z_w^2} \qquad (L > L_c) \quad (12)$$

A part proportional to L (an area law) appears, and at $L = L_c$ it joins (11) in both value and slope Computed . Example: at $L = 8z_w$ in Table 4 it is $+0.892$ against the conformal -0.029. As in (12) it has the form $\sigma(L - L_c)$ plus a constant, and for large L it lies on a straight line of slope σ. The string tension carries a factor $\sqrt{4\pi g_s N}$, while the glueball mass fixed by the box up to the wall ($\sim 1/z_w$) does not, so the larger the coupling, the further apart the two scales (the λ-dependence of the ratio and its sources are in 17-09 § 08). This is arithmetic within the model; the actual geometry is treated in 17-09 and 17-10.

08

Correspondences that can be written exactly — what is a theorem and what is a proposal

"Exact" has two meanings: being correct as mathematics closed on one side alone (hyperbolic geometry, Lie groups, ordinary differential equations), and the definitions of both sides agreeing within a model. Neither is a theorem of four-dimensional Yang–Mills theory, and (1) is not proved either.

Table 5 Correspondences and their level

Boundary side	Interior side	Level
Conformal group, dilatation	$SO(2,4)$, $(x, z) \mapsto (sx, sz)$	Known
$\ln(\ell/\varepsilon)$	Length of a geodesic (7)	The formula for the length Known (numbers Computed), its identification with the logarithm on the boundary Physics
Dimension Δ	The power of (9)	The power Known , the identification Physics
The form of Callan–Symanzik	Radial Hamilton–Jacobi	Physics (proposal)
$E(L)$	Minimal area of a string	The prescription Physics , (10)(11) Computed
—	Connectedness of the boundary	Known Mathematical theorem

The last row is a theorem of Witten–Yau (1999). We prepare three terms. An **Einstein manifold** is a manifold whose Ricci curvature (curvature averaged over directions) is a constant multiple of the metric; here the constant is negative (the space (6) is an example). A **conformal boundary** (in Penrose's sense) is a boundary at infinity, attached when multiplying the metric by the square of a function vanishing on the boundary makes it extend smoothly to the boundary (for (6), $z^2 ds^2$ extends to $z = 0$). $H_n(M; \mathbb{Z}) = 0$ means, roughly, that M has no n-dimensional "holes". If M is $n+1$-dimensional, N is its n-dimensional conformal boundary, M is complete (not cut off

partway in any direction), and the scalar curvature of N (curvature further condensed into a single number) is positive, then

$$H_n(M;\mathbb{Z}) = 0, \qquad \text{in particular } N \text{ is connected} \ (13)$$

(abstract: 'Let M be a complete Einstein manifold of negative curvature ... N must be connected') Known . What this chapter uses is only the conclusion that "the boundary N is in one piece (connected)". AdS/CFT is the motivation, but it is not a theorem about the duality itself. Example: the Physics rows of Table 5 all use (1) as a premise.

09

The distance to Yang–Mills — conformality, limits, where things stand

The boundary theory of (1) is not pure Yang–Mills theory. It has six scalar fields and fermions, is conformal so its coupling does not run (in contrast with 4-06), and no scale Λ is born (4-07). The $N, \lambda \to \infty$ where the gravity computation works is the opposite side from what the problem statement (0-03) asks for: any compact simple group, and a theory that agrees with asymptotic freedom ($\lambda \to 0$) at short distances. A conformal theory has no gap: if there is a state of mass $m > 0$, dilatation gives states of mass sm (for any $s > 0$) too.

$$m^2 \in \mathrm{spec}(P^2) \ \Rightarrow \ s^2 m^2 \in \mathrm{spec}(P^2) \ (s > 0) \ \Rightarrow \ \inf\left(\mathrm{spec}(P^2) \setminus \{0\}\right) = 0 \ (14)$$

P^2 is the square of the four-momentum (2-04), and the $1/L$ of (11) is another face of this circumstance Known . Example: the Clay page on the problem still writes of the mass gap 'no proof of this property is known'. There is no example in which holography has shown the mass gap as a mathematical theorem (models with a gap at the level of physics are in 17-09); string theory has no non-perturbative definition, (1) is a conjecture, and the limits lie outside the problem statement, all at once (16-05). The road back to four dimensions is in 17-10, and an example where a gap is visible from a duality under supersymmetry in 17-11.

What this chapter can say

What is said	What is not said
Known The geometry of (4)–(6), $SO(2, 4)$ and the conformal group, the power and the bound of (9), (13)(14).	A proof of (1). A mathematical definition of (8) (the quantum theory in the interior is undefined).

What is said	What is not said
Computed Tables 1–4, Figures 1 and 2, the constants of (10)(11), the numbers of (2).	The wall of (12) is a model, not the actual geometry of confinement.
Physics (1)(8), the prescription for Wilson loops, the radial direction and the renormalisation group, the wall model.	SYM has no gap. A bridge to pure Yang–Mills, finite N, asymptotic freedom. This book itself shows neither the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is in Volume 2).

Next chapter to read: 17-09 The mass gap becomes geometry — reading glueball masses as eigenvalues in the geometry of a shrinking circle.

The mass gap becomes geometry — when a circle shrinks and spacetime ends, a gap opens in the spectrum

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — The argument by which, when spacetime ends in a "cigar" where a circle shrinks, an area law and positive, discrete glueball masses (radial eigenvalues) come out. The numbers retraced on this machine, and the record against the lattice. That the ratios move a lot depending on which scalar is taken as the reference.

Prerequisite chapters — 17-08 (AdS, the dictionary, the string computation). The variational principle is in 2-05 § 08 and 1-10, glueballs in 17-01 § 06.

Said first — The gap here is in the supergravity approximation, $N \to \infty$, $\lambda \to \infty$, and is a linear eigenvalue problem on a fixed background. AdS/CFT is a conjecture, and the models are not pure Yang–Mills theory. This chapter does not solve the mass gap problem, and this book itself shows nothing about it.

The order of this chapter

1. What to translate into geometry
2. Putting in a scale with temperature
3. The circle shrinks (Figure 1, Detour: the temperature of a black hole)
4. The string lies down at the bottom
5. Glueballs are eigenvalues (Figure 2)
6. Why positive, why discrete
7. Comparing with the lattice (Later analysis: which scalar is lightest)
8. Two scales
9. Another way of closing off

01

What to translate into geometry — the gap and the area law

The boundary theory of AdS is conformal and has no gap (17-08 (14)), and in 17-08 § 07 a scale was put in with a wall placed by hand. In this chapter we look at models in which **the geometry itself ends at a finite depth**. Witten (1998) read two things from this Physics . The area law, from the coefficient of the boundary directions dx_i^2 being at least a positive constant in the interior. The gap, from the wave equation in the interior having only positive, discrete eigenvalues $m_1^2 < m_2^2 < \cdots$. Said on the boundary, the latter means that two-point functions such as that of $\mathrm{tr}\, F^2$ become sums of free propagators.

$$\langle \mathcal{O}(x)\, \mathcal{O}(0) \rangle = \sum_{n \geq 1} |c_n|^2 \, \frac{e^{-m_n |x|}}{4\pi |x|} \qquad \text{(the boundary is three-dimensional)} \quad (1)$$

The fraction on the right is the propagator of mass m in three dimensions Known ; at long distance the first term dominates, and the correlation length is $1/m_1$ (2-05 § 05, 4-11). Example: looking at the two-point function of $\mathrm{tr}\, F^2$ in the model of § 05 (the lowest dilaton mode), in the normalisation of § 03 where the temperature is $T = 1/\pi$, $m_1 = 3.404$ and the correlation length is 0.294 Computed . But among all the supergravity fields, another scalar coming from fluctuations of the metric is lighter, $m^2 = 5.457$ (the dilaton is 11.588) (Brower–Mathur–Tan 2000; § 07) Physics . (1) is the leading term in $1/N$, and Witten writes that interactions destroy the discreteness but the gap remains.

02

Putting in a scale with temperature — the circle of imaginary time and antiperiodicity

Thermal equilibrium at temperature T is the path integral with imaginary time wound on a circle of period $\beta = 1/T$ (the inverse temperature; the β of this chapter is not the lattice inverse coupling) (2-07 § 06). Bosons return to themselves after one turn, and fermions change sign (antiperiodic), so the momenta in the direction of the circle are

$$\omega_n = \frac{2\pi n}{\beta} \ \text{(bosons)}, \qquad \omega_n = \frac{(2n+1)\pi}{\beta} \ \text{(fermions)}, \qquad n \in \mathbb{Z} \quad (2)$$

Known . Fermions have no $\omega = 0$ and drop out at long distances. Witten put the $\mathcal{N} = 4$ theory on $\mathbb{R}^3 \times S^1$ to break supersymmetry, and since the scalars also become heavy at one loop, held that a three-dimensional gauge field remains at long distances Physics . Csáki–Ooguri–Oz–Terning (1998; COOT below) call this QCD_3. As a metaphor, the

circle is a mould. More precisely, the radius R of the circle is an ultraviolet cutoff of the three-dimensional theory (17-06 § 08). Example: the lowest fermion momentum is πT, and the lowest non-zero boson momentum $2\pi T$.

03

The circle shrinks — the geometry of the cigar

If there is a circle on the boundary, the interior becomes an AdS black hole. Witten scaled that solution to obtain the following metric (the overall R^2 omitted) Physics .

$$ds^2 = g\,d\tau^2 + \frac{d\rho^2}{g} + \rho^2 \sum_{i=1}^{3} dx_i^2, \qquad g = \frac{\rho^2}{b^2} - \frac{b^2}{\rho^2}, \qquad \rho \geq b \quad (3)$$

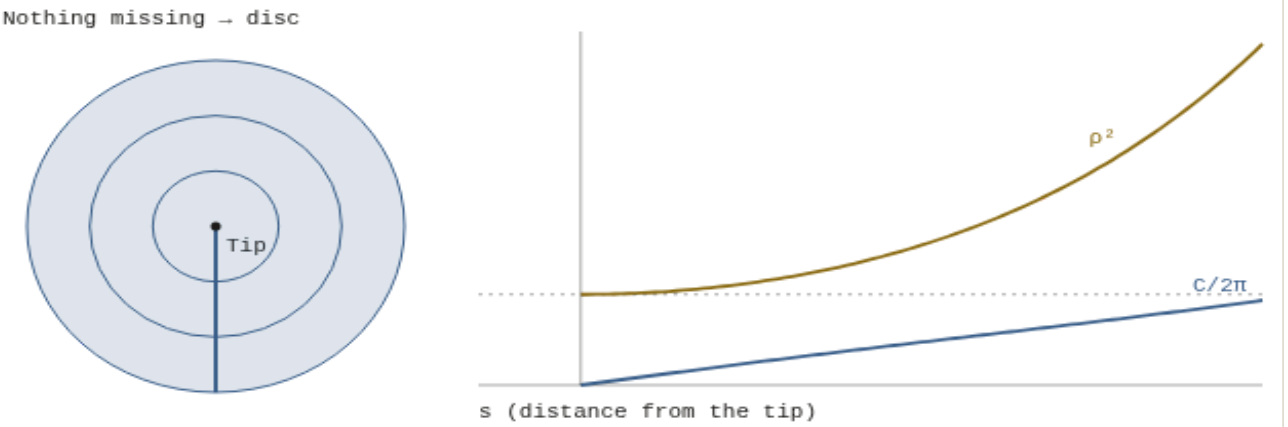
b is the curvature radius, and $\rho \to \infty$ is the boundary, where it returns to AdS (17-08 § 03). At $\rho = b$, $g = 0$ and the circle shrinks. Written with the distance r from the tip ($\rho \approx b + r^2/b$),

$$g\,d\tau^2 + \frac{d\rho^2}{g} \;\approx\; dr^2 + r^2\,d\theta^2, \qquad \theta = \frac{2\tau}{b} \quad (4)$$

these are polar coordinates in the plane. But if the period of τ deviates from πb, the tip is the vertex of a cone (a singularity). Smoothness fixes the period to πb. Near the boundary, dividing the metric by ρ^2 gives $d\tau^2/b^2 + \sum dx_i^2$, so the circumference measured on the boundary is $\pi b/b = \pi$, and the temperature is fixed to $T = 1/\pi$ independently of b Known . The numbers of this chapter are written in this normalisation (circumference π, $T = 1/\pi$). "$b = 1$" in the tables means that b was set to 1; the eigenvalues of (7) do not depend on b, since b disappears on setting $\rho = bu$.

(ρ, τ) is a cigar-shaped disc. As a metaphor, spacetime "ends there". More precisely, the tip is the centre of the disc. For $b = 1$ it can be written $\rho^2 = \cosh 2r$, agreeing with numerical integration to 8 digits Computed .

Figure 1 Left: near the tip (the edges of a sector of angle $2\pi\beta/\beta_1$ identified). Right: the radius of the circle $C/2\pi$ (blue) and the coefficient ρ^2 of dx^2 (yellow). Moving the period away from 1 makes the tip a cone



β/β₁ = 1.00, circumference/(2π×distance) → 1.00, smooth (centre of a disc), minimum of the dx² coefficient b² = 1

Values of the curves of Figure 1 ($\beta/\beta_1 = 1$, $b = 1$; s is the distance from the tip)

ρ	s	$C/(2\pi s)$	ρ^2
1.001	0.0316	0.9997	1.002
1.1	0.3186	0.9719	1.210
2	1.0317	0.9385	4.000
4	1.7324	1.1522	16.00

Computed The numbers in this figure were computed on this machine (the curves are $\rho^2 = \cosh 2s$; the table gives values from numerical integration, and closer to the tip $C/(2\pi s)$ comes closer to 1).

Detour: the temperature of a black hole is the same computation

A subsection you may skip.

If the imaginary-time Schwarzschild metric $f\,d\tau^2 + dr^2/f + \cdots$ ($f = 1 - r_s/r$) is smooth at $r = r_s$, the period is $4\pi r_s$. Reading this as $\hbar c/(k_B T)$ gives

$$T = \frac{\hbar c^3}{8\pi G M k_B} \quad (5)$$

and for a solar mass $T = 6.17 \times 10^{-8}$ K Computed . This derivation is attributed to the method of Gibbons–Hawking (1977) Known .

04

The string lies down at the bottom — the area law

The Wilson loop is fixed as $e^{-\alpha(D)}$ by the regularised area $\alpha(D)$ of a surface in the interior (17-08 § 06) Physics . In (3) the surface can only enter $\rho \geq b$, and the coefficient ρ^2 of dx_i^2 is at least b^2, so with A the enclosed area,

$$\alpha(D) \;\geq\; b^2 A - (\text{boundary and regularisation terms}), \qquad \sigma = b^2 \times (\text{string tension}) \quad (6)$$

and the area law (17-01 § 04) comes out (Witten). We computed the area per unit length $E(L)$ of a string joining two points at distance L by the same method as 17-08 (10).

Table 1 The string in the cigar (unit $R^2/(2\pi\alpha')$, $b = 1$). Conformal is 17-08 (11)

L	$E(L)$	**Conformal** $-1.4355/L$	$E - L$
0.1	−14.355	−14.355	–
1	−1.307	−1.436	−2.307
2	−0.032	−0.718	−2.032
6	4.000	−0.239	−2.000

At short distances it is the conformal $1/L$, at long distances $E \approx L - 2.000$, and the slope 1 is $\sigma = b^2$ Computed . The string goes down to the bottom $\rho = b$ and lies flat. No wall (17-08 § 07) is needed. Example: rescaling the boundary scale by s makes the temperature T/s and multiplies the tension by $1/s^2$, so $\sigma \propto T^2$ (Witten).

05

Glueballs are eigenvalues — the radial equation of the dilaton

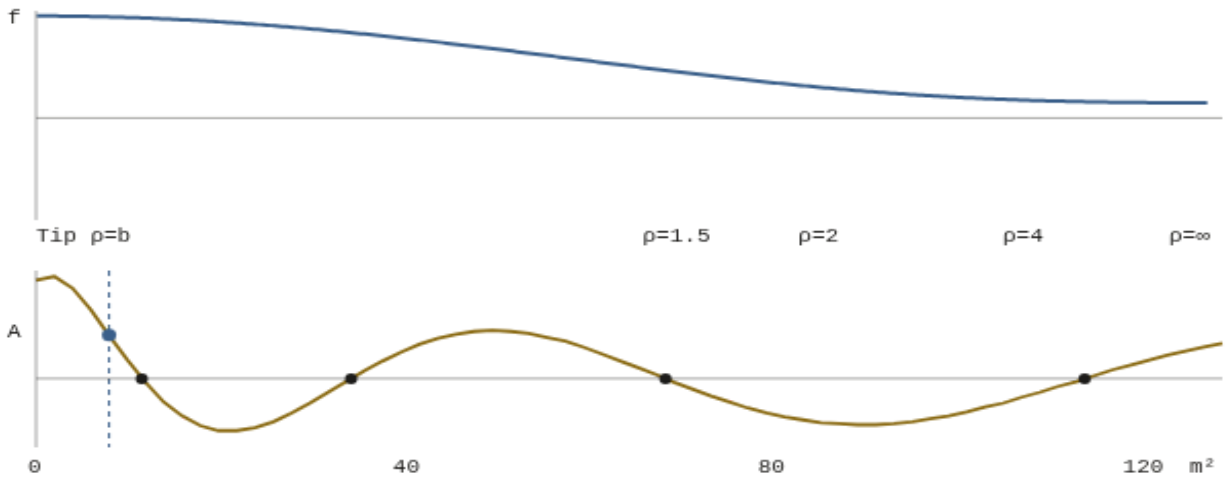
$\mathrm{tr}\, F^2$ corresponds to the dilaton (17-08 § 05). Witten studied waves $\phi = f(\rho) e^{ik\cdot x}$ on (3) that do not depend on τ (waves with momentum in the τ direction are heavier; a comparison within the same field; § 08). The equation is

$$-\frac{1}{\rho}\,\frac{d}{d\rho}\Big(\rho^3 g\,\frac{df}{d\rho}\Big) = m^2 f, \qquad m^2 = -k^2 \quad (7)$$

(for $b = 1$, $\rho^3 g = \rho^5 - \rho$) Physics , where m is the mass of a three-dimensional particle. There are two conditions. **Smooth at the tip**: one solution diverges as $\log(\rho - b)$, and the smooth solution is unique up to a constant multiple. **Normalisable at infinity**: of the solutions $f \sim 1$ and $f \sim \rho^{-4}$, the latter. The constant component is the source on the boundary (17-08 (8)).

Smoothness at the tip is the condition that the slope measured with the radial coordinate r of polar coordinates in the plane ((4)) is 0. Since $\rho - b \propto r^2$, the slope measured with ρ is not 0; from (7), $f'(1) = -m^2 f(1)/4$ ($b = 1$), which for the first eigenfunction is $-2.90 f(1)$ Computed . The abstract of de Mello Koch et al. (1998) also states this condition: there is no smooth solution whose slope in ρ vanishes at the horizon. The method is shooting: the zeros of the constant component $A(m^2)$ that the smooth solution from the tip leaves at infinity are the eigenvalues.

Figure 2 Top: the solution f shot from the tip (left) (horizontal axis θ, $\rho = \sec\theta$). Bottom: the constant component A left on the boundary (times $1 + m^2/4$). Varying m^2, at $A = 0$ the solution lands on the boundary at 0



m² = 8.0, constant component left on the boundary A = +0.148 (f=1 at the tip), nodes: 0

Computed The numbers in this figure were computed on this machine (the bottom is a table of a precise integration; the top is a Runge–Kutta integration of the same formula in the page, agreeing with the table to 4 digits).

Table 2 The eigenvalues m_n^2 of (7) ($b = 1$). There are $n - 1$ nodes. T_L is from (9)

n	This machine	COOT	$6n(n+1)$	$(\pi/T_L)^2(n+\frac{1}{2})^2$
1	11.5877	11.59	12	12.92
2	34.5270	34.53	36	35.89
3	68.9750	68.98	72	70.34
6	241.237	241.2	252	242.61

Shooting and the Chebyshev collocation method (moved to $u = 1/\rho^2$) agree to 7 digits and reproduce the 6 rows of Table 1 of COOT Computed . The ratio to the temperature is $m_1/T = 10.69$.

06

Why positive, why discrete — the variational principle and the length of the box

Positive. Multiplying (7) by ρf and integrating by parts, the boundary terms at the tip ($\rho^3 g = 0$) and at infinity vanish and

$$m^2 = \frac{\int_b^\infty \rho^3 g\,(f')^2\,d\rho}{\int_b^\infty \rho\, f^2\,d\rho} \tag{8}$$

If the numerator is 0 then f is constant, but a constant is not normalisable ($\int^\infty \rho\,d\rho = \infty$), so $m^2 > 0$ Known . The minimum of the right-hand side is m_1^2, and the gap is the

best constant of a Poincaré inequality (1-10, 2-05 § 08).

Discrete. Changing the variable to $t = \int_1^\rho d\rho'/\sqrt{\rho'^4 - 1}$ and the unknown function to $\psi = (\rho^6 - \rho^2)^{1/4} f$ (a Liouville transformation; $b = 1$), (7) becomes the Schrödinger equation on the interval $[0, T_L]$

$$-\frac{d^2\psi}{dt^2} + V(t)\,\psi = m^2 \psi, \qquad T_L = \int_1^\infty \frac{d\rho}{\sqrt{\rho^4 - 1}} = \int_0^1 \frac{ds}{\sqrt{1 - s^4}} = 1.31103 \quad (9)$$

Known . $V = (\rho^6 - \rho^2)^{-1/4} \frac{d^2}{dt^2} (\rho^6 - \rho^2)^{1/4}$ diverges at both ends: $V \approx -1/(4t^2)$ at the tip, $V \approx (15/4)/(T_L - t)^2$ at the end at infinity Computed . Even so, the length of the box T_L is finite, so the eigenvalues are discrete, just as for a particle in a box.

The type of each end also fixes the phase of the approximation. At an end where the potential is $(\nu^2 - \frac{1}{4})/u^2$ (u the distance from the end), the allowed solution is $\sqrt{u}\, J_\nu(mu)$ (J_ν the Bessel function of order ν), which away from the end oscillates like $\cos(mu - \nu\pi/2 - \pi/4)$. The tip has $\nu = 0$ and brings in a phase $\pi/4$, the end at infinity has $\nu = 2$ and brings in $5\pi/4$, so the n-th eigenvalue is $m_n T_L \approx \pi(n-1) + \pi/4 + 5\pi/4 = \pi(n + \frac{1}{2})$, that is $m_n \approx (\pi/T_L)(n + \frac{1}{2})$. At $n = 6$ the difference shrinks to 0.6% in m^2 (0.3% in m) Computed . The $6n(n+1)$ of Table 2 is an approximate formula from exact WKB analysis, which COOT cite as a private communication from Takei–Koike. Exact WKB analysis is a theory that handles mathematically divergent series expanded in a large parameter by summing them with Borel's method (4-12), and this formula assumes their summability (COOT note that there is no proof in this case).

In AdS the length $\int_0 d\rho/\rho^2$ down to the lower end $\rho = 0$ is infinite, solutions oscillate deep inside, and the spectrum is continuous from 0 (Witten). "Spacetime ends" here means "the Liouville length is finite". In the five-dimensional models of Gürsoy–Kiritsis–Nitti (2007) too, it is stated, by analysis within the model, that for the exponent α of the growth of the potential deep inside, confinement and a gap hold for $\alpha \geq 1$, and a purely discrete spectrum for $\alpha > 1$ (at $\alpha = 1$, a continuous spectrum above the gap). The same paper also has the sentence 'confinement and discrete spectra imply each other' Physics .

07

Comparing with the lattice — three and four dimensions

What supergravity produces are numbers in units of a single scale, so COOT matched the lowest dilaton state to the 0^{++} of the lattice (5-08) (in three dimensions, the lattice $N \to \infty$ value 4.065, printed as 4.07 in the table of COOT) and compared the rest. 0^{--} comes from the equation of a two-form field.

Table 3 Three dimensions (unit $\sqrt{\sigma}$). Lattice: Teper (values cited by COOT)

State	Lattice $N=3$	Lattice $N\to\infty$	COOT	This machine
0^{++*}	6.52(9)	6.18(13)	7.02	7.02
0^{++**}	8.23(17)	7.99(22)	9.92	9.92
0^{--}	6.48(9)	5.91(25)	6.10	6.10

Taking the dilaton as the reference, the ratio $0^{--}/0^{++}=1.50$ agrees with the lattice 1.45 ± 0.03 to 3%, and the excited states come out 14% and 24% higher than the $N\to\infty$ lattice Computed . Which scalar to take as the reference is treated in "Later analysis" below.

Four dimensions is the D4-brane background of 17-07 § 09 (radius R_2 of the antiperiodic circle). The equation of the dilaton-type scalar of COOT, with $y^2=\rho$ (the λ of the original paper) and in units placing the tip at $y=1$ (then $M_{\mathrm{KK}}=1/R_2=3$), is the following (the solutions at infinity are 1 and y^{-9}) Physics .

$$(y^7-y)\,f''+(10y^6-4)\,f'+m^2y^3f=0 \quad (10)$$

Table 4 Four dimensions (GeV, 0^{++} matched to 1.61). The right end is in units of $M_{\mathrm{KK}}=1/R_2$; 0^{++} and 0^{++*} are values from formula (10) of COOT, 0^{-+} the value from the three-form equation of COOT

State	Lattice (values cited by COOT)	COOT	This machine	m/M_{KK}
0^{++}	1.61(15)	Input	Input	2.03
0^{++*}	2.8 (no error)	2.38	2.38	3.01
0^{-+}	2.19(32)	1.83	1.93	2.44

$0^{-+}/0^{++}$ is 1.14 in COOT and 1.36 ± 0.32 on the lattice of the time. COOT obtain 0^{-+} from a component of the 11-dimensional three-form field. Solving that equation on this machine, the lowest value is $m^2=53.376$ (1.93 GeV if the 0^{++} of (10) is 1.61 GeV, ratio 1.20), agreeing with the value for the same equation (N4) in Table 2 of Brower–Mathur–Tan (2000; BMT below) Computed . The 1.83 GeV in the table of COOT cannot be reproduced from this equation. For the lattice 0^{++*}, a note says it may be a bound state of two glueballs.

Later analysis — which scalar is lightest

BMT turned all the supergravity fields (metric, three-form, size of the sphere) into radial eigenvalue problems. We list the four-dimensional scalar-type modes. "Assignment" is the quantum numbers J^{PC} read from the operator to which the mode couples.

Table 5 The lowest four-dimensional modes (m^2 in units placing the tip at 1; the right end in units of M_{KK})

Equation	Field of origin	Assignment	This machine	BMT Table 2	m/M_{KK}

Equation	Field of origin	Assignment	This machine	BMT Table 2	m/M_{KK}
S4	The $\tau\tau$ component of the metric	0^{++} (the lightest)	7.3083	7.308	0.901
T4	Metric, dilaton	2^{++}, 0^{++} and others (0^{++} couples to $\mathrm{tr}\, F^2$)	22.0966	22.097	1.567
V4	The τi components of the metric and others	1^{-+}, 0^{-+}	31.9853	31.985	1.885
(10) of COOT	Dilaton	0^{++} (COOT)	37.1699	–	2.032
N4	Three-form	1^{+-}, 0^{+-} (BMT), 0^{-+} (COOT)	53.3758	53.376	2.435

The T4 equation differs from (10) only in the first-order term.

$$(y^7 - y)\, f'' + (7y^6 - 1)\, f' + m^2 y^3 f = 0 \quad \text{(10')}$$

In the later analysis, the dilaton-type 0^{++} coupling to $\mathrm{tr}\, F^2$ is degenerate with 2^{++} at $1.567\, M_{\mathrm{KK}}$, and the lightest 0^{++} is another mode, S4, at $0.901\, M_{\mathrm{KK}}$ Physics . The 2.03 in Table 4 is the value from formula (10) of COOT. In three dimensions too there is a scalar (S3 of BMT, 5.457) lighter than the dilaton (11.588) Computed . BMT write 'the lowest mass scalar comes from the gravitational multiplet, not the dilaton', and call the agreement of ratios to a few per cent 'a misconception'. At the same time they write that the overall pattern of spins and masses corresponds well with the lattice results Physics .

So the ratios move depending on which modes are taken as numerator and denominator. The three-dimensional $0^{--}/0^{++}$ is 2.19 with S3 as the reference. In four dimensions, the three-form value of COOT divided by T4 is 1.55, and with the assignment of BMT (0^{-+} is V4) V4/T4 is 1.20 and V4/S4 is 2.09 Computed . For $SU(3)$ on today's lattice, $0^{-+}/0^{++} = 1.549(16)$ and $0^{++*}/0^{++} = 1.720(16)$ (the table of 17-01). The holographic ratios with the reference of COOT (1.14, 1.20, 1.48) come out 26%, 23% and 14% smaller respectively Computed .

08

Two scales — the tension is not predicted, and the scale of the circle does not go away

Glueball masses are fixed by an eigenvalue problem and do not depend on the coupling $\lambda = g_{\mathrm{YM}}^2 N$, but the string tension is proportional to λ. In the D4 model, from formula (2.7) of Kruczenski–Mateos–Myers–Winters (2003) Physics

$$\sigma = \frac{2}{27\pi}\,\lambda\, M_{\mathrm{KK}}^2, \qquad \frac{m0^{++}}{\sqrt{\sigma}} = \frac{m0^{++}}{M_{\mathrm{KK}}}\sqrt{\frac{27\pi}{2\lambda}} \quad (11)$$

(it may be off by a factor of 2 depending on the convention for λ). The value changes depending on which is put into $m0^{++}/M_{\mathrm{KK}}$ on the right: 2.03 from formula (10) of COOT, 1.567 from T4 of BMT (dilaton type), or 0.901 from S4 (the lightest).

Table 6 $m0^{++}/\sqrt{\sigma}$ from (11). The lattice $SU(\infty)$ is 3.072(14)

$m0^{++}/M_{\mathrm{KK}}$	$\lambda = 1$	10	30	100	1000	λ matching 3.072
2.03 (formula (10) of COOT)	13.2	4.19	2.42	1.32	0.42	19
1.567 (T4 of BMT)	10.2	3.23	1.86	1.02	0.32	11
0.901 (S4 of BMT)	5.87	1.86	1.07	0.59	0.19	3.7

At $\lambda \gg 1$, where supergravity is reliable, the ratio goes to 0 as $\lambda^{-1/2}$ Computed . The λ matching 3.072 is 3.7 to 19, moving by a factor of about 5 depending on which mode is taken, and in every case it is a fit, not a prediction. Klebanov–Strassler too acknowledge a 'large separation of scales' between the tension and the glueballs. On the lattice it is 3 to 4 (17-03).

In models cut off by a wall, the λ-dependence of the ratio is $\lambda^{-1/4}$. With a hard wall ((12) of 17-08) the tension is $\sigma = \sqrt{\lambda}/(2\pi z_w^2)$ and the glueball mass $\sim 1/z_w$ (Boschi-Filho–Braga 2003, imposing a Dirichlet condition at the wall). With a soft wall the tension is $\frac{R^2}{\alpha'}\frac{e}{4\pi}c$, from (19) of Andreev–Zakharov (2006) and $g = R^2/\alpha'$, and the squared mass is proportional to c ((15) of Karch–Katz–Son–Stephanov 2006; the case of mesons). In both the tension is proportional to $\sqrt{\lambda}$, so the ratio goes as $\lambda^{-1/4}$; the difference from the $\lambda^{-1/2}$ of the D4 model comes from the tension in (11) being proportional to λ Physics .

The other is the scale of the circle. In three dimensions, in the normalisation of § 03 the circumference on the boundary is π, so $R = 1/2$ and $m_1 = 3.404 = 1.70/R$ (COOT use another normalisation, placing the horizon at $b = 1/(2R)$). In four dimensions 0^{++} is $0.90/R_2$ to $2.03/R_2$, and whichever mode is taken, the glueballs are of the same order as the circle Computed . The KK modes on the sphere (17-06 § 02) are also 'of the same order' (COOT), and the states regarded as glueballs are chosen by hand. Removing them needs $\lambda \to 0$, which is the 'opposite' of the direction in which supergravity works. Witten himself called the computation at small $\eta = g_4^2 N$ 'a tall order' Physics . On the order of limits, see 17-10.

09

Another way of closing off — Klebanov–Strassler and the record

Klebanov–Strassler (2000) placed D3-branes (17-08 § 02) on a six-dimensional cone (the conifold) and built a background in which the singularity at the tip is deformed in the IR, leaving a finite sphere.

$$\sum_{i=1}^{4} z_i^2 = 0 \;\; \text{(conifold)} \;\longrightarrow\; \sum_{i=1}^{4} z_i^2 = \epsilon^2 \;\; \text{(deformed)}, \qquad z_i \in \mathbb{C} \tag{12}$$

Example: restricting z_i to real numbers, the right is an S^3 of radius ϵ, the sphere left at the tip Known . The flux of the five-form field through a cross-section of the cone (a quantity corresponding to the number of D3-branes) changes logarithmically with the radius r: $\mathcal{K}(r) = N + a\, g_s M^2 \ln(r/r_0)$. g_s is the string coupling (17-08 (3)), M the number of "fractional branes" wrapped on the sphere in the cone, and a a constant of order 1 (original paper). The authors read this decrease as a sequence (a cascade) in which the gauge group $SU(N+M) \times SU(N)$ shrinks step by step as $N \to N - M$ Physics . The deformation of the tip is held to be the breaking $\mathbb{Z}_{2M} \to \mathbb{Z}_2$ of the R-symmetry (the chiral symmetry of this theory) of the $\mathcal{N} = 1$ supersymmetric Yang–Mills remaining in the IR, made visible as geometry Physics . At the tip the coefficient of dx^2 is finite, so an area law comes out as in § 04. But the theory is $\mathcal{N} = 1$ supersymmetric, the UV cascade 'goes on forever', and the KK modes of S^3 and the glueballs 'both scale as $m/(g_s M)$'.

Table 7 The record (years are arXiv years)

Model	What fits	Input	What misses / is not predicted
Witten, QCD_3	$0^{--}/0^{++}$ 1.50 against 1.45(3) (with the dilaton as reference; 2.19 with S3 as reference)	0^{++}	Excited states 14–24%, tension, circle
Witten, QCD_4	$0^{-+}/0^{++}$ 1.14 against 1.36(32) (1998; with the dilaton of formula (10) of COOT as reference)	0^{++}	14–26% from today's lattice, ratios 1.14–2.09 depending on the choice of modes, $m/\sqrt{\sigma}$
Klebanov–Strassler (2000), Maldacena–Núñez (2000)	Area law, breaking of R-symmetry (chiral symmetry) (geometric)	—	$\mathcal{N} = 1$, same scale as KK
Gürsoy–Kiritsis–Nitti (2007)	$2^{++}/0^{++}$ 1.40 against 1.46(5)	0^{++*} $/0^{++}$	The potential is a fit, $N = \infty$

In every model the gap is shown as "a linear eigenvalue problem on a fixed background", and the part saying that the background describes pure Yang–Mills theory on $\mathbb{R}^4$ remains a conjecture. The Clay page too writes 'no proof of this property

is known'. The distance from the problem statement (0-03) is in 17-10, the seams in 16-05.

What this chapter can say

What is said	What is not said
Known (4)(8)(9)(12). Mathematics on a fixed background.	That the background describes pure Yang–Mills theory.
Computed Tables 1–6, Figures 1 and 2, (5), the behaviour of V of (9) at both ends. Reproducing the 0^{++} tables of COOT for $\mathbf{QCD_3}$ and $\mathbf{QCD_4}$. Reproducing the lowest values of S4, T4, V4, N4 in Table 2 of BMT and of S3 in three dimensions.	Reproducing the 0^{-+} (1.83 GeV) of $\mathbf{QCD_4}$. The convention for λ in (11). Settling which mode is to be regarded as which state.
Physics The readings of (1)(3)(6)(7)(10)(10′)(11), glueball = eigenvalue, the assignment of quantum numbers, the comparisons of Tables 3, 4, 5 and 7.	Outside $N, \lambda \to \infty$. This book itself shows neither the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is in Volume 2).

Next chapter to read: 17-10 Back to four dimensions — the order of limits and the distance from the problem statement.

Back to four dimensions — the direction that removes the extra dimensions is opposite to the direction in which geometry can compute

> This chapter organises established knowledge. § 03 is this book's own investigation.

What this chapter shows — That $R \to 0$, which removes the extra dimensions, is because of dimensional transmutation the same direction as $\lambda \to 0$. That geometry can compute in the opposite direction, $\lambda \to \infty$, where the KK tower remains at the same height as the glueballs. That the uniformity needed to exchange the limits is missing.

Prerequisite chapters — 17-09. We also use dimensional transmutation in 17-01, 't Hooft's counting in 17-04 and the Curie–Weiss model in 2-08.

Said first — (2)(3) and the arithmetic of the tables are physical estimates, not theorems. Within the range we searched we found no result justifying the limit from the models to the four-dimensional theory, and this book itself shows nothing about the mass gap or the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. Three knobs — N, λ, R and the problem statement
2. Dimensional transmutation fixes the direction — $R \to 0$ is $\lambda \to 0$
3. Supergravity works in the opposite direction — the window and the floor (Figure 1)
4. Extra things remain — the KK tower and supersymmetry
5. $N \to \infty$ — when the group is fixed to one
6. The order of limits — exchanging them needs uniformity
7. Detour: seeing non-uniform convergence (Figure 2)
8. The distance from the problem statement — five requirements
9. What remains — the problem moves

01

Three knobs — N, λ, R and the problem statement

The question of this chapter is **whether the models of 17-09 can be brought back to the four-dimensional theory of the prize problem**. The knobs are three: the N of $SU(N)$, the 't Hooft coupling $\lambda = g^2 N$ at the scale M_{KK} (17-04), and the radius of the circle of the extra dimension $R = 1/M_{KK}$ (the spacing of the KK tower, 17-06). With Λ the glueball mass, the ratio ΛR measures how visible the extra dimensions are. The requirements of the problem statement (Jaffe–Witten § 4, 0-03) are

G fixed one at a time (e.g. $SU(3)$), space is $\mathbb{R}^4$ ($R = 0$), agrees with asymptotic free

and the third is that the correlation functions agree at short distances with the predictions of asymptotic freedom and perturbative renormalisation theory (§ 4; quotation in 0-03 § 07) Known . The models, conversely, can compute where $N = \infty$, $\lambda \gg 1$ and ΛR is of order 1 (§ 03, § 05).

Example: the Sakai–Sugimoto model fixes $M_{KK} \simeq 949$ MeV and $\kappa = \lambda N_c/(216\pi^3) \simeq 7.45 \times 10^{-3}$ from experimental values. For $N_c = 3$, $\lambda \approx 16.6$ Computed . This is the value in the coupling convention of Sakai–Sugimoto, and can differ from the λ of (2) in the next section by a factor of about 2 because of the difference in convention. The numbers put into (2) below are rough guides. The 776 MeV of the ρ meson is 0.82 times M_{KK}, at the same height as the tower.

02

Dimensional transmutation fixes the direction — $R \to 0$ is $\lambda \to 0$

Removing the extra dimensions means taking $R \to 0$ with Λ fixed. Λ is born from the running of the coupling (17-01, 4-07). Rewriting the one-loop formula $\mu\, dg/d\mu = -b_0 g^3$ ($b_0 = 11N/(48\pi^2)$) of (1) of 17-01 in terms of $\lambda = g^2 N$ gives

$$\mu \frac{d\lambda}{d\mu} = 2gN\,\mu \frac{dg}{d\mu} = -2b_0 N\, g^4 = -\frac{2b_0}{N}\,\lambda^2 = -\frac{11}{24\pi^2}\,\lambda^2$$

Dividing both sides by λ^2 gives $d(1/\lambda)/d\ln\mu = 11/(24\pi^2)$, so $1/\lambda$ is linear in $\ln\mu$. Below, λ without an argument is the value at $\mu = M_{KK}$.

$$\frac{1}{\lambda(\mu)} = \frac{1}{\lambda} + \frac{11}{24\pi^2}\ln\frac{\mu}{M_{KK}}$$

Lowering μ decreases the right-hand side, which becomes 0 at $\mu = M_{KK}\exp\big(-24\pi^2/(11\lambda)\big)$ (the one-loop coupling diverges here). This scale where the coupling becomes strong is a rough guide to Λ:

$$\Lambda R \;\sim\; \exp\!\Big(-\frac{24\pi^2}{11\,\lambda}\Big) \quad (2)$$

Physics . $\sim$ means "equal up to a constant multiple", and the constant changes with the definition of Λ (the Λ parameter, or the glueball mass) and with conventions. Solving the other way gives

$$\lambda(M_{KK}) \simeq \frac{24\pi^2/11}{\ln\big(1/(\Lambda R)\big)} \;\xrightarrow[R\to 0]{}\; 0 \quad (3)$$

(a constant multiple only adds a constant to the denominator, so it does not affect the direction of $R \to 0$), and **removing the extra dimensions is the same direction as $\lambda \to 0$**. Witten (1998 § 4) writes 'Asymptotic freedom should say that as $\eta \to 0$, the particle masses become exponentially small' (η is the λ of this chapter), and Csáki–Ooguri–Oz–Terning, putting the masses as $M^2 = f(\lambda)\Lambda_{UV}^2$, state 'To take the continuum limit $\Lambda_{\mathrm{UV}} \to \infty$, we have to simultaneously take $\lambda \to 0$' Physics ((2) is (10) of 17-07). As a metaphor, R plays the role of the lattice spacing; more precisely, it is the same logic as sending the bare coupling to 0 as the spacing $a \to 0$ (5-05).

Table 1 Estimates of ΛR (with the constant multiple in (2) set to 1) and the rough guide $\lambda^{-3/2}$ to the string correction

λ	One loop (2)	Two loops	$\lambda^{-3/2}$
1	4.45×10^{-10}	2.17×10^{-9}	1
5	0.0135	0.0334	0.0894
10	0.116	0.215	0.0316
16.6	0.274	0.409	0.0147
100	0.806	0.565	0.0010

Computed Two loops: from $\mu\, dg/d\mu = -b_0 g^3 - b_1 g^5$ ($b_1 = \frac{34N^2}{3(16\pi^2)^2}$), the formula of 17-01 with the next term added, the right-hand side of (2) multiplied by $(11\lambda/48\pi^2)^{-51/121}$ ($51/121 = b_1/(2b_0^2)$). The coefficients can change with convention, and the rows with large λ are rough guides outside the range where (2) can be used (that is also why, at $\lambda = 100$, the two-loop column is smaller than the one-loop one; § 03). Example: $\Lambda R = 10^{-3}$ needs $\lambda \le 3.12$ (two loops 2.66), and 10^{-6} needs $\lambda \le 1.56$ (1.41).

03

Supergravity works in the opposite direction — the window and the floor

Gravitational geometry can compute when $\lambda \gg 1$ (17-08). Csáki et al. evaluated the leading string correction to the f in the $M^2 = f(\lambda)\Lambda_{UV}^2$ of § 02, and for the 0^{++} glueball of **three-dimensional** pure Yang–Mills (QCD_3) obtained

$$f(\lambda) = c_0 + c_1 \lambda^{-3/2} + \cdots, \qquad c_1 < 0 \quad (4)$$

(the lowest 0^{++} state and the first five excited levels) Physics . $c_1 < 0$ means that with the ultraviolet cutoff Λ_{UV} fixed, decreasing λ lowers the mass, the direction consistent with the expectation of a continuum limit. The power in four dimensions is not in this paper. Below we borrow $p = 3/2$ as a rough guide for four dimensions.

The same paper writes, for the three-dimensional case, of taking $g_4^2 N \to 0$ as $R \to 0$ (to keep the QCD_3 coupling $g_3^2 N = g_4^2 N / R$ constant): 'This is the opposite of the limit that is required for the supergravity description to be valid'. The grounds for four dimensions are Witten's sentence in § 02 and the sentence 'To take the continuum limit ...' in the introduction of Csáki et al. Witten too writes of showing asymptotic freedom and computing masses at small η: 'This looks like a tall order, given our limited knowledge of worldsheet field theory with Ramond-Ramond fields in the Lagrangian' (world-sheet field theory is explained in § 09).

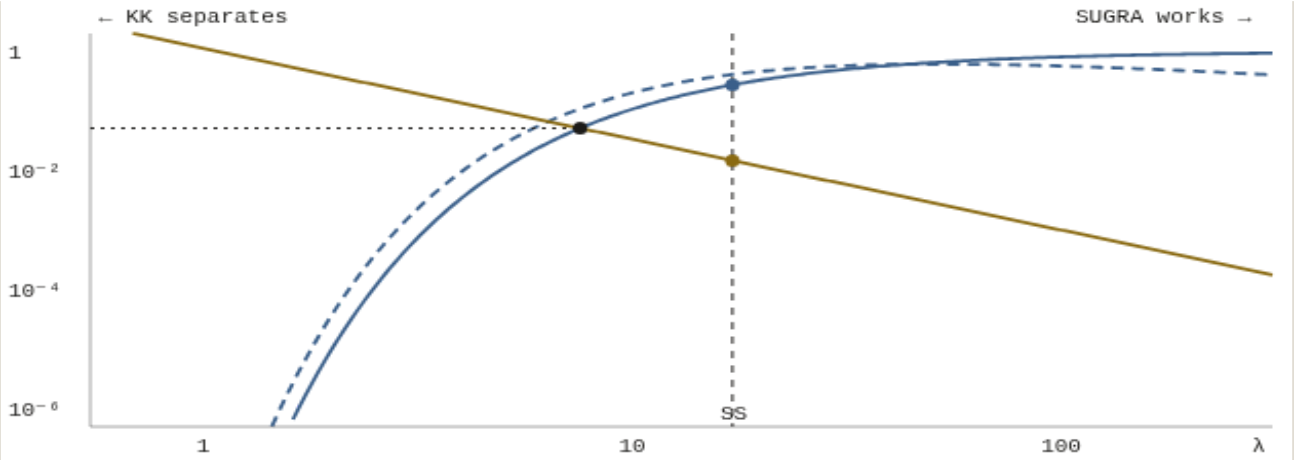
We look at the tug of war in numbers, with $e_{KK} = \Lambda R$ (the constant multiple in (2) set to 1) for how visible the tower is, and $e_{\text{str}} = \lambda^{-p}$ with coefficient 1 (borrowing (4), $p = 3/2$) as the rough guide to the string correction. We call the value at the crossing point λ^* of the two curves the **floor**.

$$F_p = e_{KK}(\lambda^*) = e_{\text{str}}(\lambda^*) \quad (5)$$

$\log e_{KK} + p \log \lambda$ is increasing in λ (at one loop and at two loops, if $p \geq 1$), so there is exactly one crossing point. The one-loop e_{KK} increases towards 1 and e_{str} decreases, so to the left of the crossing e_{str}, and to the right e_{KK}, exceeds F_p. That is, in the one-loop estimate $F_p = \min_\lambda \max(e_{KK}, e_{\text{str}})$, and **for any λ the larger of the two guides does not fall below F_p** Computed .

With the two-loop formula things differ. e_{KK} reaches its maximum 0.61 at $\lambda \approx 51$, and beyond that decreases towards 0 as $\lambda \to \infty$. So if the upper limit on λ is removed, the minimum of the max approaches 0 (for $p = 3/2$: 0.067 up to $\lambda \leq 10^4$, 0.038 for $\lambda \leq 10^5$, 0.014 for $\lambda \leq 10^6$) Computed . This is the behaviour of the perturbative formula for the running of the coupling extended to the large-λ side, outside the range where (2) can be used. The two-loop rows of Table 2 are crossing values, and also agree with the minimum of the max restricted to $\lambda \leq 316$ (the range of Figure 1).

Figure 1 Varying λ lets you read the values there of ΛR (blue; solid one loop, dashed two loops) and λ^{-p} (yellow). The horizontal dotted line is the one-loop floor F_p. SS is the λ of Sakai–Sugimoto (it can be off by a factor of about 2 by convention). The dashed line falling to the right of $\lambda \approx 51$ is outside the range where (2) can be used



λ = 16.63, ΛR: one loop 0.274, two loops 0.409, λ^−3/2 = 0.015, floor F = 0.051 (two-loop crossing 0.067)

Computed The numbers in this figure were computed on this machine (the curves are computed on the spot from the formulas; the floor agrees with Table 2).

Table 2 The floor F_p (the value at the crossing) and the crossing point λ^*

Formula for ΛR	p	λ^*	F_p
One loop	1	9.55	0.105
One loop	3/2	7.25	0.051
Two loops	1	7.77	0.129
Two loops	3/2	6.09	0.067

There is a **window** where both are around 5–13%, which does not contradict ratios agreeing with the lattice to a few per cent (when the three-dimensional $0^{--}/0^{++}$ is compared with the dilaton as reference; changing the reference mode or the states gives deviations of 14–26%: 17-09). But what a theorem needs is a **limit** sending the errors to 0, and in the one-loop estimate the floor blocks it. Both guides are crude, with coefficient 1; the point is not the value of the floor itself but that there is no direction making both small at once. Example: putting the $\lambda \approx 16.6$ of Sakai–Sugimoto straight into (2) gives $e_{KK} = 0.27$ (two loops 0.41) and $e_{\mathrm{str}} = 0.015$. Allowing for the difference of convention, halving λ (8.3) or doubling it (33) gives e_{KK} of 0.075–0.52 and e_{str} of 0.042–0.005, and their order does not swap Computed . This is a rough guide suggesting that the tower side remains large.

04

Extra things remain — the KK tower and supersymmetry

At $\lambda \gg 1$ the KK tower comes at the same height as the glueballs. The squared masses of fluctuations on a fixed background are eigenvalues of Laplace-type operators, and changing the metric as $g \mapsto s^2 g$ multiplies all eigenvalues by s^{-2}.

$$m_n^2 = \frac{c_n}{R^2} \qquad (c_n \text{ numbers fixed by the shape of the background alone})$$ (6)

If the background has a single length R, glueballs and KK modes alike are some multiple of $1/R$ (the counting of powers is Known ; the part saying that the background describes Yang–Mills is Physics). But the string tension involves λ, and Klebanov–Strassler write $T_s \sim g_s M\, m_{\text{glueball}}^2$ (the same circumstance as 17-08 § 07). That the tower does not separate is acknowledged by the authors in Table 3 (for Witten's background, by Csáki et al. and Klebanov–Strassler) Physics .

Table 3 What remains, and the authors' words

Model	What remains	The authors' words
Csáki et al. (Witten's background)	$SO(6)$ non-singlets	'their masses are of the same order as the SO(6) singlet states ... Presumably λ^{-1} corrections make them heavy'. Some fields removed by hand
Maldacena–Núñez	KK on the fivebranes	'the masses of glueballs are comparable to the masses of Kaluza Klein states on the fivebrane'
Klebanov–Strassler	KK on S^3	'in the SUGRA limit both scale as m/(g_sM)'. States explicitly that Witten's background also has extra modes
Polchinski–Strassler	$\mathcal{N} = 4$ matter	'the N=4 matter cannot be decoupled within the supergravity regime'
Sakai–Sugimoto	A tower of mass M_{KK}, $SO(5)$	'the same energy scale of the mass of the vector mesons'. A footnote says 'believed somewhat optimistically' (the latter in a footnote of hep-th/0507073)

How supersymmetry remains

In Witten's type (1998 § 4; fermions made antiperiodic on the circle), the fermions acquire masses of order $1/R$ at tree level, the scalars 'very plausibly get masses ... at one-loop level', and it continues 'If this is so, the low energy theory will be the pure SU(N) theory without supersymmetry' (§ 2.2, on the three-dimensional case, has a sentence to the same effect: at weak coupling the long-distance behaviour is 'very plausibly' only a three-dimensional gauge field). Klebanov–Strassler and Maldacena–Núñez preserve $\mathcal{N} = 1$ supersymmetry, so a further limit making the gluino (the fermion that is the supersymmetric partner of the gluon) heavy is needed. The five-dimensional model of Gürsoy–Kiritsis is of the kind (bottom-up) that puts a five-dimensional gravity model directly rather than deriving it from a string-theory background, and takes the β function as input ('using input ... as well as QCD') Physics . Example: within the range we examined, among the models built from string-theory backgrounds (top-down), only Witten's type yields non-supersymmetric pure Yang–Mills, and that too at the same scale as the tower.

05

$N \to \infty$ — when the group is fixed to one

Gravitational geometry becomes classical as $N \to \infty$. The quantities of the gauge theory are arranged by 't Hooft's counting (17-04) into a sum over genus h.

$$\log Z = \sum_{h \geq 0} N^{2-2h} F_h(\lambda) \quad (7)$$

What the gravity computation gives is the leading part of F_0 on the large-λ side, and for $SU(3)$ ($1/N^2 = 1/9$) all the remaining terms matter. That the ratios move slowly with N on the lattice (17-04) Physics does not give the existence of the theory at fixed N either. There is a gap in the kinds of group too: D-branes give $U(N)$ and $SU(N)$, and orientifolds (backgrounds divided by an operation that reverses the orientation of strings) give SO and Sp (17-07). Within the range we searched we found no holographic dual of four-dimensional pure Yang–Mills for the exceptional groups $G_2, F_4, E_{6,7,8}$, and geometric engineering can make types ADE, and types B, C, F, G by folding with outer automorphisms (automorphisms of Dynkin diagrams), but within supersymmetric theories (17-07). Example: in the problem statement, $SU(2)$ and G_2 are each a single theory.

06

The order of limits — exchanging them needs uniformity

The gravity computation takes the supergravity limit $\lambda \to \infty$ after the $N \to \infty$ that makes the string classical, and uses R as the unit.

$$N \to \infty \ \longrightarrow \ \lambda \to \infty, \qquad R \text{ fixed} \quad (8)$$

The problem statement's side fixes N and takes $R \to 0$, that is, by (3), $\lambda \to 0$. A standard theorem of analysis gives the condition under which two limits may be exchanged Known . A double sequence $a_{m,n}$ converges to b_m as $n \to \infty$ **uniformly in** m when

$$\sup_m \left| a_{m,n} - b_m \right| \xrightarrow[n \to \infty]{} 0$$

that is, when a single n makes the errors for every m small at once. Then the following holds.

$$a_{m,n} \xrightarrow[n \to \infty]{} b_m \ (m\text{-uniformly}), \quad a_{m,n} \xrightarrow[m \to \infty]{} c_n \implies \lim_{m \to \infty} b_m = \lim_{n \to \infty} c_n \quad (9)$$

Without uniformity the exchange is in general not allowed. Example: for $a_{m,n} = m/(m+n)$, $\lim_m \lim_n a_{m,n} = 0$ while $\lim_n \lim_m a_{m,n} = 1$ (since $\sup_m m/(m+n) = 1$, the

convergence to 0 as $n \to \infty$ is not uniform).

What is needed is that the $1/N$ corrections be uniformly small in λ, that the string corrections be uniformly small in N, and an unbroken road down to $\lambda \to 0$. (4) is the leading term of the correction in three dimensions, neither uniformity nor a limit. **Within the range we searched we found no result justifying this exchange.** As a metaphor, the supergravity region ('fixed ultraviolet cutoff … in the strong ultraviolet coupling regime') is in the position of a coarse lattice at strong coupling. More precisely, on the strong-coupling lattice the existence of the infinite-volume limit is proved (Osterwalder–Seiler 1978, 5-04), but this correspondence stays a metaphor.

07

Detour: seeing non-uniform convergence

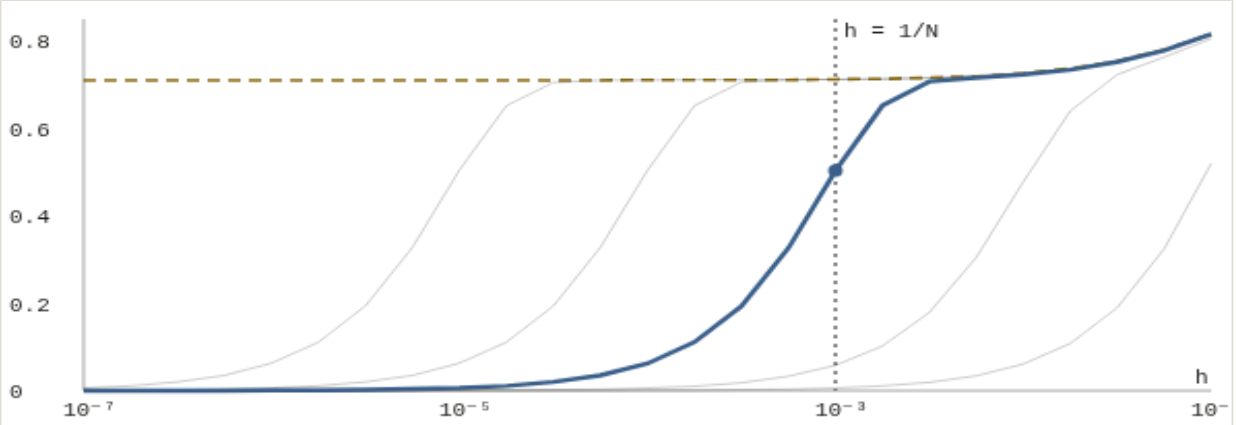
A section you may skip.

Spontaneous magnetisation changes value with the order of $h \to 0$ and $N \to \infty$ ((10) of 2-08). In the Curie–Weiss model ($J = 1$, inverse temperature $\beta = 1.25$) we count where it is non-uniform. The magnetisation per spin is written $\bar{m}$, as in 2-08, to distinguish it from mass. At finite N it can be written exactly as a sum of binomial coefficients.

$$\langle \bar{m} \rangle_{N,h} = \frac{\sum_k \binom{N}{k} \bar{m}_k \, e^{\beta N (\bar{m}_k^2/2 + h\bar{m}_k)}}{\sum_k \binom{N}{k} \, e^{\beta N (\bar{m}_k^2/2 + h\bar{m}_k)}}, \qquad \bar{m}_k = \frac{2k - N}{N} \tag{10}$$

By the symmetry of flipping all spins, $\langle \bar{m} \rangle_{N,0} = 0$, so $\lim_N \lim_{h \to 0} = 0$, while $\lim_{h \downarrow 0} \lim_N = \bar{m}^* = 0.71041$.

Figure 2 As N grows, the range over which $\langle \bar{m} \rangle_{N,h}$ (blue) clings to the $N = \infty$ curve (yellow dashed) extends to the left. The vertical dotted line is $h = 1/N$



N = 10³, ⟨m̄⟩ at h = 1/N = 0.503 ((11) at x = 1: 0.505)

Computed The numbers in this figure were computed on this machine ((10) evaluated exactly and embedded in steps of 0.25 in $\log_{10} h$).

Table 4 $\langle \bar{m} \rangle_{N,h}$ ($\beta = 1.25$). Bold is the $h = 1/N$ column

N	$h = 10^{-2}$	10^{-3}	10^{-4}	10^{-5}	$h = 0$
10^2	**0.4780**	0.0579	0.0058	0.0006	0
10^3	0.7231	**0.5028**	0.0625	0.0063	0
10^4	0.7255	0.7117	**0.5045**	0.0629	0
10^5	0.7257	0.7120	0.7105	**0.5047**	0
∞	0.7257	0.7120	0.7106	0.7104	$\bar{m}^*$ $(h \downarrow 0)$

Following a row to the right leads to 0, following a column down leads near $\bar{m}^*$, and the diagonal is about 0.5. For large N the distribution splits into two peaks at $\pm\bar{m}^*$ with weights in the ratio $e^{2\beta h N \bar{m}^*}$, so

$$\langle \bar{m} \rangle_{N,\, x/N} \longrightarrow \bar{m}^* \tanh(\beta \bar{m}^* x) \qquad (N \to \infty) \quad (11)$$

Against the value 0.50468 at $x = 1$, the exact value at $N = 10^5$ was 0.50467 Computed . **Non-uniformity sits in the band $h \sim 1/N$, which escapes to the left as N grows.** Here (10) can be written exactly, so the position of the band is known, but for the two knobs of (8) there is as yet no way of checking.

08

The distance from the problem statement — five requirements

The problem statement is 'Prove that for any compact simple gauge group G, a non-trivial quantum Yang–Mills theory exists on R^4 and has a mass gap $\Delta > 0$', and existence includes satisfying axiomatic properties (Jaffe–Witten § 4) Known .

Table 5 The requirements, and where the extra-dimensional models stand (every row at the level of Physics)

Requirement	Where things stand
Fix the group G	$N \to \infty$ for $SU(N)$. No duals for exceptional groups found (§ 05)
On $\mathbb{R}^4$	ΛR of order 1 on $\mathbb{R}^4 \times$ (extra dimensions) (§ 03)
Asymptotically free at short distances	The ultraviolet is a five-dimensional theory or the (2,0) theory (17-07). The cascade of Klebanov–Strassler 'goes on forever as the scale is increased'
Exists, satisfying the axioms (4-10)	AdS/CFT is a conjecture (17-08 § 08). The string-theory side has no non-perturbative definition
Mass gap	A supergravity eigenvalue problem (semiclassical). Witten: 'A mass gap likewise can be demonstrated ... by using the large λ behavior of the metric' (this λ is a radial coordinate of the metric)

None of the rows of Table 5 is satisfied yet. Jaffe–Witten § 6 wrote 'at present we do not know any non-trivial relativistic field theory that satisfies the Wightman (or any other reasonable) axioms in four dimensions' (a sentence from 2000; the existence of the four-dimensional theory is given by a construction published in 2026 as the limit of

Wilson's lattice, which the committee has assessed; Volume 2). On the mass gap, the problem page of the Clay Mathematics Institute still writes 'no proof of this property is known' Known (the definition of the gap is in 4-11). Example: the ratios the models hit to a few per cent (17-09; only the three-dimensional ratio with the dilaton as reference) are also numbers obtained while satisfying none of the rows of Table 5.

09

What remains — the problem moves

The problem does not vanish; it moves. Witten, noting that a singularity appears in the geometry as $\eta \to 0$, writes 'Apparently, in this approach, the mysteries of four-dimensional quantum gauge theory are encoded in the behavior of string theory near this singularity', and Csáki et al. write that under the conjecture the problem of QCD at large N reduces to 'that of controlling the α′ corrections to the two-dimensional sigma-model with the Ramond-Ramond background' Physics . We give the meanings of the words briefly. α' is the square of the string length (the string tension is $1/(2\pi\alpha')$, (1) of 17-05). The two-dimensional sigma model is the field theory on the two-dimensional surface swept out by a string (the **world sheet**), whose fields are maps from the world sheet to spacetime. Ramond–Ramond fields are fields sourced by D-branes. The α' corrections are corrections coming from the curvature radius of spacetime being finite compared with the string length, and (4) evaluates the leading term of this expansion. The 'worldsheet field theory with Ramond-Ramond fields' that Witten named in § 03 (a field theory on the world sheet whose Lagrangian contains Ramond–Ramond fields) is also this two-dimensional theory.

$$\text{4-dim. pure YM} \xleftarrow{\text{limit (3)}} \text{extra-dim. models} \xleftarrow{\text{conjecture}} \text{strings, M-theory} \ (12)$$

Example: neither arrow in (12) is a mathematical theorem (the left is unjustified, the right a conjecture), and the object at the right end has no non-perturbative definition either (17-13, 16-05).

An idea from this book's study (before verification)

Restricted to linear fluctuations of the supergravity fields, we see the "single length" of (6) as the reason the tower does not separate, and also as the reason that makes "a single scale" (17-12, 23-01) trivial on a fixed background. But the string tension involves λ (the formula of Klebanov–Strassler in § 04), and once strings are included the lengths are not exhausted by one. Going back to four dimensions is a change of vehicle from R to Λ, and the question remains after that. This is neither a theorem nor a claim of the literature (23-17).

What this chapter can say

What is said	What is not said
Known The powers in (6), (9), the quotations from the problem statement.	That the background describes four-dimensional pure Yang–Mills theory (a conjecture).
Computed Tables 1, 2 and 4, Figures 1 and 2, the floor of (5) (the value at the crossing) and that for the one-loop formula it is the minimum of the max, the maximum of the two-loop formula ($\lambda \approx 51$), $\lambda \approx 16.6$ and the range of a factor of 2 around it, the check of (11).	Coefficients independent of convention. e_{str} is a rough guide, not the actual string correction. The power in (4) is for the three-dimensional 0^{++}; the power in four dimensions is not given. The behaviour of the two-loop formula for $\lambda \gtrsim 51$ is outside the range of (2).
Physics That $R \to 0$ and $\lambda \to 0$ are the same direction, that the tower does not separate (the authors' words), the order in (8).	A justification of exchanging the limits (none found within the range searched). This book itself shows neither the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is in Volume 2).

2026-10-01 · chapter Yang–Mills and the mass gap Part 17 From the side of physics supersymmetry and electric–magnetic duality

Supersymmetry and Seiberg–Witten — switching to the dual, the strongly coupled vacuum becomes a weakly coupled theory of monopoles

> This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — That the low energies of the N=2 supersymmetric `SU(2)` theory are fixed by a single holomorphic function and its singularities and monodromies.
That at a strongly coupled point the mass of the monopole becomes 0, and that on breaking to N=1, confinement and a gap appear through monopole condensation as a weak-coupling calculation.
How far this is an argument of physics, and where theorems of mathematics begin.

Prerequisite chapters — 17-08. The tools are dual superconductivity in 17-02, dimensional transmutation in 17-01 and SU(2) in 1-04. Holomorphic functions, harmonic functions and the periods of a torus are defined on the spot.

Said first — The theory of this chapter is not pure Yang–Mills (it contains scalar fields and fermions). The central results are at the level of physics, and the N=2 theory itself has not been constructed mathematically. Nothing is shown about the mass gap of the problem statement.

The order of this chapter

1. What can be seen in a neighbouring theory — the one-loop coefficients
2. The minimum of supersymmetry — the set of fields, the flat directions, the coordinate u
3. A single holomorphic function — one loop and instantons
4. The contradiction with positivity — a harmonic function has no minimum in the interior
5. Exchanging electric and magnetic — $\tau \to -1/\tau$ and the BPS masses

6. Singularities and monodromy — the points where the monopole becomes light (Figure 1)
7. Writing with the periods of a curve — the periods of a torus and $\operatorname{Im}\tau > 0$ (Figure 2; Detour: at $u = 3$ we get $\tau = i$)
8. Reading the instanton coefficients from the exact solution — a series with rational coefficients, checked against one loop
9. The perturbation to N=1 — monopole condensation and the mass gap
10. The distance from pure Yang–Mills — the border between physics and mathematics

---

01

What can be seen in a neighbouring theory — three theories and their one-loop coefficients

Pure Yang–Mills is hard because the coupling becomes strong at the low energies where the gap is decided, and perturbation theory does not work (17-01). Gauge theories with two sets of supersymmetry (N=2) are the typical **neighbouring theory** that can be computed into the strongly coupled side, and Seiberg and Witten (1994, SW below) proposed to fix the low-energy effective theory exactly in the case of `SU(2)`. The abstract says 'The "strongly coupled" vacuum turns out to be a weakly coupled theory of monopoles, and with a suitable perturbation confinement is described by monopole condensation' Physics .

The three theories differ in their set of fields and in the coefficient b of the one-loop running (in the convention where pure Yang–Mills has $11N/3$). One Weyl fermion in the adjoint representation (a two-component fermion; the Dirac fermion of the electron has four components) adds $-2N/3$, and one complex scalar adds $-N/3$ Known .

$$b_{\mathrm{YM}} = \tfrac{11}{3}N, \qquad b_{\mathcal{N}=1} = \tfrac{11}{3}N - \tfrac{2}{3}N = 3N, \qquad b_{\mathcal{N}=2} = \tfrac{11}{3}N - 2\cdot\tfrac{2}{3}N - \tfrac{1}{3}N = 2N \quad (1)$$

Example: for `SU(2)` these are, in order, $22/3,\ 6,\ 4$. The N=2 theory has no gap, since a massless photon remains; a gap appears only when it is broken to N=1 in § 09. Section 6.6 of the problem statement also cites Seiberg–Witten as an example of a route to understanding the gap in theories with matter ('for example, see [41]') Known .

02

The minimum of supersymmetry — the set of fields, the flat directions, the coordinate u

Supersymmetry is a symmetry that exchanges bosons and fermions, and N counts how many sets of its generators (supercharges) there are. A set of fields carried into one another by supersymmetry is called a **multiplet**. The smallest set for an N=2 gauge theory is the gauge field A_μ, two Weyl fermions λ, ψ and a complex scalar ϕ, all in the adjoint representation (1-04). The potential of the scalar is

$$V(\phi) = \frac{1}{g^2}\,\mathrm{tr}\,[\phi, \phi^\dagger]^2 \quad (2)$$

and it is 0 if ϕ and $\phi^\dagger$ commute. For `SU(2)` a gauge transformation brings it to $\phi = \frac{1}{2} a \sigma^3$ ($a \in \mathbb{C}$), and since a and $-a$ are carried into each other, the gauge-invariant coordinate is $u = \mathrm{tr}\,\phi^2 = \frac{1}{2}a^2$ Known . The vacua with $V = 0$ form a family numbered by the complex number u (a moduli space), and SW argue that this family is not lifted in the quantum theory either Physics .

For $a \neq 0$ the only elements commuting with ϕ are the diagonal `U(1)`, and the remaining two gauge fields (the W bosons) acquire mass by the **Higgs mechanism** (the mechanism by which a scalar field that takes a value gives mass to gauge fields; 3-07). The `U(1)` photon stays massless, so there is no gap. Example: if $\phi = \sigma^+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, then $[\phi, \phi^\dagger] = \sigma^3$ and $V = 2/g^2 > 0$; if $\phi = \frac{1}{2} a \sigma^3$, then $V = 0$.

03

A single holomorphic function — the prepotential, one loop, instantons

A complex function is **holomorphic** if it can be differentiated as a function of a complex number. Under N=2 supersymmetry the low-energy effective theory can be written with a single holomorphic function $\mathcal{F}(a)$ (the **prepotential**) (Seiberg 1988, SW § 2) Physics . The complex number combining the coupling g and the θ angle,

$$\tau(a) = \frac{\theta}{2\pi} + \frac{4\pi i}{g^2} = \mathcal{F}''(a), \qquad ds^2 = \mathrm{Im}\,\tau(a)\,|da|^2 \quad (3)$$

gives the coupling of the photon and the distance (metric) on the family of vacua. Where $|a|$ is large, the theory is asymptotically free and weakly coupled (4-06). The original writes

$$\mathcal{F}(a) = \frac{i}{2\pi}\,a^2 \ln \frac{a^2}{\Lambda^2} + \sum_{k \geq 1} \mathcal{F}_k \left(\frac{\Lambda}{a}\right)^{4k} a^2 \quad (4)$$

and continues 'Higher order perturbative corrections are absent. Instantons lead to new terms.' The first term is one loop, and the k-th term is the contribution of k instantons (3-05) Physics .

The power $4k$ comes from the $b = 4$ of (1). In the convention of (3) in 17-01, with $b_0 = b/16\pi^2 = 1/4\pi^2$,

$$\Lambda^4 = \mu^4 \exp\Big(- \frac{8\pi^2}{g^2(\mu)} \Big) \quad (5)$$

and the exponential is the weight of a single instanton. $(\Lambda/a)^4$ appears at no order of perturbation theory (4-12) Known . Example: in the units that put the singularities at $u = \pm 1$, one loop gives $\operatorname{Im}\tau \approx (2/\pi)\ln(2|a|)$ (from the numbers in § 07). The coefficient $2/\pi = 8\pi b_0$ agrees with the running of (5) Computed .

04

The contradiction with positivity — a harmonic function has no minimum in the interior

The metric of (3) must be positive. But the imaginary part of a holomorphic function is a **harmonic function**.

$$\Big(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \Big) \operatorname{Im}\tau = 0 \qquad (a = x + iy) \quad (6)$$

The value of a harmonic function at the centre of a circle equals its average over the circle, and unless it is constant it cannot have a minimum in the interior of a region (the minimum principle) Known .

If τ is a single function on the whole a-plane, then $\operatorname{Im}\tau$ goes to $+\infty$ as $|a| \to \infty$, so it has a minimum somewhere, contradicting the principle. The original writes 'if Im τ(a) is globally defined it cannot be positive definite as the harmonic function Im τ cannot have a minimum', and concludes that the description by a is only locally correct Physics . Example: the one-loop $(2/\pi)\ln(2|a|)$ is negative for $|a| < 1/2$, and at $|a| = 1/4$ it is -0.44; that is, "$4\pi/g^2$ is negative" Computed . On the strongly coupled side another variable is needed.

05

Exchanging electric and magnetic — $\tau \to -1/\tau$ and the BPS masses

Maxwell's equations with magnetic charges added were symmetric under exchanging electric and magnetic ((6) in 17-02). Including the θ angle, the exchange is $\tau \to -1/\tau$,

and shifting θ by 2π gives $\tau \to \tau + 1$; the two generate the group $SL(2,\mathbb{Z})$ (integer entries, determinant 1) Known . SW set $a_D = \partial\mathcal{F}/\partial a$ and wrote the metric symmetrically in a and a_D.

$$ds^2 = \operatorname{Im}\left(da_D\, d\bar{a}\right), \qquad \tau_D = -\frac{1}{\tau} \quad (7)$$

With a_D as the coordinate the form is the same, and the coupling changes to $-1/\tau$. The original stresses that this is another description of the same theory Physics . The mass of a particle with electric charge n_e and magnetic charge n_m has a lower bound, and the mass m_{BPS} of particles equal to the bound (BPS states) is

$$m_{\mathrm{BPS}} = \sqrt{2}\,|n_e\, a + n_m\, a_D| \quad (8)$$

(Witten–Olive 1978, SW § 4) Physics . The W boson is $(n_m, n_e) = (0,1)$, the monopole $(1,0)$, and the dyons $(1,n)$. Example: classically $a_D = \tau_{\mathrm{cl}} a$, and the monopole is $|\tau_{\mathrm{cl}}| \approx 4\pi/g^2$ times heavier than the W, about 12.6 times for $g = 1$. On the strongly coupled side the ratio is reversed (Figure 2).

06

Singularities and monodromy — the points where the monopole becomes light

Differentiating the one-loop term of (4) gives $a_D \approx \frac{i}{\pi} a\left(\ln \frac{a^2}{\Lambda^2} + 1\right)$. For large u, $a \approx \sqrt{2u}$, so when u goes once round a large circle, $a \to -a$ and $\ln a^2 \to \ln a^2 + 2\pi i$, and $a_D \to -a_D + 2a$. Written as a matrix acting on the column vector $(a_D, a)^{\mathsf{T}}$ (the **monodromy**),

$$\mathsf{M}_\infty = \begin{pmatrix} -1 & 2 \\ 0 & -1 \end{pmatrix} \quad (9)$$

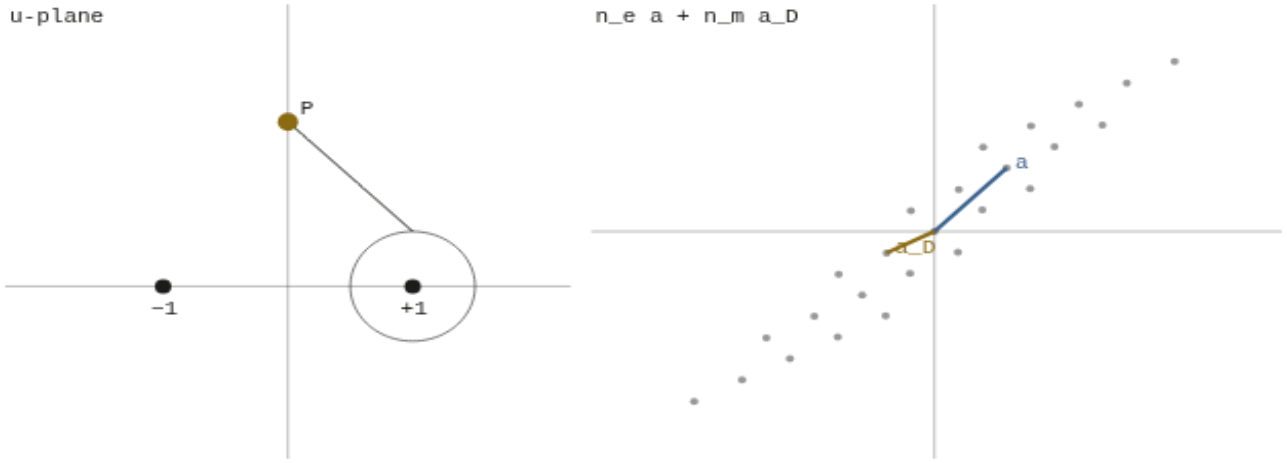
If every monodromy commuted with M_∞, then a^2 would be a global coordinate and we would be back at the contradiction of § 04. SW therefore proposed that there are two singularities at finite places (choosing units, $u = \pm 1$), where the mass of a monopole or a dyon becomes 0 Physics . Near $u = 1$ the effect of the light monopole gives $a \approx a_0 + (i/\pi) a_D \ln a_D$, and one turn gives $a \to a - 2a_D$.

$$\mathsf{M}_1 = \begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix}, \qquad \mathsf{M}_{-1} = \begin{pmatrix} -1 & 2 \\ -2 & 3 \end{pmatrix}, \qquad \mathsf{M}_1 \mathsf{M}_{-1} = \mathsf{M}_\infty \quad (10)$$

(The formulas of SW. In the same Figure 1, SW write the product in the order that puts the matrix of the loop traversed first on the right.) The charge $q = (n_m, n_e)$ of the

particle that becomes massless satisfies $q\mathsf{M} = q$; for M_1 it is $q = (1,0)$, that is, the monopole.

Figure 1 With "Play", u goes once round a singularity from $P = 1.5i$ (left), and a (blue) and a_D (yellow) move (right; the points are $n_e a + n_m a_D$). After one turn the pair is rewritten by a matrix



u = 0.000+1.500i, a = 1.256+1.256i, a_D = −0.832−0.424i

Computed The numbers in this figure were computed on this machine (the equation (PF) of § 07 solved along the path from P by the Runge–Kutta method; the matrices agree with Table 1).

Table 1 The matrices for one anticlockwise turn from the base point $P = 1.5i$ (deviation from integers at most 10^{-12})

Point encircled	Matrix	$q = (n_m, n_e)$ with $q\mathsf{M} = q$
$u = 1$: $\mathsf{M}(1)$	$\begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix}$	$(1,0)$ monopole
$u = -1$: $\mathsf{M}(-1)$	$\begin{pmatrix} 3 & 2 \\ -2 & -1 \end{pmatrix}$	$(1,1)$ dyon
Both: $\mathsf{M}(\infty)$	$\begin{pmatrix} -1 & 2 \\ 0 & -1 \end{pmatrix}$	None

In Table 1 the matrix for going round path A and then path B is written $\mathsf{M}_A\mathsf{M}_B$ (the order of analytic continuation). Seen from P, the large loop is "-1 and then $+1$", so $\mathsf{M}(-1)\mathsf{M}(1) = \mathsf{M}(\infty)$, and $\mathsf{M}(-1) = \mathsf{M}_\infty \mathsf{M}_1^{-1} = \mathsf{M}_\infty \mathsf{M}_{-1} \mathsf{M}_\infty^{-1}$ Computed . It is conjugate to the M_{-1} of SW, and the charge of the massless dyon changes from $(1,-1)$ to $(1,1)$. This is an instance of the original's 'complete democracy among dyons' (conjugating by M_∞ shifts the charge by 2).

07

Writing with the periods of a curve — the periods of a torus and $\operatorname{Im}\tau > 0$

SW § 6 assigns to each u the curve

$$E_u:\ y^2=(x-1)(x+1)(x-u)\quad (11)$$

Gluing the two sheets of $y=\pm\sqrt{\cdots}$ along two cuts joining the branch points $-1,1,u,\infty$ gives a surface with one hole (a **torus**). A torus is the plane divided by a lattice $\mathbb{Z}\omega_1+\mathbb{Z}\omega_2$, and with the orientation of $\tau=\omega_2/\omega_1$ chosen consistently, $\operatorname{Im}\tau>0$ Known . The branch points coincide only at $u=\pm1,\infty$, which agree with the singularities. Set the periods to be

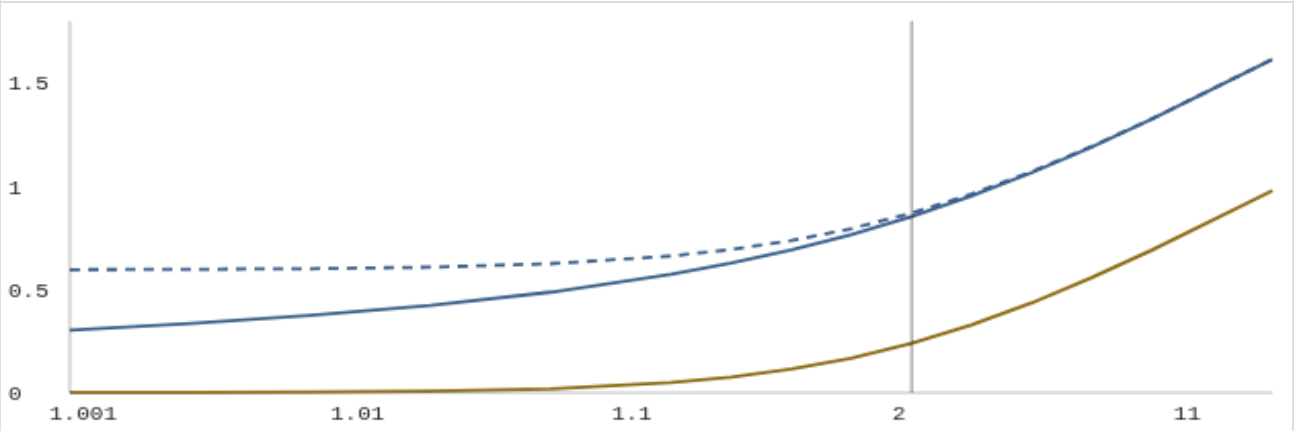
$$a=\frac{\sqrt{2}}{\pi}\int_{-1}^{1}\frac{\sqrt{x-u}}{\sqrt{x^2-1}}\,dx,\qquad a_D=\frac{\sqrt{2}}{\pi}\int_{1}^{u}\frac{\sqrt{x-u}}{\sqrt{x^2-1}}\,dx,\qquad \tau=\frac{da_D/du}{da/du}\quad (12)$$

Differentiating in u, the integrand becomes a constant multiple of dx/y, and da/du and da_D/du are integrals along the two loops of the torus, that is, periods of the lattice (times the same constant). τ is their ratio, so $\operatorname{Im}\tau>0$ holds automatically (the properties of the curve are Known ; the correspondence with the theory is Physics). The two periods satisfy the same equation $4(u^2-1)\Pi''+\Pi=0$ (the Picard–Fuchs equation, (PF) below) (relative residual at most 10^{-15} on the real axis $u>1$ Computed). Figure 1 integrates this equation numerically along the path. Near $u=1$,

$$a_D\approx\frac{i(u-1)}{2},\qquad a\approx\frac{4}{\pi}-\frac{(u-1)\ln(u-1)}{2\pi}\quad (13)$$

and the $a\to a-2a_D$ of (10) comes out. Example: the numerical integration of (12) agreed with the closed form in hypergeometric functions to within 10^{-8}, and $a(1)=4/\pi$ Computed .

Figure 2 Choosing u (>1) on the real axis with the knob lets you read the mass ratio of monopole to W, $|a_D|/a$ (yellow), and the coupling $\operatorname{Im}\tau=4\pi/g^2$ (blue; the dashed line is one loop, $(2/\pi)\ln 2a$)



u = 1.989, W: √2a = 2.773, monopole: √2|a_D| = 0.662, ratio 0.239, Im τ = 0.853 (one loop 0.870)

Computed The numbers in this figure were computed on this machine (15 points of the numerical integration of (12) embedded).

Table 2 Periods and coupling on the real axis $u > 1$ (in units that put the singularities at $u = \pm 1$)

u	a	$\lvert a_D\rvert/a$	$\operatorname{Im}\tau$	One loop
1.001	1.2750	0.0004	0.303	0.596
1.5	1.6776	0.1448	0.735	0.771
3	2.4320	0.3727	1.000	1.007
100	14.1421	1.4912	2.128	2.128

The one-loop column is $(2/\pi)\ln 2a$. As $u \to 1$, $\operatorname{Im}\tau$ goes to 0 and the electric coupling diverges.

Detour: at $u = 3$ we get $\tau = i$

A subsection you may skip.

Under $x \mapsto (x+1)/2$ the branch points move to $0, 1, 2, \infty$ and the curve becomes $y^2 = x(x-1)(x-2)$. Under $x \mapsto 2 - x$ the right-hand side changes sign, so $(x, y) \mapsto (2 - x, iy)$ carries the curve to itself and returns to the start after 4 steps. This is a symmetry that turns the lattice by 90° onto itself, and such a lattice is square Known . If it is square, τ is a value carried to i by $SL(2, \mathbb{Z})$, and in the normalisation of (12) it was exactly $\tau(3) = i$ Computed . Since $-1/\tau = \tau$, it is the point where the electric and magnetic couplings are equal.

08

Reading the instanton coefficients from the exact solution — a series with rational coefficients, checked against one loop

Expanding (12) at large u and solving inversely for a gives a series with rational coefficients c_k Computed .

$$u = \frac{a^2}{2} + \sum_{k\geq 1} c_k\, a^{2-4k}, \qquad c1 = \tfrac{1}{4}, \quad c2 = \tfrac{5}{64}, \quad c3 = \tfrac{9}{128}, \quad c4 = \tfrac{1469}{16384} \tag{14}$$

Matone (1995) introduced $\mathcal{G} = \pi i\big(\mathcal{F} - \tfrac{1}{2} a\, a_D\big)$, and the abstract says it is modular invariant. Putting $\mathcal{G} = u$ into (4), the one-loop term gives $a^2/2$ and the k-th term gives $2\pi i k$ times the term in a^{2-4k}, so the coefficient of a^{2-4k} in (4) reads as $c_k/(2\pi i k)$. The equation of the abstract, $(1 - \mathcal{G}^2)\mathcal{G}'' + \tfrac{1}{4} a\, \mathcal{G}'^3 = 0$, also becomes the same equation as (PF) on setting $\mathcal{G} = u$ Computed .

We check this reading with a_D. Example: at $u = 2$ the numerical integration of a_D/i gives 0.473434. One loop alone gives 0.462621, up to $k = 1$ 0.473083, and up to $k = 3$ 0.473432; each added term shrinks the difference by more than one digit Computed .

Dorey–Khoze–Mattis (1996) computed one and two instantons directly and reported 'precise agreement' Physics .

09

The perturbation to N=1 — monopole condensation and the mass gap

In the language of N=1, the N=2 set splits into the set (A_μ, λ) (the vector multiplet) and the set Φ of ϕ, ψ. Adding a term $m\,\mathrm{tr}\,\Phi^2$ that gives mass to Φ, an N=1 theory remains at low energies. The original describes this theory as 'strongly believed to generate a mass gap', and lists confinement, the breaking $\mathbb{Z}_4 \to \mathbb{Z}_2$ and that there are exactly two vacua (citing Witten 1982) Physics . $\mathbb{Z}_4$ is the symmetry generated by the transformation that multiplies the phase of λ by i, and the remaining $\mathbb{Z}_2$ is multiplication by -1.

Near $u = 1$ we use the dual photon set A_D and the monopole fields $M, \tilde{M}$ (names of fields, not masses). The holomorphic function that fixes the interactions (the superpotential) and the conditions for the vacuum are

$$\widehat{W} = \sqrt{2}\,A_D M\tilde{M} + m\,U(A_D); \qquad \sqrt{2}\,M\tilde{M} + m\,\frac{du}{da_D} = 0, \quad a_D M = a_D\tilde{M} = 0 \tag{15}$$

where $U(A_D)$ is the coordinate u written as a function of A_D for the whole set. If $m \neq 0$ and $du/da_D \neq 0$, then $M, \tilde{M} \neq 0$ is required, and $a_D M = 0$ gives $a_D = 0$, that is, $u = 1$. From (13), $du/da_D = -2i$, so the solution with $|M| = |\tilde{M}|$ has $|M|^2 = \sqrt{2}\,|m|$ (in the units of § 06) Computed .

The monopoles condense. The dual photon acquires mass by the Higgs mechanism, and the original writes 'Expanding around this vacuum, it is easy to see that there is a mass gap'. What condenses is magnetic charge, so the electric field is squeezed into tubes and electric charges are confined (exactly the picture of 17-02) Physics . At $u = -1$ a dyon condenses, and there are two vacua. Example: for $m = 0.01$, $|M| = 0.119$ Computed . There are two scales, Λ and m, so the situation differs from "a single scale" of pure Yang–Mills (17-12).

10

The distance from pure Yang–Mills — the border between arguments of physics and theorems of mathematics

To reach pure Yang–Mills, two limits are needed: decoupling Φ with $m \to \infty$, and sending the mass of the fermion λ to infinity as well. The weak-coupling description of § 09 is for small m, and that the gap and confinement are not interrupted along the

limits remains an expectation; there is no means to control it (17-10) Physics . The whole argument also presupposes that the N=2 theory exists. The example of SW is the typical case where, in four dimensions, confinement was derived from a duality at the level of physics (semiclassical calculations also exist, such as Polyakov's in three dimensions; 17-02), but what remained on the side of mathematics took another form.

Table 3 Claims and levels

Claim	Level
The integral over the space of instantons with $\varepsilon 1, \varepsilon 2$ (the two parameters of rotations in four dimensions) put in has, as $\varepsilon 1, \varepsilon 2 \to 0$, a limit that agrees with the SW prepotential (Nekrasov's conjecture)	Known Theorem: Nakajima–Yoshioka, Nekrasov–Okounkov ($SU(N)$), Braverman–Etingof (general simple groups)
Invariants of four-manifolds made by counting the solutions of the Seiberg–Witten equations (a mathematical definition)	Known (3-06, the four-dimensions article)
That these invariants are equivalent to the Donaldson invariants (the abstract of Witten 1994: 'Recent developments ... suggest a new point of view', 'one can define equivalent four-manifold invariants')	Physics (the current state of proofs on the side of mathematics was not investigated in this chapter)
(11) and (12) describe the low energies of the N=2 theory, and for $m \neq 0$ condensation, confinement and a gap appear	Physics
The gap of pure Yang–Mills	This chapter says nothing

The mathematics in Table 3 consists of theorems and definitions about integrals over the space of instantons and about solutions of equations, not claims about the spectrum (4-11). Example: the coefficients of (14), once the conventions are aligned, are numbers guaranteed by a theorem as integrals over the space of instantons. That the same numbers are "properties of the N=2 quantum field theory" cannot be said, since the construction of the theory (7-01) is missing. It is accurate to read this as an instance, at the level of physics, of the "duality transformations" of § 6.6 of the problem statement (17-13, 16-05).

What this chapter can say

What is said	What is not said
Known (1), the curve (11) and the properties of the torus, the proof of Nekrasov's conjecture, the definition of the SW invariants, § 6.6 of the problem statement.	That the N=2 and N=1 theories exist as quantum field theories (they have not been constructed).

What is said	What is not said
Computed Tables 1 and 2, Figures 1 and 2, (PF), (14), the one-loop constant, $\tau(3) = i$, the $\lvert M\rvert^2 = \sqrt{2}\lvert m\rvert$ of the monopole field. All start from (12).	That (11) and (12) are derived from the N=2 theory (the determination by holomorphy and duality is an argument of physics). How far the equivalence of the SW invariants and the Donaldson invariants has been shown as mathematics (not investigated in this chapter).
Physics The points where the mass of the monopole becomes 0, condensation, confinement and the gap for $m \neq 0$, agreement with the direct instanton calculations.	Control of the two limits back to pure Yang–Mills, and what they imply for the gap. This book itself shows neither the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is in Volume 2).

The sentence that plays the role of an equivalence principle — cutting out "a single scale" as one assumption

> This chapter is this book's own investigation. § 01, § 02, § 08 and § 09 are established knowledge; § 10 is a map of open questions.

What this chapter shows — We take out of the path of pure Yang–Mills one sentence that stands in the same place as the equivalence principle at the start of general relativity: "the tube of confinement has no length parameter other than the string tension". We follow in formulas how joining four lengths by three chains gives "the diffusive-relaxation-time assumption", and check it with the lattice tables and with examples where one scale breaks and where it holds.

Prerequisite chapters — 17-01 How physics sees it and 4-07 Dimensional transmutation and Λ. The Poincaré constant (1-10) and the correlation length (2-08) are defined on the spot as far as needed.

Said first — The correspondence with the equivalence principle is an analogy, not a mathematical equivalence. "A single scale" is not a theorem of the four-dimensional continuum theory, and neither the relaxation-time assumption nor any of the three chains has been proved. This chapter does not show the mass gap; it names the one sentence that remains unproved. The lattice numbers are values from primary sources.

The order of this chapter

1. General relativity began from one sentence — there is no second kind of mass
2. Detour: measuring a second kind of mass — the 10^{-15} of MICROSCOPE
3. A single scale — two kinds of length — the ball length and the string length line up
4. Looking at the lattice tables — the form of the extrapolation comes in from outside
5. Four lengths and three chains — splitting the relaxation-time assumption into a product of ratios

6. Which chain plays the role of the equivalence principle — a table of correspondences (an analogy)
7. Dropping candidates — the other three candidates
8. Examples where one scale breaks — U(1), supergravity, the leading strong-coupling term
9. Examples where one scale holds, and the input needed — three-dimensional $\mathbb{Z}_2$, and I and R
10. Where it differs from the equivalence principle — it cannot be put as an assumption

---

01

General relativity began from one sentence

General relativity is sometimes explained as a combination of the **equivalence principle**, the **constancy of the speed of light**, **general covariance** (the form of the laws is the same in any coordinates) and **Riemannian geometry**. Riemannian geometry is a tool of mathematics, the constancy of the speed of light is a premise inherited from special relativity (setting $c = 1$ is a convention of units), and general covariance is a requirement on how laws are written. On top of these, the one sentence of physics newly added about gravity is the equivalence principle. We write falling in Newtonian mechanics.

$$m_{\mathrm{i}}\, a = m_{\mathrm{g}}\, g \quad \Longrightarrow \quad a = \frac{m_{\mathrm{g}}}{m_{\mathrm{i}}}\, g \tag{1}$$

m_{i} is the **inertial mass** (how hard a body is to move), and m_{g} is the **gravitational mass** (how strongly gravity pulls on it). They are defined by separate experiments, and the theory gives no reason for them to be equal. The equivalence principle says that the ratio $m_{\mathrm{g}}/m_{\mathrm{i}}$ is the same for every body; that is, **there is no second kind of mass**. Then gravity disappears locally inside a freely falling box, and gravity can be written as the geometry of spacetime (said to begin with Einstein 1907; the spacetime article) Physics. Example: if the ratio differs between materials by η, the difference in acceleration is about ηg (§ 02).

The question is: **does the path to the mass gap also contain "one sentence that is obvious physically and unproved mathematically"?** It does: "the tube of confinement has no length parameter other than the string tension". Its role, however, differs from that of the equivalence principle (§ 10).

02

Detour: measuring a second kind of mass

A section you may skip.

The difference in how two bodies fall is measured by the signed quantity $\eta = 2(a_1 - a_2)/(a_1 + a_2)$ (a_1, a_2 are the accelerations of the two bodies). Long ago there was the torsion balance of Eötvös and others (said to be a paper of 1922), and the satellite MICROSCOPE reported this final result with titanium and platinum Known .

$$\eta(\mathrm{Ti}, \mathrm{Pt}) = \left[-1.5 \pm 2.3\,(\mathrm{stat}) \pm 1.5\,(\mathrm{syst}) \right] \times 10^{-15} \quad (2)$$

Combining the errors in quadrature gives $\pm 2.75 \times 10^{-15}$, compatible with 0 Computed . More precisely, experiment only narrows the band and cannot show $\eta = 0$. Physics puts this one sentence as an axiom and keeps checking it.

03

A single scale — two kinds of length

Classical four-dimensional Yang–Mills has no constant with the dimension of mass, and in the quantum theory a single scale Λ appears (4-07). Physics takes a quantity whose mass dimension is k to be a constant multiple of Λ^k (for example the mass of the lightest glueball $m = c_1 \Lambda$ and the string tension $\sigma = c_2 \Lambda^2$; 17-01 § 03) Physics . Then the ratio $m/\sqrt{\sigma} = c_1/\sqrt{c_2}$ is a pure number fixed by the group alone. On the lattice (5-01) what is measured is am and $a\sqrt{\sigma}$ in lattice units; as $\beta \to \infty$ both go to 0, and in the ratio a cancels. Below, m, σ are numbers in lattice units. Making "a single scale" into an inequality uniform in β gives the following sentence (as the record of this book's study writes it).

$$c\,\sigma(\beta) \;\le\; m(\beta)^2 \;\le\; C\,\sigma(\beta) \qquad (\beta \ge \beta_0) \quad (3)$$

The constants $c, C > 0$ do not depend on β. It assumes neither $m > 0$ nor $\sigma > 0$; it only says that if they go to 0, they do so at the same rate. In terms of length, we call the length $\xi = 1/m$ of the lightest glueball (glue plus ball) the **ball length** below (the correlation length: the distance over which correlations decay as $e^{-|x|/\xi}$; 2-08 § 03). $\xi_\sigma = 1/\sqrt{\sigma}$ is the **string length**. $A \asymp B$ means that the ratio A/B is bounded above and below by positive constants independent of β. (3) is the same as $\xi \asymp \xi_\sigma$. It is a claim of the same form as "two kinds of mass", and in the language of physics it is the statement that **no second dimensionless parameter appears**. If there were a second parameter z, the ratio would be $F(z)$, and could go to 0 or to infinity.

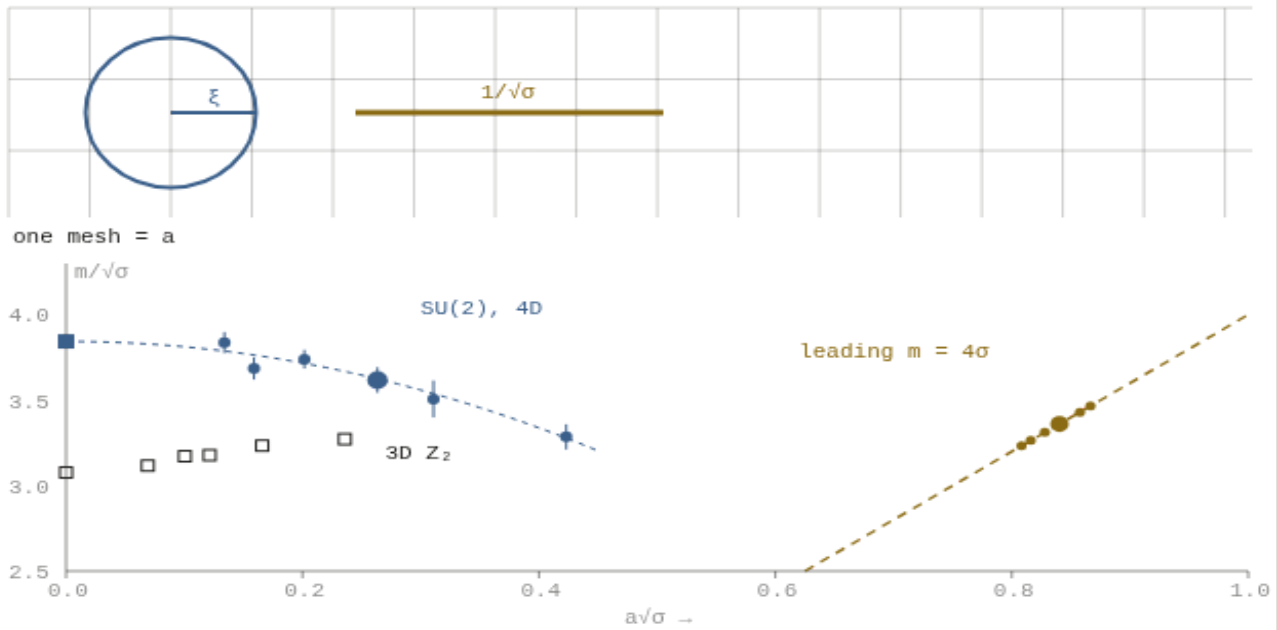
Example: for SU(2) at $\beta = 2.60$ (24^4), $a\sqrt{\sigma} = 0.13395$ and $am = 0.514$ (Lucini–Teper), so in lattice units $\xi_\sigma = 7.47$ and $\xi = 1.95$, and the ratio is 3.837 Computed . That this ratio stays bounded is the content of (3).

04

Looking at the lattice tables — the form of the extrapolation comes in from outside

These are the six SU(2) points of Lucini–Teper (2001). σ is the mass am_l of a tube of glue wound once round the periodic direction, plus the string-fluctuation correction $\pi/(3L)$, divided by the length L (in lattice steps) (equation (4) of the original paper: $am_l = a^2\sigma L - \pi/(3L)$). In using this formula the authors state 'we are assuming that we have linear confinement' (17-01 § 06).

Figure 1 The top is drawn in physical units (the string length $1/\sqrt{\sigma}$ fixed as the length of the bar). Raising β with the knob makes only the lattice mesh (spacing a) finer, and the ball length ξ (the radius of the circle) hardly changes. The bottom is the ratio $m/\sqrt{\sigma}$ (the square is three-dimensional $\mathbb{Z}_2$). The button overlays the leading strong-coupling term (dashed)



β = 2.4 (12⁴) a√σ = 0.2634 am = 0.953, in lattice units 1/√σ = 3.80、ξ = 1.05 m/√σ = 3.618, leading term 3.361

Table A $m/\sqrt{\sigma}$ for SU(2) (from Lucini–Teper Table 1. The master copy of the six values of am is 16-05 Table 3, and of $a\sqrt{\sigma}$ 5-09 Table 1)

β	Lattice	$a\sqrt{\sigma}$	am	$m/\sqrt{\sigma}$
2.25	8^4	0.4231(25)	1.390(30)	3.285(74)
2.30	10^4	0.3108(17)	1.090(33)	3.507(108)
2.40	12^4	0.2634(14)	0.953(19)	3.618(75)

β	Lattice	$a\sqrt{\sigma}$	am	$m/\sqrt{\sigma}$
2.475	16^4	0.2016(13)	0.754(10)	3.740(55)
2.55	20^4	0.15896(63)	0.586(10)	3.686(65)
2.60	24^4	0.13395(62)	0.514(8)	3.837(62)

Computed The numbers in this figure and table were computed on this machine (ratios of values from primary sources; the errors are a rough guide, treated as independent).

The string length in lattice units, $1/(a\sqrt{\sigma})$, grows from 2.36 to 7.47, but the ratio stays within 3.29–3.84, and broadly increases, approaching from below (it falls once from 2.475 to 2.55, within the errors). A fit with a constant independent of a is rejected with $\chi^2 = 38.6$ (5 degrees of freedom), so the ratio depends on a Computed . The continuum value is extrapolated after fixing the form of this dependence.

$$\frac{m}{\sqrt{\sigma}}(a) = r_0 + c\,(a\sqrt{\sigma})^p \quad (4)$$

Table B Fits of (4) (least squares weighted by the errors, all 6 points)

p	Continuum value r_0	χ^2 / dof
2	3.844(43)	2.39 / 4
1	4.053(73)	2.73 / 4
Primary source (Table 5)	3.844(61)	—

$p = 2$ agrees with the primary source in the central value, but $p = 1$ gives a χ^2 just as good, with a continuum value of 4.05 Computed . **The data alone cannot choose the form of the extrapolation.** The authors write 'the functional form of such corrections is known' and use $O(a^2)$, that is, $p = 2$ (5-05). 3.844 is a number resting on the premise that the limit exists and is approached in this form (17-01 § 08) Physics .

05

Four lengths and three chains — the diffusive-relaxation-time assumption

There are four lengths, each counted in lattice steps: the **bookkeeping length** ξ_{RG}, the string length ξ_σ, the ball length ξ, and the **length over which fluctuations are smoothed out** $\sqrt{CP}$.

The bookkeeping length is the length fixed by writing down, for each step that coarsens the lattice by a factor b (one step of the renormalisation group, 7-05), how much the coupling β falls, and piling up the steps. After k steps lengths are multiplied by b^k, so the number of steps needed to fall to a coupling of a fixed strength decides "how many lattice steps make one physical unit". We call that the bookkeeping length, and in this unit set the lattice spacing to $a := 1/\xi_{\mathrm{RG}}$ (the definition in the record of this

book's study; 23-02). Counting by the one-loop running alone (4-06), for SU(2), up to a constant factor, $\xi_{\mathrm{RG}} \approx e^{3\pi^2\beta/11}$ ($\beta = 4/g^2 = 2N/g^2$ of the table of notation; the coefficient in the exponent is a rewriting of the one-loop coefficient b_0) Known .

C_P is, for the probability distribution μ of the lattice gauge field (SU(2), Wilson action, infinite volume, no gauge fixing),

$$\mathrm{Var}_\mu(f) \;\le\; C_P\,\mathcal{E}(f), \qquad \mathcal{E}(f) = \mathbb{E}_\mu\Big[\sum_\ell |\nabla_\ell f|^2\Big] \quad (5)$$

the best constant for which this holds for every f (the Poincaré constant). Var_μ is the variance under μ, and ∇_ℓ is the derivative in the SU(2) directions of the link ℓ. Depending on whether the derivative is taken in the angle ϑ of the link ($U = e^{i\vartheta\cdot\sigma}$) or in the field $A = \sqrt{\beta}\,\vartheta$, $\mathcal{E}$ changes as $\mathcal{E}_A = \mathcal{E}/\beta$, and C_P differs by a factor β. In the free approximation $C_P = (g^2/4)\xi^2$ for the former and $C_P = \xi^2$ for the latter. Whether the band (6) below holds depends on this choice (with the angle normalisation the lower side breaks logarithmically even in the free approximation: 18-05 § 03). The best constant is the inverse of the gap (1-10 § 07). The dynamics at work is **Langevin dynamics**, a stochastic time evolution that moves each link little by little in the direction that lowers the action while adding a small random shake. Run for long, the distribution settles to μ. $\lambda_1 = 1/C_P$ is the gap of this dynamics, and C_P is the time of the slowest return. More precisely, C_P equals the return time only for reversible dynamics in continuous time (Langevin); for discrete-time updates or HMC it is a different quantity (18-03 § 06). The assumption the record of this book's study makes is that the length of fluctuations is on the same scale as the bookkeeping length, which in band form is (6) below. The names follow A-06 Index of names. **The relaxation-time assumption** is the statement at the level of powers $\lim \ln C_P / \ln \xi = 2$, and (6) is the band statement H_{band} (naming the normalisation, $H_{\mathrm{band}}[\mathcal{E}_\vartheta]$ or $H_{\mathrm{band}}[\mathcal{E}_A]$) combined with the chains (ii)(iii).

$$a^2 C_P \asymp 1 \qquad (\text{i.e. } \sqrt{C_P} \asymp \xi_{\mathrm{RG}}) \quad (6)$$

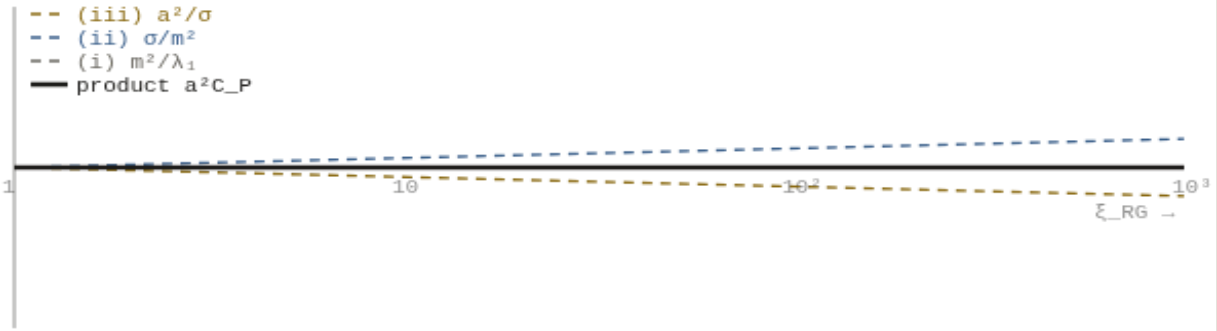
We split this into a product of three ratios.

$$a^2 C_P \;=\; \underbrace{\frac{a^2}{\sigma}}_{\text{(iii)}} \cdot \underbrace{\frac{\sigma}{m^2}}_{\text{(ii)}} \cdot \underbrace{\frac{m^2}{\lambda_1}}_{\text{(i)}} \quad (7)$$

That each factor is $\asymp 1$ we call one **chain**. (i) $\lambda_1 \asymp m^2$: the fluctuation length and the ball length line up (the relaxation chain). Langevin dynamics is diffusive, so smoothing out fluctuations of length ξ takes a time of order ξ^2 (dynamical exponent $z = 2$) Physics . That is why λ_1 is compared not with m but with m^2. (ii) $m^2 \asymp \sigma$: the ball length and

the string length line up (one scale, (3)). (iii) $\sigma \asymp a^2$: the string length and the bookkeeping length line up (confinement happens at the bookkeeping scale). If all three hold, (6) follows. Under (ii)(iii), (6) is the same as the band statement $C_P \asymp \xi^2$, and the double-well relaxation-time power statement follows from it (A-06). The converse does not follow: if the factors cancel each other, the product is constant even when chains are broken (Figure 2). The algebra in the direction from (7) to (6) is machine-checked Lean (`chain_band`, `sq_times_poincare_band`, `LatticeGaugeOneScale.lean`. The hypotheses are three band inequalities, and the conclusion is that $a^2 C_P$ lies in a positive band. The list is in 23-13), but none of the three chains themselves has been proved.

Figure 2 Changing the powers p of the three factors (factor $\propto \xi_{\mathrm{RG}}^{p}$) with the knobs tilts the three dotted lines and the solid line of the product $a^2 C_P$. If the product is horizontal, (6) holds. In the initial position ((iii) −0.3, (ii) +0.3) two chains are broken, yet the product is horizontal



`Product a²C_P ∝ ξ_RG^(+0.00)  (6) : holds, chains: (i) ○  (ii) ×  (iii) ×`

Computed A schematic drawing of the sum of the logarithms in (7), drawn on the spot (not a measurement).

06

Which chain plays the role of the equivalence principle

(i) is a relation between the dynamics chosen as a tool and the gap of the theory (the gap of the transfer matrix, 5-03); change the dynamics and the statement changes too. (iii) depends on how the steps are booked. If we call the small error dropped at each coarsening step the **shortfall**, (iii) is governed by the one-loop coefficient and by the shortfalls summed over the steps (23-02). In the record's arrangement, only (ii) is a sentence of the theory that depends neither on the tool nor on the bookkeeping.

The one sentence on this path

The tube of confinement has no length parameter other than the string tension ($m^2 \asymp \sigma$, equation (3)).

In the same pattern as "there is no second kind of mass", the record made the following table of correspondences.

General relativity	This path (analogy)
Riemannian geometry (the stage)	Lattice gauge theory (a probability measure in finite dimensions)
General covariance (a requirement on how laws are written)	One step of the renormalisation group (coarsening the lattice leaves the content the same)
The convention of units coming from the constancy of the speed of light ($c = 1$)	The convention of setting the scale (the convention of units that sets $\sqrt{\sigma} = 1$; 17-01 § 07)
The equivalence principle (one sentence of physics)	(ii) One scale (there is no second length parameter)

As a metaphor, just as general relativity made "weight" one kind, this sentence makes "length" one kind. More precisely, the table is an analogy and no theorem joins its left and right; the equivalence principle is an equality at each point, while (3) is a uniform inequality.

07

Dropping candidates — dual superconductivity, centre vortices, asymptotic scaling

(a) Dual superconductivity and **(b) centre vortices** (17-02) are statements about configurations after fixing a gauge and projecting. In raw form they depend on how the gauge is fixed (Gribov copies, 17-02 § 04), and do not become a sentence about the probability measure. The core that can be written gauge-invariantly ('t Hooft's vortex free energy) is a statement about σ, and merges into chain (iii). **(c) Non-perturbative asymptotic scaling** is the sentence that lengths in lattice units grow as perturbation theory predicts. The two-loop prediction is the following f_2 (SU(N), $g^2 = 2N/\beta$) Known .

$$f_2(\beta) = (b_0 g^2)^{-b_1/(2b_0^2)} \exp\Big(-\frac{1}{2b_0 g^2}\Big), \qquad b_0 = \frac{11N}{48\pi^2}, \quad b_1 = \frac{34N^2}{3(16\pi^2)^2} \tag{8}$$

The coefficients agree with the values in the PDG review (without quarks) (checked at $N = 3$ Computed). (c) says "the inverse of every length in lattice units, for example am/f_2 or $a\sqrt{\sigma}/f_2$, converges to a positive constant". If f_2 is read as the scale marking of physical units, the convergence of am/f_2 is itself the statement that the mass gap in physical units is positive and finite. Since it contains the conclusion we want to show, the record set it aside as circular.

It differs numerically too. For SU(2) with the bare coupling $g^2 = 4/\beta$, as $\beta = 2.40 \to 2.60$, $a\sqrt{\sigma}/f_2$ goes 57.26→48.23 (−15.8 %), while the ratio goes 3.618→3.837 (+6.1 %) Computed . The ratio moves less, and does not use perturbation theory either.

The bare coupling β carries large corrections peculiar to the lattice. Lucini–Teper use the mean-field improved coupling $\beta_I = \beta \cdot \frac{1}{N}\langle \mathrm{Re}\,\mathrm{Tr}\,U_p\rangle$ (U_p is the matrix of the plaquette) and write 'Transforming this to β_I is known to remove a large part of the lattice corrections at small a.' (§ 5 of the original paper, the sentence after equation (11); as the origin of this coupling the original paper cites earlier literature) Physics . The values obtained by finding the two-loop Λ with this coupling and extrapolating to the continuum limit are in Table 6 of the original paper, but for the SU(2) extrapolation it says 'the best continuum fit is very poor'.

08

Examples where one scale breaks

That (3) is not obvious is seen from examples where it breaks. **Three-dimensional compact U(1)**: Göpfert–Mack proved $\sigma > 0$ at all couplings Known , and also state that in the continuum limit, with the mass fixed in physical units, the string tension goes to infinity ($\sigma/m^2 \to \infty$) (from the abstract of the same paper; Villain action; the main text not read). If that description is right, there is confinement and yet the ratio $m/\sqrt{\sigma}$ goes to 0 (17-02 § 03). **The supergravity regime of holography**: the ratio goes to 0 as $\lambda^{-1/2}$, and $\lambda = g^2 N$ is the second parameter (17-09 § 08) Physics .

The leading term of the strong-coupling expansion is not a counterexample but an approximation with the opposite slope. With the action $S = \beta \sum_p \left(1 - \frac{1}{2}\,\mathrm{Tr}\,U_p\right)$ (the sum over all plaquettes, 5-01), the leading term for SU(2) gives, with $u = I_2(\beta)/I_1(\beta)$ (a ratio of modified Bessel functions), $\sigma = -\ln u$, and the lightest state is $m = -4\ln u = 4\sigma$ (5-02) Known , so

$$\frac{m}{\sqrt{\sigma}} = 4\,a\sqrt{\sigma} \quad (9)$$

which is the dashed line in Figure 1 (a straight line that would pass through the origin if extended). Extended to $a\sqrt{\sigma} \to 0$ the ratio falls to 0, the opposite direction to the lattice numbers. The leading term at $\beta = 2.40$ gives $a\sqrt{\sigma} = 0.840$ (measured 0.2634) Computed , outside the region where the expansion converges.

09

Examples where one scale holds, and the input needed

An example where it holds: the three-dimensional $\mathbb{Z}_2$ gauge model. The group is abelian, but by a duality transformation it maps to the three-dimensional Ising model; the glueball mass becomes the inverse of the correlation length, and the string tension becomes the interface tension. Agostini–Carlino–Caselle–Hasenbusch (1997), taking it

that $\sigma\xi^2$ should be constant in the scaling limit, found the continuum value $0.1056(19)$, checked that it agrees with the prediction $0.1024(88)$ of ϕ^4 theory, and obtained $m/\sqrt{\sigma} = 3.08(3)$ Physics .

The ratio $1/\sqrt{\sigma\xi^2}$ is 3.272(11) at $a\sqrt{\sigma} = 0.236$, 3.117(52) at 0.069, and 3.077(28) in the continuum, approaching from above (from Table 6 of the original paper Computed). The physical explanation is this. A **relevant direction** is a direction of couplings whose effect grows as the lattice is coarsened. Within the range that keeps the $\mathbb{Z}_2$ symmetry (in the Ising model, with no magnetic field), there is only one relevant direction near the critical point, so m and $\sqrt{\sigma}$ are fixed by one and the same ξ (2-08 § 07) Physics . It is not a theorem.

If the description of the continuum limit of three-dimensional U(1) is right, one scale breaks for the abelian U(1) and holds for the abelian $\mathbb{Z}_2$, so **it is not decided by whether the group is non-abelian**. What is needed is "an input that forbids a second small parameter". The record takes this input in four-dimensional SU(2) to be the positivity of the one-loop coefficient (asymptotic freedom, 4-06), and rewrote it in two forms. I: there is one relevant direction, and m and $\sqrt{\sigma}$ are fixed by the same ξ. R: the rotational symmetry broken by the lattice comes back at long distances (the shape of the tube matters; 17-03 § 08). Whether these two are enough is not known.

10

Where it differs from the equivalence principle — a sentence that cannot be put as an assumption

In general relativity the equivalence principle is an axiom. The prize problem asks us to *prove* existence and the gap from the definitions, so (ii) cannot be added as an axiom; it has to be made a theorem or bypassed.

The problem statement defines the gap Δ as there being no spectrum in $(0, \Delta)$, and continues 'The supremum of such Δ is the mass m, and we require m < ∞.' Known . Splitting the form $C_P \asymp \xi^2$ of (6) under (ii)(iii) (the band statement H_{band}) into upper and lower halves, in the record's reading $C_P \lesssim \xi^2$ (the relaxation-time upper-bound assumption) corresponds to the side of $\Delta > 0$, and $C_P \gtrsim \xi^2$ (the relaxation-time lower-bound assumption) to the side where the mass does not collapse to infinity (the form $m < \infty$). The precise treatment that splits the relaxation-time assumption itself into upper and lower halves is in 23-01. The lower-bound assumption is a different thing from "non-trivial" in the Clay sense (that there are interactions).

The lower half of (ii), $m^2 \gtrsim \sigma$, reduces to an operator inequality saying that the deficit of the tube is at least c/ℓ for perimeter ℓ (called the tube transfer-operator inequality in

the record) Lean (`mass_sq_ge_of_tube`, `LatticeGaugeTubeEntropy.lean`. Hypothesis: the norm of the transfer operator is at most $e^{-2\sqrt{c\sigma}}$, that is, a consequence of the tube inequality. Conclusion: $m^2 \geq 4c\sigma$. The list is in 23-13). There is no pattern of proof for the tube inequality itself (23-02). From finitely many measurements only an upper bound on m follows (a restatement of a known relation; 23-02). The one sentence can be named, but there are not yet tools to make it a theorem.

What this chapter can say

What is said	What is not said
Physics That "a single scale" can be written as (3), and that (ii) is the only chain that depends neither on the tool nor on the bookkeeping (the record's arrangement).	That the table of correspondences is a mathematical equivalence (it is an analogy). That (ii) is a sufficient input for the relaxation-time assumption.
Computed Tables A and B, Figures 1 and 2, the numbers in § 02, § 07, § 08 and § 09.	These are ratios and fits of values from primary sources, not measurements. The data alone cannot choose the form of the extrapolation.
Lean The algebra of the product in the direction from (7) to (6) (`chain_band`, `sq_times_poincare_band`). The reduction of the lower half of (ii) to the tube inequality (`mass_sq_ge_of_tube`).	Proofs of the chains (i)(ii)(iii), the relaxation-time assumption, (3) and the tube inequality. This chapter shows nothing about one scale, the mass gap or the construction of the four-dimensional continuum theory.
Known The area law at all couplings for three-dimensional U(1), the form of the leading term.	The continuum limit of three-dimensional U(1) (main text not checked). One scale for $\mathbb{Z}_2$ and SU(2) is at the level of numbers and physics.

Next chapter to read: 17-13 Where the way physics digs parts from mathematics — picking up, from the whole of Part 17, the places where physics and mathematics part. For the detailed form of the relaxation-time assumption, go to 23-01.

Where the way physics digs parts from mathematics — translating a sentence of physics into a sentence of mathematics brings the assumptions into the open

> This chapter organises established knowledge. § 04 is this book's own investigation.

What this chapter shows — The premises that come attached when a sentence of physics is translated into a mathematical statement. The seven moves through which premises enter, and where the theorems stop in each. How much of the string picture is in the denominator of the lattice ratio $m/\sqrt{\sigma}$ (recomputed from the tables of the primary source).

Prerequisite chapters — 17-10 (together with 17-01–17-03, 5-01 and 4-10).

Said first — This is an arrangement to avoid mistaking the level of results of physics for theorems; it does not discuss whether the methods of physics are good or bad. This chapter shows neither the existence of the mass gap nor the construction of the continuum limit. The numbers are recomputations from the tables of the primary sources.

The order of this chapter

1. Translating a sentence of physics into a sentence of mathematics
2. Measuring after putting that it exists
   - Detour: why the gap in a finite box is easy
3. The string picture enters the denominator
4. How much the ratio moves when the string picture is removed (Figure 1)
5. Extrapolating from finite β
6. Looking from the side of a small parameter
7. Moving to a neighbouring theory and coming back with a knob (Figure 2)
8. Looking after choosing a gauge
9. What physics regards as one

10. A list of the places where they part

01

Translating a sentence of physics into a sentence of mathematics

Table 5 of Lucini–Teper 2001 gives 3.844(61) as the continuum value of the ratio of the mass $m_{0^{++}}$ of the lightest glueball of $SU(2)$ to the string tension σ Physics . Translated into a mathematical statement, this sentence is

$$\lim_{\beta\to\infty} \frac{m(\beta)}{\sqrt{\sigma(\beta)}} = 3.844\ldots \quad (1)$$

($\beta = 2N/g^2$, and m and σ are quantities in units of the lattice spacing a; 5-01). (1) brings in four premises.

a. For each β the infinite-volume limit exists and is unique. Subsequential limits always exist by compactness, so the question is uniqueness.

b. For each β, $m(\beta) > 0$ and $\sigma(\beta) > 0$.

c. The limit $\beta \to \infty$ exists.

d. The limit is a ratio of quantities of a continuum theory satisfying the axioms (4-10).

For four-dimensional $SU(2)$ at large β, none of (a)–(d) is a theorem (§ 05) Known . "(61)" is an estimated numerical error, not an error bound given by inequalities. What this chapter calls "parting" is a place where some stage of the procedure of physics has no corresponding theorem and can only be put as an assumption.

02

Measuring after putting that it exists

The calculations of physics presuppose that a four-dimensional pure Yang–Mills theory exists, and is one. In a finite box B (a finite cube of lattice points) and at finite β, the probability measure on the link variables $U_\ell \in G$,

$$d\mu_{B,\beta}(U) = \frac{1}{Z_{B,\beta}} \exp\Big(\frac{\beta}{N} \sum_{P\subset B} \operatorname{Re}\operatorname{tr} U_P\Big) \prod_{\ell\subset B} dU_\ell \quad (2)$$

is properly defined (U_P is the product of the link variables once round the plaquette P, and dU_ℓ is Haar measure) Known . The premises enter in the limits. The problem statement does not accept weak existence by compactness (convergence of

subsequences) alone as a solution, unless the properties of the limit (the gap and the axioms) are shown by other means (footnote 2 of § 6.5 of the problem statement, 17-01). Further, in § 5 the problem statement names a **uniform** gap: 'the existence of a uniform gap for finite-volume approximations may play a fundamental role in the proof of existence of the infinite-volume limit' Known . The numbers of physics are "predictions made after assuming that it exists". For the construction published on 2026-11-10, which builds a theory satisfying the Wightman axioms as a limit of Wilson's lattice gauge theory, the committee's assessment is that it is proved in Lean. However, the infinite-volume limit is taken along a subsequence, and neither its uniqueness nor the mass gap, on which the numbers of physics rest, is shown ((a) above is a statement at each β of the lattice and lies outside this construction) (6-04).

Detour: why the gap in a finite box is easy

A subsection you may skip.

The β of this detour is the inverse temperature of the Ising chain (not the β of lattice gauge theory). The transfer matrix of the one-dimensional Ising chain (weight $e^{\beta s_i s_{i+1}}$, $s_i = \pm 1$) is

$$T = \begin{pmatrix} e^{\beta} & e^{-\beta} \\ e^{-\beta} & e^{\beta} \end{pmatrix}, \qquad \lambda_0 = 2\cosh\beta, \;\; \lambda_1 = 2\sinh\beta, \;\; \ln\frac{\lambda_0}{\lambda_1} = \ln\coth\beta \tag{3}$$

and correlations decay as $(\tanh\beta)^{|i-j|}$. The largest eigenvalue of a matrix whose entries are all positive is simple and strictly larger than the others (Perron–Frobenius) Known . Example: at $\beta = 1, 2, 3$ the gaps are 0.272, 0.0366 and 0.00496 Computed . It is positive at every finite β.

In lattice gauge theory too, the gap in a finite box is positive. More precisely, the link variables take values in a continuous group, so the transfer matrix is not a matrix but an integral operator with a positive continuous kernel. In a finite box the kernel is continuous and the group is compact, so this operator is compact. Then by an infinite-dimensional version of Perron–Frobenius (a generalisation of Jentzsch's theorem; the source is in 5-03) the largest eigenvalue is simple and isolated (the construction of the transfer matrix is Lüscher 1977 and Osterwalder–Seiler 1978; 5-03) Known . The question is whether, as $a \to 0$, $(\text{gap})/a$ remains positive uniformly in the volume (for two dimensions, 2-09).

03

The string picture enters the denominator

The σ in the denominator of (1) cannot be measured directly. What is measured is the mass m_l of a flux tube closed once round a periodic box (side L lattice points), and Lucini–Teper regard the tube as a string and subtract the Lüscher term (17-03 § 03) Physics .

$$am_l = a^2\sigma L - \frac{\pi}{3L} \quad (4)$$

The authors write 'in using eqn(4) we are assuming that we have linear confinement ..., that the effective string theory ... is in the Nambu-Gotto universality class, and that our string is in fact long enough', and also note 'with only two values of L ... we cannot claim to have evidence for both the 1/L functional form and for its coefficient'. The full form of the Nambu–Goto ground state (equation (23) of Athenodorou–Bringoltz–Teper) is

$$E_0(l)^2 = (\sigma l)^2 - \frac{\pi\sigma(d-2)}{3}, \qquad d = 4 \quad (5)$$

($l = aL$ is the length of the tube and d the dimension of spacetime; the primary source writes D). Taking the square root and expanding in $1/l$, the first two terms are (4) Known . That is, (4) is a long-string approximation, and the shorter the tube, the more the later terms matter. On the lattices of the primary source the tube lengths are $L\sqrt{\sigma} \approx 3.1$ to 3.4 (lengths in units of $1/\sqrt{\sigma}$) Computed , and that (4) is enough at these lengths is, as in the quotation above, put as an assumption by the authors too.

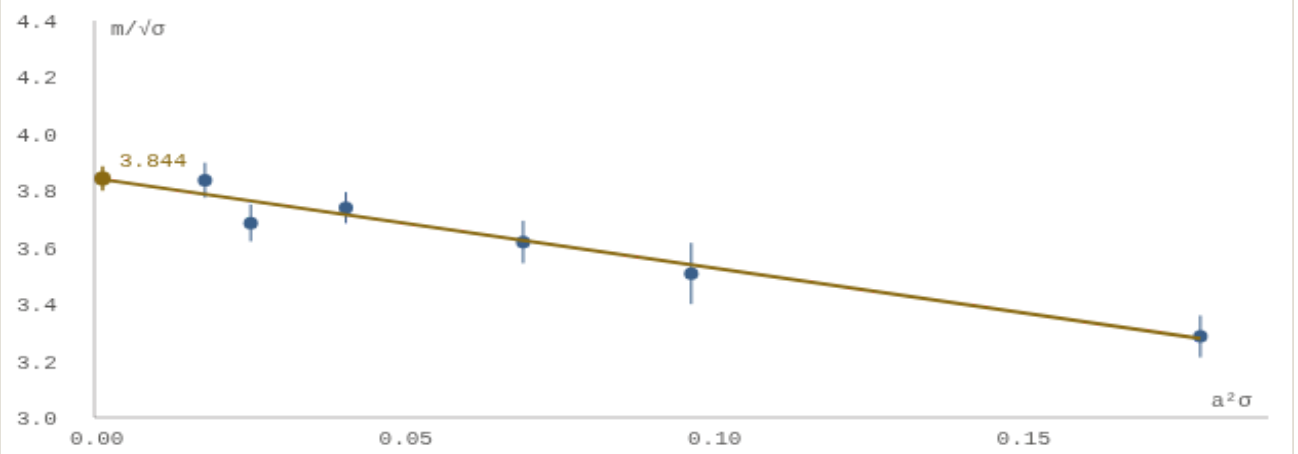
04

How much the ratio moves when the string picture is removed

From the tube masses in Table 1 of the primary source we extracted σ in three ways (no correction $a^2\sigma = am_l/L$, (4) and (5)) and recomputed the ratio Computed . No correction is the ruler that measures the contribution of the string picture.

How to read the fits — The ratio at each β is placed against the horizontal axis $a^2\sigma$ (the coarseness of the lattice), each point is weighted by the inverse square of its error, and a straight line is drawn (weighted least squares; the form of the line is (6) of § 05). The value at the left end $a^2\sigma = 0$ is the continuum value. χ^2 is the sum of the squares of the deviations between points and line, each divided by the error of the point; if it is of about the same size as the degrees of freedom (number of points − 2), the line fits the points within the errors. The errors of the ratios in Table 1 are the square root of the sum of the squared relative errors of $am_{0^{++}}$ and $a\sqrt{\sigma}$, treated as independent.

Figure 1 Changing how σ is taken and how many coarse points are dropped changes the fitted line and the continuum value (left end). The dashed line is equation (4), all points



Equation (4), points dropped: 0 → continuum value 3.844(43), χ²/dof 2.38/4, difference from equation (4), all points: 0.0 %

Computed The numbers in this figure were computed on this machine (the results of the same calculation as Table 1 embedded).

Table 1 $m_0{}^{++}/\sqrt{\sigma}$ for $SU(2)$, by how σ is taken (from Lucini–Teper Table 1. The master copy of the six values of am is 16-05 Table 3. How the errors are obtained is in "How to read the fits" above)

β	$L\sqrt{\sigma}$	No correction	(4)	(5)
2.25	3.38	3.447(78)	3.286(74)	3.278(73)
2.30	3.11	3.715(115)	3.508(108)	3.496(108)
2.40	3.16	3.825(80)	3.619(75)	3.608(74)
2.475	3.23	3.943(59)	3.740(55)	3.729(54)
2.55	3.18	3.894(69)	3.686(65)	3.676(64)
2.60	3.21	4.048(66)	3.837(62)	3.826(62)
Continuum value (all points)		4.059(45)	3.844(43)	3.833(42)

The central value 3.844 for (4) with all points agrees with Table 5 of the primary source. With or without the Lüscher term the continuum value moves by 5.6% (about 3.5 times the primary source's error 0.061), and the difference between (4) and (5) is 0.3% Computed . On the lattices of Table 1 the correction is 9–11% of the leading term σL. The precision of the ratio rests on **the leading correction of the string picture being right** (Athenodorou–Bringoltz–Teper report that many of the low states are well described by Nambu–Goto) Physics .

Translated into mathematics, the starting point of the string picture is a long tube of confinement, that is, confinement. Chatterjee 2018 writes that for four-dimensional non-abelian groups the area law at large β 'remains elusive', and that the area law at small β holds for all groups including $U(1)$, so it is no evidence Known .

> 05

Extrapolating from finite β

The primary source expects the lattice corrections of the plaquette action to start at a^2, and

$$\frac{m(a)}{\sqrt{\sigma(a)}} = \frac{m(0)}{\sqrt{\sigma(0)}} + c\,a^2\sigma \quad (6)$$

fits this (taking c as a constant), dropping the coarsest point if the fit is poor [Physics]. The knobs of Figure 1 reproduce this procedure; with (4) the continuum value stays within 3.84–3.86 [Computed] (for movement due to the form of the fit, see 17-12).

On the side of mathematics, the lattice correlation-length problem of Chatterjee 2018 (Chatterjee's Problem 5.1) asks for the following to be shown. Set $W_P = \operatorname{tr} U_P$, and let $f_\beta(x) = \langle W_{P_0} W_{P_x}\rangle - \langle W_{P_0}\rangle\langle W_{P_x}\rangle$ be the correlation (covariance) between the plaquette P_0 at the origin and the plaquette P_x nearest to the point $x \in \mathbb{R}^4$. For any infinite-volume limit of four-dimensional non-abelian lattice gauge theory, at every $\beta > 0$,

$$\lim_{|x|\to\infty} \frac{\log f_\beta(x)}{|x|} = -\frac{1}{\xi(\beta)}, \quad \xi(\beta) \in (0,\infty), \qquad \lim_{\beta\to\infty} \xi(\beta) = \infty \quad (7)$$

holds (ξ is the correlation length in lattice units; the continuum string-tension problem (Chatterjee's Problem 5.2) is the continuum limit of Wilson loops). In words: correlations decrease far away like $e^{-|x|/\xi}$, the length ξ is finite and positive at every β, and moreover grows without bound compared with the lattice spacing as the continuum limit is approached. The author writes 'Since none of the above has been proved', and states that at large β in dimensions higher than 2 even the uniqueness of the infinite-volume limit is unknown, and that $\beta_c = \infty$ in four dimensions is at the level of 'It is believed' [Known]. Example: even at the finest point ($\beta = 2.6$, 24^4), $\xi = 1/(am_{0^{++}}) = 1.95$ lattice spacings, and the ξ of the six points are 0.72–1.95 [Computed]. Extrapolation is the assumption that extends the slope over this range all the way to $\xi \to \infty$.

06

Looking from the side of a small parameter

Perturbation theory and semiclassics are both expansions around $g \to 0$, but the scale of dimensional transmutation (4-07) at one loop is

$$\Lambda = \mu\,\exp\Big(-\frac{1}{2b_0 g^2(\mu)}\Big), \qquad b_0 = \frac{11N}{48\pi^2} \quad (8)$$

$e^{-1/x}$ approaches 0 as $x \to 0^+$ faster than any power, and all its Taylor coefficients are 0 Known . If $\Delta = c\Lambda$, the gap appears at no order of the series in g^2 (an expectation) Physics (7-12, 4-12). Example: for $SU(3)$ at $g^2 = 0.5$, $\Lambda/\mu = 5.8 \times 10^{-7}$, while g^{20} is still 9.8×10^{-4} Computed .

The examples where semiclassics reaches the gap are none of them the theory of the problem statement. In three-dimensional compact $U(1)$, monopoles cause confinement (Polyakov 1977, semiclassical), and Göpfert–Mack proved the area law at all couplings on the lattice with the Villain action Known (the abstract of the same paper says that in the continuum limit the string tension in physical units goes to infinity; main text not read). On $\mathbb{R}^3 \times S^1$, Ünsal–Yaffe 2008 derived a gap and linear confinement for a deformed $SU(N)$ theory from a semiclassical analysis in the regime of small N where the circumference L is small enough (at the level of physics) Physics . That there is no phase transition on the way to $L \to \infty$ is a conjecture, based on the argument that there is no order parameter distinguishing small L from large L. What mathematics needs is an estimate non-perturbative in g, and the constructive methods too stop where they cross over to strong coupling (7-10).

07

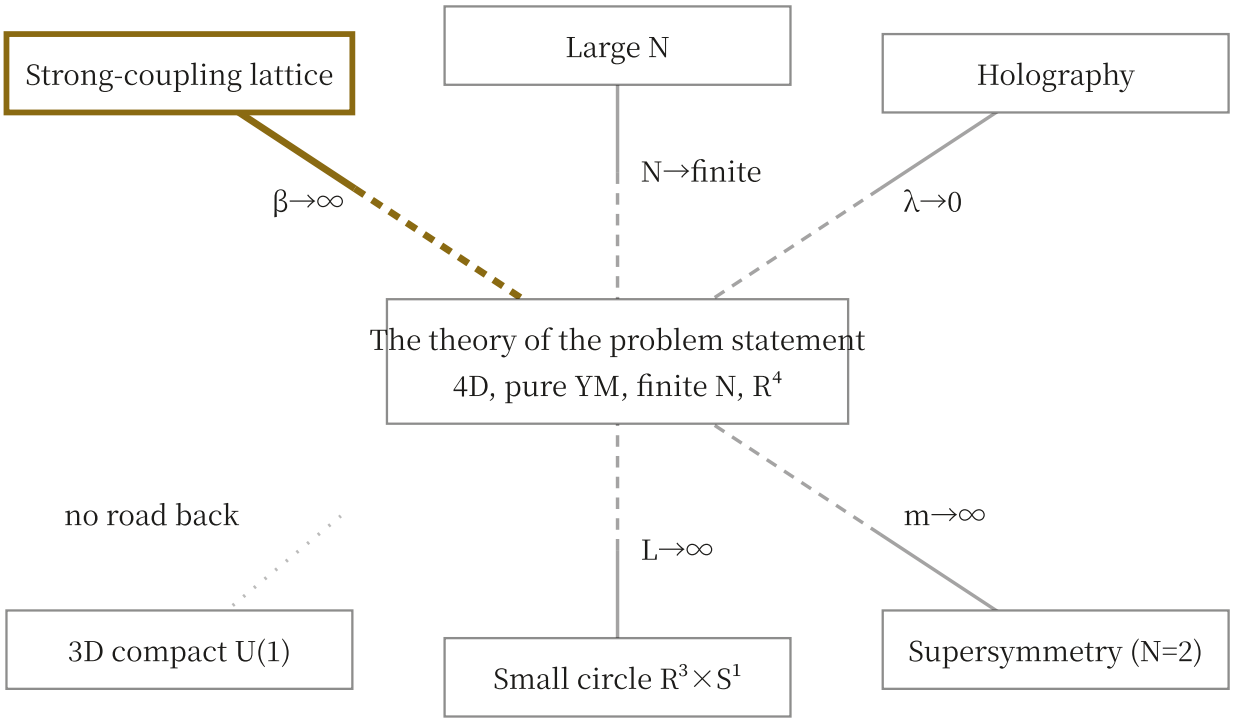
Moving to a neighbouring theory and coming back with a knob

In the move of going to a computable **neighbouring theory** and turning a knob to come back, the assumption is to put that nothing happens on the way. Translated into mathematics this is an exchange of limits, and uniformity is needed (17-10 § 06). For large N, for a dimensionless ratio F,

$$\lim_{a\to 0}\lim_{N\to\infty} F(N,a) \overset{?}{=} \lim_{N\to\infty}\lim_{a\to 0} F(N,a) \quad (9)$$

and what the problem statement needs is the limit at fixed N.

Figure 2 Choosing a shore (button, box, or row of Table 3) highlights the road back. Solid lines are the parts the calculation controls, dashed lines the roads back, and dotted lines shores with no road back



Strong-coupling lattice: The infinite-volume limit and the area law at small β (Osterwalder–Seiler). U(1) included Known , knob to come back: β→∞, needed on the way: The region of convergence does not reach weak coupling

Figure 2 is a picture of the content of Table 3, and has no numbers.

Table 3 Neighbouring theories and the knobs to come back

Shore	What can be said as mathematics	Knob to come back	What is needed on the way
Strong-coupling lattice	The infinite-volume limit and the area law at small β (Osterwalder–Seiler). U(1) included Known	β→∞	The region of convergence does not reach weak coupling
Large N	Sums over strings for strongly coupled SO(N) (Chatterjee). A representation as sums over surfaces at all β (Cao–Park–Sheffield) Known	N to finite	Uniformity of the 1/N corrections
Holography	The eigenvalue problem after fixing the background Known . The correspondence is a conjecture (17-08)	λ→0	Beyond supergravity; the definition of string theory
Supersymmetry (N=2)	Instanton integrals give the prepotential (17-11) Known	Mass→∞	That the gap is not interrupted
Small circle $R^3\times S^1$	Semiclassics at small N and small L (Ünsal–Yaffe) Physics	L→∞	That there is no phase transition
3D compact U(1)	The area law at all couplings (Göpfert–Mack, Villain action) Known	None	The scale does not become one (the abstract of the same paper)

For large N, 't Hooft 1983 is said to have constructed planar field theory under the condition "all particle masses non-zero and the coupling small enough" (bibliographic data and search summaries only), and the gap is an input. In § 6.6 the problem statement writes of 1/N as 'perhaps a good starting point for a rigorous proof (for sufficiently large N)' Known . Example: the lattice ratio is 3.405(21) for $SU(3)$ (Athenodorou–Teper 2020, 2021) and 3.072(14) for $SU(\infty)$ (same, 2021) Physics . Physics reads this as "large N is close", but what mathematics needs is a proof of the uniformity in (9).

08

Looking after choosing a gauge

Many mechanisms of confinement are told in terms of variables defined after choosing a gauge (monopoles, centre vortices, the Landau-gauge propagator) (17-02) Physics . On the side of mathematics, there is in general no globally continuous gauge fixing (Singer, 3-04), and even local conditions leave several solutions (Gribov, 4-08) Known . On the lattice, the expectation of a local quantity equals the expectation of that quantity averaged over gauge transformations (its gauge-invariant part), and components that change under gauge transformations have expectation 0 (Elitzur; for example $\langle U_\ell \rangle = 0$) Known .

The target of the problem statement is gauge-invariant local fields. For example, for $O = \operatorname{tr} F_{\mu\nu}F_{\mu\nu}$ (summed over μ, ν),

$$\left| \langle O(x)\, O(0) \rangle - \langle O \rangle^2 \right| \leq C\, e^{-\Delta |x|} \quad (10)$$

is one way the gap Δ shows itself (4-11). For the propagator, $D(0)$ is reported to look finite and non-zero on large lattices ('seems to') (Cucchieri–Mendes), and Zwanziger argues that copies inside the region do not affect expectations Physics . There is no theorem deriving (10) from $D(p)$.

There are gauge-invariant bridges too. The **centre** of a group G is the set of elements that commute with every element; for $SU(N)$ it is the identity matrix times an N-th root of 1, $e^{2\pi i k/N} I$. **Centre symmetry** is the symmetry under the transformation that multiplies all links of one layer by the same element of the centre (which does not change the values of the plaquettes), and we say it is "unbroken" when no measure changes under this transformation (precisely, on a slab of finite thickness, for every boundary condition; 17-02). Tomboulis–Yaffe 1985 are said to have bounded the Wilson loop from above by the free energy of centre vortices for $SU(2)$ (search summaries only). Chatterjee 2021 proved two things on the lattice for Wilson loops in representations acting non-trivially on the centre (representations in which some

element of the centre maps to something other than the identity matrix; for example the fundamental representation of $SU(N)$) Known : that if centre symmetry is unbroken there is confinement (in the sense $V(R) \to \infty$, weaker than the area law), and that if exponential decay of correlations for any boundary condition is assumed, centre symmetry is unbroken and the area law follows. What is missing is that this assumption holds at weak coupling in four dimensions (the claim of Tomboulis 2007 has been pointed out to have 'missing links'; Ito–Seiler).

09

What physics regards as one

Physics regards the scale after dimensional transmutation as one, and treats separate quantities as faces of the one scale (17-01 § 03). Translated into mathematics, the sentence splits.

Table 4 Sentences of physics and the translated statements

Sentence of physics	Mathematical statement and its current state
The mass and the string tension are constant multiples of the same Λ	That m^2/σ is bounded above and below uniformly in β (the diffusive-relaxation-time assumption of 17-12). Examples where it breaks: three-dimensional compact $U(1)$, the supergravity regime (17-09) Physics
Confinement and the gap are one phenomenon	Separate claims. The problem statement asks only for $\Delta > 0$; confinement is an extension problem ('natural extensions' in § 5 of the problem statement). There is no theorem deriving confinement from a gap in the sense of the problem statement (17-02 § 02). On the lattice, from the strong form, exponential decay for any boundary condition, the area law follows for groups with a non-trivial centre (Chatterjee 2021 Thm 2.4) Known . For finite groups, exponential decay of correlations of gauge-invariant quantities has been proved at weak coupling (Adhikari–Cao; a form on a box with no condition imposed at the boundary, different from the strong form) Known . That they do not confine is at the stage of belief (Chatterjee 2021 writes 'believed'; 5-10) Physics
The gap is the mass of the lightest glueball	The gap and an isolated one-particle state above it are different things. The latter is an extension problem (4-11) Known

10

A list of the places where they part

In every row, what is missing is not the line of argument of physics but the corresponding theorem.

Table 5 The seven moves, and where the translated statements stand

Move (section)	Translated into a mathematical statement	Current state

Move (section)	Translated into a mathematical statement	Current state
Placing it as existing (§ 02)	Construction of a limit satisfying the axioms	The construction published on 2026-11-10 (the committee's assessment is that it is proved in Lean; the infinite-volume limit is along a subsequence, with no uniqueness and no mass gap; 6-01)
Taking σ from the string picture (§ 03, § 04)	The area law at large β	'remains elusive' Known
Extrapolating (§ 05)	(7) and the continuum limit of Wilson loops	At the stage of being posed as problems (the lattice correlation-length problem, the continuum string-tension problem) Known
Expanding in a small parameter (§ 06)	An estimate non-perturbative in g	All Taylor coefficients of $e^{-1/x}$ are 0 Known . $\Delta = c\Lambda$ is an expectation of physics Physics
Coming back from a neighbouring theory (§ 07)	The uniformity in (9)	Within the range we searched, no justification found
Choosing a gauge (§ 08)	Gauge-invariant correlations (10)	Up to conditional lattice theorems Known
Regarding as one (§ 09)	Separate statements and a uniform comparison	At the stage of being cut out as an assumption Physics

Most of the places where they part lie not in divergences but in **limits and uniformity** (7-11), and for mathematics the numbers of physics are not steps of a proof but **targets and checks**. Where the translation succeeded, the result is **conditional theorems** on the lattice. The overall picture set beside the side of mathematics is in 16-05, and the parallel list of names is the parallel table in 16-05.

What this chapter can say

What is said	What is not said
Computed From Table 1, that the continuum value moves by 5.6% with or without the Lüscher term, and that the difference between (4) and (5) is 0.3%. That the central value for (4) with all points agrees with 3.844.	Whether the string picture is right. Confinement itself. The breakdown of the primary source's error 0.061 (0.043 in the fit on this machine).
Known For the seven moves, the translated statements and the current state as stated by the primary sources.	That the seven are exhaustive (the division is this chapter's arrangement). That the hypotheses of the conditional theorems hold.

What is said	What is not said
Physics The readings of semiclassics, large N, holography and supersymmetry in § 06 and § 07.	The existence of the limits taken by turning the knobs. The mass gap and the construction of the continuum limit (this book does not show them).

Next chapter to read: 18-01 How to read the dictionary (the entrance to Part 18, which sets the words of physics and of mathematics side by side in two columns of standing, definition and reality).

How to read the dictionary — grading in two columns, and naming who judges "the same"

> This chapter is a guide (how to read the dictionary).

What this chapter shows — The two grades of each row of the dictionary: (a) the correspondence as definitions, and (b) existence in four-dimensional Yang–Mills. That the inconsistencies of a one-column grade are resolved by two columns (Figure 1).
Who judges "the same" (theorem, definition, convention, conjecture, analogy), and how to read the Conditions entry (Figure 2).

Prerequisite chapters — 0-03 Reading the problem statement word by word. § 03 and § 08 are easier to read after 4-10 and 4-11. Words not in 0-03 get a one-phrase explanation where they first appear, and the details are left to the linked chapters. Within Volume 3, this part is read after Part 17 (From the side of physics).

Said first — This chapter only fixes how to read. The grades in Table 2 are this book's reading, and the grounds are in 18-02–18-04. This book itself shows neither the existence of the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is read in Volume 2).

The order of this chapter

1. Two vocabularies pointing at the same thing
2. The entries of a row — nine entries (including the measurement column)
3. The definition column: the correspondence as definitions — Settled, Conditional, Unsettled
4. The existence column: existence in four dimensions — Constructed, Conditional, None (not yet constructed)
5. Two columns resolve the inconsistencies — Figure 1, Table 2
6. Which vocabulary to put first
   - Detour: false friends
7. Who judges "the same" — five judges
8. How to read the Conditions entry — Figure 2, Table 3

9. What comes along if the existence column moves

01

Two vocabularies pointing at the same thing — why a dictionary is needed

The "path integral", "vacuum" and "glueball" of physics are assigned in mathematics to "a probability measure", "a unit vector in the reconstructed Hilbert space (1-10)" and "an isolated eigenvalue of the mass operator $M = \sqrt{H^2 - P^2}$ (the operator that reads the rest mass from the energy H and the momentum P)". Whether words of different origins point at the same thing, and how certain the correspondence is, differs from row to row, and can only be checked row by row. That is the subject of this chapter.

There are three answers: it can be said by a theorem to be the same, it can be said only under assumptions, or it cannot be said. Moreover, in four dimensions the object on the side of mathematics has often not yet been made (0-03 § 04). So we give a row the following form.

$$\underbrace{\text{physical word}}_{\text{origin}} \longleftrightarrow \underbrace{\text{mathematical word}}_{\text{origin}} \qquad [\ (a)\ \text{correspondence as definitions}\ ;\ (b)\ \text{existen}$$

$\longleftrightarrow$ only places the two side by side as a pair; whether they are the same is stated by the two grades. Example: "instanton $\longleftrightarrow$ anti-self-dual connection" is (a) Settled, (b) Constructed (classical). For classical fields there is the precedent of Wu–Yang (1975) (abstract: 'identification with the mathematical concept of connections'; 1-07). An attempt to read the assumptions of this book's record in the words of physics is in 18-05.

02

The entries of a row — nine entries and a sample

There are nine entries: concept, the physical word and its origin, the mathematical word and its origin, the definition column, the existence column, the measurement column, judge, conditions (the assumptions needed for the identification and the gap that remains), and chapter.

The sample is the Feynman–Kac formula. The imaginary-time evolution of $H = -\frac{1}{2}\Delta + V$ (Δ is the Laplacian, not the Δ of the mass gap) can be written as an expectation over Brownian motion B_s started from x (a random path made by piling up independent small Gaussian displacements; 1-08) Known .

$$(e^{-tH}f)(x) = \mathbb{E}_x\Big[\exp\Big(-\int_0^t V(B_s)\,ds\Big) f(B_t)\Big] \quad (2)$$

Filling in the entries: the concept is "writing e^{-tH} as an integral over paths", the physical word is the path integral (Feynman 1948), the mathematical word is the Feynman–Kac formula (Kac 1949), (a) Settled, (b) Not applicable (a row of quantum mechanics with finitely many degrees of freedom, so not asked; § 04), the judge is a theorem, the conditions are "V bounded below, etc.; the real-time e^{iS} does not become a measure", and the chapter is 2-07. Two kinds of thing go into the Conditions entry. "V bounded below, etc." is a hypothesis of the theorem, and "the real-time e^{iS} does not become a measure" is a gap that remains even after the identification. Among the arrows, $\Longleftrightarrow$ is a theorem in both directions and $\Longrightarrow$ a theorem in one direction, while $\longleftrightarrow$, as in (1), only places the two side by side as a pair.

The measurement column: the direction reachable by finite measurement. Besides (a) and (b) we attach one more grade: for a quantity on the side of mathematics, which direction follows as a firm inequality from numbers measured with finitely many observables, finite time t and finitely many lattices. There are four values: **Upper bound only**, **Lower bound only**, **Both** and **Out of reach** (statements about limits, uniformity or all observables, which finite measurement settles in neither direction). Rows that name no quantity (rows that are only a correspondence of definitions or theorems) get "—". The grounds for the judgement are (8) and (9) of § 08. A sum of exponentials with weights $w_n \geq 0$ is log-convex, so the effective mass $m_{\mathrm{eff}}(t)$ decreases in t and approaches μ_O from above, and at every finite t, $m \leq \mu_O \leq m_{\mathrm{eff}}(t)$ Known ((3) in 4-11). So the gap and its relatives (positions of eigenvalues, decay rates) fall under "Upper bound only", and the lengths and times that are their inverses (the correlation length ξ, the Poincaré constant C_P) under "Lower bound only". This is the box "The asymmetry of upper and lower bounds" in 1-10 made into an entry of the dictionary. The row of the sample, the Feynman–Kac formula, gets "—".

03

The definition column: the correspondence as definitions — Settled, Conditional, Unsettled

The definition column asks: "**if both objects existed**, would they be the same?" Whether they exist is the job of the existence column.

Settled	Conditional	Unsettled
There is a theorem giving the same object, or the side of	The same only under assumptions that are in neither definition (the	They seem to point at the same thing, but no theorem says so.

mathematics defines it so.	assumptions go into the Conditions entry).	

Even when Settled, the arrow has a direction. The sample is the Osterwalder–Schrader (OS) reconstruction theorem (4-10). We call the axioms of real-time quantum field theory the Wightman axioms (4-09), and the five conditions imposed on imaginary-time correlations (Schwinger functions) the Osterwalder–Schrader axioms: regularity (E0), Euclidean covariance (E1), reflection positivity (E2; correlations with the quantity reflected in the mirror of time are not negative), permutation symmetry (E3) and clustering (E4). The **linear-growth** condition (E0′) is a strengthening of regularity, requiring the estimates of the n-point functions to stay within roughly factorial growth in n (4-10 § 03) Known .

$$\textbf{there: Wightman theory} \implies (\mathrm{E0}) \wedge \cdots \wedge (\mathrm{E4}), \qquad \textbf{back: } (\mathrm{E0}') \wedge (\mathrm{E1}) \wedge \cdots \wedge (\mathrm{E4}) \implies \mathbf{W}$$

On the way there, analytically continuing the correlations of a Wightman theory to imaginary time, using that the energy is positive, gives the five axioms. On the way back the linear-growth condition is needed, and whether this condition follows from a Wightman theory is not known (Summers § 3, 4-10 § 03). Since the conditions differ on the way there and the way back, even though (a) is Settled we write the arrow as two $\Longrightarrow$, not as $\Longleftrightarrow$. How the construction published on 2026-11-10 used this way back to reconstruct a Wightman theory is read in 12-08 Reconstruction and the Wightman axioms.

The sample of Conditional is the mass gap and the decay of correlations. § 5 of the problem statement writes in one direction: 'An important consequence of the existence of a mass gap is clustering'. The converse needs a dense family of observables to decay at a uniform rate (§ 08).

Unsettled comes in three types. (i) No definition on the side of mathematics: the four-dimensional Λ. (ii) Definitions on both sides, but within the range we searched no theorem saying they are the same: centre symmetry (Chatterjee writes that the mathematical physics literature has no mathematical definition, and then that his definition on the lattice was inspired by the physical definition through the Polyakov loop). (iii) Correspondences inside conjectures or analogies: the radial direction of holography and the scale of renormalisation (17-08).

Read as two groups, "Settled" are pairs that **are settled to point at the same thing**, and "Conditional" and "Unsettled" are pairs that **mathematical certainty has not been able to assert**. The dictionary of mass and length (18-03 § 01) adds a fourth grade, "Does not correspond", for pairs known to be different quantities. Row 9 of Table 2 (a false friend, the detour in § 06) is graded at this level in the entry "gap in physical units" of 18-03.

04

The existence column: existence in four dimensions — Constructed, Conditional, None

The existence column writes, with a **level**, whether the object the mathematical word points at has been made in four dimensions. There are four levels: classical (smooth connections), formal power series (each order of perturbation), lattice (spacing a fixed), and continuum quantum theory (a measure and a Hilbert space on $\mathbb{R}^4$); the problem statement asks for the last (0-03 § 03).

Constructed	Conditional	None
Made at the level the row names (the level is added).	Only versions of limited range (strong coupling, lattice fields satisfying an admissibility condition, and so on).	Not yet made at the named level. It has not been shown not to exist (versions at lower levels go into the Conditions entry).

These are the three grades. For rows that are not objects of four-dimensional Yang–Mills (quantum mechanics with finitely many degrees of freedom, extra dimensions, and so on) (b) is not asked, and we write "Not applicable" (the sample in § 02).

The last rule is the key. "None" as the name of a grade means "not yet constructed"; it has not been shown not to exist. The problem asks exactly about that existence. The measure on a finite lattice exists for every β (the coefficient of the coupling in the lattice action) (5-01), but the continuum measure is its limit, and for four-dimensional non-abelian groups it has not yet been constructed Known .

$$d\mu_a(U) = \frac{1}{Z}\, e^{-S_W(U)} \prod_{\ell} dU_\ell \quad \text{(exists)}, \qquad \mu = \lim_{a \to 0} \mu_a \quad \text{(not constructed)} \ (4)$$

U_ℓ is the link variable and S_W the Wilson action. Example: instantons are Constructed classically (ADHM 1978), and the transfer matrix (the operator that advances imaginary time by one step on the lattice, § 08) is Constructed on the lattice (Lüscher 1977). Rows 10 and 11 of Table 2 point at the same geometry, but 10 names the classical level and 11 the lattice level. The second Chern number of a smooth connection exists classically, so the (b) of 11 is Conditional because assigning an integer to a lattice field needs an admissibility condition (U_p close to 1 on each plaquette). On the strongly coupled lattice an isolated one-particle state has also been shown (Schor 1984), but at the lattice level, and on the opposite side from the continuum limit (5-09).

05

Two columns resolve the inconsistencies — fourteen samples

With a one-column grade, "are they the same as definitions?" and "do they exist in four dimensions?" are mixed into one grade, and which of the two decided the grade changes from row to row.

$$\text{one-column grade} = f\big((a),(b)\big), \qquad f \text{ chosen implicitly row by row } (5)$$

Example: rows 4 and 5 of Table 2 are the same pair, yet asking about definitions gives Conditional, and asking about a four-dimensional instance gives Unsettled. The same holds for 6 and 7, and 1 (the path integral) is Settled as a definition but Conditional in one column. In two columns these fall into the same cell. With a one-column grade that "takes the weaker", the rows of continuum quantum theory almost all line up at "None", and the correspondences of definitions become invisible.

Figure 1 The slider gives the one-column grade (left) and the two columns (right; vertical (a), horizontal (b)). The numbers are rows of Table 2; pressing a point or a row shows its grades. Dashed lines join the same pairs

The positions are the grades of Table 2 (this book's reading). With JavaScript disabled, the still figure and the table can be read.

Table 2 Fourteen samples (details in 18-02–18-04). "One column" is the grade given without separating the two questions. (c) is the measurement column of § 02 (the direction reachable by finite measurement).

#	Physical word ⟷ mathematical word	One column	(a)	(b)	(c)	Judge
1	Path integral ⟷ Euclidean probability measure	Conditional	Settled	None	—	Definiti
2	Wick rotation ⟷ OS reconstruction theorem	Settled	Settled (⇒)	None	—	Theorer
3	Existence of the lattice Hamiltonian ($T = e^{-aH}$ positive and self-adjoint) ⟷ reflection positivity of the Wilson action	Settled	Settled	Constructed (lattice)	—	Theorer
4	One-particle state ⟷ isolated eigenvalue of the mass operator	Conditional	Conditional	None	Upper bound only	Theorer conditic
5	Glueball ⟷ isolated eigenvalue of the mass operator	Unsettled	Conditional	None	Upper bound only	Theorer conditic convent
6	Spacetime and lattice ⟷ the $a \to 0$ limit of $a\mathbb{Z}^4$	Unsettled	Conditional	None	Out of reach	Definiti + conditic
7	Continuum limit ⟷ scaling limit	Conditional	Conditional	None	Out of reach	Definiti + conditic
8	Mass gap ⟷ spectral gap, exponential decay of correlations	Conditional	Conditional	None	Upper bound only	Theorer conditic
9	Gap in physical units ⟷ uniform gap in lattice units	Unsettled	Unsettled (false friend)	Conditional (strong coupling, etc.)	Out of reach	Convent
10	Instanton ⟷ anti-self-dual connection	Settled	Settled	Constructed (classical)	—	Theorer
11	Topological charge (lattice) ⟷ second Chern number of a lattice field	Conditional	Conditional	Conditional (lattice: fields with U_p close to 1 on each plaquette)	—	Theorer conditic
12	Renormalisability ⟷ BPHZ, Epstein–Glaser (for YM, BRS and flow equations)	Conditional	Conditional	Constructed (formal power series)	—	Theorer (for YM see the note below)

#	Physical word ⟷ mathematical word	One column	(a)	(b)	(c)	Judge
13	Λ, "a single scale" ⟷ the diffusive-relaxation-time assumption: $C_P \asymp \xi^2$	Unsettled	Unsettled	None	Lower bound only (C_P; the relaxation-time upper-bound assumption is out of reach)	Analogy
14	Radial direction of holography ⟷ Fefferman–Graham expansion	Unsettled	Unsettled	None	—	Conject

Note: column (b) of Table 2 is the reading from before the published construction (2026-11-10). Rows 2, 6 and 7 moved with the published construction (6-01, §09).

Notes on the words of Table 2. Row 11 names the level of the lattice (§ 04). The "theorem" in the judge of row 12 is Hepp 1966 for scalar fields, Becchi–Rouet–Stora 1976 for gauge theories (for a semisimple group, with a choice of gauge in which every field gets a mass, showing the identities of gauge symmetry to all orders of perturbation), and Efremov–Guida–Kopper 2017 for massless $SU(2)$ pure Yang–Mills (by the flow equations of the renormalisation group). The source for pure Yang–Mills with a general compact group has not been confirmed. In row 13, Λ is the mass scale the theory produces by itself (4-07), C_P is the Poincaré constant (how slowly configurations return to equilibrium under the stochastic gradient flow, that is, Langevin dynamics; 1-10, 18-03), ξ is the correlation length (the length over which correlations decrease as $e^{-r/\xi}$, the inverse of the gap in lattice units), and the diffusive-relaxation-time assumption is the assumption $C_P \asymp \xi^2$ made by the record of this book's study (that the two are proportional within constant factors; 23-01). The Fefferman–Graham expansion of row 14 is the formula expanding the interior metric in powers of the depth from the boundary (18-04).

06

Which vocabulary to put first — look up by the physical word, judge by the mathematical statement

The dictionary is ordered so that it can be looked up from the physical words that many readers know first, and the grades are judged after translating into mathematical statements (17-13 § 01). When a physical word has two meanings, the row is split. The criterion for splitting is whether the grade in the definition column differs between the two meanings. If it is the same, they stay in one row; if it differs, they are split. The sample is "unitarity" Known .

positive norm	$\Longleftrightarrow$ reflection positivity	(Settled; within tl
positive norm $\wedge$ asymptotic completeness	$\Longrightarrow$ unitarity of the S-matrix	(Conditional; und

Positive norm means that the inner product of states is positive definite (there are no states of negative norm). Asymptotic completeness means that the Hilbert space is exhausted by states of free particles in the far past and far future (asymptotic states) (18-02 § 05). The upper row is a statement within the correspondence between OS and Wightman: from reflection positivity come a positive-definite Hilbert space and $H \geq 0$ (reconstruction). The converse is the way-there direction of (3): the positivity of a Wightman theory becomes the reflection positivity of the Schwinger functions (4-10). The lower row is a statement under the Haag–Ruelle scattering theory, which builds asymptotic states by assuming an isolated one-particle mass shell.

Put into one row, the Settled grade would read as if it extended to the S-matrix. "Confinement" is another example of a split row. The three criteria are $V(R) \to \infty$ ($V(R)$ is the energy of a heavy quark pair placed at distance R, read from how Wilson loops decrease), the area law $\sigma > 0$ ($\sigma = \lim_{R\to\infty} V(R)/R$ is the string tension), and unbroken centre symmetry (invariance under transformations by the centre of the group; in physics, the expectation of the Polyakov loop at finite temperature is 0). In physics they mean almost the same thing, but the mathematical theorems are one-directional and on the lattice. Chatterjee's Theorem from Centre Symmetry to Confinement (Theorem 2.2 of Chatterjee 2021) shows, on the lattice $\mathbb{Z}^d$ at fixed coupling, "centre symmetry unbroken $\Rightarrow V(R) \to \infty$" (for Wilson loops in representations acting non-trivially on the centre; 18-03 § 03).

Detour: false friends

A subsection you may skip.

In learning foreign languages, words that look alike but differ in meaning are called "false friends". The typical one is "gap". A uniform gap in lattice units is, in physical units, a property of the side where the mass goes to infinity, the opposite side from the continuum limit, so we make the definition column Unsettled and write "false friend" in the Conditions entry (row 9 of Table 2). Precisely, the same word points in the two languages (physics and mathematics) at objects with different conditions, and one holding does not imply the other holding (it lies rather on the opposite side). "Continuum limit" is not quite a false friend, but it is an example where the conditions included differ. The scaling limit of probability theory does not include "the limit is not Gaussian", which the physical word implicitly includes (for the four-dimensional Ising type and ϕ^4 it is Gaussian: Aizenman–Duminil-Copin 2021, 7-08). This difference goes into the Conditions entry of row 7 of Table 2. For the difference between "the mass of a particle" and the gap, see 16-08 and 16-05.

07

Who judges "the same" — five judges

Theorem: there is a theorem in both directions or in one ((2), (3), (6)). **Definition**: the side of mathematics has fixed an object as the meaning of the physical word. Fixing the path integral as a countably additive probability measure is such a case. § 4 of Jaffe's review lists as a "problem" of the time that the path integral had no definition as 'a true integral, given by a countably-additive Borel measure'. This way of fixing it does not go as far as agreement with other calculations. **Convention**: the habit of calling things by the same name. Calling the lowest state measured in each channel on the lattice a "glueball", and calling uniform exponential decay in lattice units a 'strictly positive mass gap' (Shen–Zhu–Zhu). **Conjecture**: for the correspondence between the radial direction and scale, the side of physics too writes that 'what cutoff on the field theory corresponds to a radial cutoff in the bulk?' is 'left unanswered' (Heemskerk–Polchinski). **Analogy**: pointing out a similarity of form. "A single scale" and the relaxation-time assumption (17-12).

$(a) = \text{Settled} \;\Rightarrow\; \text{the judge includes a theorem or a definition,} \qquad \text{judge only convention, cc}$

Example: row 5 of Table 2 is "Theorem + conditions, convention". The correspondence with an isolated eigenvalue is a conditional theorem (1-10), and calling the lowest state a "particle" is a convention. When they coexist we write both, and grade the definition column by the stronger.

08

How to read the Conditions entry — a single correlation gives only an upper bound on the gap

The Conditions entry is where the hypotheses of theorems are kept. We read row 8 of Table 2 with a small model. The transfer matrix is the operator $T = e^{-H}$ that advances imaginary time by one step on the lattice (taking the step as 1; 4-10, 5-03). Let its levels be $0 = E_0 < E_1 < E_2 < \cdots$; the state Ω with $E_0 = 0$ is the vacuum. The correlation at imaginary-time separation t can be written with the levels and the overlaps $w_n \geq 0$ of the observable O with each level (if the levels are discrete) Known .

$$C_O(t) = \langle O(t)O(0)\rangle - \langle O\rangle^2 = \sum_{n\geq 1} w_n e^{-E_n t}, \qquad w_n = \left|\langle n|O|\Omega\rangle\right|^2 \quad (8)$$

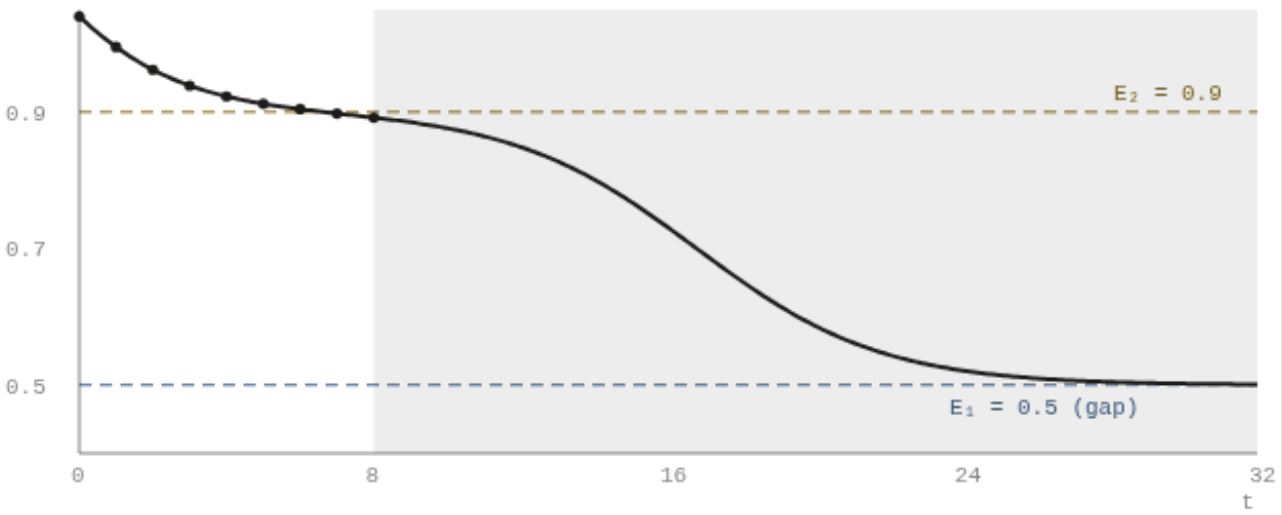
The gap is $m = E_1$. The rate at which the correlation decreases is fixed by the first level with $w_n > 0$.

$$\mu_O = \min\{E_n : w_n > 0\} \;\geq\; m, \qquad m_{\text{eff}}(t) = \log \frac{C_O(t)}{C_O(t+1)} \;\xrightarrow[t\to\infty]{}\; \mu_O \quad (9)$$

What a single correlation can say is only the upper bound $m \le \mu_O$. One observable suffices for the upper bound, and equality needs $w_1 > 0$. The lower bound $m \ge c$ needs every member of a family of observables dense in the part orthogonal to the vacuum to decrease at rate at least c (uniformity). Which observables overlap with E_1 is not known in advance, so a family is needed. This is the content of the conditions of row 8 (4-11 § 02, 18-03. Easy from above and hard from below is the same shape as the variational principle: the box "The asymmetry of upper and lower bounds" in 1-10). The measurement column of the dictionary (§ 02) attaches this asymmetry to each row.

Example: if $E = (0.5, 0.9, 1.4)$, $w_2 = 1$, $w_3 = 0.5$ and $w_1 = 10^{-3}$, then $m_{\mathrm{eff}}(8) = 0.892$, 1.78 times the gap, and it comes within 5% only from $t = 24$ Computed . For $t \le 8$ the difference between $w_1 = 10^{-3}$ and $w_1 = 0$ is at most 1.3% Computed ; at finite t a small overlap cannot be told apart from no overlap.

Figure 2 Changing the overlap w_1 and the measured range t_max changes the effective mass (line) and the values that can be read (points). Dashed lines are E_1 (the gap) and E_2; the shading is the unmeasured range



w₁ = 1.0e-3 m_eff(8) = 0.892 (1.78 times the gap), within 5%: t = 24 onwards

Computed The numbers in this figure were computed on this machine ((8) and (9) computed on the spot).

Computed **Table 3** $m_{\mathrm{eff}}(t)$ (with the same E, w_2 and w_3 as above). The right end is the first integer t with $m_{\mathrm{eff}} \le 1.05 E_1$.

w_1	$t = 1$	8	16	32	Within 5%
1	0.7013	0.5132	0.5005	0.5000	7
0.1	0.9322	0.6018	0.5054	0.5000	13
0.01	0.9888	0.8108	0.5481	0.5001	18
0.001	0.9953	0.8918	0.7305	0.5009	24

w_1	$t = 1$	8	16	32	Within 5%
0	0.9960	0.9036	0.9001	0.9000	—

09

What comes along if the existence column moves — reading the problem from the dictionary

What the problem asks for is to move the existence column from "None" to "Constructed" at the level of continuum quantum theory. "None" here means, as defined in § 04, not that it has been shown not to exist, but that it has not yet been made. What then comes along is shown by the definition column.

$$(b):\ \text{None} \to \text{Constructed} \ \text{ and } \ (a) = \text{Settled} \implies \text{the row can be used as it stands}$$ (10)

In Table 2 the existence column is "None" in 9 rows, and the "Constructed" rows 3, 10 and 12 are also at levels below continuum quantum theory. If a four-dimensional measure satisfying the conditions of the way back in (3), $(\mathrm{E0}')$–$(\mathrm{E4})$, were made, the Settled rows 1 and 2 could be used as they stand, and the reconstruction theorem would give the Hilbert space, the Hamiltonian and the vacuum. For the Conditional rows 4 and 5 the upper gap (§ 5 of the problem statement counts 'an upper gap, in addition to the mass gap' as an extension), and for row 8 a uniform decay rate, that is the gap itself, must be checked separately. The Unsettled rows 13 and 14 and the false friend of row 9 are not settled even when the measure is made. In this book's reading, this is also why existence and the gap stand side by side in one sentence of the problem statement (0-03 § 01).

The construction published on 2026-11-10 moved part of this to the level of continuum quantum theory (the committee's assessment is that it is proved in Lean): a Wightman theory for each component of the phases, with its Hilbert space, Hamiltonian and vacuum, and local operators corresponding to polynomials in the curvature (6-01). The probability measure (row 1 of Table 2), one-particle states (4, 5) and uniform decay (8) remain None (6-04). The existence columns of Table 2 and of 18-02 to 18-04 are left as the reading from before publication.

What this chapter can say

	What is said	What is not said
Known	(2), the way there and the way back of (3), (6) (under the premises attached), (8), (9). The constructions of ADHM, Lüscher 1977 and Schor 1984	That these hold in four-dimensional continuum Yang–Mills theory
This book's reading	How the two-column grades, levels and judges are fixed, how the measurement column is fixed, (7) and (10), the grades of Table 2	That the grades are unique (the grounds are in 18-02–18-04)
Computed	$m_{\mathrm{eff}}(t)$ of the three-level model (Table 3, Figure 2)	The actual spectrum of Yang–Mills
Overall	—	This book itself shows neither the existence of the mass gap nor the construction of the continuum limit (the published construction of the continuum limit is in Volume 2)

Next chapter to read: 18-02 A dictionary of the theory itself.

A dictionary of the theory itself — the Settled pairs line up in front of a single measure

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — Nineteen pairs of words for the space, the measure and the states on which the theory rests, with their two-column grades and the grounds for them.
That many of the Settled pairs lie inside a single premise: "if a measure satisfying the conditions exists".
A calculation that sees that local symmetry does not break (Elitzur's theorem) through the order in which the external field is removed.

Prerequisite chapters — 4-02 and 4-10. The two columns of grades are from 18-01. We also draw on tools from 4-11 (particles, spectrum), 5-03 (the transfer matrix), 3-04 (orbit space, Singer's theorem), 2-08 (the order of removing the external field) and 5-01 (Haar measure). Words not in the prerequisite chapters are defined where they first appear.

Said first — We only line up pairs and grade them; we make neither the measure nor the Hilbert space of four-dimensional Yang–Mills theory. "None" in the existence column means, as in 18-01 § 04, "not yet made"; it has not been shown not to exist. The exception is the entry "gauge fixing": that there is no global continuous gauge fixing (on the four-dimensional sphere) is Singer's theorem ("ruled out" in Table 0).

The order of this chapter

1. The overall picture — nineteen pairs and one premise (Table 0)
2. The container — the path integral, the measure, the space of states
3. Real time and imaginary time — three faces of a correlation
4. The contents — the vacuum, the Hamiltonian, particles
5. Scattering and positivity — two kinds of "unitarity"
6. Approximation — spacetime, regularisation, renormalisation
7. Fields have no values at points — operator-valued distributions

8. Gauge — slices and physical states
9. Local symmetry does not break — Elitzur's theorem (the entry "local symmetry does not break")
    - Detour: gauge theory at $\beta = \infty$ is the Ising model

---

01

The overall picture — nineteen pairs and one premise

The grades are the two columns of 18-01. (a) is "if both existed, would they be the same?", and (b) is whether the mathematical object exists in four-dimensional Yang–Mills theory (level in parentheses). The judge is what supports "the same" (theorem, definition, convention, and so on; 18-01 § 07), and the chapter is the chapter that treats it in detail.

Note: column (b) of Table 0 is the reading from before the published construction (2026-11-10). As at the end of §01, rows 3, 4, 5 and 8 leave room to be regraded at the level of the published construction.

Notes on the words of Table 0. (c) is the measurement column of 18-01 § 02 (the direction reachable by finite measurement), given only for rows that name a quantity. The entries "Källén–Lehmann representation" and "one-particle state" are rows where a single correlation gives an upper bound on the lowest point (18-01 § 08), and the entries "vacuum and uniqueness" and "spacetime and lattice" are statements about limits. "None" in (b) means not yet constructed at the continuum level, and "None (Constructed at the lattice level)" means rows made only at the lattice level. Only "ruled out" in the entry "gauge fixing" has the opposite sense: it is a theorem that a global section does not exist. * "Not applicable" in the entry "path integral (quantum mechanics)" means that, being a pair from quantum mechanics with finitely many degrees of freedom, it has no four-dimensional entry (18-01 § 04).

Many of the Settled pairs lie inside a single premise. If on $\mathbb{R}^4$ there is a measure μ satisfying the Osterwalder–Schrader (OS) conditions, the reconstruction theorem gives the rest (4-10 § 05) Known .

$$\mu \text{ satisfies } (\mathrm{E0}')\text{–}(\mathrm{E4}) \implies (\mathcal{H},\ H \geq 0,\ \Omega), \quad \{S_n\} \to \{W_n\}, \quad d\rho_O \geq 0 \tag{1}$$

On the left are the OS conditions (growth, Euclidean covariance, reflection positivity, symmetry, clustering; 4-10 § 03), and on the right the Hilbert space, Hamiltonian and vacuum, the passage from the Schwinger functions S_n to the Wightman functions W_n, and the positivity of the spectral measure. Before the publication of 2026, the left was missing in four-dimensional Yang–Mills theory, so at the continuum level the existence column lined up almost entirely at "None" (Table 0 is that reading). The exceptions are rows for which the premise is not enough even if it holds (the entries "one-particle state", "S-matrix" and "unitarity of the S-matrix"), and rows decided outside the premise (Singer's theorem in the entry "gauge fixing", Elitzur's theorem in the entry "local symmetry does not break"). Example: for the four-dimensional free field the left of (1) exists, and the objects of every row except the gauge rows are present.

The committee's assessment is that the construction published on 2026-11-10 showed a variant of the OS axioms for each component of the phases, starting not from a measure but from the side of correlations (Schwinger functions), and reconstructed the Hilbert space, Hamiltonian and vacuum on the right (6-01, 12-08). The existence column of the entries "space of states", "Wick rotation", "Green functions" and "Hamiltonian" leaves room to be regraded at that level (18-01 § 09). The measure, one-particle states and the S-matrix remain None (6-04).

02

The container — the path integral, the measure, the space of states

"Container" is a metaphor. More precisely, it means the space on which the theory rests (the totality of field configurations), the measure on it, and the Hilbert space made from them.

Path integral (quantum mechanics) ⟷ Feynman–Kac formula

The physical word is "a weighted sum over all the paths a particle can take", and the mathematical word is an expectation over Brownian motion. They can be said to be the same after moving to imaginary time and putting conditions such as the potential being bounded below.

Writing the e^{-tH} of quantum mechanics in this form is the Feynman–Kac formula (Kac 1949; equation (2) of 18-01, 2-07 § 05) Known . Feynman's (1948) sum has the real-time weight $e^{iS/\hbar}$, and moving it to imaginary time gives this formula. The real-time weight does not become a measure.

Functional integral ⟷ Euclidean probability measure

The physical word is a sum over all field configurations with weight e^{-S}, and the mathematical word is a probability measure on the space of configurations. They can be said to be the same because the side of mathematics defined $\int \mathcal{D}A\, e^{-S}$ as a countably additive probability measure (the judge is a definition; § 4 of Jaffe's review).

$$\frac{1}{Z}\int \mathcal{D}\phi\; e^{-S(\phi)} F(\phi) \;\rightsquigarrow\; \int F\, d\mu, \qquad \mu:\ \mathcal{S}'(\mathbb{R}^4) \text{ etc.: a probability measure on it} \quad (2)$$

Example: the free field is the Gaussian measure with covariance $(-\Delta + m^2)^{-1}$ (Δ is the Laplacian, not the Δ of the mass gap) (4-10 § 02). Two-dimensional Yang–Mills theory has also been constructed (Driver 1989, 7-02). On the lattice, equation (9) of 4-02 is a genuine measure. The measure of four-dimensional Yang–Mills has not been constructed (the construction published on 2026-11-10 does not make the measure either; 6-04), and the space it rests on (a completion of the space of connections divided by gauge) has not yet been fixed either (3-04).

Space of states ⟷ reconstructed Hilbert space

The physical word is Fock space (the space that lines up states by number of particles, 2-06), and the mathematical word is the Hilbert space (3) made from the measure. They can be said to be the same for free fields, and, with interactions, when asymptotic completeness (§ 05) holds.

Let $\mathcal{E}_+$ be the totality of functions determined only by fields at positive times, and Θ time reversal (4-10 § 05).

$$\mathcal{H} = \mathcal{E}_+ / \mathcal{N}, \qquad \mathcal{N} = \{F : \mathbb{E}[\Theta F\, F] = 0\} \quad (3)$$

$\mathcal{N}$ is the totality of functions of norm 0, and dividing by it and completing gives $\mathcal{H}$. (i) For free fields it agrees with Fock space (4-10 § 07). (ii) With interactions, the representation of the canonical commutation relations at time 0 becomes inequivalent to the Fock representation (ϕ^4_3, Jaffe § 6). The Fock space of physics is the space of asymptotic particles, so agreement needs asymptotic completeness.

03

Real time and imaginary time — three faces of a correlation

"Three faces" is a metaphor. More precisely, it means the values of the same correlation read at different places (real time, imaginary time, time-ordered) of a single analytic function (the entry "Green functions").

Wick rotation ⟷ OS reconstruction theorem

The physical word is the computational procedure of setting $t = -i\tau$ and rotating the contour, and the mathematical word is the theorem that builds a Wightman theory from Schwinger functions. They can be said to be the same under the conditions (E0′)–(E4), in the direction from imaginary time to real time.

Wick rotation is Wick's (1954) procedure (4-02 § 02), and its mathematical partner is the reconstruction theorem, which has a direction Known .

$$\{S_n\} \text{ satisfy (E0}'\text{)–(E4)} \implies \text{a Wightman theory}, \qquad W_n(\ldots,(-i\tau_j, x_j),\ldots) = S_n(\ldots,(\tau$$

A condition on the ordering of times is needed because S_n does not change when its arguments are exchanged, while W_n changes with the order in which the operators stand (the example in the entry "Green functions"). Care is needed in the reverse direction. The Schwinger functions obtained from a Wightman theory need not satisfy (E0′). The first OS paper (1973) claimed an equivalence, but the proof had an error, which Glaser (1974) fixed. The second (1975) states it in the form of a sufficient condition with (E0′) added (the abstract has '(necessary and) sufficient', with parentheses).

Green functions ⟷ Wightman functions and Schwinger functions

The physical word "Green function" refers to any of the time-ordered product G_T, the Wightman function W and the Schwinger function S, while mathematics defines these

three as separate functions. They can be said to be the same in the sense of the theorem that the three are values of one analytic function. Example: for an oscillator of angular frequency ω ($\hbar = m = 1$),

$$F(z) = \frac{e^{-\omega z}}{2\omega} \ (\mathrm{Re}\, z \geq 0): \qquad S(\tau) = F(|\tau|), \qquad W(t) = F(it), \qquad G_T(t) = F(i|t|) \tag{5}$$

W is the boundary value on the imaginary axis, S is the restriction to the real axis folded by $|\tau|$, and G_T is glued together by sign (Wightman 1956, Symanzik 1966). For $\tau > 0$, $W(-i\tau) = F(\tau) = S(\tau)$, which is the two-point case of (4). For $\tau < 0$, extending the formula for W as it is grows as $e^{\omega|\tau|}$, disagreeing with $S(\tau)$. $W \to S$ follows from positive energy alone, but $S \to W$ needs (E0′).

Källén–Lehmann representation ⟷ spectral measure

The physical word is the formula that writes a two-point correlation as a superposition over energies (masses), and the mathematical word is the spectral measure of the Hamiltonian. They can be said to be the same when H exists by reconstruction (under the premise of (1)). The representation of Källén (1952) and Lehmann (1954) can be written, in the form of equation (6) of 4-11, as

$$\langle O\Omega,\ e^{-\tau H} O\Omega\rangle = \int_{[0,\infty)} e^{-E\tau}\, d\rho_O(E), \qquad d\rho_O(E) = d\langle O\Omega,\ P_H(E)\, O\Omega\rangle \geq 0 \tag{6}$$

$P_H(E)$ is the projection onto the part of H with energy at most E (the spectral theorem of 1-10 § 05). The positivity of the weights comes from reflection positivity (Table 2 of 4-10). Example: (5) is the case where ρ has weight at the single point $E = \omega$, and on the lattice $\rho_O = \sum_n |\langle n|O|\Omega\rangle|^2 \delta_{E_n}$ (equation (8) of 18-01). The breaking of positivity of the gauge-fixed gluon propagator is treated in 17-02.

04 The contents — the vacuum, the Hamiltonian, particles

"Contents" is also a metaphor. More precisely, it means the particular vector (the vacuum) and operators (the Hamiltonian, the mass operator) fixed on the Hilbert space of § 02.

Vacuum and uniqueness ⟷ Ω and clustering

The physical word is "the state with nothing in it", and the mathematical word is $\Omega = [1]$, obtained in the reconstruction as the class of the constant 1. They can be said to be the same when the vacuum of physics is read as "the state of lowest energy" (a theorem under the premise of (1)).

Uniqueness means that the eigenvalue 0 of H is simple (Jaffe § 2), and on the Euclidean side it is paired with clustering Known .

$$\Omega \text{ unique} \iff \lim_{|a|\to\infty} S_{n+m}\big(x_1,\dots,x_n,\,y_1+a,\dots,y_m+a\big) = S_n(x)\,S_m(y), \qquad a=(0,$$

Non-uniqueness of the infinite-volume limit, degeneracy of the ground state and phase transitions are the same phenomenon (Jaffe § 7.2). Example: on the low-temperature side of the two-dimensional Ising model, the difference between the lowest two levels closes with the width (2-09 § 08). The identification with the procedure of physics that builds the vacuum by switching on interactions slowly from the vacuum without interactions (attributed to Gell-Mann and Low) is not mathematically justified, since Haag's theorem (attributed to Haag 1955) denies in general the existence of the interaction picture (the way of writing that evolves in time by the interaction alone on the space of free fields).

Hamiltonian ⟷ logarithm of the transfer matrix

The physical word is the operator that generates the advance of time (the energy), and the mathematical word is the logarithm of the transfer matrix T that advances imaginary time by one step on the lattice. They can be said to be the same at the lattice level; agreement with the continuum H is conditional on the continuum limit.

$$H_a = -\frac{1}{a}\log T, \qquad T = T^{*} > 0 \quad (8)$$

a is the lattice spacing in the time direction. A positive self-adjoint T was made by Lüscher (1977) (5-03 § 05), and it connects to the H of Kogut–Susskind (1975) by sending the time step to 0 (Creutz 1977, 5-03 § 07) Known . It is a different thing from the generator L of stochastic quantisation (18-03 § 05).

One-particle state ⟷ isolated eigenvalue of the mass operator

The physical word is a particle classified as an irreducible representation of the Poincaré group (Wigner 1939), and the mathematical word is an isolated eigenvalue of the mass operator M. They can be said to be the same in the reconstructed theory, when that eigenvalue is isolated in the spectrum (4-11 § 05).

$$M = \sqrt{H^2 - \vec{P}^{\,2}}, \qquad m \text{ an eigenvalue of } M \text{ with } (m-\delta, m+\delta)\cap\sigma\big(M|_{\Omega^{\perp}}\big) = \{m\} \quad (\delta >$$

$\vec{P}$ is the momentum, $\sigma(\cdot)$ the spectrum, and $\Omega^{\perp}$ the part orthogonal to the vacuum. Jaffe writes that scattering theory assumes this and 'It entails both a lower gap and an upper gap' (§ 7.1; § 5 of the problem statement also counts the upper gap among the extensions) Known . It has been shown for weakly coupled $P(\phi)_2$ (Glimm–Jaffe–

Spencer 1974), and there is also a one-particle state at strong coupling on the lattice (Schor 1984). Example: for the free field the continuous spectrum above m starts at $2m$. The glueball row is in 18-03 § 04.

05

Scattering and positivity — two kinds of "unitarity"

"Unitarity" in physics is used in two senses, so we split it into the entry "positive norm" (no states of negative norm) and the entry "unitarity of the S-matrix" (probability conserved in scattering) (18-01 § 06). We put the tool of scattering (the entry "S-matrix") first.

S-matrix ⟷ Haag–Ruelle scattering theory

The physical word is the amplitude from a set of particles in the far past to a set of particles in the far future, and the mathematical word is an operator built from two isometries. They can be said to be the same when there is an isolated one-particle mass (the entry "one-particle state").

The mass hyperboloid is the surface $p^2 = m^2$ in momentum space (on the side $p^0 = \sqrt{\vec{p}^{\,2} + m^2}$), and the one-particle states of mass m lie on it. An isometry is a map that preserves inner products, and Ran is the range (the totality of values of the map). $\mathcal{F}$ is the Fock space of asymptotic particles, the space that lines up, by number of particles, the states of particles flying freely in the far past (or future). The scattering theory of Haag (1958) and Ruelle (attributed to 1962) builds the isometries $W^{\mathrm{in}}, W^{\mathrm{out}} : \mathcal{F} \to \mathcal{H}$ from an isolated mass hyperboloid.

$$S = (W^{\mathrm{out}})^* W^{\mathrm{in}}, \qquad \mathrm{Ran}\, W^{\mathrm{in}} = \mathrm{Ran}\, W^{\mathrm{out}} \implies S^*S = SS^* = 1 \quad (10)$$

The rightward direction of (10) is elementary. For an isometric W, $W^*W = 1$, and WW^* is the projection onto the range; if the ranges are the same, $W^{\mathrm{out}}(W^{\mathrm{out}})^*$ does not change the values of W^{in}, so $S^*S = (W^{\mathrm{in}})^* W^{\mathrm{out}} (W^{\mathrm{out}})^* W^{\mathrm{in}} = (W^{\mathrm{in}})^* W^{\mathrm{in}} = 1$, and $SS^* = 1$ likewise Paper . Example: for the free field $W^{\mathrm{in}} = W^{\mathrm{out}}$ and $S = 1$. Asymptotic completeness is the claim that the two ranges are the whole of $\mathcal{H}$. Within the range we searched, we found no theorem deriving asymptotic completeness in the usual sense in general. Dybalski–Gérard (2014) showed a "generalised" form under lower and upper mass gaps Known . There are partial results for individual models (unitarity of the S-matrix for weakly coupled $P(\phi)_2$ on even states with energy below about $4m$: Spencer–Zirilli 1976).

Positive norm ⟷ reflection positivity

The physical word is that there are no states of negative norm (Wightman positivity), and the mathematical word is the reflection positivity of the Schwinger functions. They can be said to be the same within the correspondence between OS and Wightman, and this is a theorem.

Reflection positivity gives the Hilbert space and $H \geq 0$, and is preserved in limits (Jaffe § 4), so if a limit exists it can be carried over from the lattice. It holds for Wilson's lattice (Osterwalder–Seiler 1978, Lüscher 1977) Known . Example: negative weights of Pauli–Villars type break it (4-10 § 08).

Unitarity of the S-matrix ⟷ positive norm + asymptotic completeness

The physical word is that probability is conserved in scattering ($S^*S = 1$), and the side of mathematics is the entry "positive norm" with the agreement of the ranges in (10) added. They can be said to be the same when asymptotic completeness holds.

For gauge theories, the abstract of Kugo–Ojima (1979) writes that "unitarity of the physical S-matrix" is shown in general ('quite generally') on the basis of representations of the algebra of the BRS charge (the Q_B of § 08). This is a general theory assuming representations of the algebra and asymptotic fields, and its stage is a space with indefinite metric (an inner product that allows negative norms). Those assumptions have been checked within perturbation theory.

06

Approximation — spacetime, regularisation, renormalisation

Spacetime and lattice ⟷ the $a \to 0$ limit of $a\mathbb{Z}^4$

The physical word is four-dimensional spacetime with Minkowski signature ($\mathbb{R}^4$ after Euclideanisation), and the side of mathematics is the $a \to 0$ limit of measures on the lattice $a\mathbb{Z}^4$ of spacing a. They can be said to be the same when the limit exists and the rotational symmetry $O(4)$ comes back.

The rotational invariance of Euclideanised spacetime is the $O(4)$ invariance of Euclidean covariance (Osterwalder–Schrader axiom E1) (for the signature, the existing article One sign is different). What remains on the lattice is rotations by 90° and reflections, and the abstract of Wilson (1974) writes of the strong-coupling limit 'no Lorentz (or Euclidean) invariance' Known .

symmetries of the hypercube (order $2^4 \cdot 4! = 384$) $\subset O(4)$, $\qquad \mu_a \xrightarrow[a\to 0]{?} \mu$ ($O(4)$ -invaria

Example: for the free field on the lattice, the difference between correlations along an axis and along a diagonal vanishes as a^2 (Table 2 of 4-02). For pure gauge theories, the continuum limit of the lattice has been shown for non-abelian groups in two dimensions and for U(1) in three and four dimensions (Driver 1989, Gross 1983, Driver 1987, among others). The abstract for three dimensions writes that with the Villain action it converges to the free electromagnetic field. The free electromagnetic field is invariant under rotations, so rotational symmetry has come back too.

Regularisation ⟷ family of measures with lattice spacing a

The physical word covers all devices that temporarily stop infinities, and what the side of mathematics can treat as a family of measures is mainly the lattice. They can be said to be the same when the limit with the device removed does not depend on the choice of device (universality).

§ 6.5 of the problem statement writes that there are few ways of recovering the reflection positivity lost in dimensional regularisation, Pauli–Villars and the like. What Reisz (1989) shows is that the continuum limit of the lattice is finite at each order of perturbation.

$$\lim_{a\to 0} \mu_a^{\text{Wilson}} \stackrel{?}{=} \lim_{a\to 0} \mu_a^{\text{Villain}} \stackrel{?}{=} \cdots \quad (12)$$

The non-perturbative (12) has been shown in two dimensions. Chevyrev–Shen (2023, arXiv:2302.12160) showed on the two-dimensional torus, for connected compact groups, that lattice gauge theories with the Wilson, Villain and Manton actions give the same limit. Convergence of the two-dimensional lattice approximation is also in Driver (1989).

Renormalisability ⟷ BPHZ, Epstein–Glaser

The physical word is that infinities vanish at each order of perturbation after adjusting finitely many constants, and the mathematical word is the finiteness theorems of a subtraction rule (BPHZ) and of an inductive construction from causality (Epstein–Glaser). They can be said to be the same at the level of formal power series (4-05).

In physics, Dyson (1949), and for Yang–Mills 't Hooft (1971) and Becchi–Rouet–Stora (1976). In mathematics, Bogoliubov–Parasiuk (1957), Hepp (1966), Zimmermann (1969) and Epstein–Glaser (1973).

$$S_n^{\text{ren}}(x;g) = \sum_{k\geq 0} c_{n,k}(x)\, g^k \in \mathbb{C}[[g]] \qquad (\text{each } c_{n,k} \text{ finite}) \quad (13)$$

The abstract of Epstein–Glaser writes that the inductive construction gives 'at each order, finite terms' and is equivalent to BPHZ Known . It does not include convergence

of the sum (the series is thought to diverge, 4-12).

07

Fields have no values at points — operator-valued distributions

Field $\phi(x)$ ⟷ operator-valued distribution

The physical word is an operator $\phi(x)$ at each point x, and the mathematical word is an operator-valued distribution, in which only $\phi(f)$, smoothed with a test function f, is an operator. They can be said to be the same when $\phi(x)$ is read as "a symbol for the smoothed value, just before the smoothing width is sent to 0".

Distributions are in 1-11 § 04 (the reading of fields is Jaffe § 3) Known . For the free field of mass m ($\omega_p = \sqrt{p^2 + m^2}$),

$$\phi(f) = \int \phi(x) f(x)\, d^4x, \qquad \|\phi(f)\Omega\|^2 = \int \frac{d^3p}{(2\pi)^3} \frac{|\hat{f}(\omega_p, p)|^2}{2\omega_p} < \infty \quad (14)$$

Example: taking f to be a bump of integral 1 and width ε, $f_\varepsilon(x) = \varepsilon^{-4} g(x/\varepsilon)$, we have $\hat{f}_\varepsilon(p) = \hat{g}(\varepsilon p)$, so in four dimensions the right-hand side diverges as ε^{-2} (1-09). The point value $\phi(x)$ is the limit as f approaches δ, so as an operator it does not exist. The point fields of Yang–Mills are $\mathrm{Tr}\, F_{ij}F_{kl}(x)$, and § 4 of the problem statement requires those operators. The local-field footnote of the problem statement (footnote 1 of Jaffe–Witten) says that a natural one-to-one correspondence between classical differential polynomials and operators 'does not exist', and expects a correspondence between the spaces of dimension $\le d$ (0-03 § 08). Dimension here is the power under a change of the length scale (2 for F, 4 for $\mathrm{Tr}\, F^2$; 1-11 § 06). A Wilson loop is a quantity on a curve, outside the axioms of point fields (4-10 § 09).

08

Gauge — slices and physical states

Gauge fixing ⟷ section of the orbit space

The physical word is choosing one representative from each gauge orbit by a condition $F(A) = 0$, and the mathematical word is a section of the projection to the orbit space $\mathcal{A}/\mathcal{G}$ (a map that assigns continuously one point to each orbit); as definitions they are the same. On the four-dimensional sphere, however, it is a theorem that there is no global section.

The geometry of slices is in 3-04 § 05. The source of the Faddeev–Popov (1967) rule is

$$1 = \Delta_{\mathrm{FP}}(A) \int_{\mathcal{G}} dg\ \delta\big(F(A^g)\big), \qquad \Delta_{\mathrm{FP}}(A) = \Big|\det \frac{\delta F(A^g)}{\delta g}\Big|_{g=1} \quad (15)$$

(15) holds when the condition surface $F = 0$ meets each orbit exactly once. (15) evaluates the determinant at the single point $g = 1$ and takes it outside the integral, so if it meets many times the right-hand side becomes a sum of ratios of the determinants at each intersection, and is neither 1 nor the number of intersections. Putting the determinant inside the integral gives the number of intersections $N(A)$.

$$N(A) = \int_{\mathcal{G}} dg\ \delta\big(F(A^g)\big) \Big|\det \frac{\delta F(A^g)}{\delta g}\Big| \quad (15a)$$

The actual Faddeev–Popov rule uses $\det$ without absolute value, so it counts intersections with signs (the detour in 4-08 § 05). Gribov (1978) pointed out that "exactly once" breaks down in non-abelian theories, and the abstract of Singer (1978) writes, on S^4, 'no continuous choice of exactly one connection on each orbit can be made' Known . The lattice integrates with Haar measure (the uniform probability measure on the group, unchanged by multiplication), so no gauge fixing is needed and it avoids this row (5-01, 4-08).

Physical states ⟷ reconstruction from gauge invariants

The physical word is states satisfying the Gauss constraint, or BRST cohomology, and the mathematical word is the space made by carrying out (3) with gauge-invariant quantities only. They can be said to be the same up to the lattice level; in the continuum it is Unsettled.

The Gauss constraint is the non-abelian version of Gauss's law $\nabla \cdot \boldsymbol{E} = 0$, and on the side of states it is the condition "the state does not change under gauge transformations at fixed time" (Kogut–Susskind 1975, 4-01). On the lattice, $\psi(U^g) = \psi(U)$ for gauge transformations g at fixed time. The BRST Q_B is an operator satisfying $Q_B^2 = 0$ (the BRST charge), and $\mathbf{Ker}\, Q_B / \mathbf{Im}\, Q_B$ is "the states annihilated by Q_B, identified up to the range of Q_B". An indefinite metric is an inner product that allows negative norms.

$$\mathcal{H}_{\mathrm{phys}}^{\mathrm{BRST}} = \mathbf{Ker}\, Q_B / \mathbf{Im}\, Q_B \ \ \text{(indefinite metric)}, \qquad \mathcal{H}_{\mathrm{inv}}^{\mathrm{OS}} = \mathcal{E}_{+}^{\mathrm{inv}} / \mathcal{N} \ \ \text{(positive definite)} \quad (16$$

On the lattice, transition probabilities between gauge-invariant states are not negative (Lüscher 1977), and gauge fixing does not change the Green functions of gauge singlets (operators unchanged by gauge transformations) (Creutz 1977) Known . In the continuum it has not been shown that the two sides of (16) are the same, and non-perturbative BRST remains hard to define because of Gribov copies.

09

Local symmetry does not break — Elitzur's theorem

Local symmetry does not break ⟷ Elitzur's theorem

The physical word is the claim "gauge symmetry (local symmetry) does not break spontaneously", and the mathematical word is a theorem stating it as a limit in an external field. They can be said to be the same when compared in the order "put in an external field, make the volume infinite, then remove the field".

The abstract of Elitzur (1975) argues, in the form 'It is argued that', that spontaneous breaking of local symmetry is impossible in a symmetric gauge theory without gauge fixing, and says it is shown in a simple system of abelian gauge fields on a lattice Known . Mathematical successors include a proof, for an abelian Higgs model on the lattice, that the magnetisation becomes 0 when the external field is removed (De Angelis–de Falco–Guerra 1978) Known . If the external field is 0, the Haar average makes the expectation 0 (equation (9) of 17-02). Spontaneous breaking is a question of the order in which the external field is removed (2-08).

Comparing in the order of removing the external field

We write Elitzur's argument out for the weight $\exp(\beta \sum_p U_p + h \sum_\ell U_\ell)$ of $\mathbb{Z}_2$ lattice gauge theory in d dimensions (link variables $U_\ell = \pm 1$, with U_p the product of the four links round a plaquette). A gauge transformation at one point x flips the $2d$ links touching x, and does not change $\sum_p U_p$. So for ℓ touching x,

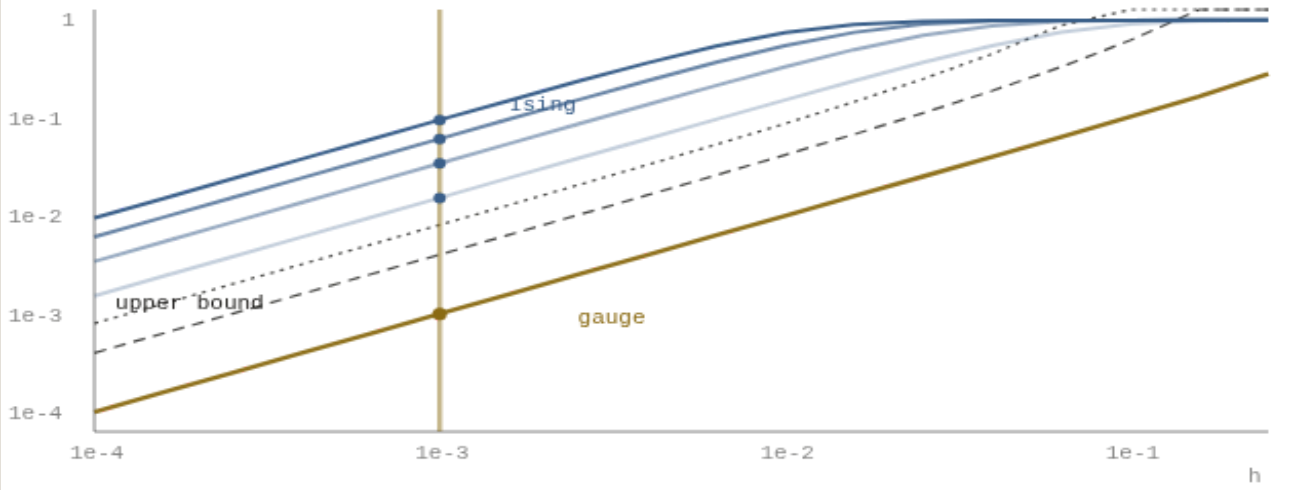
$$\langle U_\ell \rangle_h = -\langle U_\ell \, e^{-2hQ_x} \rangle_h, \quad Q_x = \sum_{\ell' \ni x} U_{\ell'} \quad \Longrightarrow \quad |\langle U_\ell \rangle_h| = \tfrac{1}{2} \big| \langle U_\ell (1 - e^{-2hQ_x}) \rangle_h \big| \le \tfrac{1}{2}$$

Paper . The right-hand side depends neither on the volume nor on β. In the Ising model (global $\mathbb{Z}_2$) all spins must be flipped, and the upper bound from the same argument is $\frac{1}{2}(e^{2h|\Lambda|} - 1)$, which loses its meaning as the volume grows. The only difference is whether one symmetry transformation touches finitely many variables or all of them. The slope at $h = 0$ is

$$\frac{d\langle U_\ell \rangle_h}{dh}\Big|_0 = \sum_{\ell'} \langle U_\ell U_{\ell'} \rangle_0 = 1, \qquad \frac{d\langle \sigma_0 \rangle_h}{dh}\Big|_0 = \sum_y \langle \sigma_0 \sigma_y \rangle_0 \approx M_0^2 \, |\Lambda| \quad (18)$$

On the left, the term with $\ell' = \ell$ is 1. The terms with $\ell' \neq \ell$ are 0 because, gauge-transforming at the endpoint of ℓ that does not touch ℓ', only U_ℓ of the two changes sign and $U_{\ell'}$ does not (in a box of side at least 3 such an endpoint always exists). The right is on the low-temperature side, where even distant spins keep the correlation M_0^2, so it is proportional to the volume.

Figure 1 Choosing the external field h (log scale) shows below ⟨σ⟩ (Ising, blue, darker in the order L = 4 to 10) and ⟨U⟩ ($\mathbb{Z}_2$ gauge, ochre) for the two-dimensional L×L periodic box. "Play" lowers h towards 0 (the direction of removing the external field). The dashed and dotted lines are the upper bound (17) (d = 2, 4)



h = 1.0e−3 ⟨σ⟩ : L=4 0.0152, L=6 0.0342, L=8 0.0607, L=10 0.0946 ⟨U⟩ 0.00100, upper bound 0.00402

Computed The numbers in this figure were computed on this machine (exact values by diagonalising the transfer matrix).

Computed Table 1 The two-dimensional $L \times L$ periodic box. Ising at $\beta = 0.6$ (low-temperature side), gauge at $\beta = 2$

h	$\langle\sigma\rangle$ $L=4$	**6**	**8**	**10**	$\langle U\rangle$ $L=4$–**10**	**(17)** $d=2$
10^{-4}	0.0015	0.0034	0.0061	0.0095	0.000100	0.00040
10^{-3}	0.0152	0.0342	0.0607	0.0946	0.001000	0.00402
10^{-2}	0.1512	0.3288	0.5396	0.7314	0.010002	0.04164
10^{-1}	0.8979	0.9792	0.9810	0.9810	0.1017–0.1016	0.61277

The Ising columns rise with L, and $\langle\sigma\rangle/(hL^2)$ at $h = 10^{-4}$ is 0.9529, 0.9505, 0.9494, 0.9489, approaching 0.9479, the square of the formula $M_0 = (1 - \sinh^{-4} 2\beta)^{1/8}$ cited for the spontaneous magnetisation (attributed to Yang 1952) Computed . In the gauge column, for $h \le 10^{-2}$, $L = 4$–10 agree to 6 decimal places, and the slope is the 1 of (18). The "breaking of gauge symmetry" of physics is said to be reread as, for example, the breaking of a global symmetry after gauge fixing Physics ; taken literally it is a false friend (18-01).

Detour: gauge theory at β = ∞ is the Ising model

A subsection you may skip.

As $\beta \to \infty$ all plaquettes line up at $U_p = +1$ (a flat field). On a simply connected region one can write $U_{xy} = g_x g_y$ ($g_x = \pm 1$), so the external-field term becomes

$$h \sum_{\langle xy \rangle} U_{xy} = h \sum_{\langle xy \rangle} g_x g_y \qquad (19)$$

the Ising model with coupling $K = h$. The expectation of a link is its nearest-neighbour correlation (about $\tanh h$ for small h), and does not become a magnetisation. The periodic box (torus) of Table 1 is not simply connected. The products of links once round the box (holonomies, 1-07) fall into four classes, ± 1 horizontally and vertically, and the $\beta \to \infty$ limit is the sum of four Ising models with periodic and antiperiodic boundary conditions. At the computed $h = 0.1$ and 0.3 (the high-temperature side of Ising), the difference from the periodic Ising model alone becomes exponentially small with L.

Computed Table 2 $\langle U \rangle$ in the $L \times L$ periodic box and the nearest-neighbour correlation of Ising ($K =$ difference between the periodic Ising model alone and the sum of the four classe

h	Gauge $\beta = 4$, 8	Sum of the four classes	Periodic Ising	Difference $L = 4$	
0.1	0.101689	0.101689	0.101689	1.2e−3	1.4e
0.3	0.352256, 0.352257	0.352257	0.356234	6.9e−2	1.7e

The first three columns are $L = 8$. At $h = 0.1$ they agree to 6 decimal places; at $h = 0.3$ a difference is visible between the gauge value 0.35226 and periodic Ising 0.35623, and the sum of the four classes agrees Computed .

Next chapter to read: 18-03 A dictionary of mass and length.

A dictionary of mass and length — pairs that overlap on the lattice and come apart on the side of the limit

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — We pair 20 physical words about "mass" and "length" with mathematical words, and see two layers: an inner layer where they overlap once the lattice is fixed, and an outer layer, on the side where the lattice spacing is sent to 0, where the conditions gather. We also fix here the distinction between "two times" and two η.

Prerequisite chapters — 4-11, 5-08 and 2-08. The Poincaré constant is in 1-10, and the two columns of grades in 18-01. Words not in the prerequisite chapters (asymptotic freedom, stochastic differential equations, log-Sobolev, mixing time, the Polyakov loop, central charge, and so on) are defined in a line each where they are used.

Said first — We only line up correspondences; we show neither the mass gap, nor confinement, nor the continuum limit. The assumptions of the record of this book's study (the diffusive-relaxation-time assumption and others) remain assumptions.

The order of this chapter

1. The overall picture — two layers, two-column grades, how to read Table 0
2. The mass gap and the correlation length — lattice units and physical units
3. Potential, string tension, confinement — only one direction is a theorem
4. Λ, one scale, glueballs — the distinction between a gap and a particle
5. Two times — H_T and L, the unit of time
6. Autocorrelation times and the Poincaré constant — times that split into three
7. Critical slowing down — z, the conventional theory, the variational lower bound, two η. Detour: for the free field the relaxation time equals the susceptibility
8. Fluctuations of the tube and topological freezing — effective strings, Wulff, bottlenecks. Detour: sectors of topological charge and narrow passages

01

The overall picture — two layers and two-column grades

In physics, mass and length are two sides of one coin. More precisely, in units with $\hbar = c = 1$ the inverse of a mass has the dimension of length; the force carried by a particle of mass m stops reaching beyond a distance of about $1/m$ (Yukawa type, 3-01), and correlations fade as $e^{-r/\xi}$ with $\xi = 1/m$. In mathematics this one number splits into separate quantities: the spectral gap, the decay rate of correlations, and the rate of relaxation of a stochastic dynamics.

The pairs of Table 0 fall into two layers. The inner layer is pairs that become the same thing by the spectral theorem alone (1-10) once the lattice spacing a and the dynamics are fixed (the gap of the transfer matrix and the decay rate of correlations, for example). The outer layer is pairs that appear where $\xi \to \infty$ and $a \to 0$ are joined, and the conditions and the Unsettled grades gather there.

The two columns of the table are the grades of 18-01. (a) is "if both objects existed, would they be the same?": to the three grades Settled, Conditional and Unsettled we add "Does not correspond" for pairs known to be different quantities (the "false friend" of 18-01). (b) is the existence column of 18-01 given at the level "lattice (a fixed)", read as: Constructed = exists at every β in finite volume; Conditional = only versions of limited range, such as strong coupling; None = nothing shown at this level (including things known only numerically). At the continuum four-dimensional level every row is "None" (the construction published on 2026-11-10 does not make the mass gap, Wilson loops or one-particle states either; 6-04). Notation: $\beta = 2N/g^2$, lengths in lattice units, $m_{\mathrm{lat}} = 1/\xi$, $\Delta = m_{\mathrm{lat}}/a$. $A \asymp B$ means that the ratio A/B is bounded above and below by positive constants (A-01).

Table 0 The list of the dictionary of mass and length (from top, in the order of § 02– § 08)

#	Physical word	Mathematical word	(a) Definitions	(b) Lattice (a fixed)	(c) Finite measurement
1	Mass gap	Spectral gap, uniform decay	Conditional	Conditional (strong coupling)	Upper bound only
2	Correlation length ξ	Inverse of the gap of the transfer matrix	Conditional	Conditional (strong coupling)	Lower bound only
3	Gap in physical units	Uniform lower bound in lattice units	Does not correspond (false friend; settled as a different quantity)	Conditional (strong coupling)	Out of reach

#	Physical word	Mathematical word	(a) Definitions	(b) Lattice (a fixed)	(c) Finite measurement
4	$V(R)$	Decay rate of Wilson loops	Conditional	Conditional	Upper bound only
5	String tension σ	Coefficient of the area law, the d of the continuum string-tension problem (Chatterjee's Problem 5.2)	Conditional	Conditional ($\sigma > 0$ at strong coupling)	—
6	Confinement	One-directional theorems	Conditional	Conditional	—
7	Centre symmetry	Centre invariance on a slab	Unsettled	None (whether it holds is unproved)	—
8	Λ, one scale	No counterpart	Unsettled	None	—
9	$m/\sqrt{\sigma}$	The limit of the pair of the lattice correlation-length problem and the continuum string-tension problem	Unsettled	None (numerical only)	Out of reach
10	Glueball	Isolated eigenvalue of the mass operator	Conditional	Conditional (strong coupling; see note)	Upper bound only
11	Langevin relaxation	Generator L	Settled	Constructed (finite volume)	Upper bound only ($\mathrm{gap}(L)$)
12	$z = 2$	$\mathrm{gap}(L) \asymp \mathrm{gap}(H_T)^2$	Unsettled	None (a statement about a family; see note)	Out of reach
13	Exponential autocorrelation time	Poincaré constant C_P	Settled in continuous time	Constructed (finite volume)	Lower bound only
14	Thermalisation time	Mixing time	Conditional	Constructed (finite volume)	Lower bound only
15	Dynamical exponent z	$C_P \asymp \xi^z$	Unsettled	None (a statement about a family; see note)	Out of reach
16	$z = 2 - \eta_s$	Variational lower bound $C_P \geq \chi$	Conditional	Constructed (lower bound only)	Lower bound only

#	Physical word	Mathematical word	(a) Definitions	(b) Lattice (a fixed)	(c) Finite measurement
17	No slowing down away from criticality	Uniform mixing ⟺ uniform log-Sobolev	Conditional	Conditional (strong coupling)	Out of reach
18	Lüscher term	Casimir energy of a strip	Unsettled	None (numerical only)	—
19	Roughening, shape of the tube	Wulff construction	Unsettled	None (a picture of physics)	—
20	Topological freezing	Bottleneck in state space	Conditional	None (freezing numerical only)	Lower bound only

Note: (c) is the measurement column of 18-01 §02 (the direction reachable by finite measurement). Relatives of the gap (the entries "mass gap", "V(R)", "glueball" and "Langevin relaxation") reach an upper bound from a single correlation or test function, and the lengths and times that are their inverses (the entries "correlation length ξ", "exponential autocorrelation time", "thermalisation time", "z=2-η_s" and "topological freezing") swap direction and reach a lower bound. Statements about uniformity, families or limits (the entries "gap in physical units", "m/√σ", "z=2", "dynamical exponent z" and "no slowing down away from criticality") are out of reach. The ground for the entry "topological freezing" is (14) (choosing one set gives a lower bound on C_P; §08), and for the entry "thermalisation time" the definition of mixing time (§06; if the total variation distance exceeds ε on a single event, that time is before the mixing time). The entry "string tension σ" (the string tension) gets "—", since the main text of this book does not treat a form that pins down one side from finite measurements. The (b) of the entry "glueball" has the form that for each momentum there is a dispersion curve isolated from the energy spectrum, since the lattice has no Lorentz symmetry and the mass operator M is not defined as it is (Schor 1984; §04). Both sides of the entries "z=2" and "dynamical exponent z" are defined on a fixed lattice, but $\asymp$ is a statement about a family with the lattice spacing sent to 0, so on a single lattice it has no content. "None" in (b) means that nothing has been shown about that family.

02

The mass gap and the correlation length — lattice units and physical units

The problem statement (Jaffe–Witten) defines the mass gap as the Hamiltonian H having no spectrum in $(0, \Delta)$ (§ 4), and lists equal-time clustering as a consequence (§ 5) Known . After OS reconstruction (4-10), if the vacuum Ω is unique, the spectral theorem gives

$$\langle O\Omega, e^{-tH} O\Omega\rangle - |\langle \Omega, O\Omega\rangle|^2 = \int_{[\Delta,\infty)} e^{-tE}\, d\rho_O(E) \;\le\; e^{-t\Delta}\, \|O\Omega\|^2 \quad (1)$$

(ρ_O is the spectral measure of $O\Omega$ with 0 removed). The converse of (1) holds only when a dense family of observables decreases at a *uniform* rate (the entry "mass gap"). On the lattice, reflection positivity lets one build a positive self-adjoint transfer matrix $T = e^{-HT}$ (Lüscher 1977, 5-03), and from its eigenvalues $\lambda_0 > \lambda_1 \ge \cdots$,

$$m_{\mathrm{lat}} = -\log \frac{\lambda_1}{\lambda_0}, \qquad \xi = \frac{1}{m_{\mathrm{lat}}} \quad (2)$$

The correlation length of the plaquette correlation of Chatterjee (2018) is in general $\xi_{\mathrm{plaq}} \le 1/m_{\mathrm{lat}}$ (equality needs overlap with the lowest state). Example: for the free field $\xi = 1/(2\,\mathrm{arsinh}(m/2))$ (Table 1).

Two quantities under one word

Many of the results called "the mass gap is positive" in mathematics are uniform lower bounds in lattice units, $m_{\mathrm{lat}} \ge c > 0$. An example that can be checked is Shen–Zhu–Zhu (2023), whose abstract states a 'strictly positive mass gap' for strongly coupled lattice Yang–Mills Known . Then $\Delta = m_{\mathrm{lat}}/a \ge c/a \to \infty$, which in physical units is a property of the side where the mass goes to infinity, the opposite side from the continuum limit. A gap in physical units needs $\xi \to \infty$ to cancel $a \to 0$, and the lattice correlation-length problem (Chatterjee's Problem 5.1) also asks for $\xi(\beta) \to \infty$ as $\beta \to \infty$ (5-09, 16-08). This is why the entry "gap in physical units" in Table 0 is "Does not correspond".

03

Potential, string tension, confinement — only arrows in one direction are theorems

The static potential $V(R)$ is the energy of an infinitely heavy quark pair placed at distance R, read, following Wilson (1974), from the $R \times T$ Wilson loop (5-01) as

$$V(R) = -\lim_{T\to\infty} \frac{1}{T} \log\langle W_{R,T}\rangle, \qquad \sigma = \lim_{R\to\infty} \frac{V(R)}{R} \quad (3)$$

Taking the left as the definition it is Settled, but identifying it with the ground-state energy of static charges needs the $T \to \infty$ limit and overlap with the ground state (the entry "V(R)"). From the monotonicity and concavity of V shown by Bachas (1986), $\sigma \in [0, \infty)$ exists Known . The area law holds at strong coupling for every group (Osterwalder–Seiler 1978, 5-02). The continuum string tension is a proposal to define it as the d of Chatterjee's continuum string-tension problem.

$$\log\langle W_{R/\varepsilon,\,T/\varepsilon}\rangle = -c\,(R+T) - d\,RT + o(1), \qquad \varepsilon(\beta)\to 0,\ c(\beta)\to\infty,\ d \neq 0 \quad (4)$$

He himself writes that it is not clear whether the perimeter term is needed. The physical rule of thumb is $\sqrt{\sigma} \approx 485(6)$ MeV. This is a conversion that tentatively applies to the $r_0\sqrt{\sigma} = 1.160(6)$ of SU(3) pure gauge theory the length scale $r_0 = 0.472$ fm fixed by lattice calculations of QCD, and the authors themselves note that it is a conversion that cannot be made exactly, since pure gauge theory and QCD are different theories (Athenodorou–Teper 2020) Physics .

Three ways of saying confinement

The three are (a) $V(R) \to \infty$, (b) $\sigma > 0$ and (c) unbroken centre symmetry. The physical definition of (c) is at finite temperature. On a lattice whose time direction is a ring of length $1/T$ (T is the temperature), the trace of the product of links once round the time direction from a point is called the Polyakov loop, and its expectation being 0 is taken as the sign of confinement (Polyakov 1978, Susskind 1979; the universality argument through an order parameter transforming under the centre is Svetitsky–Yaffe 1982) Physics . A centre transformation multiplies all the time-direction links crossing the surface at some time by an element of the centre of the gauge group (for $SU(N)$, $e^{2\pi ik/N}$ times the identity matrix). The action does not change and only the Polyakov loop is multiplied by $e^{2\pi ik/N}$, so if this symmetry is unbroken the expectation is 0.

What has been shown in mathematics is only the one-directional implications of Table A (Chatterjee 2021) Known . The definition of unbroken centre symmetry (Definition 2.1 of Chatterjee 2021) is that for some $N \geq 1$ the theory restricted to the slab $\{0, \dots, N\} \times \mathbb{Z}^{d-1}$ is invariant under centre transformations for every boundary condition, and the definition of strong decay (Definition 2.3 of Chatterjee 2021) is uniform exponential decay for every cube and boundary condition (strong decay). The Wilson loops of the Theorem from Centre Symmetry to Confinement (Theorem 2.2 of Chatterjee 2021) are those in representations acting non-trivially on the centre.

Table A Implications between the ways of saying confinement (lattice)

Direction, example	Status
Strong exponential decay (Definition 2.3 of Chatterjee 2021) $\Longrightarrow$ unbroken $\wedge$ area law	Theorem (the Theorem from Uniform Decay to the Area Law)
Unbroken centre symmetry (Definition 2.1 of Chatterjee 2021) $\Longrightarrow$ $V(R) \to \infty$	Theorem (the Theorem from Centre Symmetry to Confinement)
Area law $\Longrightarrow$ $V(R) \to \infty$	Trivial
$V \to \infty \Longrightarrow \sigma > 0$	Not shown
Weak decay (for particular boundary conditions only) $\Longrightarrow$ confinement	Not shown
Finite groups, weak coupling: decay of two-point correlations for particular boundary conditions / no confinement	Theorem (Adhikari–Cao 2025) / belief

The gap and confinement are separate claims (17-02, 16-08, 5-10). On centre symmetry, Chatterjee proposes the definition of unbroken centre symmetry on the grounds that there is "to my knowledge" no mathematical definition, and cites Borgs–Seiler (1983) for the finite-temperature analogue. Whether the two definitions separate the same phases is unproved (the entry "centre symmetry").

04

Λ, one scale, glueballs — the distinction between a gap and a particle

The value of the dimensionless coupling g changes with the scale μ at which it is measured. Asymptotic freedom means that g becomes smaller the larger μ is (the shorter the distance) (4-06), and the one-loop coefficient that fixes the rate is b_0. Solving the one-loop formula,

$$\Lambda = \mu \exp\!\Big(-\frac{1}{2b_0\, g^2(\mu)}\Big), \qquad b_0 = \frac{11N}{3}\cdot\frac{1}{16\pi^2} \quad (5)$$

becomes a mass scale independent of μ (dimensional transmutation, 4-07). In physics every mass is a constant multiple of Λ, and $m/\sqrt{\sigma}$ is read as a pure number Physics . The side of mathematics has no definition of the four-dimensional Λ (the lattice Λ_L is in 18-04). The record of this book's study writes "a single scale" as chain (ii) $m^2 \asymp \sigma$, and calls it, by *analogy*, the sentence that plays the role of an equivalence principle (17-12). There is no proof. If the continuum string-tension problem holds with $\varepsilon(\beta)$ and $\varepsilon\xi \to \ell \in (0,\infty)$, then

$$\frac{m}{\sqrt{\sigma}} = \lim_{\beta\to\infty}\frac{1/(\varepsilon\,\xi)}{\sqrt{d}} = \frac{1}{\ell\sqrt{d}} \quad (6)$$

and this pairing is a reading not in Chatterjee's text. The numbers are 3.781(23) for SU(2), 3.405(21) for SU(3) and 3.072(14) for SU(∞) (0^{++}, Athenodorou–Teper 2020, 2021) Physics . There are also opposite examples. In three-dimensional compact U(1) (Villain action) the string tension is positive at every coupling, the continuum limit is a free field of mass m_D, and σ/m_D^2 in physical units diverges to infinity (Göpfert–Mack, abstract) Known . It is an example where there is confinement but the scale does not become one (17-12).

Glueballs are measured as the lowest decay rate in each J^{PC} (spin, parity, charge conjugation) channel (5-08; the SU(3) 0^{++} is $r_0 m = 4.21(11)(4)$, Morningstar–Peardon 1999) Physics . The rotational symmetry of the lattice is only the 48 rotations and reflections that carry the cube onto itself (the group O_h), so the channels are divided by the irreducible representations of O_h. The correspondence with continuum spin presupposes the recovery of rotational symmetry. A one-particle state in mathematics is an isolated eigenvalue of the mass operator

$$M = \sqrt{H^2 - P^2} \;\geq 0 \quad (7)$$

(P is the momentum; § 6 of the problem statement), and in § 5 the problem statement counts "an isolated one-particle state (the upper gap)" among the extensions Known . A gap and a particle are separate claims. The lattice has no Lorentz symmetry and M is not defined as it is, so what has been shown at strong coupling on the lattice has the

form that for each momentum there is a dispersion curve isolated from the energy spectrum (Schor 1983, 1984) Known .

05

Two times — the H_T of the transfer matrix and the L of Langevin

There are two times. One is the imaginary time of the path integral: correlations are carried by $T = e^{-H_T}$, and the gap is $1/\xi$. The other is the "fictitious fifth time" s of stochastic quantisation (Parisi–Wu 1981, 7-09) (the abstract of Zwanziger 1981): the whole configuration moves by the following stochastic differential equation and settles to e^{-S}/Z (the time of Monte Carlo methods is of the same kind).

$$d\phi_x = -\frac{\partial S}{\partial \phi_x}\, ds + \sqrt{2}\, dW_x(s) \quad (8)$$

$W_x(s)$ is a Brownian motion independent at each point x (1-09), and dW_x is the Gaussian increment over time ds, with mean 0 and variance ds. The first term moves in the direction that lowers the action, and the second adds fluctuations. On a computer one advances with step h as $\phi_x \leftarrow \phi_x - h\,\partial S/\partial\phi_x + \sqrt{2h}\,Z_x$ (Z_x independent standard normals), which is called the Euler–Maruyama method. The operator that generates the time change of the expectation of a function f (the generator) is

$$Lf = -\Delta f + \nabla S \cdot \nabla f, \qquad \langle f, Lf\rangle_\mu = \mathcal{E}(f) = \int |\nabla f|^2 \, d\mu \quad (9)$$

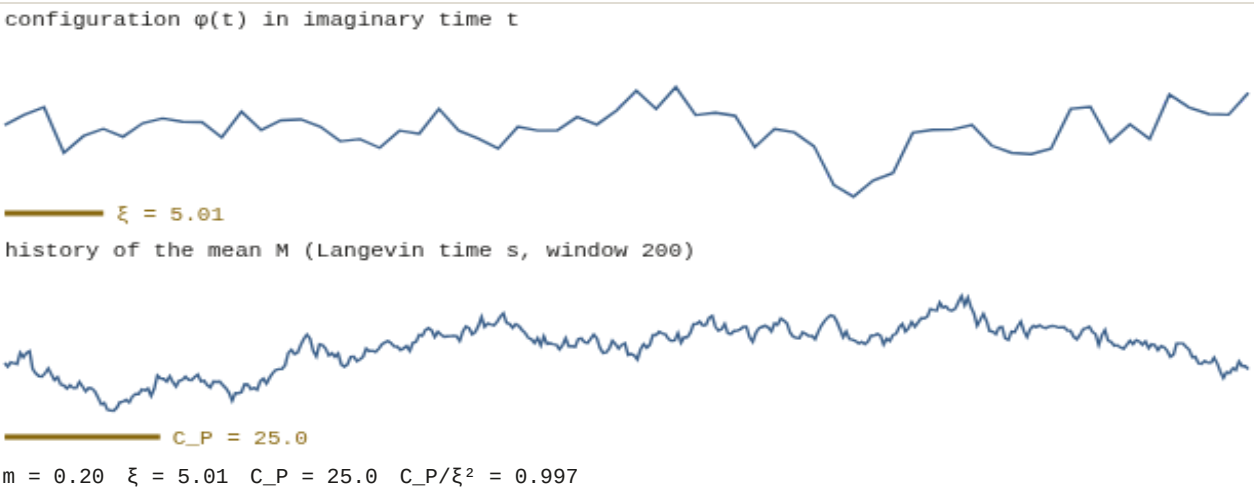
($\mu = e^{-S}/Z$, and $\mathcal{E}$ is the Dirichlet form; the Δ in (9) is the Laplacian, not the Δ of the mass gap), and the inverse of the gap above 0 is the Poincaré constant C_P (1-10). On a finite lattice both are defined (the entry "Langevin relaxation"), but H_T acts on the Hilbert space of a time slice, while L acts on the space $L^2(\mu)$ of functions of the whole configuration (functions square-integrable with respect to μ), and no theorem joins the two in general. For the free field $\mathrm{gap}(H_T) = 2\,\mathrm{arsinh}(m/2) \approx m$ and $\mathrm{gap}(L) = m^2$, so $C_P \approx \xi^2$ (1-10).

The diffusive-relaxation-time assumption and the unit of time

The relaxation-time assumption of the record of this book's study is the assumption that $\mathrm{gap}(L) \asymp \mathrm{gap}(H_T)^2$ holds uniformly in the lattice spacing (23-01, 18-05). However, the unit of time of L is fixed by the normalisation of S and of the noise. Replacing S by βS multiplies the gap of L, in the Gaussian case, by exactly β. In gauge theory with $S = \beta\times$ (Wilson action), in the free approximation $C_P \approx \xi^2/\beta$; that is, C_P is proportional to $g^2(a)\,\xi^2$, and this factor moves with the lattice spacing. Written at the level of a band (constant factors), the relaxation-time assumption is a statement made after

fixing this normalisation once (23-01). By the convention of the record, the relaxation-time assumption is put at the level of powers, and the band level is split off as a separate assumption that names the normalisation (18-05 § 03).

Figure 1 Changing m with the knob, the bar ξ at the top (the configuration φ(t) in imaginary time) grows as about 1/m, and the bar C_P at the bottom (the history of the mean M along the Langevin time s) as $1/m^2$. "Play" runs equation (8)



Computed The numbers in this figure were computed on this machine. The fluctuations are Euler–Maruyama with step $h = 0.05$. At this step the mean M is multiplied by $1 - hm^2$ each step and noise is added, a first-order recurrence whose integrated autocorrelation time $1/m^2 - h/2$ agrees with $1/m^2$ to within 2.5% over the whole range of the knob ($0.1 \le m \le 1$). Measured on the histories run, it was checked at $m = 0.3,\ 0.5,\ 1$ and agrees to within 10%. Without JavaScript it can be read from Table 1.

Computed Table 1 The two gaps of the free field on the lattice (zero-momentum channel)

m	gap(H_T)	ξ	$C_P = 1/m^2$	C_P/ξ^2
1.00	0.962424	1.039	1.00	0.9263
0.10	0.099958	10.004	100	0.9992
0.02	0.020000	50.001	2500	1.0000

The gap agrees to 6 digits with the slope of the correlation on a ring of length 8192, and C_P with the smallest eigenvalue of $-\Delta_{\text{lat}} + m^2$ on a ring of 256 points Computed . $C_P/\xi^2 \to 1$ is the $z = 2$ of the free field.

06

Autocorrelation times and the Poincaré constant — equality only in continuous time

When the dynamics is run from equilibrium, the correlation between values of an observable f separated by time t, divided by the variance, is called the autocorrelation $\rho_f(t)$. The time of its slowest decay is τ_{exp}, $\tau_{\text{int},f} = \frac{1}{2} + \sum_{t \ge 1} \rho_f(t)$ is the integrated autocorrelation time, and the variance of the sample mean is about $2\tau_{\text{int},f}\,\text{Var}(f)/n$

(Wolff 2004) Known . In continuous time the sum is replaced by an integral, $\tau_{\mathrm{int},f} = \int_0^\infty \rho_f(s)\,ds$. For reversible dynamics in continuous time $\rho_f(s) = \int e^{-s\lambda} d\nu_f(\lambda)$, with ν_f supported on $[\mathrm{gap}, \infty)$, so

$$\tau_{\exp} = \frac{1}{\mathrm{gap}(L)} = C_P, \qquad \tau_{\mathrm{int},f} = \int \frac{d\nu_f(\lambda)}{\lambda} \;\le\; C_P \quad (10)$$

For a reversible chain in discrete time (eigenvalues $1 > \lambda_2 \ge \cdots > -1$) they split into three (Levin–Peres–Wilmer § 12.2) Known .

$$C_P = \frac{1}{1-\lambda_2}, \qquad t_{\mathrm{rel}} = \frac{1}{1-\lambda_\star}, \qquad \tau_{\exp} = \frac{-1}{\log \lambda_\star}, \qquad \lambda_\star = \max_{\lambda \neq 1} |\lambda| \quad (11)$$

Example: for the AR(1) chain $X_{n+1} = \rho X_n + \sqrt{1-\rho^2}\,Z$ (eigenvalues ρ^k) with $\rho = -0.9$, $C_P = 5.263$, $t_{\mathrm{rel}} = 10$ and $\tau_{\exp} = 9.491$, all three different, and τ_{int} is 0.026 for x and 4.763 for x^2. In continuous time (Ornstein–Uhlenbeck) all three line up at 1 Computed . For a lazy chain (one that stays put with probability 1/2 each time, so all eigenvalues are at least 0), $\lambda_\star = \lambda_2$ and $C_P = t_{\mathrm{rel}}$ (LPW § 12.2, Exercise 12.3) Known .

Differences of dynamics, and mixing time

The heat-bath method (redrawing variables one at a time from their conditional distributions), Langevin and HMC (hybrid Monte Carlo, Duane et al. 1987: add fictitious momenta, move by classical mechanics for a fixed time, and correct by acceptance or rejection) have different generators, and regarding the time of HMC as the C_P of Langevin is an assumption (5-07). Thermalisation time and mixing time are also a Conditional pair. The mixing time $t_{\mathrm{mix}}(\varepsilon)$ is the number of steps until, from any initial state, the total variation distance (the largest difference between the probabilities two distributions give to the same event) between the distribution and the equilibrium distribution π is at most ε. The $\log(1/\pi_{\min})$ in the upper bound $t_{\mathrm{mix}}(\varepsilon) \le t_{\mathrm{rel}} \log(1/(\varepsilon\pi_{\min}))$ (LPW Theorem 12.4; $\pi_{\min}$ is the smallest probability of π) grows with the volume. This is a theorem for reversible chains with finitely many states; for gauge fields taking values in a continuous group $\pi_{\min}$ has no meaning, and other tools are needed, such as the log-Sobolev constant (§ 07).

07

Critical slowing down — z, the conventional theory, two η

As ξ grows, the relaxation of the dynamics also becomes slower (critical slowing down). Physics writes this with the dynamic scaling hypothesis $\tau \propto \xi^z$ and calls z the dynamical exponent (Halperin–Hohenberg 1969, Hohenberg–Halperin 1977). z changes with the dynamics and the observable. (8) is the relaxational dynamics

without conserved quantities called model A in the classification of Hohenberg–Halperin. In mathematics it is $C_P \asymp \xi^z$, but the existence of a power is itself a hypothesis, and there is no theorem fixing as a power the ξ-dependence of C_P in Yang–Mills (the entry "dynamical exponent z").

The conventional theory and RG

The static exponents are those of 2-08: $\xi \sim |t|^{-\nu}$, $\chi \sim |t|^{-\gamma}$ (t is the distance in temperature from the critical point), and η_s is the amount by which the critical correlation $G(x) \sim |x|^{-(d-2+\eta_s)}$ deviates from the power of the free field (the anomalous dimension). From the scaling relation $\gamma = \nu(2-\eta_s)$, $\chi \propto \xi^{\gamma/\nu} = \xi^{2-\eta_s}$ Physics . The conventional theory (called by van Hove's name) is summarised as making the relaxation time proportional to χ, giving $z = 2 - \eta_s$ Physics . The abstract of Halperin–Hohenberg–Ma (1972), who applied Wilson's expansion method to a continuum version of the kinetic Ising model, writes that the results 'disagree with the mode-mode coupling approach and the conventional (Van Hove) theory'. RG (the ε expansion) and numerics both suggest $z > 2 - \eta_s$ (Table 2) Physics .

Table 2 The dynamical exponent z and $2-\eta_s$ (η_s is the static anomalous dimension)

Model, method	$2-\eta_s$	z	$\eta_{\mathrm{dyn}} = 2 - z$
2D Ising, Glauber numerics	1.75	2.1665(12)	−0.1665
2D Ising, 5 loops (ε expansion)	1.75	2.14(2)	−0.14
3D Ising, Glauber numerics	1.9637	2.032(3)	−0.032
3D Ising, 5 loops (ε expansion)	1.9637	2.0235(8)	−0.0235
Free field, Langevin	2	2	0

Computed $2-\eta_s$ ($\eta_s = 1/4$ in two dimensions, $\eta_s = 2\Delta_\sigma - 1$ in three, with the scaling dimension of the spin $\Delta_\sigma = 0.5181489(10)$) and η_{dyn} computed on this machine. z and Δ_σ are values from primary sources Physics . Glauber is a dynamics that updates spins one at a time at random.

The variational lower bound

The counterpart on the side of mathematics is the variational lower bound. Putting $f = M = \sum_x \phi_x$ into (9), $|\nabla M|^2 = |\Lambda|$ (the number of points) and $\mathrm{Var}(M) = |\Lambda|\chi\Lambda$, so

$$C_P \;\geq\; \frac{\mathrm{Var}(M)}{\mathcal{E}(M)} = \chi\Lambda \quad (12)$$

which is a theorem holding on every lattice of finite volume Known . For the free field $\chi = 1/m^2 = C_P$, with equality (Table 1). Moving from here to a lower bound on the exponent needs two hypotheses: dynamic scaling $C_P \asymp \xi^z$ and static scaling $\chi \asymp \xi^{\gamma/\nu}$, under which $z \geq \gamma/\nu = 2 - \eta_s$ Physics (a lower bound regarded as standard in the

Monte Carlo literature). An example of a firm lower bound from an inequality of the same type is $z_{\mathrm{SW}} \geq \alpha/\nu$ for the Swendsen–Wang method (α is the specific-heat exponent; the abstract of Li–Sokal 1989) Known . The value of the conventional theory sits exactly at this lower bound, and the z of Table 2 all lie above it.

In gauge theory this form does not reach ξ^2 Physics . Measuring the dimension Δ of an operator by the power when correlations behave at short distances like $|x|^{-2\Delta}$, the lowest dimension of a gauge-invariant local operator is 4. The two-point correlation of a dimension-4 operator decreases as $|x|^{-8}$, so its sum χ in four dimensions is decided at short distances and does not grow with ξ (23-01).

Two η

We split η into two. The static η_s is the anomalous dimension above, the dynamic one is $\eta_{\mathrm{dyn}} := 2 - z$, and they are equal only within the conventional theory (in Table 2 they differ even in sign). This book always attaches the subscript, and which one the record's η is is fixed in 18-05.

No slowing down away from criticality

Conversely, the premise of physics is that if ξ is finite there is no slowing down (the entry "no slowing down away from criticality"). For the mathematical form we use two tools. The log-Sobolev inequality bounds the entropy, instead of the variance, by $\mathcal{E}$:

$$\int f^2 \log \frac{f^2}{\int f^2 \, d\mu} \, d\mu \;\leq\; 2C_{LS}\, \mathcal{E}(f)$$

It is stronger than the Poincaré inequality and gives $C_P \leq C_{LS}$ Known . The Dobrushin–Shlosman mixing condition is that, whatever boundary condition is imposed on a finite box, correlations inside the box decrease exponentially with distance at a uniform rate. The mathematical form of "no slowing down away from criticality" is, for discrete spin systems (finite spin space, finite range), the equivalence theorem "uniform mixing independent of boundary conditions (Dobrushin–Shlosman) $\Longleftrightarrow$ uniform log-Sobolev" (Stroock–Zegarlinski 1992; bibliographic data only) Known . A finite correlation length alone is not enough of a hypothesis. For gauge fields taking values in a continuous group the equivalence is not found within the material of this chapter. For lattice Yang–Mills, Shen–Zhu–Zhu (2023) show Poincaré, log-Sobolev and exponential decay at strong coupling. Neither result fixes the power on the side $\xi \to \infty$.

Detour: for the free field the relaxation time equals the susceptibility

A subsection you may skip.

For the free field $S = \frac{1}{2}\sum_x[(\phi_{x+1} - \phi_x)^2 + m^2\phi_x^2]$, summing (8) over points, the nearest-neighbour coupling terms cancel, and the mean M obeys

$$dM = -m^2 M\, ds + \sqrt{2/N}\, dW(s)$$

(N is the number of points and W a single Brownian motion). M is a single Ornstein–Uhlenbeck process, with relaxation time $1/m^2$, the same value as the susceptibility $\chi = \sum_x \langle \phi_x \phi_0 \rangle = 1/m^2$ (in the calculation on this machine too, χ and C_P agree for every m in Table 1) Computed . The "relaxation time $\propto \chi$" of the conventional theory has the same form as this relation, exact for the free field. With interactions the two are said to drift apart, and the $z > 2 - \eta_s$ of Table 2 corresponds to that drift Physics .

08

Fluctuations of the tube and topological freezing — effective strings, Wulff, bottlenecks

Effective strings and the Lüscher term

A long flux tube spontaneously breaks transverse translation, and Goldstone bosons live in 1+1 dimensions (Lüscher 1981). A Goldstone boson is a massless fluctuation that appears when a continuous symmetry is spontaneously broken; here it is the fluctuation of the transverse position of the tube. These fluctuations add a universal $1/R$ term to $V(R)$ (Lüscher–Symanzik–Weisz 1980, 17-03).

$$V(R) = \sigma R + \mu + \frac{\gamma}{R} + O(R^{-2}), \qquad \gamma = -\frac{\pi(d-2)}{24} \quad (13)$$

A two-dimensional conformal field theory (a two-dimensional field theory with a symmetry that includes scaling of distances) has a number called the central charge c, and one free boson has $c = 1$. The part of the ground-state energy of fluctuations confined to a strip of width R that depends on the width (the Casimir energy) is proportional to c (Blöte–Cardy–Nightingale 1986, Affleck 1986): $-\pi c/(24R)$ for an open strip and $-\pi c/(6L)$ for a periodic strip of circumference L. Setting $c = d - 2$, the former is γ and the latter at $d = 4$ is $-\pi/(3L)$, which agrees with the correction subtracted when extracting the string tension on the lattice (Lucini–Teper 2001) Computed . The lattice σ contains the physical assumption "the central charge of the tube is $d - 2$" (the entry "Lüscher term").

Rigid tubes and roughening

At strong coupling, where the area law has been shown, the tube is said to be rigid. More precisely, each shift of the surface by one lattice step costs a small weight, so transverse fluctuations are exponentially suppressed (17-03). The shape of the tube at strong coupling can be read by analogy with the Wulff construction from a direction-dependent tension. The Wulff construction is a drawing that gives, under a tension $\tau(\mathbf{n})$ depending on direction, the shape that minimises the total tension of the boundary for a fixed enclosed area (17-03). It is said to be separated from the region of fluctuating tubes by the roughening transition. This is a picture of physics found in the title (abstract) of Lüscher 1981, and no theorem showing its existence in lattice gauge theory is found in the material of this chapter Physics (the entry "roughening, shape of the tube").

Topological freezing and bottlenecks

In HMC for pure gauge theory, the effective dynamical exponent of the square of the topological charge is about 5, and Wilson loops decouple from this slow mode (the abstract of Schaefer–Sommer–Virotta 2011) Physics . The mathematical word is a bottleneck: putting into the variational principle a smoothed version f of the indicator function of a set A of configurations (configurations with topological charge close to 1, say),

$$C_P \;\geq\; \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} \;\approx\; \frac{\mu(A)\big(1-\mu(A)\big)}{\mathcal{E}(f)} \qquad (14)$$

and the narrower the passage joining A and its outside, the larger C_P Known (the two-valley model, 1-10). More precisely, the configurations near the boundary of A have small measure, so $\mathcal{E}(f)$ becomes small. (14) is a theorem, but that it is the cause of freezing, and carrying the phenomenon of HMC over to the C_P of Langevin, have not been checked (the entry "topological freezing", 23-02).

Detour: sectors of topological charge and narrow passages

A subsection you may skip.

For continuum fields the topological charge (the second Chern number, 3-05, 18-04) is an integer, and sectors of configurations with different values are not joined by smooth deformations. On the lattice the topological charge is an integer only approximately, and the sectors are joined through rough configurations at the scale of the lattice spacing. These passages are expected to become narrower as $a \to 0$ Physics . Taking the A of (14) to be "configurations with topological charge close to 1", this expectation translates into the lower

bound on CP becoming larger. There is no theorem showing how fast the passages become narrow.

What this chapter can say

What is said	What is not said
Known One direction of (1), (2), the existence of σ, the Theorem from Centre Symmetry to Confinement and the Theorem from Uniform Decay to the Area Law (Chatterjee 2021), (10)(11), $CP = t_{\mathrm{rel}}$ for lazy chains, the variational lower bounds (12)(14), "uniform mixing $\Longleftrightarrow$ uniform log-Sobolev" for discrete spin systems, the results for three-dimensional compact U(1) (abstract).	The converse theorems for every pair. That these quantities exist in the four-dimensional continuum theory. Which way the "Unsettled" pairs will move. The equivalence of mixing and log-Sobolev for gauge fields taking values in a continuous group.
Computed Table 1, the differences in Table 2, Figure 1 and the autocorrelation time of the mean M, the example in § 06, that for the free field the relaxation time agrees with χ, $\pi/(3L)$.	The z of Table 2 are not measurements on this machine.
Physics The numbers for $m/\sqrt{\sigma}$, $\sqrt{\sigma}$, glueballs and z, $z \geq \gamma/\nu$ under the two scaling hypotheses, the rigidity and roughening of the tube, the passages between topological sectors.	Not theorems. The form of extrapolation and $c = d - 2$ are assumptions. The conversion of $\sqrt{\sigma}$ into MeV is borrowed from another theory.
Which pairs the relaxation-time assumption and chain (ii) correspond to (the entries "Λ, one scale" and "z=2"), and that the relaxation-time assumption is a statement with the normalisation of time fixed.	Their proofs. Nothing is shown about the mass gap, confinement or the continuum limit.

Next chapter to read: 18-04 A dictionary of scales and limits. For the correspondence with the assumptions of the record, see 18-05.

A dictionary of scales and limits — words of flow translate into maps, words of limits into questions of existence

This chapter organises established knowledge (sources carry the “Known” label in the text). This book's own investigation is mainly in Part 15 and Volume 3 (Parts 16–28 and the appendices).

What this chapter shows — We pair 23 physical words about scale and limits with mathematical words, and grade them in the two columns of 18-01. We also see that a change of scheme is a one-off shift (Table 1), and the flow of the approximate Migdal–Kadanoff recursion (Figure 1).

Prerequisite chapters — 4-06, 7-05 and 17-08. The two columns are in 18-01, and mass and length in 18-03. The characters and Bessel functions of § 04 are in 7-02, and the minimum is supplied in § 04.

Said first — We only line up correspondences; we construct neither a flow nor a continuum limit. Figure 1 is a calculation of an approximate recursion, not a claim about the four-dimensional lattice theory.

The order of this chapter

1. The overall picture — Table 0
2. The renormalisation group and the β function — sequences of steps and Polchinski's equation
3. Flow on the lattice — Table 1
4. Migdal–Kadanoff and hierarchical lattices — Figure 1 / Detour: why the decrease per step is $(1-b^{-2})/3$
5. The continuum limit and a(β) — two kinds of scaling
6. Universality, Symanzik, marginality — the price of improvement
7. Large N, the master field, holography, the KK tower
8. Topology, instantons, the Wilson flow, the Gribov region
9. What had no word on the side of mathematics — the trace anomaly

01

The overall picture — flow, limits, geometric scales

The words fall into three groups. Words of **flow** (renormalisation group, β function, Λ) translate into properties of the maps of the steps. Example: "the β function is negative" becomes "a step that doubles the lattice spacing lowers β by an almost constant amount on the weak-coupling side" (§ 02, § 03).

Words of **limits** (continuum limit, $a(\beta)$, universality) translate into the question "does the limit exist, and is it unique?". Example: "universality" is the uniqueness claim "changing the details of the action leads to the same limiting measure" (§ 05, § 06).

Words of **geometric scale** (N, an extra direction, flow time, topology) look at the theory by adding another scale. Classically, many of them agree by theorems. Example: an "instanton" is exactly an anti-self-dual connection (§ 07, § 08).

Notation: $\beta = 2N/g^2$ is the coefficient of the lattice coupling (not the inverse temperature of statistical mechanics), b is the factor of one step (multiplying the lattice spacing a by b), and $\kappa = 4Nb_0$ (0.3715 for SU(2), A-01). Writing asymptotic freedom (4-06) in the lattice coupling gives the running per step. For SU(2), doubling a lowers β by about 0.2575, and halving a raises it by the same amount.

$$\beta(ba) = \beta(a) - \kappa \ln b + O(1/\beta) \qquad \text{(one loop; } O(1/\beta) \text{ is two loops and beyond)} \quad (1)$$

Table 0 The list of the dictionary of scales and limits ((a) correspondence as definitions, (b) existence in four dimensions, (c) direction reachable by finite measurement; levels and conditions in the text)

#	Physical word	Mathematical word	(a)	(b)	(c)
1	Renormalisation group	Sequence of steps, UV stability	Conditional	Conditional	—
2	β function	Recursion for the effective coupling	Conditional	Conditional	—
3	Polchinski's equation	Polchinski equation of a decomposition of the measure (heat flow)	Settled	None	—
4	Δβ of MCRG	The map of one step	Conditional	None	—
5	Change of scheme for Λ	Reparametrisation of the coupling	Settled	Constructed (formal power series)	—
6	Migdal–Kadanoff	Exact recursion on hierarchical lattices	Conditional	Constructed (hierarchical lattice)	—

#	Physical word	Mathematical word	(a)	(b)	(c)
7	Continuum limit	Scaling limit	Conditional	None	Out of reach
8	a(β), setting the scale	ε(β) (the continuum string-tension problem)	Unsettled	None	—
9	Scaling	Limit of dimensionless ratios	Unsettled	None	Out of reach
10	Asymptotic scaling	Asymptotic form of ε(β)	Unsettled	None	Out of reach
11	Universality	Uniqueness of the limit	Conditional	None	Out of reach
12	Symanzik's $O(a^2)$	The shortfall per step δ(b)	Unsettled	None	—
13	Improved action	Loss of reflection positivity (contributions with negative weight)	Settled (for actions with dimension-6 operators added)	Constructed (lattice)	—
14	Marginal coupling	Critical Sobolev exponent	Settled	Constructed (classical)	—
15	Large N, planar diagrams	Planar maps, sums over strings	Conditional	Conditional	—
16	Master field	Limit of non-commutative distributions	Conditional	None	—
17	Radial direction of holography	Fefferman–Graham expansion	Unsettled	None	—
18	KK tower	λ_1 of the internal Laplacian	Conditional	Not applicable	Upper bound only
19	Topological charge	Second Chern number	Conditional	Conditional (lattice)	—
20	Instanton	Anti-self-dual connection	Settled	Constructed (classical)	—
21	Wilson flow	Yang–Mills heat flow	Settled	Constructed (classical)	—
22	Gribov region	Region where the FP operator is positive	Settled	Constructed (classical)	—
23	Trace anomaly	No counterpart	Unsettled	None	—

Note: column (b) of Table 0 is the reading from before the published construction (2026-11-10). As in §02 and §09, the rows for the continuum limit (row 7) and the trace anomaly (row 23) are candidates to move with the published construction.

(c) is the measurement column of 18-01 §02 (the direction reachable by finite measurement). The rows about limits and uniqueness (the entries "continuum limit", "scaling", "asymptotic scaling" and "universality") are out of reach, and for the λ_1 of the entry "KK tower" a single test function gives an upper bound (1-10). "None" in (b) means, as in 18-01 §04, "not yet made".

The entries "Δβ of MCRG", "scaling" and "asymptotic scaling" have lattice numbers (at the level of physics), treated in §03 and §05.

02

The renormalisation group and the β function — translated into sequences of maps

The renormalisation group is the operation of integrating out fluctuations at short scales and moving to an effective action at long scales. Wilson (1971) rewrote Kadanoff's theory of scaling in the form of differential equations (abstract: 'The Kadanoff theory of scaling ... is cast in differential form') Known . The existence of the map and convergence to a fixed point are premises in physics. In mathematics this becomes a **sequence of steps** that estimates the compositions of the one-step map R_b uniformly (7-05).

$$\mu_a \xrightarrow{R_b} \mu_{ba} \xrightarrow{R_b} \mu_{b^2 a} \to \cdots, \qquad \text{control the effective action } S_k \text{ uniformly in } k \quad (2)$$

For four-dimensional pure gauge theory, Bałaban (1987, 1989) built a sequence of effective actions and showed UV stability in finite volume. Chatterjee (2018) § 6 calls the existence of convergent subsequences UV stability Known . In Bałaban's method, convergence of the orbits and limits of observables are unproved (7-07). The construction published on 2026-11-10 takes limits of correlations of local observables with a sequence of renormalisation steps of a different design (Parts 9–11). Agreement of the sign of the β function (the entry "β function") with an exact flow is a theorem for the two-dimensional Gross–Neveu model (Gawędzki–Kupiainen 1985). In four dimensions it goes as far as Bałaban's recursion in the small-field approximation.

Polchinski's equation

Polchinski (1984) wrote, for four-dimensional $\lambda\phi^4$, the change of the effective action as the momentum cutoff is moved continuously as an exact renormalisation group equation. On that basis he showed perturbative renormalisability Known . The same equation exists on the side of mathematics. Splitting the covariance of a Gaussian measure into a sum over scales and integrating one layer at a time from the fine scales, the remaining effective action V_t obeys this equation. Rewritten for e^{-V_t}, it is convolution with a Gaussian kernel, that is, the flow of the heat equation Known . The pair is equation to equation, so the (a) of the entry "Polchinski's equation" is Settled.

There are also criteria standing on this equation. The log-Sobolev inequality is an inequality of the form $\mathrm{Ent}_\mu(f^2) \le 2C \int |\nabla f|^2 d\mu$. It is a stronger version of the Poincaré inequality $\mathrm{Var}_\mu(f) \le C \int |\nabla f|^2 d\mu$ (1-10), with the variance replaced by the entropy $\mathrm{Ent}_\mu(g) = \int g \ln g \, d\mu - \int g \, d\mu \, \ln \int g \, d\mu$, and it guarantees how fast a stochastic dynamics

returns to equilibrium. Bauerschmidt–Bodineau (2021) extended the Bakry–Émery criterion (1-10) to multiple scales by controlling Polchinski's equation, and showed an asymptotically optimal log-Sobolev inequality for the massive continuum sine-Gordon model (a two-dimensional model, with coupling $\beta_{\mathrm{sG}} < 6\pi$) Known . The criterion is a tool standing on the pair, so it goes on the side of the conditions. There is no application to four dimensions, so (b) is "None".

03

Flow on the lattice — MCRG and a one-off shift

MCRG (Swendsen 1979) fixes $\Delta\beta$ so that observables blocked with $b = 2$ match a lattice with coupling $\beta - \Delta\beta$. The first results for SU(3) (Gupta et al. 1984) reported no asymptotic scaling for fundamental-representation coupling $K_F < 6.1$ Known . $\Delta\beta$ is the amount by which β is lowered when a is doubled, the same quantity, measured by another method, as "the step that halves a" in Table 4 of 4-06. The mathematical partner is the one-step map $\beta \mapsto \beta - \Delta(b)$ ($\Delta(b)$ is the decrease per step, not the Δ of the mass gap), and with the same projection (the way of matching to the Wilson form) chosen, they are the same quantity (the entry "Δβ of MCRG").

Consider one step within the same way of fixing things (scheme). If at leading order at weak coupling ($\beta \to \infty$) Δ does not depend on β, then two steps in succession and a single multiplication by $b_1 b_2$ are the same, so

$$\Delta(b_1 b_2) = \Delta(b_1) + \Delta(b_2) \quad \Longrightarrow \quad \Delta(b) = C \ln b \ \text{(3)}$$

(Cauchy's functional equation under monotonicity). The constant C is not fixed by additivity alone; comparing with (1) (one loop) gives $C = \kappa$. From two loops on, Δ keeps a β-dependence of order $O(1/\beta)$, and (3) is the leading-order formula that ignores it.

Integrating (1), the one-loop formula is $\beta = -\kappa \ln(a\Lambda)$ (the one-loop part of equation (8) of 4-06). A change of the way of fixing things, $\tilde{\beta} = \beta - c + O(1/\beta)$, only moves the map by conjugation and does not change the leading term of Δ. What changes is the reading of Λ: from $\tilde{\beta} = -\kappa \ln(a\Lambda e^{c/\kappa})$, $\tilde{\Lambda} = \Lambda e^{c/\kappa}$, that is, Λ is multiplied once only by $e^{c/\kappa}$ (the entry "change of scheme for Λ"). Dashen–Gross (1981) found this ratio to be $\Lambda_{\mathrm{MS}}/\Lambda_{\mathrm{L}} = 38.852704\, e^{-3\pi^2/(11N^2)}$ (19.823 for N = 2) (Wilson action) Known .

Computed Table 1 The Dashen–Gross ratio and the corresponding shift of β, $c_N = \kappa_N \ln(\text{ratio})$ ($\kappa_N = 11N^2/12\pi^2$). c_N is the amount by which β is lowered, $\beta_{\mathrm{MS}} = \beta_{\mathrm{L}} - c_N$ (the one-loop relation compared at $\mu = 1/a$). Number of steps $c_N/(\kappa_N \ln 2)$

N	Ratio	c_N	Steps

N	Ratio	c_N	Steps
2	19.823	1.1096	4.309
3	28.809	2.8092	4.848
∞	38.853	–	5.280

For SU(2), $c_2 = 1.1096$ is about 4.3 steps of the running $\kappa \ln 2 = 0.2575$ of one step with $b = 2$. Moving from the Wilson action to MS is the same as lowering β once only by about 4.3 steps, that is, taking once only about 4.3 extra steps that double a. A map whose constant shifts at every step, $\Delta(b) = \kappa(\ln b - \delta(b))$, breaks (3) and moves the reading of Λ step by step. The record of this book's study calls $\delta(b)$ in this form "the shortfall" (23-02, 18-05).

04

Migdal–Kadanoff and hierarchical lattices — reading an approximation as an exact recursion on another lattice

Kadanoff (1976) rederived Migdal's (1975) recursion formula as an approximation to decimation, and proposed the scheme of potential (bond) moving (abstract) Known . Here we write one step as a pair of two operations. **Bond moving** gathers b^{d-2} plaquettes in one place and turns the weight f into $f^{\,b^{d-2}}$. **Decimation** combines $b \times b$ plaquettes of a plane into one. Decimation is exact in two dimensions (7-02).

We set down the notation a line at a time. Let the eigenvalues of an element U of SU(2) be $e^{\pm i\theta}$, and write the weight of one plaquette of the Wilson action as $e^{\beta \cos\theta}$ ($\beta = 4/g^2$). χ_n is the character of the n-dimensional irreducible representation (spin $(n-1)/2$), $\chi_n(U) = \sin n\theta / \sin\theta$, with dimension $d_n = n$. I_n is the modified Bessel function $I_n(x) = \frac{1}{\pi}\int_0^\pi e^{x\cos\theta}\cos n\theta \, d\theta$. Expanding the weight in characters as $f = a_1 \sum_n d_n c_n \chi_n$, we call the coefficients c_n ($c_1 = 1$) the normalised coefficients, and decimation is $c_n \mapsto c_n^{\,b^2}$. 7-02 writes the weight as $e^{\beta \,\mathrm{Re\,tr}\, U}$, so the β of 7-02 is the $\beta/2$ of this chapter.

$$c_n \longmapsto \left[c_n\left(f^{\,b^{d-2}}\right)\right]^{b^2}, \qquad \text{for the SU(2) Wilson action } c_2 = \frac{I_2(\beta)}{I_1(\beta)} \quad (4)$$

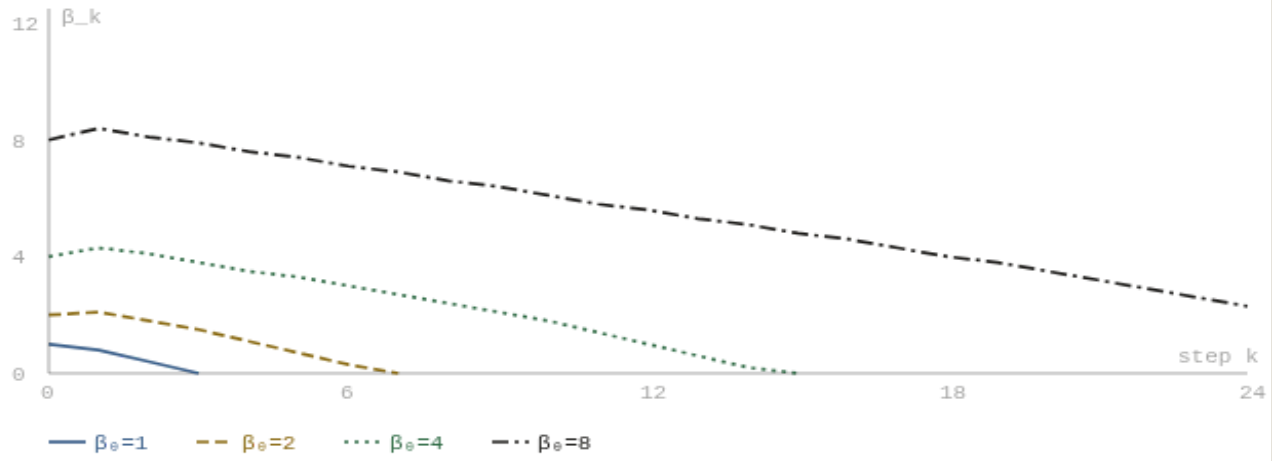
The approximation lies only in bond moving. On the lattice made by repeating the two operations in a nested way (a hierarchical lattice), (4) is exact by construction. For spin systems there are the hierarchical lattices of Griffiths–Kaufman (1982). For gauge theories Ito (1985) showed permanent confinement for groups such as SU(N) in a four-dimensional hierarchical lattice gauge theory on which the MK recursion holds exactly (abstract: 'hierarchical lattice gauge theories in which the Migdal-Kadanoff approximate renormalization recursion formulas hold exactly') Known . The

"approximation" of physics is, in mathematics, "an exact map on another lattice" (the entry "Migdal–Kadanoff"; (b) is at the level of this hierarchical lattice).

Example: at strong coupling $c_2 \approx \beta/4$, so one step with $d = 4$, $b = 2$ is $\beta' \approx 4\beta^4$, and with decimation alone $\beta^4/64$ (at $\beta = 0.1$, 3.895×10^{-4} and 1.560×10^{-6}) Computed . The latter is the strong-coupling formula of one step of bookkeeping in the record (23-02), and the missing factor b^{d-2} is known in the record too.

Where the flow goes, and the decrease per step

Figure 1 The Migdal–Kadanoff flow ($b = 2$). Changing d with the knob and the group with the buttons changes where β_k goes from four starting points. "Play" advances the steps. The colour and dash pattern of each line correspond to the starting point β_0 in the legend at the bottom



d = 4, SU(2): 1 → towards strong coupling, 2 → towards strong coupling, 4 → towards strong coupling, 8 → 24 steps, down to 2.3

Computed The numbers in this figure were computed on this machine (the weight function iterated with 8000 points and 400 characters; β is read from the c_2 of (4), and for U(1) from I_1/I_0). Without JavaScript it can be read from the next two paragraphs.

For $d < 4$ the flow goes towards strong coupling, for $d > 4$ towards weak coupling, and $d = 4$ is the border. For SU(2) at $d = 4$, all the starting points examined ($\beta_0 \le 20$) go towards strong coupling ($\beta_0 = 8$ reaches $\beta < 0.05$ in 31 steps, and 20 in 79 steps) Computed . For U(1), starting points with $\beta_0 \ge 1$ stop at values of about $\beta \approx 1.4$ or more and lie on a line of fixed points (5-06). The first step goes up, since it moves from the Wilson form to the settled form of the recursion; this too is a one-off shift.

The decrease per step after the form has settled at weak coupling (SU(2) at $d = 4$, the 10th step from $\beta_0 = 60$) is 0.2503, 0.2965 and 0.3126 for $b = 2, 3, 4$ Computed . The step given by one loop, $\kappa \ln b$, is 0.2575, 0.4081 and 0.5150. The MK values match the formula $(1 - b^{-2})/3$ of the detour below (0.2500, 0.2963, 0.3125) Computed . For $b = 2$ it is 97% of the one-loop value, but two steps with $b = 2$ (0.5006) and one step with $b = 4$ (0.3126) differ, so (3) is not satisfied. The $a(\beta)$ of MK depends on b.

Detour: why the decrease per step is (1−b⁻²)/3

A subsection you may skip.

There is a weight whose form is preserved by decimation $c_n \mapsto c_n^{b^2}$: the weight with coefficients $c_n = e^{-(n^2-1)/(2\beta)}$, called the SU(2) **heat kernel** (the Q_t of 7-02 § 04 with $t = 4/\beta$). Decimation only moves it as $\beta \mapsto \beta/b^2$. When θ is small, this weight can be written

$$f_\beta(\theta) \propto \frac{\theta}{\sin\theta}\, e^{-\beta\theta^2/2}, \qquad \frac{\theta}{\sin\theta} = 1 + \frac{\theta^2}{6} + \cdots \approx e^{\theta^2/6}$$

Known . It differs from the Wilson weight $e^{\beta\cos\theta} \approx e^{\beta} e^{-\beta\theta^2/2}$ only by the prefactor $\theta/\sin\theta$. Raising to the power b^2 by bond moving ($d = 4$), the prefactor is also multiplied b^2 times. The heat-kernel form needs only one, so the extra $b^2 - 1$ enter the exponent as $e^{(b^2-1)\theta^2/6}$.

$$f_\beta^{b^2} \propto \frac{\theta}{\sin\theta}\, e^{-\left(b^2\beta - \frac{b^2-1}{3}\right)\theta^2/2} : \qquad \beta \mapsto b^2\beta - \frac{b^2-1}{3} \xrightarrow{\text{decimation}} \beta - \frac{1-b^{-2}}{3}$$

The decrease per step is $(1 - b^{-2})/3$, independent of β. Unlike $\kappa \ln b$, it is not additive in b, because the decrease comes not from a logarithm but from the coefficient $1/6$ of θ^2 in $\theta/\sin\theta$. This calculation is only the leading term for small θ, so agreement with the numbers in the text (0.2500 and 0.2503, and so on) is within the range checked by computation Computed .

For how this book uses this, see 15-04 § 02 (the invariant curve and the contraction of the same single-step map).

05

The continuum limit and a(β) — two kinds of scaling

On the continuum limit (the entry "continuum limit"), Chatterjee (2018) § 5 summarises the usage of physics: if the correlation length diverges at a critical point β_c one says 'the model has a continuum limit' Known . The scaling limit is the operation of shrinking the lattice to $\varepsilon\mathbb{Z}^d$, normalising the field and letting it converge weakly as a distribution (2-08); once what is held fixed and the normalisation are specified, it is the same operation. The non-triviality that the physical word includes is not in the definition, and the limits of the four-dimensional Ising type and of ϕ^4 are Gaussian (Aizenman–Duminil-Copin 2021, 7-08).

There are two ways of choosing $a(\beta)$ (the entry "a(β), setting the scale"). The explanation in § 5 fixes the correlation length, and the continuum string-tension problem quantifies existentially with Wilson loops (the same formula as equation (4) of 18-03).

$$\log\langle W_{R/\varepsilon, T/\varepsilon}\rangle = -c\,(R+T) - d\,RT + o(1), \qquad \varepsilon(\beta) \to 0,\ c(\beta) \to \infty,\ d\ /= 0 \quad (5)$$

The d here is the coefficient of the area law (the number corresponding to the continuum string tension), a different symbol from the dimension d in (8). The continuum string-tension problem does not presuppose the lattice correlation-length problem (Problem 5.1), and the existence of either $\varepsilon(\beta)$ is unproved. Physics fixes the scale by the string tension (Creutz 1980) or r_0 (Sommer 1994) Physics .

Scaling (the entry "scaling") is that dimensionless ratios stop depending on a, and **asymptotic scaling** (the entry "asymptotic scaling") is that $a(\beta)$ follows the two-loop formula.

$$\frac{m_{\mathrm{lat}}(\beta)}{\sqrt{\sigma_{\mathrm{lat}}(\beta)}} \to \text{constant} \qquad \text{and} \qquad a\Lambda_{\mathrm{L}} = (b_0 g^2)^{-b_1/(2b_0^2)} e^{-1/(2b_0 g^2)}\bigl(1 + O(g^2)\bigr) \tag{6}$$

In the lattice numbers the two behave separately. The deviation on the right shows up in the report that MCRG for SU(3) sees no asymptotic scaling for $K_F < 6.1$ (Gupta et al. 1984). In Table 4 of 4-06 too, the data for the step that halves a (0.35–0.52) do not reach the two-loop value (about 0.61) Physics . The left is supported by dimensionless ratios lining up at one value in extrapolations that assume a^2 corrections (the $m/\sqrt{\sigma}$ of Lucini–Teper 2001, the $\sqrt{8t_0}/r_0$ of Lüscher 2010) Physics . Fits for SU(N) with $N > 4$ do not pin down $a(\beta)$ in units of $\Lambda_{\overline{\mathrm{MS}}}$ (Allton–Teper–Trivini 2008) Physics . The mathematical partners are, for the left, the limit of the pair of the lattice correlation-length problem and the continuum string-tension problem (the entry "m/√σ" of 18-03), and for the right, the asymptotic form of $\varepsilon(\beta)$; neither has a theorem (5-05, 5-09).

06

Universality, Symanzik, marginality — two errors in different variables

Universality (the entry "universality") is that the same limit comes out independently of the details of the action. Griffiths (1970) and others stated it as a hypothesis, and Wilson (1971) explained it by irrelevant variables. In mathematics it is uniqueness of the limit, and the theorems are in two dimensions: Ising on isoradial graphs (Chelkak–Smirnov), and the Wilson, Villain and Manton actions going to the same measure for the YM measure of the trivial bundle on the two-dimensional torus (Chevyrev–Shen) Known . In four dimensions, that the Wilson action and improved actions give the same theory is a premise.

Symanzik's (1983) improvement (the entry "Symanzik's O(a²)") is the idea of reducing the errors at finite a systematically by adding irrelevant terms. Under a single action, the error of a dimensionless ratio is expanded in a.

$$R(a) = R(0)\bigl(1 + s\,a^2 + \cdots\bigr) \ \ (a \to 0\text{: vanishes}) \qquad \text{versus} \qquad \sum_{j<k} \kappa\,\delta(b_j) \ \ (\text{accumulates ste}$$

For Yang–Mills the logarithmic corrections to a^2 are also said to be weak (Husung–Marquard–Sommer 2020) Known . The record's $\delta(b) = c_2/b^2 + c_3/b^3 + O(b^{-4}\ln b)$ is an expansion in the factor b, a different variable, so the pairing with Symanzik remains an analogy (Unsettled). Example: over 20 steps, the left is $4^{-20}s \approx 9 \times 10^{-13}s$, and the right, with b fixed, is $20\kappa\delta(2)$. In an example where the factor increases by one at each step, $b_j = j + 2$, the leading terms alone give $2.39\kappa\delta(2)$ (the limit with the steps continued without end is $4(\pi^2/6 - 1) \approx 2.58$ times) Computed .

The price of improvement (the entry "improved action")

Lüscher–Weisz (1984) wrote that adding dimension-6 operators to the Wilson action means 'physical positivity is lost in general', and showed that the transfer matrix can still be defined. It has two properties. Complex eigenvalues can appear ('may occur'). The spectral decomposition of two-point functions always has contributions with negative weight ('there are always contributions ... that come with a negative weight') Known . In the language of reflection positivity (5-03), the mathematical word of the entry "improved action" is "loss of reflection positivity (contributions with negative weight)", grounded on the 'always'. (a) is Settled for actions with dimension-6 operators added (the judge is a theorem). The kernel that sets $\delta(2) = 0$ in the record also has negative weights; whether it is of the same type is treated in 18-05.

Marginality (the entry "marginal coupling")

Shrinking as $A_\lambda(x) = \lambda A(\lambda x)$,

$$\int_{\mathbb{R}^d} \operatorname{tr} F_\lambda^2 \, d^d x = \lambda^{4-d} \int_{\mathbb{R}^d} \operatorname{tr} F^2 \, d^d x, \qquad g^2 \sim (\text{length})^{d-4} \tag{8}$$

so at $d = 4$ the action is scale invariant (the border in Figure 1). In mathematics this is the critical Sobolev exponent. The L^p norm $\|F\|_{L^p} = (\int |F|^p \, d^d x)^{1/p}$ gives stronger control the larger p is, and under shrinking $\|F_\lambda\|_{L^p}^p = \lambda^{2p-d}\|F\|_{L^p}^p$. The exponent that does not change under a change of scale, $p = d/2$, is the critical exponent (1-11, 1-12). Uhlenbeck's (1982) weak compactness (the theorem extracting a convergent subsequence from a sequence of connections) needs $p > d/2$ for boundedness of the L^p norm of the curvature. The four-dimensional action has $p = 2 = d/2$, exactly at the threshold Known . The problem statement writes the outlook that asymptotic freedom rescues the case where the Sobolev inequality is at the borderline (0-03). The agreement goes only as far as classical dimension counting (7-09, the four-dimensions article).

Large N, the master field, holography, the KK tower — words that add another scale

The four words of this section look at the theory by adding one scale outside four-dimensional spacetime: the size N of the group, the depth from the boundary into the interior, and the size of rolled-up extra dimensions.

Large N and planar diagrams (the entry "large N, planar diagrams")

't Hooft (1974) showed that with $\lambda = g^2 N$ fixed and $N \to \infty$, planar diagrams dominate (perturbation theory, 17-04). Two things agree as theorems: planar maps of matrix models (Guionnet–Maurel-Segala), and Wilson loops of the strongly coupled SO(N) lattice written as sums over trajectories of strings (Chatterjee, Basu–Ganguly) Known .

The master field

The idea that as $N \to \infty$ fluctuations disappear and gauge invariants are fixed by a single configuration. In mathematics it corresponds to a deterministic limit of non-commutative distributions. A non-commutative distribution regards the totality of expectations of traces of products, $\frac{1}{N}\mathbb{E}\,\mathrm{tr}(X_{i_1}\cdots X_{i_k})$, for a set $X_1, X_2, \ldots$ of random $N \times N$ matrices, as the "distribution" of the matrices (the language of free probability). For planar two-dimensional Yang–Mills, Lévy showed that Wilson loops approach a deterministic limit in this sense (17-04) Known .

The radial direction of holography

Since the infrared of the interior is mirrored in the ultraviolet of the boundary (Susskind–Witten 1998), the radial direction is read as the scale of the boundary (17-08). What is certain in mathematics is only the expansion of the metric near the boundary (Fefferman–Graham). It expands the metric of the interior in powers of the depth z from the boundary, in the form $ds^2 = (dz^2 + g_z)/z^2$, $g_z = g_{(0)} + z^2 g_{(2)} + \cdots$ ($g_{(0)}$ is the metric of the boundary) Known . The side of physics too says the correspondence with the cutoff is 'left unanswered' (Heemskerk–Polchinski 2010) Physics .

The KK tower

Rolling up extra dimensions into an internal space K makes a sequence of masses appear. For a massless scalar on an unwarped product,

$$m_1^2 = \lambda_1(\Delta_K) \qquad \text{(for a circle of radius } R,\ 1/R^2\text{)} \ (9)$$

(17-06) Known . $\lambda_1(\Delta_K)$ is the smallest non-zero eigenvalue of the Laplacian on K. No construction is known that separates the KK tower from Λ while keeping geometric calculation (17-10). Pure Yang–Mills has no extra dimensions, so (b) is Not applicable.

08

Topology, instantons, the Wilson flow, the Gribov region — words that are Settled classically

The four words of this section agree with mathematical words by theorems for classical fields. Where they are carried into quantum fields, they become conditional or at the level of physics.

Instantons

The conventions of this section are the same as A-01: g is put in front of the action and not included in F: $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - i[A_\mu, A_\nu]$ ($A_\mu = A_\mu^a T^a$). The Hermitian generators are normalised as $\operatorname{tr} T^a T^b = \frac{1}{2}\delta^{ab}$, so the action is $S = \frac{1}{2g^2}\int \operatorname{tr} F_{\mu\nu}F_{\mu\nu} = \frac{1}{4g^2}\int F^a_{\mu\nu}F^a_{\mu\nu}$. Setting the dual to $\tilde F_{\mu\nu} = \frac{1}{2}\varepsilon_{\mu\nu\rho\sigma}F_{\rho\sigma}$ (ε totally antisymmetric with $\varepsilon_{1234} = 1$), $\int (F^a \mp \tilde F^a)^2 \geq 0$ bounds the action below by the topological charge.

$$S \geq \frac{8\pi^2}{g^2}|Q|, \qquad Q = \frac{1}{32\pi^2}\int F^a_{\mu\nu}\tilde F^a_{\mu\nu}\, d^4x \in \mathbb{Z} \quad (10)$$

Equality holds only for (anti-)self-dual fields (3-03). (12) of 3-03 is written in the canonical normalisation $D_\mu = \partial_\mu - igA_\mu$, and rewriting with $A = gA_{\text{3-03}}$ (and so $F = gF_{\text{3-03}}$) agrees with (10). With the solution of BPST (1975), the construction of all solutions by ADHM (1978), and Uhlenbeck's (1982) "finite-action fields on $\mathbb{R}^4$ come from S^4", they are Settled as classical objects Known . Approximating the path integral by sums over instantons is a separate, quantum claim.

Topological charge

The topological charge is the second Chern number. The second Chern number is an integer determined by $\frac{1}{8\pi^2}\int \operatorname{tr} F \wedge F$ for a connection on a closed four-dimensional manifold (for example S^4) (in the convention with A anti-Hermitian, A-01), unchanged when the connection is varied continuously (the four-dimensional version of the first Chern number of 1-07). It differs from the Q of (10) only by a sign convention (the detour in 3-05). On the lattice, from fields with each plaquette U_p close enough to the identity (action density below a threshold: admissible) a bundle can be built, and it is an integer (Lüscher 1982, 3-05) Known . Otherwise the sectors are 'a dynamical property of the theory' (Lüscher 2010, SU(3)) Physics .

The Wilson flow

The Wilson flow is the equation $\dot{B}_\mu = D_\nu G_{\nu\mu}$, $B_\mu|_{t=0} = A_\mu$, which smooths the field by adding a flow time t. $G_{\mu\nu}$ is the field strength of B, and D_ν the covariant derivative by B. It is steepest descent of the action, and the equation is exactly the Yang–Mills heat flow. The radius $\sqrt{8t}$ is the value at $d = 4$ of the spread $\langle |x|^2 \rangle = 2dt$ of the heat kernel $e^{t\Delta}$. Its action on quantum fields goes as far as the three-dimensional case under a GFF assumption (Cao–Chatterjee) and two-dimensional YM and three-dimensional YMH (a model including a Higgs field, CCHS) through stochastic quantisation Known . Four dimensions is at the stage of Lüscher's 'suggest' Physics .

The Gribov region

Gribov (1978), faced with the ambiguity of the Landau gauge $\partial_\mu A_\mu = 0$, restricted the integral to fields where the FP determinant is positive (3-04, 4-08). The FP operator $M(A) = -\partial_\mu D_\mu(A)$ is the operator expressing the change in the gauge condition when the field is moved a little by a gauge transformation, and its determinant is the Faddeev–Popov determinant that multiplies the path integral. $D_\mu(A)X = \partial_\mu X - i[A_\mu, X]$ is linear in A, so

$$\Omega = \{A : \ \partial_\mu A_\mu = 0, \ M(A) \geq 0\}, \qquad M\big(tA_1 + (1-t)A_2\big) = tM(A_1) + (1-t)M(A_2) \quad (11)$$

and Ω is convex ($M \geq 0$ in the sense of positive semi-definite as an operator). Zwanziger (1982) showed 'bounded in every direction', and Dell'Antonio–Zwanziger (1991) showed that every orbit enters this region Known . The picture that the measure on it produces confinement is at the level of physics (17-02).

09

What had no word on the side of mathematics — the trace anomaly

In classical four-dimensional Yang–Mills, the scale invariance of (8) makes the trace $T^\mu{}_\mu$ of the energy-momentum tensor vanish (3-03). The trace is a quantity that measures locally the change of the action when the field is shrunk by $x \mapsto \lambda x$, and it is 0 if the action does not change under a change of scale. In the quantum theory, integrating the fluctuations needs a cutoff (a lattice spacing, say), and a length enters there. The coupling $g(\mu)$ runs with respect to that length, so scale invariance breaks. Writing the way it breaks locally is the trace anomaly.

Here we write F in the canonical normalisation ($D_\mu = \partial_\mu - igA_\mu$, the convention of 3-03). It is related to the field of the convention of (10) by $F_{(10)} = gF$, and writing (12) in the convention of (10), the coefficient becomes $\frac{\mu\, dg/d\mu}{2g^3}$.

$$T^{\mu}{}_{\mu} = \frac{\mu\, dg/d\mu}{2g}\, F^{a}_{\mu\nu} F^{a\,\mu\nu}, \qquad \mu\frac{dg}{d\mu} = -b_0 g^3 + O(g^5) \quad (12)$$

This is a formula cited in standard form (the normalisation differs between references; Collins–Duncan–Joglekar 1977) Physics , and the coefficient is the β function itself. Under asymptotic freedom ($\mu\, dg/d\mu < 0$) the trace does not become 0. This is the local mechanism of dimensional transmutation (4-07). Before the publication of 2026 there was no counterpart on the side of mathematics, because there was no four-dimensional continuum theory and no place to put this operator (as with the Λ of 18-03). The committee's assessment is that the construction published on 2026-11-10 defined the stress tensor and its trace as renormalised local operators and showed their properties (13-02 The trace anomaly, and not being free). Agreement with perturbation theory at all orders has not been shown (6-04). The 7 rows of Table 0 whose (a) is Settled are agreements of equations, definitions or classical objects, and in the reading from before publication no row has (b) "exists" in four-dimensional continuum quantum theory (if the rows are regraded, the entry "trace anomaly" is a candidate to move; 18-01 § 09).

What this chapter can say

What is said	What is not said
Known The leading term of (3) (excluding $O(1/\beta)$) and the change of scheme by conjugation, the Dashen–Gross ratio, (8) (10)(11), that MK is exact on hierarchical lattices (Ito 1985), the rows whose (a) is Settled.	The existence of the objects in the rows whose (b) is "None". Where the Conditional and Unsettled pairs will go.
Computed Table 1, Figure 1, the numbers in § 04 and § 06. Physics (12), the numbers for asymptotic scaling and scaling, the radial direction.	MK and the Physics labels are not theorems.
That the record's $\delta(b)$ and Symanzik differ in the variable of expansion.	The summability of δ (18-05). Nothing is shown about the flow, the continuum limit or the mass gap.

Next chapter to read: 18-05 The physical counterparts of our assumptions.

The physical counterparts of our assumptions — are the record's assumptions stronger than the hypotheses of physics?

This chapter is this book's own investigation. The established knowledge it builds on is in 18-03 and 18-04.

What this chapter shows — We set the assumptions that the record of this book's study put in the language of mathematics against the hypotheses of physics, one row at a time, and attach "the same", "a conditional restatement" or "an analogy" in the form of questions. The record's η is fixed to $\eta_{\mathrm{dyn}} = 2 - z$.

Prerequisite chapters — 18-03 (two times, critical slowing down), 18-04 (change of scheme) and 17-12 (a single scale, the diffusive-relaxation-time assumption, the three chains). The two-column grades are in 18-01. The detailed treatment of the relaxation-time assumption is in 23-01, in a later part.

Said first — The correspondences are put as questions and analogies, and none of the assumptions has been proved. No row shows anything about the mass gap or the continuum limit.

The order of this chapter

1. The overall picture — setting the assumptions against the hypotheses of physics, and dividing them into the same, conditional, analogy (Table 0)
2. Fixing the record's η to one — the η in the power form is the dynamic η_dyn = 2 − z
3. The diffusive-relaxation-time assumption and z = 2 — the same power, but uniformity up to constant factors breaks logarithmically depending on the normalisation (Table 1). Detour: why diffusion takes ξ^2
4. The relaxation-time upper-bound assumption and z ≤ 2 — three conditions for the restatement to hold (Figure 1)
5. The relaxation-time lower-bound assumption and the lower bound of critical slowing down — the same inequality, and dimension-4 operators do not reach ξ^2 (Table 2)

6. Summability of the shortfall — step-by-step shifts and changes of scheme, MCRG, kernels with negative weights
7. The equivalence of the physical-unit gap statement — readable as the product of the invariance of mass and z = 2, with cancellation when the premise is dropped (Figure 2, Table 3)
8. A single scale and extra dimensions — dimensional analysis inside the models, which stays an analogy
9. What is known and settled — five rows not counted as results

---

01

The overall picture — setting the assumptions against the hypotheses of physics, one row at a time

The record of this book's study wrote the line towards the continuum limit as a sequence of "bookkeeping of steps" (23-01), and put assumptions in the language of mathematics along the way. The answers given against the old hypotheses of physics are of three kinds: **the same** (reducing to the same inequality or definition), **a conditional restatement** (the same once the power form or the choice of dynamics is added), and **an analogy** (similar in form, but no theorem joins them). They correspond to Settled, Conditional and Unsettled in the definition column of 18-01 (the existence column is "None" in every row). The central relaxation-time assumption splits into an upper and a lower half.

$$(\xi^2)\ (C_P \asymp \xi^2)\ =\ (\xi^2)\uparrow\,(C_P \lesssim \xi^2)\ \wedge\ (\xi^2)\downarrow\,(C_P \gtrsim \xi^2)$$

In the formula, (ξ²) is the diffusive-relaxation-time assumption, (ξ²)↑ the upper-bound assumption and (ξ²)↓ the lower-bound assumption.

Table 0 The record's assumptions and the candidates on the side of physics ("stronger" means that the record's assumption is the stronger; γ and ν are the exponents of the susceptibility and the correlation length, 18-03 § 07)

The record's assumption	Candidate on the side of physics	(a), strength
The relaxation-time assumption: $C_P \asymp \xi^2$	Dynamical exponent $z = 2$ (model A)	Unsettled, stronger
The upper-bound assumption: $C_P \lesssim \xi^2$	$z \le 2$ under the power form	Conditional, the same
The lower-bound assumption: $C_P \gtrsim \xi^2$	Lower bound $z \ge \gamma/\nu$	Conditional, stronger
$\sum_k \delta(b_k) < \infty$	Change of scheme, MCRG, error of the projection	Unsettled

The record's assumption	Candidate on the side of physics	(a), strength
Physical-unit gap statement $\Longleftrightarrow \sum \delta < \infty \wedge \eta_{\mathrm{dyn}} = 0$	Renormalisation-group invariance of mass + $z = 2$	Unsettled
A single scale $\Longleftrightarrow$ extra dimensions are visible	Non-separation of KK	Unsettled

02

Fixing the record's η to one — $\eta_{\mathrm{dyn}} = 2 - z$

The record's η pointed at two quantities (18-03 § 07). The **static** η_s is the power of correlations fixed by the scaling dimension Δ of an operator O (not the Δ of the mass gap) as $\eta_s(O) = 2\Delta - (d-2)$, and the record's Lean theorems that deal with static exponents (theorem names and hypotheses in 23-13) are about this one. What enters the power form of C_P and the correlation length ξ is the **dynamic** exponent.

$$C_P \asymp \xi^{\,2-\eta} \quad \text{and} \quad C_P \asymp \xi^{\,z} \quad \Longrightarrow \quad \eta = 2 - z =: \eta_{\mathrm{dyn}} \ (1)$$

This book fixes the η of the power form and of the equivalence of the physical-unit gap statement (§ 07) to η_{dyn}, and uses η_s only for the test-function lower bound (§ 05). The two are equal only within the conventional theory $z = 2 - \eta_s$.

There is one price. The record had put the premise $\eta \geq 0$ of the equivalence as an assumption, grounded on Källén–Lehmann positivity (18-02). What follows from that positivity is $\eta_s \geq 0$ (the unitarity bound) Physics . For the Glauber dynamics of the two-dimensional Ising model, $\eta_s = 1/4$ yet $\eta_{\mathrm{dyn}} = -0.1665$ (18-03 Table 2). The premise $\eta_{\mathrm{dyn}} \geq 0$ is $z \leq 2$, that is, it includes the power form of the upper-bound assumption (§ 04) among the premises.

03

The relaxation-time assumption and $z = 2$ — the same power, but different uniformity up to constant factors

The relaxation-time assumption is the assumption that the slowest relaxation time C_P of Langevin dynamics lines up with the square of the correlation length up to constant factors independent of the lattice spacing (18-03 § 05, 23-01).

$$c\,\xi^2 \ \leq \ C_P \ \leq \ C\,\xi^2 \qquad (0 < c \leq C \text{ independent of the lattice spacing}) \ (2)$$

(2) is the way of writing at the level of a band, and depends on the normalisation of $\mathcal{E}$ ((3) below). By the record's convention the relaxation-time assumption is put at the

level of powers, $\lim \ln C_P / \ln \xi = 2$, and the band level is split off as a separate assumption naming the normalisation (end of § 03, 23-01).

The closest thing in physics is the dynamic scaling hypothesis $\tau \propto \xi^z$ (Halperin–Hohenberg 1969, Hohenberg–Halperin 1977), with the z of Langevin dynamics (model A in that classification) set to 2 Physics . For the free field in the normalisation of the field A ($s^2 = 1$ below), (2) holds exactly (18-03 Table 1).

Question: is the relaxation-time assumption the same as "$z = 2$"? Answer: the relaxation-time assumption is stronger. The hypothesis says only the power, not uniformity up to constant factors. Moreover, (2) includes the normalisation of the Dirichlet form $\mathcal{E}$. For the Gaussian measure $N(0, s^2(K + m^2)^{-1})$ (K is the lattice Laplace operator $-\Delta$ [here Δ is the Laplacian], s^2 the amplitude, m the mass), taking $\mathcal{E}(f) = \mathbb{E}|\nabla f|^2$ makes C_P the largest eigenvalue of the covariance, s^2/m^2, while the correlation length does not depend on s (1-10) Known . Written in the link angle ϑ ($U = e^{i\vartheta \cdot \sigma}$), $s^2 \propto g^2$; written in the field $A = \sqrt{\beta}\,\vartheta$ ($A = 2\vartheta/g$ in this chapter's convention $\beta = 4/g^2$), $s^2 = 1$. The β of this chapter is the SU(2) lattice inverse coupling $\beta = 4/g^2$ (the $2N/g^2$ of the table of notation), not an inverse temperature.

The free approximation here is a model that substitutes a Gaussian field with the mass $1/\xi_{\mathrm{RG}}$ put in by hand, and does not include the gauge directions (zero modes). The bookkeeping length is the correlation length in lattice units fixed by the one-loop running (the record sets the lattice spacing to $a := 1/\xi_{\mathrm{RG}}$, § 07).

$$C_P^{(\vartheta)} = \frac{g^2}{4} C_P^{(A)}, \qquad C_P^{(A)} = \xi^2 \quad \text{(free approximation)} \ (3)$$

The record's $\mathcal{E}$ is written in link angles. Putting in the one-loop $\ln \xi_{\mathrm{RG}} = 3\pi^2\beta/11 + \text{const.}$ (SU(2), 4-06), $C_P/\xi^2 \propto 4/\beta$ falls to 0 like $1/\ln \xi$, and the effective exponent is $z_{\mathrm{eff}} = 2 - \kappa/\beta$ ($\kappa = 4Nb_0 = 11/(3\pi^2)$).

Computed Table 1 Free approximation, SU(2), link-angle normalisation

β	C_P/ξ^2 (1 at $\beta = 2.5$)	z_{eff}
2.5	1.000	1.8514
4	0.625	1.9071
100	0.025	1.9963

In powers $z = 2$, but in the link-angle normalisation the lower side of (2) breaks logarithmically. To set up the relaxation-time assumption one must first decide either to write $\mathcal{E}$ in the normalisation of the field A ($\mathcal{E}_A = \mathcal{E}/\beta$, that is, multiply the angle $\mathcal{E}$ by $g^2/4$; C_P is conversely multiplied by β), or to put the relaxation-time assumption at the level of powers ($\lim \ln C_P / \ln \xi = 2$) and split the band-level statement off as a

separate assumption naming the normalisation. In interacting theories the scale of stochastic time is also renormalised Known (at the level of perturbation theory; 23-00 Entrance — the staircase, and the random walk, the ruler and the clock, 23-01 The line of construction and the diffusive-relaxation-time assumption; there is also an example checked at one loop in supersymmetric Yang–Mills Physics), so there is no guarantee that the logarithm disappears in either normalisation.

In terms of the measurement column of the dictionary (the direction reachable by finite measurement; 18-01 § 02), the lower-bound assumption is on the "Lower bound only" side: exhibiting one test function gives a lower bound on C_P (§ 05). **The upper-bound assumption is on the "Out of reach" side**. An upper bound on C_P is an inequality about every f, so no number of added test functions, and no amount of autocorrelation measurement up to finite times, reaches it (the box "The asymmetry of upper and lower bounds" in 1-10). The upper-bound assumption and the mass gap are not the same statement, but they are of the same type in that both stand on the side of lower bounds.

Detour: why diffusion takes ξ^2

A subsection you may skip.

Smoothing out a distance ξ by a random walk takes ξ^2 steps. The Langevin dynamics of the free field is independent for each Fourier component.

$$d\hat{\phi}_k = -\left(\hat{k}^2 + m^2\right)\hat{\phi}_k \, ds + \sqrt{2}\, d\hat{W}_k(s) \quad (4)$$

s is the Langevin time, not the amplitude s^2 above. $\hat{k}^2 = \sum_\mu 4\sin^2(k_\mu/2)$ is the lattice version of $|k|^2$. The slowest is the rate m^2 at $k = 0$, which as a time is ξ^2. As a metaphor, the longer the wave, the more slowly it is smoothed out. Precisely, this is an equality for the free field; with interactions there is no guarantee they line up, and putting that they do is the relaxation-time assumption.

04

The relaxation-time upper-bound assumption and $z \leq 2$ — three conditions needed for the restatement

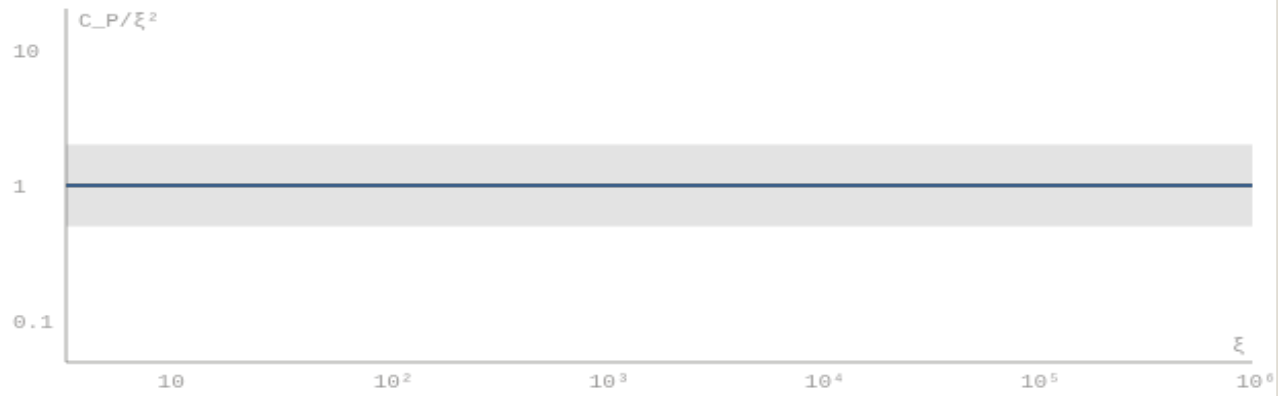
The upper-bound assumption ($C_P \lesssim \xi^2$) is, in the record's reading, the side of "the mass gap is positive" (17-12 § 10). The record restates it as $z \leq 2$. Question: is this a restatement under the dynamic scaling hypothesis? Answer: under three conditions. (i) The power form $C_P \asymp \xi^z$ exists. (ii) The dynamics is reversible Langevin in continuous time ($C_P = \tau_{\text{exp}}$ is an equality only there, 18-03 § 06). (iii) The

normalisation of $\mathcal{E}$ has been decided (§ 03). Writing q for the power of a logarithmic factor, the judgement is as follows.

$$C_P = \xi^{\,z}(\ln \xi)^q \implies \Big((\xi^2)\uparrow \iff z < 2 \text{ or } (z = 2,\ q \le 0)\Big) \quad (5)$$

The hypothesis of Hohenberg–Halperin only assumes the existence of z, and does not claim $z \le 2$. The Glauber dynamics of the Ising model in 18-03 Table 2 has $z > 2$ in both two and three dimensions Physics . Reading the upper-bound assumption as a conjecture of physics needs the condition "$\eta_s = 0$ at the relevant fixed point", and we have not checked any primary source stating it for four-dimensional Yang–Mills.

Figure 1 C_P/ξ^2 when $C_P = \xi^z(\ln\xi)^q$ (the ratio normalised to 1 at $\xi = 10$). Changing z and q with the knobs changes the curve and the judgements of the upper-bound and lower-bound assumptions. The band is constant factors $[1/2, 2]$



z = 2.0000, q = 0.00: C_P/ξ² at ξ = 10⁶ (1 at ξ = 10) = 1.00, pure power form: yes, z ≤ 2: yes, upper-bound assumption holds, lower-bound assumption holds, relaxation-time assumption holds

Computed A schematic drawing of equation (5), drawn on the spot. Without JavaScript it can be read from the next paragraph.

Examples ($\xi \to \infty$): ξ^2 satisfies both; $\xi^2/\ln\xi$ (the angle normalisation) and $\xi^{1.9}$ satisfy the upper-bound assumption only; $\xi^2 \ln\xi$ and $\xi^{2.1665}$ satisfy the lower-bound assumption only. For $\xi^2 \ln\xi$ the power is 2 and yet the upper-bound assumption breaks, so dropping (i) leaves only the one direction "upper-bound assumption $\implies z \le 2$".

05

The relaxation-time lower-bound assumption and the lower bound of critical slowing down — the same inequality, operators that do not reach

The lower-bound assumption ($C_P \gtrsim \xi^2$) is the side that can be shown with test functions: for any f, $C_P \ge \mathrm{Var}(f)/\mathcal{E}(f)$ (1-10). Physics says "local dynamics cannot relax faster than the susceptibility". Taking the magnetisation as f gives $C_P \ge \chi$

(equation (12) of 18-03) Known . Under the two hypotheses of dynamic and static scaling, $z \geq \gamma/\nu = 2 - \eta_S$ (γ is the susceptibility exponent and ν the correlation-length exponent; 18-03) Physics . It is a lower bound regarded as standard in the Monte Carlo literature, and we have not checked its authority.

Question: is the lower-bound assumption the same as this lower bound? Answer: the inequality is the same, but where it reaches differs. Taking f to be a sum of local operators of scaling dimension Δ, the lower bound is fixed by the susceptibility χ_O.

$$\frac{\mathrm{Var}(\sum_x O_x)}{\mathcal{E}(\sum_x O_x)} \asymp \chi_O \sim \begin{cases} \xi^{\,2-\eta_S(O)} & 2\Delta < d \\ \ln \xi & 2\Delta = d \\ \text{bounded} & 2\Delta > d \end{cases} \tag{6}$$

It reaches ξ^2 only when there is an operator with $\eta_S(O) = 0$, that is, of canonical dimension $\Delta = (d-2)/2$. We check this with the four-dimensional free field.

Computed Table 2 Lower bounds on C_P given by test functions for the free field on a four-dimensional lattice

m	ξ	**Dimension 1:** $\sum \phi$ **(**$= C_P$**)**	**Dimension 2:** $\sum \phi^2$	**Dimension 4:** $\sum (\nabla\phi)^2$
1.0	1.04	1	0.0783	0.0537
0.1	10.0	100	0.1719	0.0624
0.01	100.0	10000	0.2657	0.0625

Dimension 2 grows with slope 0.0408 in $\ln \xi$ (continuum estimate $1/(16\pi^2 G(0)) = 0.0409$), and dimension 4 stops at $1/16$ Computed . The infinite-volume integrals were reduced to one dimension and computed, and matched at $m = 0.5$ to 5 significant figures with sums on a 24^4 lattice.

The gauge-invariant local operators of Yang–Mills are of the $\mathrm{tr}\, F^2$ type, of dimension 4, so they fall into the third step of (6) (23-01). The link angle has dimension 1, but under the measure without gauge fixing the correlations between angles of links not sharing an endpoint are exactly 0 after averaging over gauge transformations (the same mechanism as Elitzur's theorem, 18-02). The lower-bound assumption is the demand to push the same inequality up to ξ^2 in a theory with no local order parameter, and is stronger by that much. The record checked that three families of test functions (some by U(1) calculations) do not reach it, but it does not say that the lower-bound assumption is false (23-02).

The lower-bound assumption is, in the record's reading, the side of "the mass in physical units is finite", a condition different from "non-trivial" (there are interactions) in the Clay problem statement. It is satisfied even by a free massive field.

Summability of the shortfall — do step-by-step shifts fit into a single change of scheme?

The record writes one step that coarsens by a factor b as $\beta \mapsto \beta - \kappa(\ln b - \delta(b))$, and calls $\delta(b)$ the shortfall (23-02, 18-04 § 03). δ is a number measured in the one-loop kernel model, and in the record's measurements in four dimensions it has the form $c_2/b^2 + c_3/b^3 + \cdots$ Computed (that there is no $\ln b/b^2$ term is within the detection limit). Advancing k steps with factors $b_1, b_2, \ldots,$

$$\beta_k = \beta_0 - \kappa \ln\Big(\prod_{j=1}^{k} b_j\Big) + \kappa \sum_{j=1}^{k} \delta(b_j) \quad (7)$$

For an exact step within the same scheme the third term is absent (equation (3) of 18-04), and a change of scheme shifts β once only by c (Dashen–Gross, 18-04 Table 1). If the third term converges, the step-by-step shifts add up to a one-off shift $c = \kappa \sum \delta$, indistinguishable from a single change of scheme.

$$\sum_j \delta(b_j) < \infty \iff \text{the step-by-step shifts fit into a single change of scheme} \quad \text{(within the re}$$

Rough guide: for SU(2), $\Lambda_{\overline{\mathrm{MS}}}/\Lambda_{\mathrm{L}} = 19.82$ corresponds to $\ln 19.82 = 2.987$ in $\sum \delta$ Computed . With b fixed, it is bounded only when $\delta(b) = 0$ Lean (`fixed_step_bounded_iff`. Hypothesis: the error of a step is the same at every step).

Question: which thing in physics is (8)? There are three candidates, and all are analogies. (i) It is not Symanzik's $O(a^2)$. The variables of expansion differ, a against b, and the former does not accumulate step by step (18-04 § 06). (ii) The first SU(3) result measuring the $\Delta\beta$ of gauge theory by the method of MCRG (the Monte Carlo renormalisation group, introduced by Swendsen 1979 for spin systems) was 'no asymptotic scaling' for $K_F < 6.1$ (K_F is the coupling of the Wilson action) (Gupta et al. 1984) Known . This $\Delta\beta$ and the record's decrease per step are, with the same projection, quantities that correspond by definition (the identification is this dictionary's reading). (iii) The error of truncating to the Wilson form: for untruncated perfect actions Hasenfratz–Niedermayer (1994) write 'There exist lattice actions which give cut-off independent physical predictions even on coarse grained lattices'. One reading is that δ is close to this error.

Kernels with negative weights and reflection positivity

The blocking kernel that gave $\delta(2) = 0$ in the record's calculation had a negative weight on the neighbours Computed . If the weights are non-negative, $c_2 > 0$ Lean

(`c2_ge_of_nonneg_weights`. Hypothesis: the measurement that c_2 is an increasing affine function of the amount of weight, positive at weight 0). The abstract of Lüscher–Weisz (1984) writes 'When operators of dimension 6 are added to the standard Wilson action in lattice gauge theories, physical positivity is lost in general.' Known . The pattern, a negative coefficient that removes the leading term taking away positivity, is the same. The difference is the object: theirs is the action (5-03), the record's is the blocking kernel. Whether a kernel with negative weights breaks reflection positivity has not been checked.

07

The equivalence of the physical-unit gap statement — is it the product of "mass is invariant under the renormalisation group" and "$z = 2$"?

The record treats the physical-unit gap statement (the mass gap in physical units) in the form "$a^2 C_P$ lies in a positive band independent of the lattice spacing $a = 1/\xi_{\mathrm{RG}}$", and puts two powers.

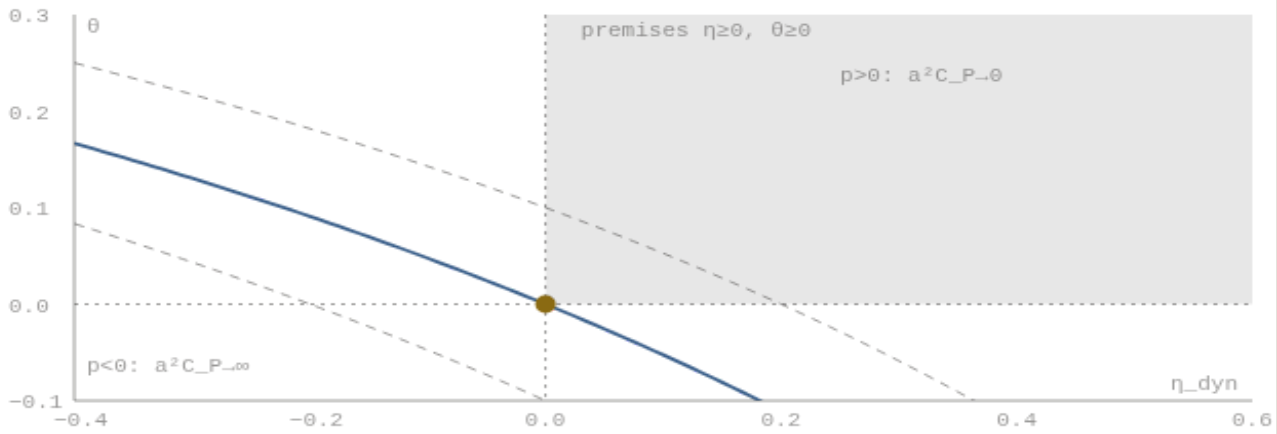
$$C_P \asymp \xi^{\,2-\eta_{\mathrm{dyn}}}, \quad \xi_{\mathrm{phys}} = a\,\xi \propto a^{\theta} \implies a^2 C_P \propto a^{p}, \quad p = \eta_{\mathrm{dyn}} + (2-\eta_{\mathrm{dyn}})\,\theta \ (9)$$

θ is the exponent of accumulation of the shortfall; in the model with b fixed, $\theta = \delta(b)/\ln b$, and if $\sum \delta < \infty$, then $\theta = 0$. If $\eta_{\mathrm{dyn}} \geq 0$ and $\theta \geq 0$, then $p = 0$ is equivalent to both being 0, and this is the content of the record's "physical-unit gap statement $\iff \sum \delta < \infty \wedge \eta = 0$" (the record's η is η_{dyn}, § 02) Lean (`drain_exponent`, `drainExp_eq_zero_iff`. Hypotheses: the power form of (9) and the sign conditions). That the error of the steps is additive and bounded, and that δ is the value in the one-loop kernel model, are also premises.

Question: is this the product of two statements of physics? Answer: within the algebra of the model, it can be read so. $\theta = 0$ is the statement "physical mass is invariant under the renormalisation group, and $m_{\mathrm{lat}}(\beta) \propto a(\beta)\Lambda$". Physics treats $\theta = 0$ as following, if a continuum theory is presupposed, from the Callan–Symanzik equation (4-04) for quantities with no anomalous dimension (dimensional transmutation is in 4-07) Physics . Physics has not made this into a named hypothesis. In mathematics, the lattice correlation-length problem of Chatterjee (2018) (Chatterjee's Problem 5.1; $\xi(\beta) \in (0, \infty)$, and $\xi \to \infty$ as $\beta \to \infty$) asks for the same direction Known . $\eta_{\mathrm{dyn}} = 0$ is $z = 2$, the expectation of § 03 and § 04.

Dropping $\eta_{\mathrm{dyn}} \geq 0$, $\theta^* = -\eta_{\mathrm{dyn}}/(2-\eta_{\mathrm{dyn}})$ gives $p = 0$, and $a^2 C_P$ lies in a constant band, yet neither the relaxation-time assumption nor $\theta = 0$ holds (the same type as Figure 2 of 17-12).

Figure 2 The $(\eta_{\mathrm{dyn}}, \theta)$ plane. Moving the point with the knobs changes where $a^2 C_P$ goes and the judgements. "Play" moves the point left along the solid line $p = 0$, and cancellation happens outside the light shading



η_dyn = 0.000 (z = 2.0000), θ = 0.000: p = 0.000, a²C_P → a constant band, relaxation-time assumption holds, θ = 0 holds

Computed A schematic drawing of equation (9), drawn on the spot. The light shading is the region of the premises, and the dashed lines are $p = \pm 0.2$. Without JavaScript it can be read from Table 3.

Computed Table 3 Examples of cancellation (z from 18-03 Table 2)

Example	z	η_{dyn}	Cancelling θ^*
2D Ising, Glauber	2.1665	−0.1665	0.0769
Free field, Langevin	2	0	0

Repeating the step that halves a 20 times, $a^2 C_P$ grows by about 10 times at $p = -0.1665$, and stays at 1 times at the point of cancellation Computed . The numerical tables alone cannot tell a breaking of the relaxation-time assumption from the exponent of accumulation of the shortfall.

08

A single scale and extra dimensions — an analogy with the non-separation of KK?

This section is easier to follow after reading 17-09 and 17-10 (the cigar, M_{KK}, supergravity). The record has the sentence "a single scale ⟺ extra dimensions are visible (radius $R \sim 1/\Lambda$)". Question: is it the same thing as the non-separation of KK? In the holographic model (Witten's 1998 cigar, 17-09) the background has a single length $R = 1/M_{\mathrm{KK}}$, and multiplying the metric by s^2 multiplies all eigenvalues of the fluctuations by s^{-2}. So $m_n = c_n M_{\mathrm{KK}}$. Since there is only one length scale R, every quantity with the dimension of length squared (both ξ^2 and C_P measured in Langevin time) is proportional to R^2, and the relaxation-time assumption becomes an identity by dimensional analysis inside the model Physics . Precisely, this is counting dimensions after defining C_P in the model. For the same reason the KK modes do not

separate from the glueballs. Sakai–Sugimoto (2005), a model of QCD with quarks, also writes about mesons: 'our D4/D8 model deviates from QCD at the energy scale of M_KK, which is, unfortunately, the same energy scale of the mass of the vector mesons'.

$\Lambda \approx M_{\mathrm{KK}}\, e^{-24\pi^2/(11\lambda)}$ (λ is the 't Hooft coupling at M_{KK} ; the coefficient depends o

At $\lambda = 30,\ 16.6,\ 10,\ 5$, $\Lambda/M_{\mathrm{KK}} = 0.49,\ 0.27,\ 0.12,\ 0.013$ Computed (16.6 is the Sakai–Sugimoto fit converted to $N_c = 3$, the λ in that convention. Putting it into the one-loop formula (10) is a rough guide, and can be off by a factor of 2 by convention). Supergravity can be used on the side of large λ, and Witten writes of the small side 'This looks like a tall order' (17-10).

Answer: an analogy. "One length $\Longrightarrow$ one scale" is obvious inside the model, but there is neither the converse nor a passage to $R \to 0$. The physical name for one scale in pure Yang–Mills is dimensional transmutation (4-07), and the $\Longleftrightarrow$ is the formulation of the record of this book's study.

09

What is known and settled — rows not counted as results

The following rows are treated as known, and are not listed as results in the later parts (this book's study). (1) The correction of direction, that a uniform gap in lattice units is on the trivial side $m_{\mathrm{phys}} \to \infty$, is just the definition that takes the continuum limit where the correlation length diverges, and the direction of the lattice correlation-length problem (Settled, 5-09). (2) $\kappa = 11/(3\pi^2)$ is $4Nb_0$ (Gross–Wilczek, Politzer 1973), and the 5-digit agreement with measurement is agreement within the one-loop model (Settled, 4-06). (3) In the record's one step of bookkeeping, the strong-coupling $\beta' = \beta^4/64$ corresponds only to the decimation step of Migdal–Kadanoff (one MK step including the bond-moving factor b^{d-2} is $\beta' \approx 4\beta^4$, 18-04 § 04), and the weak-coupling $\beta' = \beta\, b^{d-4}$ is dimension counting (Conditional). (4) Reflection positivity and the transfer operator in the reflection-positivity preservation statement (one of the eight statements of construction in 23-01), and the strong-coupling area law, are Osterwalder–Seiler 1978, Lüscher 1977 and Wilson 1974 (Settled, 5-03). (5) The infinite-volume uniqueness statement is the lattice version of uniqueness of the vacuum, and $R \le \tau_{\mathrm{int}} \le C_P$ is error analysis within the same reversible dynamics (Conditional, 18-02, 18-03).

What could not be asserted to be the same are the uniformity of the relaxation-time assumption up to constant factors (§ 03) and that step-by-step accumulation fits into a single change of scheme (§ 06); both go only as far as analogy.

What this chapter can say

What is said	What is not said
Known The type of the variational lower bound (6), the algebra of (3)(7)(9), that the rows of § 09 are known.	A theorem that the record's assumptions are the same as hypotheses of physics. None of the assumptions has been proved.
Computed Tables 1–3, Figures 1 and 2, the numbers in § 06 and § 08 (for the free field and within the model).	Whether four-dimensional Yang–Mills has $z = 2$, or a logarithmic factor. Whether kernels with negative weights break reflection positivity.
Physics The numbers for z (18-03 Table 2), the estimate (10), the testimony on the non-separation of KK.	This chapter shows nothing about the mass gap, the continuum limit or one scale.

Next chapter to read: 19-00 Entrance — how to read objects, firm theorems and premises (within Volume 3, from here we enter the objects and the firm theorems). For reading where things stand from a timeline and tables by dimension, see 16-01 How far the world has come. The conventions for η_s and η_{dyn} are in A-01 Table of notation.

Entrance — how to read objects, firm theorems and premises

> This chapter is a guide.

What this chapter shows — What Parts 19 to 22 and Part 28 contain and what they do not. In which part the definitions of the objects, the statements to be shown, the machine-checked theorems and the list of premises are each found. Three ways of choosing a reading order.

Prerequisite chapters — 0-03 (reading the problem statement word by word) and 16-09 (the stages a proof must contain). The language of the lattice is in Part 5.

Said first — These five parts do not show the mass gap. For the existence of four-dimensional Yang–Mills theory (that a theory satisfying the Wightman axioms can be made as a limit of Wilson's lattice gauge theory), the committee's assessment is that the construction published on 2026-11-10 proves it in Lean. That is read in Parts 6 to 13 of Volume 2. Every theorem of Parts 20 to 22 is a statement about a single scale with the lattice spacing fixed: results of known types, machine-checked from the definitions. Most are statements inside the strong-coupling window, at the opposite end from the questions the published construction left open. Holding uniformly across scales is on the side of the premises in Part 28. A form whose rate does not depend on the transverse size exists only for the upper bound on the vortex free energy inside the strong-coupling window (20-06), and even there the prefactor (the transverse area) remains.

The order of this chapter

1. Dividing into three — objects, theorems, premises
2. A map of the parts (Table 1)
3. Reading orders — three ways
4. How to read the labels
5. The relation to Parts 23 to 27 and Part 15 (Table 2)
6. What these five parts do not say

01

Dividing into three

Parts 23 to 27 and Part 15 are written in the order in which the study proceeded. There, statements that have been machine-checked, statements placed as assumptions, and estimates only seen in numbers sit side by side in a single chapter. Parts 19 to 22 and Part 28 take the same material and lay it out again, divided into three.

Division	Contents	Where
Objects	Things defined on the lattice: the measure, twists, the vortex ratio, reflections, the block map, the pushed-forward measure. Definitions only, with no claims	Part 19
Theorems	Equalities and inequalities about the defined objects. The assumptions are only explicit ranges (the range of the coupling, the parity of sizes and so on), and they are machine-checked in Lean 4	Parts 20 to 22
Premises	Statements on the side of "it would suffice if this could be said". Those whose form is settled and those whose form is not yet settled are listed with labels	The last chapter of Part 19, and Part 28

The line between theorems and premises is whether the objects are defined from the lattice. The chapters of theorems carry only what has its objects' definitions written in the chapter, has assumptions that are explicit ranges only, and has been machine-checked and cross-checked by another pair of eyes.

The side of premises divides in two. The statements to be shown on the ultraviolet side (matching, convergence of the full sequence, non-degeneracy, equicontinuity) and the tree of premises supporting them are statements about this book's design (the measure pushed forward by a fixed block map), and are kept as a record of the statements to be shown and sufficient conditions in this book's design. Existence itself was shown by the published construction in a different design (the comparison of the two designs is in Part 14, and the record of this book's ultraviolet attempt in Part 15). The statements to be shown on the infrared side (the band statement and the mass gap) remain open, and they are the main subject of Volume 3.

02

A map of the parts

Table 1 Parts 19 to 22 and Part 28

Part	Title	Contents

Part	Title	Contents
Part 19	Objects, and the statements to be shown	19-01 The lattice and the Wilson measure, 19-02 Twists, the vortex ratio and Polyakov loops, 19-03 Reflections and the vessel of reconstruction, 19-04 The block map and the pushed-forward measure, 19-05 The fermion weight (detour), 19-06 Objects and their Lean definitions — a table of correspondence, 19-07 The statements to be shown
Part 20	Firm theorems — the vessel and strong coupling	Reflection positivity, decay of correlations at strong coupling, the infinite-volume limit, reconstruction and the mass gap (inside the strong-coupling window), the vessel with fermions (detour), 20-06 The area law at strong coupling, and an upper bound on the vortex free energy
Part 21	Firm theorems — the vortex floor and Polyakov loops	Three results on sign systems, the thin-vortex floor, the thick-vortex floor, the minimal action of a vortex, the sign of the vortex ratio, pairs of Polyakov loops, 21-07 The vortex ratio — continuity, limit, matching
Part 22	Firm theorems — the rarity of large plaquettes	22-00 Entrance, 22-01 Rarity of large plaquettes by the Chessboard Estimate, 22-02 What this part says, and what it does not
Part 28	The tree of premises	Three chapters of implications, The list of premises, What depends on design choices, Open places

One step and many steps of the free field, and the linearisation of the block map (one-scale theorems on the ultraviolet side), are in Part 15 (15-12, 15-13) as the record of this book's ultraviolet attempt.

03

Reading orders

- **Knowing first what is to be shown**: skim the definitions of 19-01 to 19-04, then go to 19-07 The statements to be shown. From there, go on to the tree of Part 28.
- **Reading from the firm places**: Part 20 → Part 21 → Part 22. Each chapter runs in the order: objects (with references to Part 19), theorems, the route of the proof, what is not said.
- **Following the course of the study**: Parts 23 to 27 and Part 15. The correspondence between chapters on the same topic is in Table 2.

04

How to read the labels

The labels of these five parts are the same five as in Parts 23 to 27 and Part 15: Proved here Cited Computer-assisted Reading Assumption . Their meanings are the same as in the table of symbols in 15-00. Where the published construction is cited, the labels of Volume 2 (Source, Inferred, Assessment; "Labels" in 6-00) are also used. For statements

machine-checked in Lean, the name of the declaration and its range are written on the same line, outside the labels.

Most rows of the theorems in Parts 20 to 22 carry Cited . It means that a result of a known type has been machine-checked on top of this book's definitions. What machine checking guarantees is that "the written conclusion follows from the written definitions and assumptions"; that the definitions represent the intended objects rests on a cross-check by another pair of eyes.

The premises carry another set of labels (theorem, paper, form settled but unproved, form not yet settled, depends on design, literature). The legend is in 28-00.

05

The relation to Parts 23 to 27 and Part 15

Parts 23 to 27 and Part 15 are kept as the record of the study. In them one can read the roads that stopped, and why. For the same topics, the present arrangement is found as follows.

Table 2 Correspondence of topics

Topic	Record of the study	Present arrangement
Twisted boundary conditions and vortices	Part 25	Definitions in 19-02, theorems in Part 21 and 20-06
Reflection positivity and the chessboard	26-04, 26-05	20-01, Part 22
The crossover band	Part 26	Statements in 19-07, premises in 28-04
The conditional statement and the ledger	Part 27	Part 28
Ultraviolet control	Part 15	Existence in Volume 2 (reading the published construction), the comparison of the two designs in Part 14. One step of the free field in this book's design in 15-12, premises in this book's design in 28-04

06

What these five parts do not say

- They show nothing about the mass gap. The existence of four-dimensional Yang–Mills theory is not a theorem of this book but a result of the published construction (Volume 2).

- The theorems are about a fixed lattice spacing. There is no theorem about the limit in which the lattice spacing is sent to 0.
- The strong-coupling theorems are only about the window where the coupling is small. They say nothing outside the window.
- Inside the strong-coupling window there is a form in which the rate of the upper bound on the vortex free energy does not depend on the transverse size (the prefactor, the transverse area, remains; 20-06). Outside the window, the vortex-floor theorems are all about a fixed transverse size, and there is no estimate uniform in the transverse size.
- The list of premises is a dated, present arrangement. Some premises do not yet have a settled form, and the list will change.

What this chapter can say

Can say	Cannot say
This chapter is a guide and contains no statements. It shows where the contents of Parts 19 to 22 and Part 28 are found	The scope of the statements of each part is in that part's chapter on "what it says and what it does not" (Part 20, Part 21, Part 22) and in 28-06. The scope of one step of the free field is in 15-14

The list of machine-checked theorems	Guide	A-04

Words used in this chapter — object, push-forward measure, the tree of premises. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-01 The lattice, link variables and the Wilson measure — the first of the definitions.

The lattice, link variables and the Wilson measure

> This chapter is this book's own investigation. § 01 to § 06 arrange established knowledge, and § 07 is this book's investigation (the conventions on the Lean side and the bridges).

What this chapter shows — The definitions of the most basic objects that the theorems of Parts 20 to 22 talk about: the periodic lattice $(\mathbb{Z}/N)^4$, the link variables $U_\ell \in SU(2)$, the product of Haar measures, the plaquette holonomy U_p and its real part, the Wilson measure and the partition function. We also show here, once, that the partition function is positive and finite. Finally, we gather in one table the fact that on the Lean side the same objects are written in four conventions (strong coupling, vortices, fermions, ultraviolet), and the bridges between them.

Prerequisite chapters — 5-01 Wilson's lattice (introduction). For the language of probability measures, 1-08.

Said first — This is a chapter of definitions, and it states no theorems. The lattice spacing is fixed to 1 and the volume is finite. The continuum limit and the infinite-volume limit are outside this chapter (the space of infinite-volume configurations is in 19-03).

The order of this chapter

1. The lattice and links — the periodic lattice $(\mathbb{Z}/N)^4$ and oriented edges
2. SU(2) as unit quaternions — quaternions of length 1 in place of matrices
3. The Haar measure and its product — the uniform probability on the group
4. Plaquettes and holonomy — the product of four links, and its real part
5. The Wilson measure — the weight $e^{\beta \sum_p \operatorname{Re} U_p}$ and expectations
6. The partition function — positive and finite
7. Four conventions on the Lean side, and bridges — four ways of writing the same objects

---

01

The lattice and links — the periodic lattice $(\mathbb{Z}/N)^4$ and oriented edges

The introduction is in 5-01 § 02. Here we fix the form used by the later parts.

Take a positive integer N, and let the four-dimensional periodic lattice (torus) be

$$\Lambda_N = (\mathbb{Z}/N)^4 \quad (1)$$

The lattice spacing is fixed to 1. We write e_μ for the unit shift in direction μ. A **link** is a pair $\ell = (x, \mu)$, representing the edge from the point x to the point $x + e_\mu$. The point x is called the **base** of the link, and for a link in the time direction the base time is taken as the time of that link (a different word from the "root" [the statements to be shown] of the tree of premises in Part 28). There are $4N^4$ links in all.

The numbering of directions differs between parts; there are two.

- **20-01 to 20-05 of Part 20** (the torus $(\mathbb{Z}/N)^4$ of the same size in all four directions): directions are numbered $\mu \in \{0, 1, 2, 3\}$, with 0 as time. Coordinates are $x = (x_0, x_1, x_2, x_3)$ (the same as the indices of `TorusRP.Lk` in Lean). The formulas of 19-03 are also written in this numbering.
- **Parts 21 and 22, and 20-06** (the lattice of Part 21 is $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, 19-02): directions are numbered $\mu \in \{1, 2, 3, 4\}$, with $1, 2$ transverse and $3, 4$ longitudinal. Coordinates are $x = (x_1, x_2; x_3, x_4)$ (the indices 0 to 3 of `TwistedWilson.Link` in Lean are directions 1 to 4). 20-06 and Part 22 also number the directions 1 to 4 on the torus of the same size in all four directions (the Lean indices 0 to 3 are directions 1 to 4).

The formulas of this chapter are written with pairs of directions $\mu < \nu$, so that they apply to either numbering.

An edge in the reverse direction is not counted as a separate link. When a link is traversed in reverse, the inverse of its link variable is used (§ 02). Because the lattice is periodic, moving by e_i from a point with $x_i = N - 1$ brings us back to $x_i = 0$.

Part 21 uses the torus $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, whose size differs between directions 1, 2 and directions 3, 4. Its definition is placed in 19-02. Links and plaquettes are built in the same way as in this chapter.

Item	Symbol	Number
Lattice points	$x \in (\mathbb{Z}/N)^4$	N^4
Links (oriented edges)	$\ell = (x, \mu)$	$4N^4$
Plaquettes (pairs of directions $\mu < \nu$)	$p = (x; \mu, \nu)$	$6N^4$

For $N = 1$ the same link appears twice in one plaquette. For $N = 2$ there are two links joining the same two points. Both are counted with their separate indices (the Lean definitions do the same).

Link variables and configurations

On each link ℓ we place one element U_ℓ of the group $SU(2)$. This is called the **link variable**, and an assignment to all links

$$U = (U_\ell)_\ell \ \in \ SU(2)^{\{\text{links}\}} \quad (2)$$

is called a **configuration**. The space of configurations is the product of $4N^4$ copies of the compact group $SU(2)$, and is itself compact. When moving from x to $x + e_\mu$ we multiply by $U_{x,\mu}$, and when moving in reverse by $U_{x,\mu}^{-1}$.

> 02

SU(2) as unit quaternions — quaternions of length 1 in place of matrices

This book's Lean definitions write $SU(2)$ not as 2×2 matrices but as **unit quaternions**. For a quaternion $q = a + b\,\mathrm{i} + c\,\mathrm{j} + d\,\mathrm{k}$ ($a,b,c,d \in \mathbb{R}$, $\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = \mathrm{ijk} = -1$) let the norm be $\|q\| = \sqrt{a^2+b^2+c^2+d^2}$, and identify

$$SU(2) \;\cong\; S^3 = \{q \in \mathbb{H} : \|q\| = 1\} \quad (3)$$

The correspondence is given by the following matrix Cited .

$$q = a + b\,\mathrm{i} + c\,\mathrm{j} + d\,\mathrm{k} \;\longmapsto\; \begin{pmatrix} a+bi & c+di \\ -c+di & a-bi \end{pmatrix} \quad (4)$$

The determinant of this matrix is $\|q\|^2$ and its trace is $2a$. Hence the following three hold Proved here .

- The product of quaternions corresponds to the product of matrices. The product of unit quaternions is a unit quaternion ($\|pq\| = \|p\|\|q\|$).
- The inverse is the conjugate: $q^{-1} = \bar{q} = a - b\,\mathrm{i} - c\,\mathrm{j} - d\,\mathrm{k}$ (for matrices, the Hermitian conjugate).
- The real part of a quaternion is half the trace: $\mathrm{Re}\,q = a = \frac{1}{2}\,\mathrm{tr}\,q$. For unit quaternions, $|\mathrm{Re}\,q| \le 1$.

The centre is $\{+1, -1\}$. The twist of Part 21 (19-02) is the operation of putting a sign from this centre into the plaquette weight.

When this book writes $\mathrm{Re}\,U$, it means the real part of the quaternion $= \frac{1}{2}\,\mathrm{tr}\,U$. It is the same quantity as $\frac{1}{N}\,\mathrm{Re}\,\mathrm{tr}\,U$ for $SU(N)$ in 5-01 with the N of the group set to 2 (the N of 5-01 is the size of the group, a different quantity from the lattice size N of this chapter).

03

The Haar measure and its product — the uniform probability on the group

The introduction is in 5-01 § 06. On a compact group G there is exactly one probability measure invariant under multiplication from the left. It is called the normalised **Haar measure** and written dU Cited . On a compact group this measure is also invariant under multiplication from the right and under the map taking inverses Cited .

For $SU(2) \cong S^3$, the Haar measure is the uniform surface measure on $S^3 \subset \mathbb{R}^4$, normalised to total mass 1 Proved here . Reason: left multiplication by a unit quaternion is an orthogonal transformation of $\mathbb{R}^4$, so it preserves the uniform surface measure. Since there is only one left-invariant probability measure, the two coincide.

The reference measure on the space of configurations is the product of the Haar measures of the links.

$$dU = \prod_{\ell} dU_\ell \qquad (\text{there are } 4N^4 \text{ links}) \quad (5)$$

This is also a probability measure, and corresponds to choosing each link variable independently and uniformly. Taking inverses on individual links, and maps that rearrange the values of links onto other links, also preserve this product measure. The reflection (19-03) uses this property.

In Lean, the normalised Haar measure is defined as `Measure.haarMeasure ⊤` (the Haar measure taking the value 1 on the whole set). The names are `OSGap.haarProb` and `TwistedWilson.haarProb` (the same definition); that it is a probability measure is `OSGap.haarProb_isProbabilityMeasure`, and left invariance is `OSGap.haarProb_isMulLeftInvariant`.

04

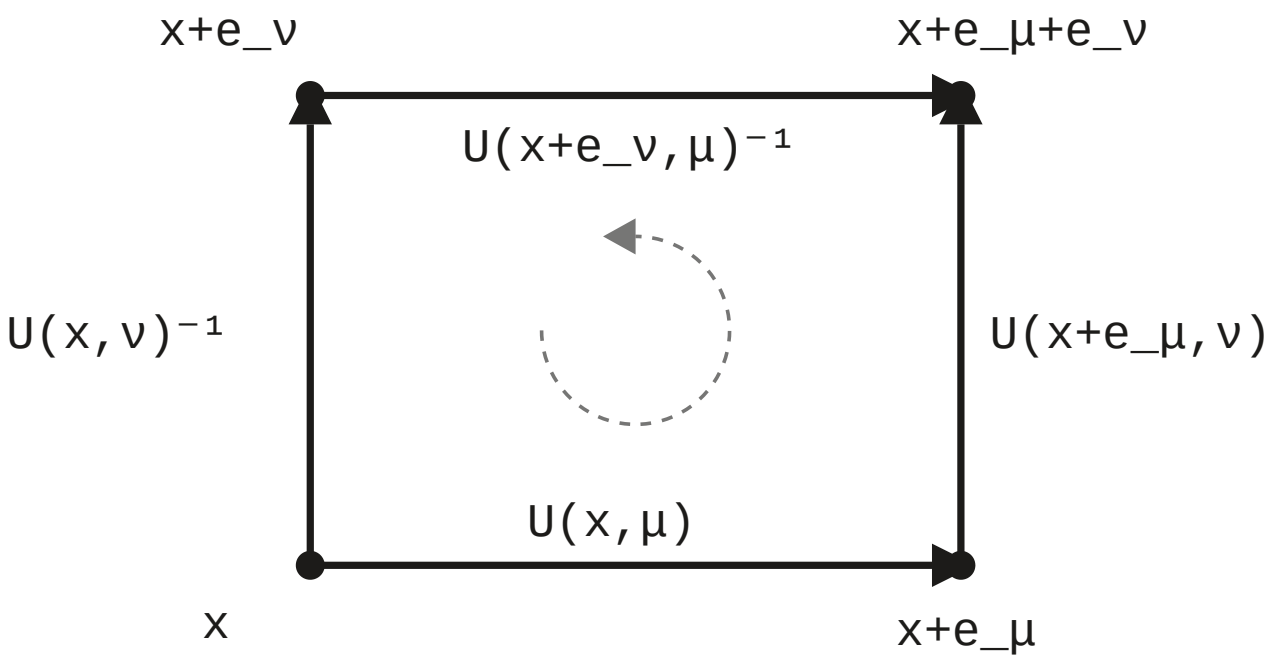
Plaquettes and holonomy — the product of four links, and its real part

The introduction is in 5-01 § 03. A **plaquette** is a pair $p = (x; \mu, \nu)$ $(\mu < \nu)$, the unit square with corners x, $x + e_\mu$, $x + e_\mu + e_\nu$, $x + e_\nu$. There are six pairs of directions ((1,2), (1,3), (1,4), (2,3), (2,4), (3,4) in the numbering of Part 21; (0,1), (0,2), (0,3), (1,2), (1,3), (2,3) in the numbering of Part 20), so there are $6N^4$ plaquettes. The orientation of a plaquette is fixed as the one turning from μ to ν, and plaquettes of the reverse orientation are not counted.

The **holonomy** of a plaquette is the product of the four link variables going once around its boundary.

$$U_p = U_{x,\mu}\, U_{x+e_\mu,\nu}\, U^{-1}_{x+e_\nu,\mu}\, U^{-1}_{x,\nu} \quad (6)$$

Figure 1 The holonomy of the plaquette $p = (x; \mu, \nu)$. Arrows show the orientation of the links. Links opposite to the direction of travel are multiplied as inverses



Proved here The dotted line in the figure is the direction of travel ($x \to x + e_\mu \to x + e_\mu + e_\nu \to x + e_\nu \to x$). The top and left edges are traversed against the orientation of their links, so inverses enter.

U_p is a unit quaternion, and its real part is $\operatorname{Re} U_p = \frac{1}{2} \operatorname{tr} U_p \in [-1, 1]$ Proved here . $\operatorname{Re} U_p = 1$ holds only when $U_p = 1$ (going once around the plaquette changes nothing).

Gauge transformations, and the invariance of the real part

A **gauge transformation** by $g_x \in SU(2)$ at each lattice point sends the link from x to $y = x + e_\mu$ to

$$U_{x,\mu} \longmapsto g_x \, U_{x,\mu} \, g_y^{-1} \quad (7)$$

The holonomy then changes by conjugation, $U_p \mapsto g_x U_p g_x^{-1}$, and the real part $\operatorname{Re} U_p$ does not change Proved here ($\operatorname{Re}(gqg^{-1}) = \operatorname{Re} q$, by cyclicity of the trace). The product of Haar measures is also invariant under gauge transformations Proved here (since each link is only multiplied from the left and the right). In Lean, the gauge transformation is written as `act` (value $g(\text{start})\, U\, g(\text{end})^*$). Gauge-invariant functions are used in Part 20 for reflection positivity through the middle plane (19-03).

05

The Wilson measure — the weight $e^{\beta \sum_p \operatorname{Re} U_p}$ and expectations

The introduction is in 5-01 § 04. Take a real number β. In Parts 19 to 22 and Part 28 of this book, the **weight** of a configuration U is

$$w_\beta(U) = \exp\Big(\beta \sum_p \operatorname{Re} U_p\Big) \quad (8)$$

The sum runs over all $6N^4$ plaquettes. It is related to the Wilson action $S_W(U) = \beta \sum_p \big(1 - \tfrac{1}{2} \operatorname{tr} U_p\big)$ of 5-01 by

$$e^{-S_W(U)} = e^{-6N^4 \beta} \, w_\beta(U) \quad (9)$$

holds Proved here. The constant $e^{-6N^4\beta}$ disappears on normalisation, so the two ways of writing give the same probability measure. β is the same quantity as in 5-01; for $SU(2)$, $\beta = 4/g^2$ Cited.

The **Wilson measure** is the probability measure obtained by multiplying the product of Haar measures by the weight w_β and normalising the whole to 1.

$$d\mu_{N,\beta}(U) = \frac{1}{Z_N(\beta)} \exp\Big(\beta \sum_p \operatorname{Re} U_p\Big) \prod_\ell dU_\ell \quad (10)$$

We fix the notation. We write $\tilde{\mu}_{N,\beta}$ for the unnormalised measure $w_\beta(U) \prod_\ell dU_\ell$ (`TorusRP.wilsonMeasure N β` in Lean), and $\mu_{N,\beta}$ for the normalised (10) (`TorusRP.wilsonProb N β` in Lean). $\tilde{\mu}_{N,\beta} = Z_N(\beta)\, \mu_{N,\beta}$.

The **expectation** of a bounded measurable function F is

$$\langle F \rangle_{N,\beta} = \int F \, d\mu_{N,\beta} = \frac{1}{Z_N(\beta)} \int F(U)\, w_\beta(U) \prod_\ell dU_\ell \quad (11)$$

The sign of β is free as far as the definition goes. Physics usually uses $\beta > 0$ (the more the plaquettes line up at 1, the heavier the weight), but some theorems of Parts 20 and 21 hold including $\beta < 0$. The range is written for each theorem.

The weight (8) is gauge invariant (§ 04). Hence the Wilson measure is also invariant under gauge transformations Proved here. Even without fixing a gauge, the integral is an integral over a finite-

dimensional, compact space.

> May be skipped. In this book the unnormalised measure $w_\beta \prod dU$ is called the "unnormalised Wilson measure". In theorems that say "a certain integral is at least 0", such as reflection positivity, multiplication by a positive constant does not change the conclusion, so many of the Lean statements are written with the unnormalised measure (§ 07). For quantities that take ratios, such as expectations and variances, the normalised measure (10) is used.

06

The partition function — positive and finite

The **partition function** is the normalising constant.

$$Z_N(\beta) = \int \exp\Big(\beta \sum_p \operatorname{Re} U_p\Big) \prod_\ell dU_\ell \quad (12)$$

For the definition (10) to make sense we need $0 < Z_N(\beta) < \infty$. This follows from the following estimate Proved here .

$$e^{-6N^4|\beta|} \;\le\; Z_N(\beta) \;\le\; e^{6N^4|\beta|} \quad (13)$$

Proof: on each plaquette $|\operatorname{Re} U_p| \le 1$, so the absolute value of the exponent is at most $6N^4|\beta|$. Hence the integrand lies between $e^{-6N^4|\beta|}$ and $e^{6N^4|\beta|}$, and the reference measure has total mass 1. (End)

This estimate gets rapidly worse with the volume. It says nothing uniform in the volume. In the infinite-volume limit (Part 20), one deals not with Z itself but with ratios of expectations.

In Lean, the two-sided bounds on the integrand are `TorusRP.wilsonWeight_le` and `TorusRP.wilsonWeight_ge` (the exponent is the number of plaquettes $\times$ $|\beta|$; that the number of plaquettes is $6N^4$ was counted by hand); that the total mass of the unnormalised Wilson measure obtained by integrating them, $\tilde{\mu}_{N,\beta}(\mathbf{whole}) = Z_N(\beta)$, is positive and finite is `TorusRP.wilsonMeasure_univ_pos` and `TorusRP.wilsonMeasure_univ_lt_top`; and that the partition function of the twisted lattice is positive is stated by `TwistedWilson.ZW_pos` (all real β, all pairs of twists).

07

Four conventions on the Lean side, and bridges — four ways of writing the same objects

This book's Lean theorems were written separately in four lines (strong coupling, vortices, fermions, ultraviolet). The object is the same: configurations of the $SU(2)$ lattice and their measure. But the indexing of the lattice, the space of link values and the way of writing the sign of the weight differ slightly. When reading the theorems of any part, check the conventions in this table.

	Strong-coupling side (Part 20)	Vortex side (Part 21)	Fermion side (19-05)	Ultraviolet side (19-04; tl
Lattice	$(\mathbb{Z}/N)^4$. Links `Lk N` = (lattice point) $\times$ (direction). Direction index 0 is time (the same as the numbering 0 to 3 of Part 20; reflection x $0 \mapsto -x0$)	$(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$. `Site N M`, `Link`, `Plaq`. Indices 0 to 3 are directions 1 to 4 (the numbering of Part 21). **Time is index 3 (x_4)** (the reflection $x4 \mapsto -x$ 4 is in 19-03)	Time circle $\mathbb{Z}/2h \times$ space $(\mathbb{Z}/N)^3$. `PhysLink N h`. Direction index 3 is time. The bridge is for $N = 2h$	The box $(\mathbb{Z}/2^m L)^4$ at st `BoxWalk.Site L m`, `Box` (lattice point $\times$ `Fin 4`
Link values	The closed unit ball of quaternions `QBall` ($\|q\| \leq 1$)	The unit sphere `SU2` ($\|q\| = 1$)	The unit sphere `SU2`. Inside the action, mapped to the matrix (4)	The closed unit ball of `ChainBlockMap.Ball`. C `ChainBlockMap.Cfg` (th block map can fall insi domain and codomain the ball; 19-04)
Reference measure	`haarBall`: the Haar measure of the sphere pushed forward to the ball. The product is `Measure.pi`	`haarCfg`: the product of Haar measures	The product of Haar measures	Not fixed on the side of push-forward measure `ChainBlockMap.vP` take probability measures o configuration spaces of each step
Weight	e^{β} action, `action` = $\sum_{\mu<\nu}$ $\mathrm{Re}\, U_p$	$\exp(\beta \sum_p z_p \mathrm{Re}\, U_p$), where $z_p = \pm 1$ is the sign of the twist (19-02)	$e^{-\beta S_W}$, $S_W = \sum_p (1 - \frac{1}{2}$ $\mathrm{Re}\,\mathrm{tr}\, U_p)$	No weight enters the de Wilson measure or ano placed on the box type
Normalisation	Not normalised (`TorusRP.wilsonMeasure`). The normalised form is `wilsonProb`	No name is given to the measure; written with the partition function `TwistedWilson.ZW` and its ratios	Not normalised (`WilsonGauge.gaugeMeasure`)	The measures taken in measures (normalised)
Notation in this book	Unnormalised $\tilde{\mu}_{N,\beta}$, normalised $\mu_{N,\beta}$ ((10)), Z_N (β) ((12))	Z_0, Z_1, θ_M (19-02)	The notation of 19-05	The notation of 19-04

We explain the meaning of the differences in convention in turn.

The closed ball and the sphere. The strong-coupling side places link values in the closed unit ball $\{\|q\| \leq 1\}$, and takes as reference measure "the Haar measure of the sphere pushed forward to the ball" (`haarBall`). Using the ball is a choice made for the construction in Lean. Since the reference measure lives on the sphere, almost every configuration takes values in $SU(2)$, and the values of integrals are the same as under the sphere convention Proved here . The conjugate (`star`) is written in place of the inverse, but the two coincide on the sphere.

The sign of the weight. The weight on the fermion side is $e^{-\beta S_W}$, which by (9) is a positive constant multiple of $e^{\beta \sum \mathrm{Re}\, U_p}$.

Bridges — identifications shown in Lean

Bridge	What it says	Lean
Sum of the actions	On the torus of the same size $N = 2h$ in all four directions, for every configuration, $\sum_{\mu<\nu} \mathrm{Re}\, U_p + S_W = 6(2h)^4$ (through the re-indexing of directions and the embedding of the sphere into the ball)	`WilsonGauge.action_add_wilsonAction`
Agreement of reference measures	Pushing the product of Haar measures on the fermion side forward by `pull` gives the product of `haarBall` on the strong-coupling side	`WilsonGauge.map_pull`
Agreement of measures	`TorusRP.wilsonMeasure (2h) β` on the strong-coupling side equals $e^{6(2h)^4\beta}$ times the push-forward of `gaugeMeasure h β` on the fermion side by the re-indexing `pull` (all real β, $2h > 1$)	`WilsonGauge.wilsonMeasure_eq_map`
Agreement of reflections	Under the same re-indexing, the reflections through lattice-point planes on the two sides correspond	`WilsonGauge.refl_pull` (19-03)
Agreement of measures (strong coupling ↔ vortices)	When $M = N$ and there is no twist ($z_p \equiv 1$), for all $N \geq 1$ and all real β, `TorusRP.wilsonMeasure N β` on the strong-coupling side equals the product of Haar measures `haarCfg N N` on the vortex side multiplied by the density $\exp(\beta \sum_p \mathrm{Re}\, U_p)$ and pushed forward by the re-indexing of links (lattice point $x \mapsto ((x_0, x_1), (x_2, x_3))$, direction indices unchanged) and the inclusion `toBall` of the sphere into the ball. There is no constant factor (both sums over plaquettes run over the $6N^4$ plaquettes with $\mu < \nu$). `toBall` is injective (`WilsonBridge.toBall_injective`)	`WilsonBridge.wilsonMeasure_eq_map`
Expectations and total mass (strong coupling ↔ vortices)	For measurable F, $\int F\, d(\mathrm{wilsonMeasure}) = \int F(\mathrm{toBall}\, U)\, e^{\beta \sum_p \mathrm{Re}\, U_p}\, d(\mathrm{haarCfg})$. With $F = 1$, the total mass is `ZW N N β false false` (converted to a value in $[0, \infty]$)	`WilsonBridge.integral_wilsonMeasure`, `WilsonBridge.wilsonMeasure_univ`
Correspondence aligning time, and reflections (strong coupling ↔ vortices)	The same equality of measures holds for the re-indexing that sends time on the strong-coupling side (index 0) to time on the vortex side (index 3, x_4) and index k to $k - 1$ (lattice point $x \mapsto ((x_1, x_2), (x_3, x_0))$). The reflections through lattice-point planes on the two sides are then the same map ($x_0 \mapsto -x_0$ on the strong-coupling side and $x_4 \mapsto -x_4$ on the vortex side). Time–space plaquettes are sent to plaquettes of reverse orientation (the real part is the same; the holonomy is conjugated)	`WilsonBridgeT.wilsonMeasure_eq_mapT`, `WilsonBridgeT.refl_toBallT`, `WilsonBridgeT.action_toBallT`
The vortex ratio (no background)	With background $n_{12} = 0$ and $M = N$, $Z_{N,N}(\beta; 0, 1)/Z_{N,N}(\beta; 0, 0)$ equals the expectation of $\exp\left(-2\beta \sum \mathrm{Re}\, U_p\right)$ (over the N^2 time–space plaquettes corresponding to $\Pi_{(0,0)}$) under the normalised measure of the strong-coupling side	`WilsonBridgeV.vortex_ratio_eq`
The definition of the Haar measure	`haarProb` on the strong-coupling side and on the vortex side are defined by the same expression `Measure.haarMeasure ⊤` (two definitions in different namespaces; inside the proof of the agreement of measures above, they are unfolded and checked to agree)	`OSGap.haarProb`, `TwistedWilson.haarProb`

When $M = N$ and there is no twist, the strong-coupling side and the vortex side are tied together in Lean as one measure. Pushing forward the product of Haar measures on the vortex side, multiplied

by the weight $\exp(\beta \sum_p \operatorname{Re} U_p)$, by the re-indexing of links and the inclusion of the sphere into the ball gives exactly the Wilson measure of the strong-coupling side (there is no constant factor, and both sums over plaquettes run over $6N^4$ plaquettes). There are two re-indexings. The one that overlays the direction indices unchanged is used for the equalities of measures, expectations and total mass. The one that overlays time on the strong-coupling side (index 0) with time on the vortex side (index 3, x_4) is used in the chapters that use reflection. With the latter, the reflections through lattice-point planes on the two sides become the same map, and time–space plaquettes are sent to plaquettes of reverse orientation. Weights and actions written only in terms of real parts do not change, but when the holonomy itself is transported a conjugation enters. Overlaying the direction indices unchanged is allowed only for the equalities of measures; where reflection is used, the re-indexing that aligns time is used.

What this bridge does not say: there is no equality transporting a twisted measure (background $n_{12} = 1$, or $n_{34} = 1$) as a measure to the strong-coupling side. The θ_M of Part 21 and the expectation $\langle\cdot\rangle_0$ of Polyakov loops are quantities of the weight with background $n_{12} = 1$, not quantities on this bridge (what the bridge transports is only the form that writes the background-free ratio $Z(0,1)/Z(0,0)$ as an expectation). Lattices with $M \neq N$ have no counterpart on the strong-coupling side. These are equalities in finite volume, and they do not restate theorems about the infinite-volume limit or the mass gap.

The Lean definitions on the ultraviolet side consist only of maps and push-forwards on box lattices and ball-valued configurations, and do not contain the Wilson weight. The correspondence between the ultraviolet side and the other three sides is dealt with in 19-04, and is not listed in this chapter's table of bridges.

What this chapter can say

Can say	Cannot say
Proved here $SU(2)$ is the group of unit quaternions, and $\operatorname{Re} q = \frac{1}{2}\operatorname{tr} q \in [-1,1]$	— (definitions and elementary facts)
Cited The normalised Haar measure is unique, and invariant under left and right multiplication and inversion	The only properties named in Lean are that it is a probability measure and left invariance

Words used in this chapter — lattice, link, link variable, configuration, unit quaternion, Haar measure, plaquette, holonomy, gauge transformation, Wilson measure, unnormalised Wilson measure, partition function. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-02 Twisted boundary conditions, the vortex ratio θ and Polyakov loops — on the same lattice, we define partition functions with the signs of plaquettes flipped one by one, and their ratios.

Twisted boundary conditions, the vortex ratio θ and Polyakov loops

This chapter is this book's own investigation. § 01 to § 04 arrange established knowledge, and § 05 to § 07 are this book's investigation (the definition of the minimal action of a vortex, and the conventions in Lean).

What this chapter shows — The definitions of the objects that the theorems of Part 21 talk about: the torus with transverse size N and longitudinal size M, the twist signs n_{12}, n_{34}, the partition functions Z_0, Z_1, the vortex ratio θ_M, the Polyakov loop $P_b(t)$, the twisted vacuum V, and the minimal action of a vortex $S_{\mathrm{v}}(N,m)$ and S_N. We also state here that the definitions are sound ($|\theta_M| < 1$, $0 \le S_N \le 2N^2$).

Prerequisite chapters — 19-01 (the lattice, plaquettes, the Wilson measure). The introduction to twists is in 25-01 § 01.

Said first — This is a chapter of definitions; it states no estimates of θ_M or of Polyakov loops (the estimates are in Part 21, and in 20-06 inside the strong-coupling window). The transverse size N is a fixed finite number, and nothing uniform in N is said. The lattice spacing is 1.

The order of this chapter

1. The torus with transverse size N and longitudinal size M — a small cross-section and a large plane
2. Twist signs — flipping the sign of plaquette weights
3. The partition functions Z_0, Z_1 and the vortex ratio θ_M — the price of inserting one twist
4. Polyakov loops — the product once around the longitudinal direction
5. The twisted vacuum — a configuration of action 0
6. The minimal action of a vortex — the price of passing one vortex through a block
7. Correspondence with Lean names — conventions on indices and truth values

01

The torus with transverse size N and longitudinal size M — a small cross-section and a large plane

The introduction is in 25-01 § 01. Take positive integers N, M, and let the lattice be

$$\Lambda_{N,M} = (\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2, \qquad x = (x_1, x_2;\, x_3, x_4) \tag{1}$$

Directions 1 and 2 are called **transverse** (size N), and directions 3 and 4 **longitudinal** (size M). The transverse part is a small two-dimensional torus T^2_N, and the longitudinal part is a large plane $(\mathbb{Z}/M)^2$; in Part 21, N is held fixed and M is made large.

Links (x, μ), plaquettes $p = (x; \mu, \nu)$ $(\mu < \nu)$, the holonomy U_p and the product of Haar measures are built in the same way as in 19-01. There are $4N^2M^2$ links and $6N^2M^2$ plaquettes.

Fixing one point $q = (x_3, x_4)$ of the longitudinal plane, the N^2 transverse lattice points sit above it. We write Π_q for the bundle of $(3,4)$ plaquettes based at these N^2 points. Within the plane, Π_q looks like a single point; transversely, it is a collection of plaquettes covering T^2_N (equation (3) of 25-01 § 01).

02

Twist signs — flipping the sign of plaquette weights

On the lattice, 't Hooft's twisted boundary conditions are introduced through signs $z_p \in \{+1, -1\}$ of the plaquette weights Cited . For two twists $n_{12}, n_{34} \in \{0, 1\}$ we set

$$z_p = \begin{cases} (-1)^{n_{12}} & p \text{ is a } (1,2) \text{ plaquette with base } (x_1, x_2) = (0,0) \\ (-1)^{n_{34}} & p \text{ is a } (3,4) \text{ plaquette with base } (x_3, x_4) = (0,0) \\ 1 & \text{otherwise} \end{cases} \tag{2}$$

That is, $n_{12} = 1$ flips the sign of the one plaquette based at the origin in each transverse $(1,2)$ plane (a single T^2_N with the longitudinal point fixed). There are M^2 flipped plaquettes in all. $n_{34} = 1$ flips the one plaquette based at the origin in each longitudinal $(3,4)$ plane (a single plane with the transverse point fixed), and the flipped plaquettes are the N^2 plaquettes of $\Pi_{(0,0)}$.

The twisted weight and partition function are

$$Z_{N,M}(\beta; n_{12}, n_{34}) = \int \exp\Big(\beta \sum_p z_p \operatorname{Re} U_p\Big) \prod_\ell dU_\ell \quad (3)$$

This satisfies $0 < Z < \infty$ Proved here (the same estimate as in 19-01 § 06; $|z_p \operatorname{Re} U_p| \le 1$).

When $N, M \ge 2$, where the flipped plaquettes are placed has no effect on the partition function. Replacing a link variable by $U_\ell \mapsto -U_\ell$ flips the signs of all plaquettes containing that link, and the Haar measure is preserved Proved here. What the partition function sees is only the parity of the number of flips piercing each plane (the flux). The proof is in the Moving-Surface Lemma of 25-01 § 02 (a statement for $N, M \ge 2$; the proof rests on each plaquette containing the same link at most once). 25-01 places the $(1,2)$ flip at $(x_1, x_2) = (N-1, N-1)$, but by this lemma it gives the same partition function.

It is related to the partition function $Z[z] = \int e^{-\beta S^z} \prod dU$ of 25-01 ($S^z = \sum_p (1 - \frac{1}{2} z_p \operatorname{tr} U_p)$) by $Z[z] = e^{-6N^2M^2\beta} Z_{N,M}(\beta; n_{12}, n_{34})$ Proved here. This constant disappears in the ratio of the next section.

03

The partition functions Z_0, Z_1 and the vortex ratio θ_M — the price of inserting one twist

In Part 21 the transverse twist is held fixed as a background at $n_{12} = 1$, and two partition functions are compared according to whether the longitudinal twist n_{34} is present.

$$Z_0 = Z_{N,M}(\beta; 1, 0), \qquad Z_1 = Z_{N,M}(\beta; 1, 1) \quad (4)$$

The **vortex ratio** is defined as

$$\theta_M = \theta_{N,M}(\beta) = \frac{Z_0 - Z_1}{Z_0 + Z_1} \quad (5)$$

The transverse N is held fixed in the notation; when needed we write $\theta_{N,M}$. Since Z_0, $Z_1 > 0$, θ_M is well defined and $|\theta_M| < 1$ Proved here. In terms of the **flux free energy** $\Delta F = \ln(Z_0/Z_1)$ (the term of "the definition of the sector and flux free energies" in 25-01; the same quantity as the vortex free energy F_v of 26-03), $\theta_M = \tanh(\Delta F/2)$ Proved here.

Meaning: flipping the N^2 plaquettes of $\Pi_{(0,0)}$ imposes the condition that one centre vortex (flux -1) pierces the longitudinal plane. θ_M close to 0 means that inserting one vortex hardly changes the partition function, that is, that vortices arise cheaply in the

plane. That θ_M decreases in M at the rate e^{-cM^2} is, through the Tomboulis–Yaffe inequality, the entrance to the argument for confinement Cited (25-01 § 02, 26-01).

$\theta_M \geq 0$ ($Z_1 \leq Z_0$) does not follow from the definition. It is a theorem of Part 21 (for even M), and is not assumed here. The continuity of the vortex ratio in the coupling, its limits, and matching it to a chosen value are in 21-07.

May be skipped. The thin-vortex floor (Part 21) is written in Lean in a form that holds whether the background n_{12} is set to 0 or 1. We write $\theta_M^{(n_{12})}$ for the ratio $(Z_{N,M}(\beta; n_{12}, 0) - Z_{N,M}(\beta; n_{12}, 1))/(Z_{N,M}(\beta; n_{12}, 0) + Z_{N,M}(\beta; n_{12}, 1))$ in that case. θ_M means $\theta_M^{(1)}$.

04

Polyakov loops — the product once around the longitudinal direction

Fix a transverse position $b \in (\mathbb{Z}/N)^2$ and a position $t \in \mathbb{Z}/M$ in direction 4, and multiply in order the M link variables going once around direction 3.

$$P_b(t) = \mathrm{Re}\Big(U_{(b;0,t),3}\, U_{(b;1,t),3} \cdots U_{(b;M-1,t),3}\Big) \quad (6)$$

This is called the **Polyakov loop**. Since the real part is half the trace, $P_b(t) = \frac{1}{2}\,\mathrm{tr}(\cdots) \in [-1, 1]$ Proved here . Being the trace of a product along a closed path, it does not change under gauge transformations Proved here .

We write $\langle\cdot\rangle_0$ for the expectation normalised with the weight of the twist background $n_{12} = 1$, $n_{34} = 0$.

$$\langle F\rangle_0 = \frac{1}{Z_0}\int F(U)\exp\Big(\beta\sum_p z_p \,\mathrm{Re}\,U_p\Big)\prod_\ell dU_\ell \qquad (n_{12}=1,\ n_{34}=0) \quad (7)$$

What Part 21 estimates is the pair of two Polyakov loops separated by T in direction 4, $\langle P_b(0)\, P_{b'}(T)\rangle_0$.

The expectation of a single loop is 0 Proved here : multiplying all direction-3 links at $x_3 = 0$ by -1, every plaquette contains 0 or 2 such links (counting repetitions), so the weight does not change, the Haar measure is preserved, and only $P_b(t)$ changes sign. What carries meaning is therefore the correlation of a pair.

05

The twisted vacuum — a configuration of action 0

Using the unit quaternions i, j, define the configuration V by

$$V_{x,1} = \begin{cases} \mathrm{i} & x_1 = 0 \\ 1 & x_1 \neq 0 \end{cases}, \qquad V_{x,2} = \begin{cases} \mathrm{j} & x_2 = 0 \\ 1 & x_2 \neq 0 \end{cases}, \qquad V_{x,3} = V_{x,4} = 1 \tag{8}$$

This is called the **twisted vacuum**. For the signs (2) with background $n_{12} = 1$, $n_{34} = 0$, on every plaquette

$$z_p \operatorname{Re} V_p = 1 \tag{9}$$

holds Proved here . For example, on the $(1,2)$ plaquette with base $(x_1, x_2) = (0,0)$, $V_p = \mathrm{i}\mathrm{j}\,\mathrm{i}^{-1}\mathrm{j}^{-1} = -1$, which cancels against $z_p = -1$. On the other plaquettes the holonomy is 1. Since the action $1 - z_p \operatorname{Re} U_p$ of each plaquette is at least 0, V gives the minimum (0) of the twisted action. Lean: `TwistBlocks.vac`; (9) is `TwistBlocks.vac_term`.

That i and j anticommute ($\mathrm{i}\mathrm{j} = -\mathrm{j}\mathrm{i}$) is the mechanism by which the transverse twist is absorbed at action 0. That the twisted vacuum is unique up to gauge transformations and global transformations is in 25-01 § 05.

06

The minimal action of a vortex — the price of passing one vortex through a block

We define the number S_N that appears in the exponent of the thick-vortex floor (Part 21). Take a positive integer m, and let the longitudinal size be $M = 2m$. The lines $x_3 \in \{0, m\}$ and $x_4 \in \{0, m\}$ divide the longitudinal plane $(\mathbb{Z}/2m)^2$ into four **blocks** of side m; we use the block at the origin, $b_0 = \{0, \dots, m-1\}^2$.

- **Frame**: the links lying on the boundary lines. Direction-3 links whose x_4 is on a line, direction-4 links whose x_3 is on a line, and links in the transverse directions 1 and 2 whose longitudinal point (x_3, x_4) is on a line.
- **Interior**: the links that are not in the frame and whose longitudinal point lies in b_0.
- **Plaquettes of the block**: all plaquettes whose base has its longitudinal point in b_0 (all six orientations, all transverse positions).

Fix the frame to the twisted vacuum V, let the interior move freely, and flip the sign only of the $(3,4)$ plaquettes above the corner point $(x_3, x_4) = (0,0)$ (the N^2 plaquettes of $\Pi_{(0,0)}$); the infimum of the resulting action is

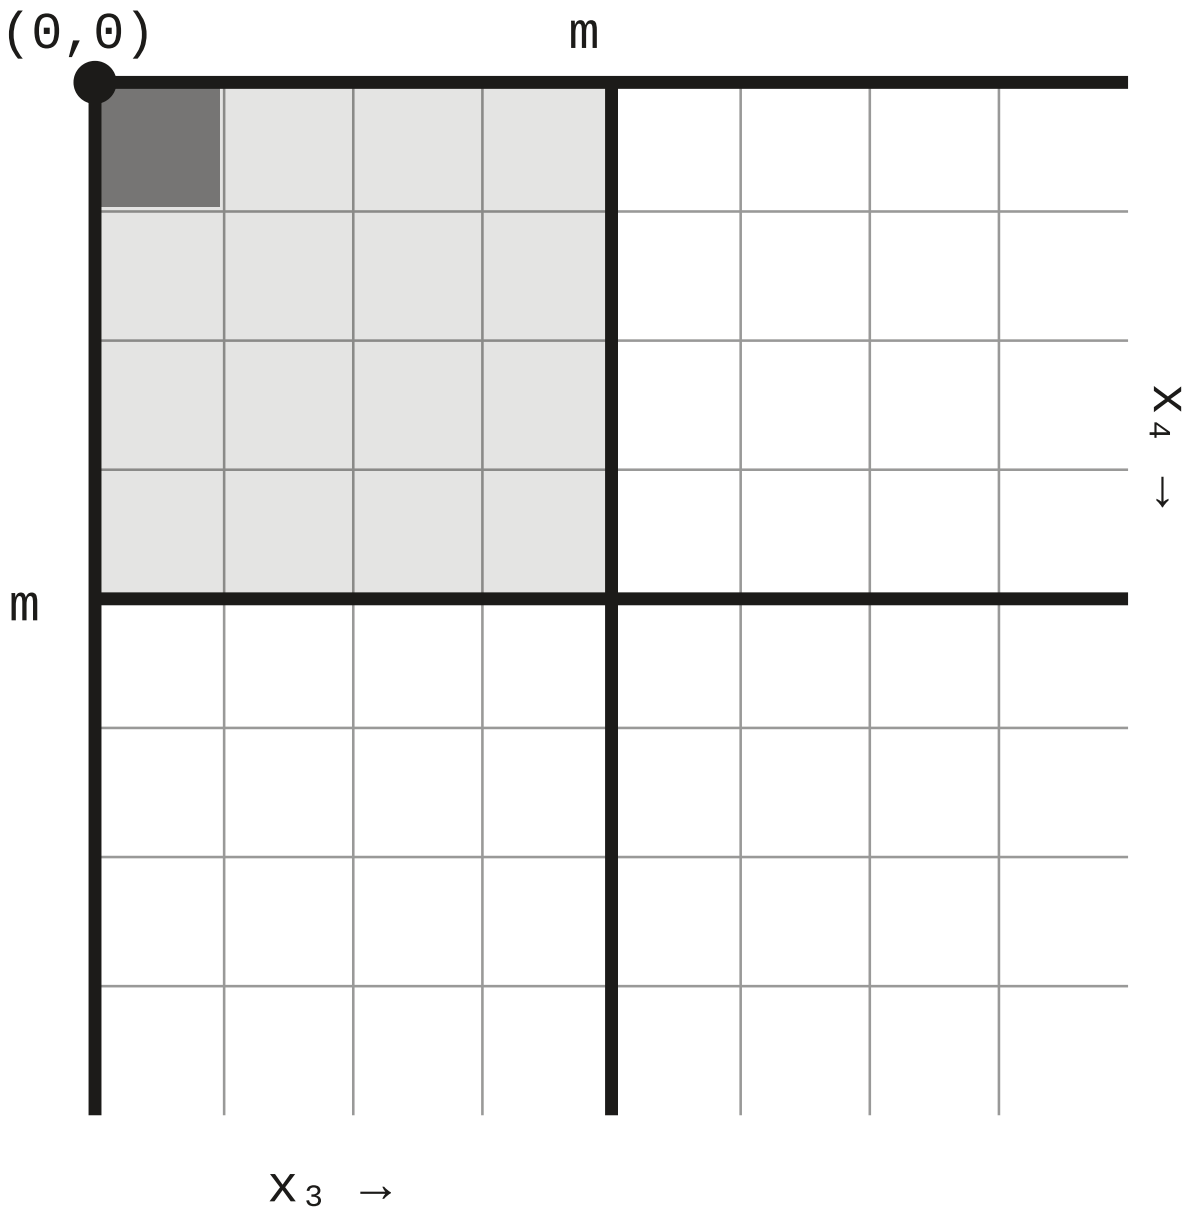
$$S_{\mathrm{v}}(N,m) = \inf_{\text{interior}} \sum_{p \in b_0} \left(1 - z_p\, \eta_p \operatorname{Re} U_p\right), \qquad \eta_p = \begin{cases} -1 & p \in \Pi_{(0,0)} \\ 1 & \text{otherwise} \end{cases} \tag{10}$$

Here z_p are the signs of the background $n_{12}=1$, $n_{34}=0$. The flipped $\Pi_{(0,0)}$ are the same plaquettes as for the longitudinal twist $n_{34}=1$, so $S_{\mathrm{v}}(N,m)$ is "the minimal action of passing one vortex through a block of side m whose boundary is fixed to the twisted vacuum". The infimum over m,

$$S_N = \inf_{m\geq 1} S_{\mathrm{v}}(N,m) \tag{11}$$

is called the **minimal action of a vortex**.

Figure 1 The longitudinal plane $(\mathbb{Z}/2m)^2$ $(m=4)$. Thick lines are the frame (fixed to the twisted vacuum), the grey area is the block $b0$ at the origin, and the black dot is the corner $(0,0)$ whose signs are flipped. Above each point sits the transverse T^2_N



Proved here The figure shows one period of the periodic plane (the right and bottom edges coincide with the left and top edges). The dark square is the square based at the corner point $(0,0)$, above which $\Pi_{(0,0)}$ sits (it refers to the same thing as the black dot in the figure).

We check that the definition is sound. Each term $1 - z_p \eta_p \operatorname{Re} U_p$ lies between 0 and 2, so the infimum is finite and $S_{\mathrm{v}}(N,m) \geq 0$. Taking the interior also to be V, all unflipped plaquettes give 0 ((9)) and each of the N^2 flipped ones gives 2, so $S_{\mathrm{v}}(N,m) \leq 2N^2$. Therefore

$$0 \leq S_N \leq 2N^2 \quad (12)$$

Proved here . Lean: `TwistBlocks.Svortex_le`, `TwistBlocks.SN_bounds`. The infimum in (10) is attained by an interior configuration (because the space of interior configurations is compact; Lean: `TwistBlocks.Svortex_attained`). The upper bound $2N^2$ is the same number as the exponent of the thin-vortex floor; whether S_N is strictly smaller than it, and whether $S_N > 0$, do not follow from the definition. The latter is a theorem of 21-05, and the former for $N = 2, 3, 4$ is a computer certificate in the same chapter.

07

Correspondence with Lean names — conventions on indices and truth values

The Lean definitions on the vortex side correspond to the notation of this chapter as follows. Direction indices start at 0, and 0, 1, 2, 3 are directions 1, 2, 3, 4 of this chapter. Twists are truth values, and `true` is $n = 1$.

This chapter	Lean	Note
$\Lambda_{N,M}$, links, plaquettes	`TwistedWilson.Site N M`, `Link`, `Plaq`	`Site N M = (ZMod N × ZMod N) × (ZMod M × ZMod M)`. Plaquettes are pairs of directions $\mu < \nu$
U_p	`TwistedWilson.hol`	The quaternion product $U_{x,\mu} U_{x+e_\mu,\nu} U^*_{x+e_\nu,\mu} U^*_{x,\nu}$
z_p (equation (2))	`TwistedWilson.zt n12 n34`	The flips are placed at bases $(x_1,x_2) = (0,0)$ and $(x_3,x_4) = (0,0)$
$Z_{N,M}(\beta; n_{12}, n_{34})$	`TwistedWilson.ZW N M β n12 n34`	Not normalised. The reference measure is `haarCfg`
Z_0, Z_1	`ZW N M β true false`, `ZW N M β true true`	
θ_M	`TwistBlocks.thetaM N M β`	The same expression as equation (5)
$P_b(t)$	`HalfSplit.polyLoop N M b t`	Direction 3 is index 2. The product is in the order $k = 0, 1, \ldots, M-1$

This chapter	Lean	Note
$\langle P_b(s) P_{b'}(t) \rangle_0$	`PolyakovT.polyExp N M β b b' s t`	`PolyakovT.corr / ZW N M β true false`. The weight `HalfSplit.wE N M β (fun _ => 1)` of `corr` is the same expression as the weight of Z_0 (`PolyakovT.wE_one`)
V	`TwistBlocks.vac`	
$S_{\mathrm{v}}(N,m)$, S_N	`TwistBlocks.Svortex N m`, `TwistBlocks.SN N`	`Svortex N m = Smin N (2m) m 2 true (0,0) (V on the frame) true`. `SN N` is the infimum over positive integers m

The block action of `Smin` in Lean also includes in its sum the plaquettes lying only on the frame. The difference is a function of the frame alone and has no effect on the infimum over the interior. The "plaquettes of the block" in equation (10) are matched to this convention.

What this chapter can say

Can say	Cannot say
Proved here $0 < Z_{N,M}(\beta; n_{12}, n_{34}) < \infty$, hence $\lvert\theta_M\rvert < 1$. Lean: `TwistedWilson.ZW_pos`	Estimates of the size and sign of θ_M (Part 21)
Proved here For $N, M \geq 2$, the placement of the flips has no effect on the partition function; only the parity of the flux matters (proof in the Moving-Surface Lemma of 25-01 § 02)	The Lean definitions of this chapter fix the placement at the origin. The lemma that moves the placement is not listed as a Lean theorem
Proved here The twisted vacuum V has $z_p \operatorname{Re} V_p = 1$ on every plaquette. Lean: `TwistBlocks.vac_term`	The uniqueness of the vacuum (25-01 § 05) is not dealt with in this chapter
Proved here $\langle P_b(t) \rangle_0 = 0$ (centre transformation)	Not listed as a Lean theorem. Estimates of the pair correlation are in Part 21
Proved here $0 \leq S_N \leq 2N^2$, and the infimum in (10) is attained. Lean: `TwistBlocks.SN_bounds`, `Svortex_attained`	$S_N > 0$ and $S_N < 2N^2$ do not follow from the definition (21-05). Nothing uniform in N is said

Words used in this chapter — twisted boundary conditions, twist sign, flux, partition function, vortex ratio, flux free energy, Polyakov loop, twisted vacuum, block, frame, minimal action of a vortex. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-03 Reflection, the transfer operator and the vessel of reconstruction — defines the reflection and the vessel that builds from it a Hilbert space and a transfer operator.

2026-11-13 · chapter Yang–Mills and the mass gap Part 19 Objects, and the statements to be shown Reflection, the vessel, the definition of the mass gap · Kiichi, Shiori and Rin

Reflection, the transfer operator and the vessel of reconstruction

This chapter is this book's own investigation. § 01 to § 04 and § 06 arrange established knowledge, and § 05, § 07 and § 08 are this book's investigation (the conventions in Lean for the vessel and for the infinite-volume space).

What this chapter shows — The definitions of the objects that the theorems of Part 20 talk about: the reflection Θ (through lattice-point planes and through middle planes), functions on the positive side, the reflection pairing $\langle F, G\rangle = \int F(\Theta\omega)G(\omega)\,d\mu$, time translation, the vessel of reconstruction (the triple of pairing, translation and constant) and the Hilbert space, vacuum Ω and transfer operator T built from it, the definition of the mass gap $\|T - P\Omega\| \le e^{-m}$, and the space of infinite-volume configurations with the periodic lift.

Prerequisite chapters — 19-01 (the lattice and the Wilson measure). Introductions in 4-10 (reflection positivity and reconstruction), 5-03 (reflection on the lattice and the transfer matrix) and 4-11 (the definition of the mass gap).

Said first — This is a chapter of definitions. Reflection positivity (that the pairing is positive semidefinite), the existence of the infinite-volume limit and estimates of the mass gap are all theorems of Part 20, and are not even assumed here. The definition of the mass gap is a quantity at a fixed lattice spacing, in units of one lattice step. It is not a definition of the mass gap of the continuum limit.

The order of this chapter

1. Reflection — lattice-point planes, and planes through the middle of links
2. The positive side — functions depending on one side of the mirror only
3. The reflection pairing — the integral of a product with the mirrored function
4. Time translation — moving the positive side one step further in
5. The vessel of reconstruction — from pairing, translation and constant to a Hilbert space and a transfer operator
6. The definition of the mass gap — T contracts by at most e^{−m} outside the vacuum

7. The space of infinite-volume configurations — configurations on $\mathbb{Z}^4$ and the periodic lift
8. Correspondence with Lean names — the three mirrors and the names of the vessel

---

01

Reflection — lattice-point planes, and planes through the middle of links

The introduction is in 5-03 § 02. The formulas of this chapter are written in the **numbering of Part 20** of 19-01 § 01 (directions $0, 1, 2, 3$, with 0 as time), and the time coordinate x_0 is written t. The lattice is periodic with even size $2M$ in the time direction. The reflections in Lean (`TorusRP.thL`, `MidRP.thM`) are defined only on $(\mathbb{Z}/2M)^4$, of the same size $N = 2M$ in all four directions.

There are two kinds of mirror.

- **Reflection through lattice-point planes**: $t \mapsto -t$. The mirror is the two planes $t = 0$ and $t = M$ passing through lattice points (by periodicity $-M \equiv M$).
- **Reflection through middle planes**: $t \mapsto 1 - t$. The mirror is the two planes $t = \frac{1}{2}$ and $t = M + \frac{1}{2}$ cutting across the middle of the time-direction links.

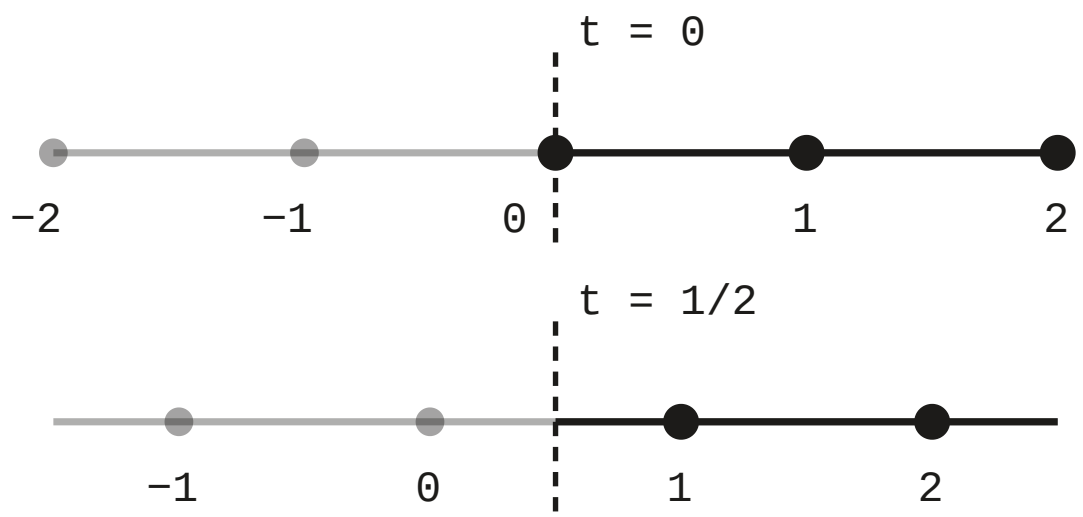
From the map of lattice points $x \mapsto \vartheta x$, the map of link variables is defined as follows. A space-direction link (x, ν) goes to $(\vartheta x, \nu)$ with its value unchanged. A time-direction link has its orientation reversed, so we take the **inverse** of the link it is mirrored to.

$$(\Theta U)_{x,\nu} = U_{\vartheta x,\nu} \quad (\nu \text{ spatial}), \qquad (\Theta U)_{x,0} = \left(U_{\vartheta(x+e_0),0}\right)^{-1} \quad (1)$$

For the reflection through lattice-point planes, $\vartheta(x + e_0) = \vartheta x - e_0$; that is, the link from t to $t + 1$ goes to the link from $-t - 1$ to $-t$. For the reflection through middle planes, the link from t to $t + 1$ goes to the link from $-t$ to $1 - t$, and the time links at $t = 0$ and $t = M$ (the links crossing the mirror) go to their own inverses.

Either Θ is a map on the space of configurations; applied twice it returns to the original, and it preserves the product of Haar measures Proved here (a rearrangement of links and an inverse on each link; 19-01 § 03). Plaquettes go to plaquettes and the value of $\mathrm{Re}\, U_p$ equals the value on the mirrored plaquette, so the Wilson weight is also preserved Proved here (for the lattice-point mirror, Lean: `TorusRP.holQ_refl`. The middle-plane mirror is the lattice-point mirror combined with a translation by one step, and the same follows from translation invariance).

Figure 1 The two mirrors seen along one row in the time direction. Dots are lattice points (space links sit on them), segments are time links. Top: the lattice-point plane $t = 0$. Bottom: the middle plane $t = \frac{1}{2}$. The dark part is the positive side



Proved here In the top row, the space links at the point $t = 0$ on the mirror do not move, and are counted on both the positive and the negative side. In the bottom row there is no lattice point on the mirror, and the time link from 0 to 1 crosses the mirror.

On the lattice $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ of the vortex side (Part 21), the reflection through lattice-point planes in direction 4, $x4 \mapsto -x4$ (M even, mirrors at $x4 = 0$ and $x4 = M/2$), is used with the same rule (1) (in the numbering of Part 21, direction 4 plays the role of time). When $M = N$, under the re-indexing that overlays time on the strong-coupling side with direction 4 on the vortex side, the reflections through lattice-point planes on the two sides are the same map (Lean: `WilsonBridgeT.refl_toBallT`, 19-01 § 07).

02

The positive side — functions depending on one side of the mirror only

One side of the mirror is called the **positive side**, and we consider functions that depend only on links on the positive side. Precisely: fix the set L_+ of links on the positive side; a function F whose values agree whenever two configurations agree on L_+ is said to "depend only on L_+".

Mirror	Links on the positive side L_+
Lattice-point planes ($t = 0, M$)	Space links at times $0 \le t \le M$, and time links whose base time is $0 \le t \le M - 1$ (the closed positive half)

Mirror	Links on the positive side L_+
Middle planes ($t = \frac{1}{2}, M + \frac{1}{2}$)	Space links at times $1 \le t \le M$, and time links whose base time is $0 \le t \le M$ (including the links at $t = 0$ and $t = M$ crossing the mirror)

Θ sends the positive side to the negative side. So if F depends only on the positive side, $F \circ \Theta$ depends only on the negative side (and the mirror) Proved here .

The class of functions used by the theorems of Part 20 is real-valued functions depending only on the positive side that are **bounded and measurable**. For the middle-plane mirror, some theorems use the class with **gauge invariance** (19-01 § 04) added. Which class is used is written for each theorem.

03

The reflection pairing — the integral of a product with the mirrored function

The introduction is in 4-10 § 04. For a finite measure μ on the space of configurations (in Part 20, the Wilson measure) and a reflection Θ, the **reflection pairing** of bounded functions F, G on the positive side is defined as

$$\langle F, G \rangle_\mu = \int F(\Theta\omega)\, G(\omega)\, d\mu(\omega) \quad (2)$$

It is bilinear in F, G. If μ is invariant under Θ, it is symmetric Proved here (change variables by $\omega \mapsto \Theta\omega$ and use $\Theta^2 = \mathrm{id}$; for the Wilson measure, Lean: `TorusRP.wilson_refl_symm`).

Reflection positivity is the property that $\langle F, F \rangle_\mu \ge 0$ for every F on the positive side. This is not a definition but a property of the measure, and that it holds for the Wilson measure is a theorem of Part 20 (20-01). It is not assumed in this chapter.

For the measure $c\mu$ multiplied by a positive constant c, the pairing is also multiplied by c, so whether it is positive semidefinite does not depend on the normalisation. This is why reflection positivity in Lean is written with the unnormalised Wilson measure (19-01 § 05).

04

Time translation — moving the positive side one step further in

Let S be the map shifting a configuration by one step in the time direction, acting on functions by $(\tau F)(\omega) = F(S\omega)$. The direction is chosen so that if F depends on links at times $[0, R]$, then τF depends on links at times $[1, R + 1]$. Then τ sends functions on the positive side to functions on the positive side.

When the measure is translation invariant and $\Theta S = S^{-1}\Theta$ holds, τ is symmetric with respect to the pairing Proved here .

$$\langle \tau F, G\rangle_\mu = \langle F, \tau G\rangle_\mu \quad (3)$$

The operator that this τ induces on the lattice is the **transfer operator** (transfer matrix). 5-03 writes it directly in the temporal gauge (5-03 § 05). Part 20 of this book builds it from the pairing and τ alone, through the vessel of the next section.

05

The vessel of reconstruction — from pairing, translation and constant to a Hilbert space and a transfer operator

The introduction is in 4-10 § 05. What is extracted from the Osterwalder–Schrader reconstruction as the part that does not depend on the measure is called the **vessel of reconstruction**. A vessel is the following tuple on a real vector space V.

Field	Condition	When built from a measure
Pairing B (bilinear form)	Positive semidefinite $B(x,x) \geq 0$, symmetric $B(x,y) = B(y,x)$	The reflection pairing (2)
Translation τ (linear map)	Symmetric with respect to B: $B(\tau x, y) = B(x, \tau y)$	Time translation (§ 04)
Constant $\mathbf{1} \in V$	$B(\mathbf{1},\mathbf{1}) = 1$, $\tau\mathbf{1} = \mathbf{1}$	The constant function 1 (probability measure)
Bounded orbits	For each x there is C with $B(\tau^k x, \tau^k x) \leq C$ for all k	For bounded functions, $C = \|F\|_\infty^2$

From a vessel we build the following.

1. **Hilbert space $\mathcal{H}$**: the completion of V with the semi-inner product B. Vectors with $B(x,x) = 0$ collapse to 0 in the completion. We write $[x]$ for the image of an element x of V.
2. **Vacuum $\Omega = [\mathbf{1}]$**. $\|\Omega\| = 1$.
3. **Transfer operator T**: the continuous extension of $T[x] = [\tau x]$. It can be extended because $B(\tau x, \tau x) \leq B(x,x)$ (τ contracts). This follows from symmetry, positive semidefiniteness and bounded orbits Proved here . Route: by Cauchy–Schwarz, $a_k = B(\tau^k x, \tau^k x)$ is log-convex ($a_{k+1}^2 \leq a_k a_{k+2}$), so the ratio a_{k+1}/a_k increases. If $a_1 > a_0$, then a_k grows exponentially, contradicting boundedness (Lean: `OrbitGrowth.contraction_of_bounded`).

The T built in this way is self-adjoint, $\|T\| \leq 1$, and $T\Omega = \Omega$ Proved here . In Lean, the vessel is written as the structure `OSGap.Datum`, the Hilbert space as `Datum.Hilb`, T as `Datum.T` and Ω as `Datum.Ω`, and the properties are stated by `Datum.contraction`, `Datum.T_symm`, `Datum.T_Ω` and `Datum.norm_Ω`.

The assembly that builds a vessel from a measure is `OSGap.measureDatum`. For a probability measure ν, a reflection and a translation, it takes three fields as assumptions — the pairing is positive semidefinite (reflection positivity), the pairing is symmetric, the translation is symmetric — and fills the remaining fields (constant, bounded orbits) itself. The theorems of Part 20 discharge these three assumptions for the limit of Wilson measures.

May be skipped. Examples satisfying all the fields of a vessel can be made even small. Lean's `OSGap.exampleDatum` is a vessel on the two-dimensional $V = \mathbb{R}^2$ in which, for $|r| \leq 1$, T acts as multiplication by r on the complement of the vacuum (`example_opNorm_eq`). It checks that the fields of the vessel are consistent (non-empty).

06

The definition of the mass gap — T contracts by at most e^{−m} outside the vacuum

The introduction is in 4-11 § 01. Let the projection onto the vacuum be $P_\Omega v = \langle \Omega, v \rangle \, \Omega$. For a real number m, a vessel D is said to **have mass gap** m if

$$\|T - P_\Omega\| \leq e^{-m} \quad (4)$$

(operator norm). Lean: `OSGap.Datum.HasMassGap D m`. The unit is one lattice step, and the lattice spacing is fixed. Since T is a self-adjoint contraction with $T\Omega = \Omega$, $\|T - P_\Omega\| \leq 1$ always holds, and for $m \leq 0$, (4) holds automatically Proved here . It carries meaning when $m > 0$.

Meaning: T does not move Ω and is self-adjoint, so it preserves the orthogonal complement of the vacuum. (4) is the same as $\|T\| \leq e^{-m}$ on that complement Proved here . If $T > 0$ ($T \geq 0$ with no kernel), we can write $T = e^{-H}$, and (4) becomes the statement that the spectrum of H on the complement of the vacuum lies in $[m, \infty)$, that is, that the gap in the sense of 4-11 is at least m. The T of Part 20 has a kernel (20-04). In that case it cannot be written as $T = e^{-H}$, and (4) is read in the form $\|T\| \leq e^{-m}$ on the complement of the vacuum.

(4) is equivalent to truncated correlations decaying at a uniform rate for every x on the positive side.

$$\|T - P_\Omega\| \le e^{-m} \iff \forall x \in V\ \exists C_x\ \forall k:\ B(\tau^k x, \tau^k x) - B(\mathbf{1}, x)^2 \le C_x\, e^{-2mk} \quad (5)$$

Lean: right to left is `OSGap.Datum.hasMassGap_of_decay`, left to right is `OSGap.Datum.decay_of_hasMassGap` (the constant is $C_x = B(x,x) - B(\mathbf{1},x)^2$). This is the form on the vessel of "the gap is equivalent to all correlations decaying uniformly" in 4-11 § 02.

There are two things this definition alone cannot say.

- **Non-degeneracy**: if $\mathcal{H}$ is only the one dimension spanned by Ω, then $T - P_\Omega = 0$ and (4) holds for every m Proved here . So the theorems of Part 20 write separately in their conclusion that there is a vector of length 1 orthogonal to the vacuum (that the complement of the vacuum is not 0).
- $T \ge 0$: the definition does not forbid negative spectrum of T. $T \ge 0$ is also a separate conclusion of Part 20.

07

The space of infinite-volume configurations — configurations on $\mathbb{Z}^4$ and the periodic lift

The introduction is in 5-04 § 01. To compare measures on tori of different sizes, we place them all on one space. Let the space of configurations on all links (x,μ) ($x \in \mathbb{Z}^4$) of $\mathbb{Z}^4$ be

$$\mathcal{C} = \prod_{\ell \text{ a link of } \mathbb{Z}^4} \{q \in \mathbb{H} : \|q\| \le 1\} \quad (6)$$

with the product topology. The closed unit ball is compact, so $\mathcal{C}$ is compact Cited (Tychonoff's theorem). Taking values in the closed ball here is the convention of 19-01 § 07.

The periodic lift: a configuration ω on the torus $(\mathbb{Z}/L)^4$ is made into a point of $\mathcal{C}$ by reading the coordinates of the links of $\mathbb{Z}^4$ modulo L. We write the probability measure on $\mathcal{C}$ obtained by pushing forward the normalised Wilson measure $\mu_{L,\beta}$ (19-01 (10)) by this map, for $L = 2(n+1)$, as

$$\mu^{\text{lift}}_{n,\beta} = (\text{periodic lift})_*\, \mu_{2(n+1),\beta} \qquad (n = 0, 1, 2, \dots) \quad (7)$$

Lean: `WilsonLimit.liftProb β n`. The sequence over all sizes L is `AllN.liftS`.

Convergence of probability measures on $\mathcal{C}$ is measured by **weak convergence** ($\int F$ converges for every bounded continuous F) Cited . That the sequence (7) converges to

one probability measure ν_β in the strong-coupling window is a theorem of Part 20 (20-03); the existence of the limit is not assumed here.

On $\mathcal{C}$, too, the reflection (lattice-point planes $t \mapsto -t$, rule (1)) and time translation are defined by the same formulas. The space of functions on the positive side is

$$W = \{F : \mathcal{C} \to \mathbb{R} \text{ bounded and continuous } : \ F \text{ depends only on finitely many links with bas}$$

W contains the constant 1 and is closed under translation. The subspace W_{gi} restricted to gauge-invariant functions is also used. The vessel of Part 20 has $V = W$ (or W_{gi}), the pairing (2) with respect to ν_β, the translation of § 04, and the constant 1.

08

Correspondence with Lean names — the three mirrors and the names of the vessel

This chapter	Lean	Note
The reflected configuration $\Theta\omega$	`LinkReflection.linkRefl θ σ ω`	$(\Theta\omega)_\ell = \sigma_\ell(\omega_{\theta\ell})$. θ is a rearrangement of links, σ a map on values
The lattice-point mirror $((\mathbb{Z}/2M)^4)$	`TorusRP.thL`, `TorusRP.sig`	Conjugate (`star`) on time links. The positive side is `TorusRP.fixP` (space links on the mirror) and `TorusRP.posP`
The middle-plane mirror	`MidRP.thM`, `MidRP.sigT`	`thM` is the lattice-point mirror combined with a translation by one step. The positive side is `TorusGauge.cr` (crossing links) and `MidRP.posM`
The mirror on the vortex side (direction 4 of Part 21)	`HalfSplit.Th` (`HalfSplit.thL`, `HalfSplit.sgL`)	M even. Links on the mirror are `HalfSplit.fixL`. `HalfSplit.thL` has the same name as `TorusRP.thL` but is a different definition
The mirror on the fermion side	`WilsonGauge.thetaPhys`	Corresponds to the mirror on the strong-coupling side through `WilsonGauge.refl_pull` (19-05)
Vessel, Hilbert space, T, Ω	`OSGap.Datum`, `Datum.Hilb`, `Datum.T`, `Datum.Ω`	The fields of the vessel are `B`, `τ`, `one` and six conditions (`nonneg`, `symm`, `τ_symm`, `one_one`, `τ_one`, `bounded`)
Vessel built from a measure	`OSGap.measureDatum`	Assumption fields: reflection positivity, symmetry of the pairing, symmetry of the translation
Mass gap	`OSGap.Datum.HasMassGap D m`	`‖D.T - vacProj D.Ω‖ ≤ Real.exp (-m)`
$\mathcal{C}$, mirror, translation	`WilsonLimit.Cfg`, `zRefl`, `zShift`	`Cfg` is a map from the links of $\mathbb{Z}^4$ to `QBall`

This chapter	Lean	Note
Periodic lift, (7)	`WilsonLimit.perLift`, `WilsonLimit.liftProb`	The torus size is `WilsonLimit.Nn n = 2(n+1)`
W, W_{gi}	`WilsonLimit.Wsub`, `GaugeZ.Wgi`	`Wgi = Wsub ⊓ Winv` (gauge invariant)

The theorems of Part 20 are stated in a form in which the fields `B`, `τ`, `one` of the vessel are tied, within the conclusion, to formula (2), § 04 and the constant 1. In a form that only says a vessel exists, the fields could be chosen trivially so as to satisfy the mass gap (the same reason as the remark on non-degeneracy in § 06).

What this chapter can say

Can say	Cannot say
Proved here The two reflections are involutions, and preserve the product of Haar measures and the Wilson weight. Lean: `TorusRP.holQ_refl` (lattice-point planes)	Reflection positivity (a theorem of 20-01) is not even assumed in this chapter
Proved here If the measure is invariant under Θ, the pairing is symmetric. For the Wilson measure, Lean: `TorusRP.wilson_refl_symm`	—
Lean: from a vessel, T can be built, and it is self-adjoint, a contraction, and $T\Omega = \Omega$ (`Datum.contraction`, `T_symm`, `T_Ω`)	That the assumptions of the vessel are satisfied for a concrete measure (Part 20)
Lean: the mass gap (4) and the uniform decay of correlations (5) are equivalent (`hasMassGap_of_decay`, `decay_of_hasMassGap`)	(4) includes neither non-degeneracy nor $T \geq 0$, and holds automatically for $m \leq 0$. The lattice spacing is fixed; it is not a definition of the mass gap of the continuum limit
Cited $\mathcal{C}$ is compact	The convergence of the sequence (7) (a theorem of 20-03) is not assumed

The block map and one step of renormalisation — families of paths, averaging, push-forward

> This chapter is this book's own investigation. § 01 is established knowledge.

What this chapter shows — We define the map B from the fine lattice $(\mathbb{Z}/2^{m+1}L)^4$ to the coarse lattice $(\mathbb{Z}/2^{m}L)^4$ through a family of paths, weights, averaging and an operation returning to the group, and set up its linear part C, the push-forward $B_*\mu$, and the multi-step family of the free field $\mathcal{M}$, G_k. The theorems of the second half of Part 15 (15-12, 15-13) talk about these.

Prerequisite chapters — 19-01 Link variables, SU(2) as unit quaternions, 7-05 § 02 The one-step transformation.

Said first — This is a chapter of definitions, and it states no theorems (only the minimum of facts is added, with their Lean names). B is one of many possible constructions, and the weights and the threshold r_0 are design choices (§ 08). The limit of lattice spacing to 0 is not dealt with. This block map is this book's design. The one step of renormalisation in the published construction is of a different design, and it is that construction which showed existence (the comparison of the two designs is in 14-02).

The order of this chapter

1. The idea of one step of renormalisation
2. Two lattices and coarse links
3. The family of paths — weights $(1/8, 3/4, 1/8)$ and six orders
4. The non-linear block map B — returning the average to the ball by a retract
5. The path kernel C — the linear part
6. The push-forward of measures
7. The multi-step family on the free-field side
8. The weights are a design choice

01

The idea of one step of renormalisation

The introduction is in 7-05 § 02 and § 05. One step of renormalisation is the operation of making coarse variables from fine variables by one rule, and carrying the measure to the coarse lattice by that rule Cited . For gauge fields, a coarse link variable is made from the "product along a path" of fine links (under a gauge transformation only the two ends move). However, group elements cannot be added and divided, and the average of path products in general leaves $SU(2)$, so a procedure that returns the average to the group is needed Cited .

The B of this chapter fixes one family of paths, averages the products along each path with weights, and shrinks the value in the radial direction to return it to the unit ball. It is one concrete form of the abstract one step T (15-03).

Below, we write $\mathbb{H}$ for the quaternions and $\mathbb{B} = \{q \in \mathbb{H} : \ |q| \le 1\}$ for their closed unit ball. $SU(2)$ is the sphere $|q| = 1$ (19-01). The conjugate q^* is the inverse on $SU(2)$.

02

Two lattices and coarse links

Take a positive integer L and a step number $m \ge 0$, and set

$$\Lambda_m = (\mathbb{Z}/2^m L)^4, \qquad \Lambda_{m+1} = (\mathbb{Z}/2^{m+1} L)^4 \quad (1)$$

Λ_{m+1} is the fine lattice and Λ_m the coarse lattice. Note that the larger number is the finer one. A coarse link is a pair $b = (y, \mu)$ ($y \in \Lambda_m$, direction $\mu \in \{1, 2, 3, 4\}$), going from y to $y + e_\mu$. In this chapter directions are written 1 to 4, corresponding in order to the Lean indices 0 to 3 (the two numbering conventions are in 19-01 § 01). Since the four directions are treated alike, which direction is called time is not specified. Fine links have the same form (x, ν), $x \in \Lambda_{m+1}$.

A coarse point y sits at the fine point $2y$. The map $y \mapsto 2y$ is well defined as $\mathbb{Z}/2^m L \to \mathbb{Z}/2^{m+1} L$ (since $2^m L \equiv 0$ goes to $2 \cdot 2^m L \equiv 0$) Proved here . On the fine lattice, a coarse link $b = (y, \mu)$ corresponds to the interval $2y \to 2y + 2e_\mu$ of length 2, whose end point $2y + 2e_\mu$ is the image $2(y + e_\mu)$ of the next coarse point $y + e_\mu$ Proved here .

A configuration is a function $U : \{\text{links}\} \to \mathbb{B}$ taking a value in the ball on each link. The Wilson measure lives on configurations with values in $SU(2)$, but since the result of averaging can fall inside the ball, the domain and codomain of the map are taken to be spaces of ball-valued configurations.

Lean: coarse links `BoxWalk.BoxLk L m`, the ball `ChainBlockMap.Ball` (other names in 19-06). A configuration takes values only on links of positive orientation, and the convention is that the value of a reversed link is read as the conjugate U^*.

03

The family of paths

For each coarse link $b = (y, \mu)$, we fix one finite family of fine paths from $2y$ to $2y + 2e_\mu$. Let n_1, n_2, n_3 be the three directions other than μ, in increasing order of number; these are called the **transverse directions**.

- **Offset** $A = (A_1, A_2, A_3)$: for each transverse direction n_t, choose one offset $d_t \in \{-1, 0, +1\}$ (27 ways).
- **Order** o: choose the order in which to move in the three transverse directions, as a permutation of three letters (6 ways).

The path $\gamma_{o,A}(b)$ joins the following three segments.

1. From $2y$, following the order o, step by d_t in the transverse direction n_t, one step at a time (no movement in directions with $d_t = 0$). Call the point reached $z = 2y + \sum_t d_t e_{n_t}$.
2. From z, take two steps in direction μ, arriving at $z + 2e_\mu$.
3. Undo the transverse offsets one step at a time in the reverse of the outgoing order, arriving at $2y + 2e_\mu$.

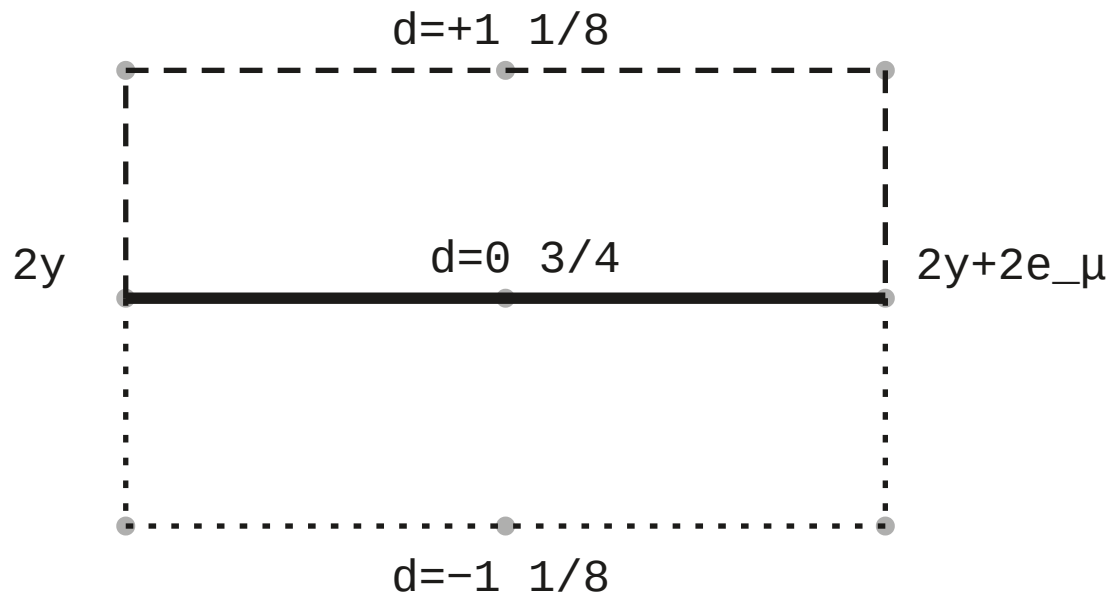
If all transverse offsets are 0, the path is the **straight path** that only takes two steps in μ. The length is $2 + 2\#\{t : d_t \neq 0\}$, at most 8. A step of a path is a pair of a link and its orientation (forward or backward), and a backward step traverses the link from its end point to its start point.

The weight of a path is the product of the per-direction weights $\mathrm{wt}(-1) = \frac{1}{8}$, $\mathrm{wt}(0) = \frac{3}{4}$, $\mathrm{wt}(+1) = \frac{1}{8}$, divided equally among the six orders.

$$w(o, A) = \frac{1}{6} \prod_{t=1}^{3} \mathrm{wt}(d_t), \qquad \sum_o \sum_A w(o, A) = 1. \quad (2)$$

Proved here The weights are non-negative and sum to 1 (the cube of $\sum_d \mathrm{wt}(d) = 1$, divided equally among the six orders). Lean: `ChainBlockMap.sixWeight_total`.

Figure 1 One coarse link ($2y \to 2y + 2e_\mu$) and three paths, drawn for one transverse direction only. There are three transverse directions; the offset is chosen independently in each and the weights are multiplied



↑ transverse n_t → μ (one fine lattice step)

In four dimensions this choice is made independently in three transverse directions, so the weight of the straight path is $(3/4)^3 = 27/64$ Proved here .

Detour: the same path counted twice

May be skipped. There are $6 \times 27 = 162$ indices (o, A), but changing the order of directions with offset 0 does not change the path, so the same path arises from several indices. In Lean this is handled by converting to a finite set of paths with merged weights (the sum of the weights of the indices giving the same path) (`BoxWalk.boxPaths`, `BoxWalk.boxW`). Merging does not change the value of the average. Counting on $\mathbb{Z}^4$, there are $\binom{3}{k} 2^k k!$ paths with k non-zero offsets, $1 + 6 + 24 + 48 = 79$ in all (1, 6, 24 and 48 paths of lengths 2, 4, 6 and 8 respectively) Proved here . On small tori, paths that are distinct on $\mathbb{Z}^4$ can fall onto the same path.

Averaging over the six orders makes the family symmetric under permutations of the three transverse directions. Since the offset weights are symmetric under $d \mapsto -d$, the family is also symmetric under reversal of transverse directions Proved here . The value of a reversed coarse link (from $y + e_\mu$ to y) is read as the conjugate, following the convention of § 02. Forming the average with the family of the same transverse steps, two steps towards $-\mu$ and the same return, and retracting, also gives a value equal to that conjugate, so the convention and the family of paths are compatible (Lean: `BoxWalk.boxMap_rev`).

Lean: paths `WalkCast.walk` (on $\mathbb{Z}^4$), weights `ChainBlockMap.sixWeight`.

04

The non-linear block map B

The product along a path. For a path $\gamma = (s_1, \dots, s_\ell)$ and a configuration U, assign U_s to a forward step s and U_s^* to a backward step, and multiply in the order of the path.

$$U(\gamma) = \prod_{i=1}^{\ell} U_{s_i}^{\pm} \quad \text{(from left to right)}, \qquad U_s^{+} = U_s, \;\; U_s^{-} = U_s^*. \tag{3}$$

The weighted average. The raw value of a coarse link b is the weighted average of path products.

$$q_b(U) = \sum_{o} \sum_{A} w(o, A)\, U\big(\gamma_{o,A}(b)\big) \;\in \mathbb{H}. \tag{4}$$

Proved here If all $|U_\ell| \le 1$, then $|q_b(U)| \le 1$ (the quaternion norm is multiplicative, and the weights are non-negative with sum 1). Lean: `ChainBlockMap.norm_sixAvg_le`.

The operation returning to the ball (retract). Fix a threshold $r_0 > 0$, and set

$$\rho_{r_0}(q) = \frac{q}{\max(|q|,\, r_0)} \tag{5}$$

If $|q| \ge r_0$, then $\rho_{r_0}(q) = q/|q|$ is a unit quaternion (an element of $SU(2)$); if $|q| < r_0$, then $\rho_{r_0}(q) = q/r_0$, with norm $|q|/r_0 < 1$. In either case $|\rho_{r_0}(q)| \le 1$, and ρ_{r_0} is continuous Proved here . For $r_0 = 1$, ρ_1 is the identity on the ball. The Lean definition makes sense for every $r_0 > 0$, but this book takes $0 < r_0 \le 1$ (for $r_0 > 1$, $|q_b| \le 1 < r_0$, so the value always falls inside the ball and never lands in $SU(2)$ Proved here).

Definition (block map). The map $B = B_m : \mathbb{B}^{\{\text{links of } \Lambda_{m+1}\}} \to \mathbb{B}^{\{\text{links of } \Lambda_m\}}$ that assigns to a ball-valued configuration U on the fine lattice the configuration on the coarse lattice

$$B(U)_b = \rho_{r_0}\big(q_b(U)\big) \qquad (b \text{ a coarse link of } \Lambda_m) \tag{6}$$

is called the **non-linear block map** of step m.

Proved here B is continuous. On the "small field" event $|q_b(U)| \ge r_0$, where the average $q_b(U)$ is at or above the threshold, $B(U)_b = q_b(U)/|q_b(U)| \in SU(2)$; below the threshold the value falls inside the ball. Lean: `ChainBlockMap.continuous_blockMap`, `ChainBlockMap.blockMap_of_small_field`.

The Lean definition is `ChainBlockMap.blockMap r₀ hr (BoxWalk.boxPaths L) (BoxWalk.boxW L) m` (`hr : 0 < r₀`). The composed map $B_m \circ B_{m+1} \circ \cdots \circ B_{n-1}$ (from step n to step m) is `ChainBlockMap.down`.

The event below the threshold is a large-field event and is dealt with separately (7-05 § 04, Parts 22 and 28).

05

The path kernel C — the linear part

We look at the form of B when U is near the identity 1. Take a field a of imaginary quaternions on the fine links ($\mathrm{Re}\, a_\ell = 0$; elements of the Lie algebra $\mathfrak{su}(2)$) and a real number ε, and set $U_\ell = \exp(\varepsilon a_\ell) \in SU(2)$ (Lean: `BlockLinearKernel.expCfg`). Expanding the path product in ε, the first-order term is the signed sum of the field along the path. Its weighted average is written

$$(Ca)_b = \sum_o \sum_A w(o,A) \sum_{s \in \gamma_{o,A}(b)} \pm\, a_s \qquad (\text{forward steps } +,\ \text{backward } -) \tag{7}$$

and C is called the **path kernel**. Its Lean name is `BlockLinear.sixSgn`. That for $0 < r_0 \le 1$, $\varepsilon \ge 0$, $|a_\ell| \le M$, $\varepsilon M \le 1/32$, the difference between $B(e^{\varepsilon a})_b$ and $\exp(\varepsilon (Ca)_b)$ is at most $257(\varepsilon M)^2$ is a theorem of Part 15 (15-13, Lean: `BlockLinearKernel.blockMap_exp_linear_le_one`). The retract does not change the linear part.

The form of the coefficients. C is a real linear map acting colour by colour (on the i, j, k components), and can be written with a table of coefficients. On the fine lattice $\Lambda_{m+1} = (\mathbb{Z}/2^{m+1}L)^4$,

$$(Ca)_\mu(X) = \sum_{r \in \Lambda_{m+1}} \sum_{\nu=1}^{4} c(r)_{\mu\nu}\, a_\nu(2X + r), \tag{8}$$

$$c(r)_{\mu\nu} = \sum_o \sum_A w(o,A) \sum_{\substack{s \text{ a step of } \gamma_{o,A} \\ \text{direction } \nu,\ \text{base point} \equiv r}} \pm 1. \tag{9}$$

Here $\gamma_{o,A}$ is the path on $\mathbb{Z}^4$ leaving the origin in direction μ. Lean: the coefficients `LatticeTorus.pathKernel` (in the form with side $2^{m+1}L$), the operator of the form (8) `TorusFourier.Cop` (built from the map $X \mapsto 2X$ and the table of coefficients). The real linear map for a single colour is `PushCov.blockLin`, and that it agrees with `Cop` is the first half of `PushCov.lattice_pushCov`.

Example (constant field). When the field a takes the same value a_ν at every point, a transverse step and its return traverse two links of the same direction with opposite signs and cancel, leaving only the two steps in μ. Hence $(Ca)_\mu = 2a_\mu$. A coarse link is as long as two fine links, so this is the expected form, "proportional to length". Proved here In terms of coefficients, $\sum_r c(r)_{\mu\nu} = 2\delta_{\mu\nu}$. This form of the sum is also the symbol of the path kernel taken at momentum 0 ($k = 0$ in `LatticePath.pathSym_closed`). The contribution of the straight path is $27/64$ each to $c(0)_{\mu\mu}$ and $c(e_\mu)_{\mu\mu}$.

C is only the first order about the identity (for the view of commuting configurations, see 15-05); linearisation about a background field $U \neq 1$ is not defined.

06

The push-forward of measures

For a probability measure μ on configurations of the fine lattice, the **push-forward** $B_*\mu$ is defined by

$$(B_*\mu)(E) = \mu\big(B^{-1}(E)\big) \qquad (E \text{ a measurable set of coarse configurations}) \quad (10)$$

B is continuous and hence measurable, and $B_*\mu$ is a probability measure on coarse configurations Proved here . In other words, it is the distribution of the coarse field $B(U)$ when U follows μ. In Lean it is `Measure.map` (in the form for probability measures, `ProbabilityMeasure.map`).

Multi-step push-forward. We write $\nu_{n,m}$ for the measure μ_n on the fine lattice of step n pushed by the composed map down to step $m \le n$. Pushing one step at a time or all at once gives the same measure: for $m < n$, $(B_m)_*\nu_{n,m+1} = \nu_{n,m}$, and $\nu_{n,n} = \mu_n$ Proved here . Lean: `ChainBlockMap.νP`; the agreement is `ChainBlockMap.hcons_blockMap` and `ChainBlockMap.νP_self`.

The μ_n being pushed is a probability measure on ball-valued configurations of the box Λ_n (the Lean type has the form of a box). The Wilson measure (19-01) and the measure with fermions (19-05) have different lattice types, so what is put in is the measure normalised and re-indexed onto configurations of the box lattice (on the fermion side, `BoxFermion.fermProbBox` in Lean).

The statements to be shown, written with this push-forward measure only, are in 19-07.

Covariance. For linear fields, the covariance of the push-forward is handled in the following form. For a measure μ on a real inner product space E, the **covariance form**

is

$$\operatorname{cov}_\mu(u,v) = \int \langle u,x\rangle\langle v,x\rangle \, d\mu(x) - \int \langle u,x\rangle \, d\mu(x) \int \langle v,x\rangle \, d\mu(x) \quad (11)$$

(Lean: `PushCov.covForm`; it is meaningful when second moments exist). The T with $\operatorname{cov}_\mu(u,v) = \langle u, Tv\rangle$ is called the covariance operator. That pushing by a linear C gives $CTC^\dagger$ is a theorem of 15-13; for the non-linear B it does not take this form.

07

The multi-step family on the free-field side

The "one step of the free field" in Part 15 (15-12) talks about operators obtained by repeating the one-step map $T \mapsto CTC^\dagger$ on the covariance operator of the free field. That this is the covariance of the Gaussian free field pushed by C is in Lean in the one-step, one-colour form (`PushCov.lattice_pushCov`); the multi-step form is a one-line argument repeating the push-forward by a linear map, and is on paper. We set up the objects in two forms, on the lattice side and on the momentum side.

Lattice side. Let the side of the coarse lattice be N, and consider a four-component field $\phi_\nu(X)$ on the torus $(\mathbb{Z}/N)^4$ (the N of this section is the side of the coarse lattice).

- **Free-field covariance** (Feynman gauge) $\mathrm{freeCov}_N$: the inverse of the lattice Laplacian $-\Delta$, taken component by component (0 on the constant component). Lean: `LatticePush.freeCov`.
- **One step**: $T \mapsto CTC^\dagger$ (from operators on $(\mathbb{Z}/2L)^4$ to operators on $(\mathbb{Z}/L)^4$). Lean: `LatticePush.stepOp`.
- **Covariance at step k**: the free-field covariance on $(\mathbb{Z}/2^kN)^4$ pushed down to $(\mathbb{Z}/N)^4$ by k one-step maps, $\mathrm{stageCov}_{k,N}$. Lean: `LatticePush.stageCov`.
- **Plaquette covariance**: the covariance $\mathrm{curl}\circ\mathrm{stageCov}_{k,N}\circ\mathrm{curl}^\dagger$ of the plaquette field $(\mathrm{curl}\,\phi)_{(a,b)}(X) = \big(\phi_a(X+e_b) - \phi_a(X)\big) - \big(\phi_b(X+e_a) - \phi_b(X)\big)$. Lean: `LatticeFace.faceCov`.

Momentum side. Let the lattice momentum be $q = (q_1,\dots,q_4)$, $q_\nu = 2\pi n_\nu/N$.

$$\omega(q) = \sum_\nu 4\sin^2\frac{q_\nu}{2}, \qquad s_\nu(q) = \sin\frac{q_\nu}{2}, \qquad P(q) = 1 - \frac{s(q)s(q)^{\mathsf{T}}}{|s(q)|^2}. \quad (12)$$

$\omega(q)$ is an eigenvalue of $-\Delta$, and $P(q)$ is the projection onto the directions orthogonal to $s(q)$. The symbol of the difference is $1 - e^{iq_\nu} = -2ie^{iq_\nu/2}\sin(q_\nu/2)$, so P is the

projection onto the "physical part" with the gradient (gauge) directions removed Proved here .

The momenta of the fine torus (side $2N$) that fall onto the coarse momentum q under $y \mapsto 2y$ are $r_\zeta(q) = q/2 + \pi\zeta$ ($\zeta \in \{0,1\}^4$, 16 of them); these are called **aliases**. The **one-step map** $\mathcal{M}$ assigns to a family G of 4×4 matrices, one for each momentum,

$$(\mathcal{M}G)(q) = \frac{1}{16} \sum_{\zeta\in\{0,1\}^4} A_\zeta(q)\, G\big(r_\zeta(q)\big)\, A_\zeta(q)^{\mathsf{T}} \tag{13}$$

$A_\zeta(q)$ is a 4×4 real matrix built explicitly from q and ζ. The family at step k is

$$G_0 = P/\omega, \qquad G_k = \mathcal{M}^k(P/\omega). \tag{14}$$

The domain is the momenta with $\omega(q) > 0$ ($\omega = 0$ is the constant component).

Lean holds the momentum as $\theta = q/4$ ($\sin 2\theta_\nu = \sin(q_\nu/2)$). The core names are `OneStepBridge.Mfam` for $\mathcal{M}$ and `TauSplit.Gs` for G_k; other names are in 19-06.

The relation between the two sides: that $\mathrm{stageCov}_{k,N}$ on the lattice side has a symbol of phase form for each momentum (`LatticePush.stageCov_phase`), that the physical part PXP of that symbol equals G_k (`LatticePush.projFam_stage`), and that the plaquette covariance equals the operator built from the momentum side (`LatticeFace.faceCov_eq_posC`) have been checked in Lean, and are used in Part 15 (15-12). What is pushed here is the linear C, not the non-linear B.

08

The weights are a design choice

The B of this chapter was defined with the following choices fixed.

Choice	Value in this chapter	Other possibilities (examples)
Weights per transverse direction $(\alpha, 1-2\alpha, \alpha)$	$\alpha = 1/8$	Other $\alpha \in [0, 1/2]$. $\alpha = 0$ gives only the straight path
Order of transverse moves	Equal average over six orders	Fixed to one order (the symmetry becomes weaker)
Operation returning to the ball	Retract ρ_{r_0}, $0 < r_0 \le 1$	Other thresholds, other ways of projecting

As long as one chooses a family of paths with non-negative weights summing to 1 and a continuous way of returning that maps the ball to the ball, the minimal facts of § 03 to § 06 (values stay in the ball, continuity, the push-forward is a probability measure) stand in the same form Proved here . The threshold-free $q \mapsto q/|q|$ is undefined at $q = 0$

and not continuous, so it does not satisfy this condition. The choice of the width of transverse offsets and of the blocking factor is dealt with in 28-05.

What depends on the choices is the coefficients (9) of the path kernel C, and A_ζ, $\mathcal{M}$, G_k built from them. The concrete constants appearing in the theorems of the second half of Part 15 (the one-step contraction rate, upper bounds on ratios of plaquette covariances, and so on) were computed with the choices of this chapter ($\alpha = 1/8$, factor 2), and cannot be used as they are with other choices. What changes when the weights are changed, and which choice makes the premises easier to satisfy, are left to 28-05 What depends on design choices.

What this chapter can say

Can say	Cannot say
Proved here The weights are non-negative and sum to 1. Lean: `ChainBlockMap.sixWeight_total`	That these weights are better than others (28-05)
Proved here B is a continuous map between ball-valued configurations, and takes values in $SU(2)$ on the event at or above the threshold. Lean: `ChainBlockMap.continuous_blockMap`, `ChainBlockMap.blockMap_of_small_field`	That B maps $SU(2)$ configurations to $SU(2)$ configurations. An estimate of the probability of the event below the threshold
Proved here The convention of reading reversed links as conjugates is compatible with the family of paths. Lean: `BoxWalk.boxMap_rev`	All forms of compatibility with local gauge transformations
Proved here The multi-step push-forward agrees with step-by-step push-forwards ($m < n$). Lean: `ChainBlockMap.hcons_blockMap`	Decay and uniformity of the push-forward measure (19-07, Part 28)
Proved here For a constant field, $(Ca)_\mu = 2a_\mu$	Linearisation about a background field $U \neq 1$

The number of paths 79, 27/64, the sum of coefficients	Proved here	Counted by hand (formulas in the detour of the text). A script enumerating the paths on $\mathbb{Z}^4$ from the definition gives the same numbers

Words used in this chapter — block map, family of paths, transverse direction, retract, threshold, small-field event, path kernel, push-forward, covariance form, alias, one-step map, covariance at a step, plaquette covariance. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-05 The fermion weight — defines one of the measures to be pushed: the measure whose weight is the determinant of the Wilson–Dirac operator.

The fermion weight — the Wilson–Dirac operator and the measure with a determinant

This chapter is this book's own investigation. § 01 is established knowledge.

What this chapter shows — On the lattice of the time circle $\mathbb{Z}/2h$ and the spatial torus $(\mathbb{Z}/N)^3$, we define the Wilson–Dirac operator $D_m(U)$ and set up the measure $\mu^{\mathrm{wf}}_{\beta,m,j}$ obtained by multiplying the gauge weight $e^{-\beta S_W}$ by $\mathrm{Re}\det D_m(U)^{2j}$. The theorems on the vessel with fermions in Part 20 (20-05) talk about this measure.

Prerequisite chapters — 19-01 Plaquettes and holonomy, the Wilson measure, the Lean conventions, 5-01, the Wilson action.

Said first — This is a chapter of definitions. Fermions appear only in the form of the determinant left after integrating them as Grassmann variables; the Grassmann integral itself is not defined. The mass m and the coupling β are bare parameters on the lattice, and their meaning in the continuum limit (mass renormalisation, chiral symmetry) is not dealt with.

The order of this chapter

1. Why a determinant weight — integrating out fermions leaves a determinant for each gauge configuration
2. The lattice and physical links — a time circle $2h$ and space N^3; the shape of this chapter's lattice
3. The convention for the gauge action — $S_W = \sum_p (1 - \frac{1}{2}\,\mathrm{Re}\,\mathrm{tr}\,U_p)$, and its relation to the weight of 19-01
4. The Wilson–Dirac operator — $r = 1$, antiperiodic in all four directions, the representation of γ
5. The determinant weight — $\mathrm{Re}\det D^{2j}$ is non-negative
6. The measure with fermions — the unnormalised measure, and the probability measure μ^{wf}
7. The range of the mass — the definitions for all m, the reflection-positivity theorem for $m > -1$

8. The relation to the conventions for gauge-field measures — five differences, and the return to the Wilson measure at $j = 0$

01

Why a determinant weight

A quark field on the lattice is represented by Grassmann variables $\psi, \bar{\psi}$ carrying at each point spin (4 components) and colour (2 components for $SU(2)$) Cited . If the action is a quadratic form $\bar{\psi} D(U) \psi$, the integral over the Grassmann variables gives, for each configuration U, the determinant $\det D(U)$. With n_f species (flavours) it is $\det D(U)^{n_f}$ Cited .

The measure after integrating out the fermions in this way is a measure on gauge configurations, with weight $e^{-\beta S_W(U)} \det D(U)^{n_f}$. The determinant can be complex, so making it a probability measure requires the weight to be a non-negative real number. In this chapter the number of flavours is taken even, $n_f = 2j$, and the real part of the weight, $\mathrm{Re} \det D^{2j}$, is used (§ 05 shows that it is non-negative).

The naive difference form of the Dirac operator on the lattice produces extra particles (doublers). Adding a second-order difference term, named after Wilson, makes them heavy Cited . That operator is D. Reflection positivity for lattice gauge theory with fermions was treated by Osterwalder–Seiler Cited (5-03, reflection positivity of the Wilson action).

02

The lattice and physical links

The lattice of this chapter, with time circle of length $2h$ ($h \geq 1$) and spatial side $N \geq 1$, is

$$\Lambda_{N,h}^{\mathrm{wf}} = (\mathbb{Z}/2h) \times (\mathbb{Z}/N)^3 \quad (1)$$

Points are written (t, x), $t \in \mathbb{Z}/2h$, $x \in (\mathbb{Z}/N)^3$. Links are (t, x, μ): for $\mu = 1, 2, 3$, the space link $x \to x + e_\mu$ within the slice at time t; for $\mu = 4$, the time link $(t, x) \to (t + 1, x)$ ($t + 1$ modulo $2h$). These are called **physical links**, and their set is written $\mathcal{L}_{N,h}$.

A configuration is $U : \mathcal{L}_{N,h} \to SU(2)$, with $SU(2)$ the unit quaternions (19-01). The reference measure on the space of configurations is the product $\prod_\ell dU_\ell$ of the Haar probability measures of the links (19-01).

The time direction is given even length $2h$ so that the planes of the reflection $t \mapsto -t$ are the two planes $t = 0$ and $t = h$ (19-03). Taking $2h = N$ gives a torus of the same size in all four directions.

Lean: the type of physical links `FermionSU2Config.PhysLink N hT` (`Fin (2 * hT) × (Fin 3 → Fin N) × Fin 4`; Lean's direction numbers 0, 1, 2 are space and 3 is time), $SU(2)$ is `FermionSU2Config.SU2` (the unit sphere of the quaternions), the reference measure is `Measure.pi fun _ => Measure.haarMeasure ⊤`, and the next time $t \mapsto t + 1 \bmod 2h$ is `FermionSliceBlock.sc`.

03

The convention for the gauge action

The Wilson action of this chapter, counting each unoriented plaquette once, is

$$SW(U) = \sum_{p} \Big(1 - \tfrac{1}{2} \operatorname{Re}\operatorname{tr} U_p\Big), \qquad U_p = U_\mu(z)\, U_\nu(z+e_\mu)\, U_\mu(z+e_\nu)^\dagger\, U_\nu(z)^\dagger \tag{2}$$

and the gauge weight is $e^{-\beta SW(U)}$ ($\beta \in \mathbb{R}$). The plaquettes are the space plaquettes (μ, ν) ($\mu < \nu \le 3$) within each time slice, and the time plaquettes $(\mu, 4)$ joining the slices at times t and $t+1$. The trace is taken by representing quaternions as 2×2 matrices, $q = a + bi + cj + dk \mapsto \begin{pmatrix} a+ib & c+id \\ -c+id & a-ib \end{pmatrix}$.

Proved here This representation preserves products, and $\frac{1}{2}\operatorname{tr}$ is the real part of the quaternion. Hence $\frac{1}{2}\operatorname{Re}\operatorname{tr} U_p = \operatorname{Re} U_p$, and with $|\mathcal{P}|$ the number of plaquettes,

$$e^{-\beta SW(U)} = e^{-\beta|\mathcal{P}|}\, e^{\beta \sum_p \operatorname{Re} U_p}. \tag{3}$$

The constant $e^{-\beta|\mathcal{P}|}$ disappears on normalisation, so the normalised measure is the same as under the convention $e^{\beta\sum_p \operatorname{Re} U_p}$ of the Wilson measure of 19-01.

Lean: the action `WilsonGauge.wilsonAction N hT`, the per-plaquette quantity `WilsonGauge.plaqE` ($1 - \frac{1}{2}\operatorname{Re}\operatorname{tr}(ABC^\dagger D^\dagger)$), the quaternion matrix `FermionSU2Config.quatMat`, and links as matrices on the configuration space `WilsonGauge.physSp` (space) and `WilsonGauge.physT` (time).

04

The Wilson–Dirac operator

The fermion field $\psi(t,x)$ is a complex vector carrying at each point 4 spin components and 2 colour components. The operator $D_m(U)$ is a square matrix on $\mathbb{C}^{2h\cdot N^3\cdot 4\cdot 2}$, and

we take Wilson's form with $r = 1$,

$$(D_m(U)\psi)(z) = (m+4)\,\psi(z) - \frac{1}{2}\sum_{\mu=1}^{4}\Big[(1-\gamma_\mu)\,U_\mu(z)\,\psi(z+e_\mu) + (1+\gamma_\mu)\,U_\mu(z-e_\mu)^\dagger\,\psi($$

$U_\mu(z)$ acts on the colour index as a 2×2 matrix, and γ_μ acts on the spin index. $m \in \mathbb{R}$ is the bare mass.

The γ matrices. The spin index is written as a pair $(s, r) \in \{0,1\}^2$. s is ordered by the eigenvalues of γ_4, $+1$ ($s=1$) then -1 ($s=0$), and with the Pauli matrices $\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $\sigma 2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$, $\sigma 3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$,

$$\gamma_4 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad \gamma_i = \begin{pmatrix} 0 & -i\sigma_i \\ i\sigma_i & 0 \end{pmatrix} \quad (i = 1,2,3) \tag{5}$$

(blocks in the order $s = 1, 0$, each block 2×2 in r). This is the arrangement exactly as in the Lean definition. They satisfy $\gamma_\mu^2 = 1$, $\gamma_\mu\gamma_\nu = -\gamma_\nu\gamma_\mu$ ($\mu \neq \nu$) Proved here .

Boundary conditions. Antiperiodic in all four directions. In space direction i, on the links leaving $x_i = N-1$, and in the time direction, on the link from $t = 2h-1$ to 0, the hopping term is multiplied by the sign -1. The gauge link variables themselves are periodic; the sign is attached to the hopping of the operator.

Lean: the operator `WilsonGauge.physDirac N hT m ω`. Its content is the per-time-slice form `FermionSliceBlock.std4` (the operator (4) with $r = 1$; within a slice, `FermionSliceBlock.stdSlice`), with spatial hopping `FermionSliceBlock.torusX` (boundary signs in `FermionSliceBlock.torusLink`) and temporal hopping (boundary sign `FermionSliceBlock.eps`) inserted. γ is `FermionSliceBlock.gammaT` (γ_4) and `FermionSliceBlock.gammaSp` (γ_i).

The component formula is in Lean: `WilsonGauge.physDirac_apply` says that each component of physDirac has the form (4).

Reading On random configurations, with $m \in \{0.3, -0.7, -4.0\}$ for $2^3 \times 2$ and $m \in \{0.3, -0.7\}$ for $2^3 \times 4$, a literal transcription of `physDirac` was compared with an operator written independently from (4) in another representation of γ (mapped by the change-of-representation matrix), and the component differences were at most 3.6×10^{-15} (numerical record of this book's investigation. Removing the boundary sign in time makes the difference 2.0, which confirms that the comparison is effective).

```
05
```

The determinant weight

With $2j$ flavours ($j = 0, 1, 2, \ldots$), the fermion weight is

$$F_{m,j}(U) = \mathrm{Re}\big(\det D_m(U)\big)^{2j} \quad (6)$$

For $j = 0$, $F \equiv 1$ Proved here .

Proved here For all $m \in \mathbb{R}$, all j and all configurations, the imaginary part of $(\det D_m(U))^{2j}$ is 0 and its real part is at least 0. Lean: `FermionSliceReflection.wilson_weight_nonneg_std4` (the torus form `FermionSliceReflection.wilson_weight_nonneg_torus`); the form on configurations is `WilsonGauge.fermWeight_nonneg`. Hence (6) is a non-negative real number even before taking the real part, and Re is a matter of notation.

$F_{m,j}$ is a continuous function of the configuration (since the matrix entries are polynomials in the components of U) Proved here . Lean's `WilsonGauge.continuous_fermWeight` is continuity on the split coordinates (next paragraph); continuity on configurations is read together with the continuity of the splitting map. Invariance of the weight under global gauge transformations and under lattice symmetries are theorems of Part 20 (20-05).

Lean's `WilsonGauge.fermWeight` writes (6) on coordinates that split a configuration at the reflection plane into "plane, positive side, negative side", and is the same as the form written with the operator on unsplit configurations (`WilsonGauge.physDirac_eq_split`). The splitting is matched to the definition of the positive side in 19-03.

06

The measure with fermions

With the product of the gauge weight and the fermion weight

$$W_{\beta,m,j}(U) = e^{-\beta S_W(U)}\, F_{m,j}(U) \;\geq 0 \quad (7)$$

as density, we set the measure on the space of configurations to be

$$\mu^{\mathrm{wf},0}_{\beta,m,j}(dU) = W_{\beta,m,j}(U) \prod_{\ell \in \mathcal{L}_{N,h}} dU_\ell, \qquad Z^{\mathrm{wf}}_{\beta,m,j} = \int W_{\beta,m,j}(U) \prod_{\ell} dU_\ell \quad (8)$$

(unnormalised). The partition function Z^{wf} is positive for all β, m, j. This is a theorem of Part 20 (20-05, Lean: `WilsonGauge.partition_pos_wilson_full`; the form with density W is `WilsonGauge.wf_partition_pos`). So

$$\mu^{\mathrm{wf}}_{\beta,m,j} = \left(Z^{\mathrm{wf}}_{\beta,m,j}\right)^{-1} \mu^{\mathrm{wf},0}_{\beta,m,j} \quad (9)$$

is called the **Wilson–fermion measure**. It is a probability measure Proved here .

Lean: the density `WilsonGauge.wfWeight N hT j m β`, the unnormalised measure `WilsonGauge.wfMeasure` (the density enters through the truncation `toNNReal` to non-negative reals; since (7) is non-negative the value does not change: `WilsonGauge.wfWeight_nonneg`), the normalised measure `WilsonGauge.wfProb N hT j m β`, and that it is a probability measure is `WilsonGauge.wfProb_isProbability` ($h \geq 1$).

This measure is also one of the measures to be pushed by the block map (19-04 § 06).

07 The range of the mass

The definitions (4) to (9) make sense for every real m. Non-negativity of the weight and $Z^{\mathrm{wf}} > 0$ also hold for every m. The range narrows on the side of the theorems.

Object or property	Range of the mass m	Where
The operator D_m, the weight $F_{m,j} \geq 0$, the measure μ^{wf}	All $m \in \mathbb{R}$	This chapter
$Z^{\mathrm{wf}} > 0$, invariance under lattice symmetries	All m	20-05
Reflection positivity through lattice-point time planes	$m > -1$	20-05

$m > -1$ includes $m = 0$ and small negative masses. Reflection positivity for $m \leq -1$ is outside the Lean statements of this book. m is a bare parameter, and its relation to the physical mass (tuning to the critical mass) is not defined in this chapter.

08 The relation to the conventions for gauge-field measures

We summarise the differences between the measure of the other chapters of Part 19 (19-01) and the measure of this chapter.

Item	The Wilson measure of 19-01	The measure of this chapter
Lattice	$(\mathbb{Z}/N)^4$, or the torus with transverse size N and longitudinal size M	$(\mathbb{Z}/2h) \times (\mathbb{Z}/N)^3$
Gauge weight	$e^{\beta \sum_p \mathrm{Re}\, U_p}$	$e^{-\beta S_W}$. Differs only by a constant multiple (equation (3))
Haar measure	On the strong-coupling side, the product of the Haar measure of the sphere pushed forward to the closed ball (19-01, the Lean conventions)	The product of Haar probability measures on the unit sphere of $SU(2)$

Item	The Wilson measure of 19-01	The measure of this chapter
Normalisation	Unnormalised $\tilde{\mu}_{N,\beta}$ (`TorusRP.wilsonMeasure`) and normalised $\mu_{N,\beta}$ (`TorusRP.wilsonProb`). The vortex side is written with ratios of partition functions	Both the unnormalised (8) and the normalised (9) are set up
Boundary	Gauge links periodic (twists in 19-02)	Gauge links periodic, fermions antiperiodic in all four directions

Proved here For $j = 0$, $F \equiv 1$, so $\mu^{\mathrm{wf}}_{\beta,m,0}$ is the normalised Wilson measure on the lattice $\Lambda^{\mathrm{wf}}_{N,h}$, and does not depend on m.

The declarations of this chapter are in the namespaces `WilsonGauge`, `FermionSliceBlock` and `FermionSU2Config`, and are definitions separate from `TorusRP.wilsonMeasure` and `TwistedWilson.ZW` of 19-01. When all four directions have the same size (spatial side $N = 2h$, $2h > 1$), it is shown in Lean that pushing forward the pure-gauge measure `WilsonGauge.gaugeMeasure` (a definition without j, whose density is the same as $\mu^{\mathrm{wf},0}$ at $j = 0$ Proved here) by the re-indexing gives a constant multiple of the Wilson measure of the strong-coupling side (`WilsonGauge.wilsonMeasure_eq_map`, 19-01, bridges). There is no theorem connecting the twisted vortex side with the measure of this chapter.

What this chapter can say

Can say	Cannot say
Proved here $\frac{1}{2}\operatorname{Re}\operatorname{tr} U_p = \operatorname{Re} U_p$, and the gauge weight differs from the convention of 19-01 only by a constant multiple (the Lean bridge for $N = 2h$ is in 19-01)	Connecting by Lean theorems to lattices with $N \neq 2h$ or to twisted measures
Proved here For all m and j, $(\det D_m)^{2j}$ is a non-negative real number. Lean: `FermionSliceReflection.wilson_weight_nonneg_std4`	The sign of $\det D_m$ itself (before raising to the power $2j$)
Proved here The normalised μ^{wf} is a probability measure ($Z > 0$ is in 20-05). Lean: `WilsonGauge.wfProb_isProbability`	An odd number of flavours; the Grassmann integral itself
Reading Difference between `physDirac` and an independent transcription of (4) $\leq 3.6 \times 10^{-15}$ (small lattices)	The numerical comparison is for small lattices only. The component formula for general N, h is in Lean (`WilsonGauge.physDirac_apply`)
Proved here At $j = 0$ it returns to the Wilson measure	Mass renormalisation, chiral symmetry, the continuum limit

Lattice, action, operator, weight, measure (§ 02 to § 06)	Lean	Lean definitions from this book's investigation (declarations of `WilsonGauge`, `FermionSliceBlock`, `FermionSU2Config`, `FermionSliceReflection`; names in the text). Table of correspondence in 19-06
Numerical cross-check of the operator (§ 04)	Reading	Numerical record of this book's investigation: comparison of the operator transcribed from the Lean text with the operator written independently from (4) (removing the boundary sign in time gives a difference of 2.0, confirming that the comparison is effective)

Words used in this chapter — Wilson–Dirac operator, Wilson term, antiperiodic, physical link, bare mass, flavour, fermion weight, Wilson–fermion measure. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-06 Objects and their Lean definitions — a table of correspondence — makes every object of Part 19 searchable in tables of symbol, meaning, Lean name and the parts that use it.

Objects and their Lean definitions — a table of correspondence

> This chapter is an index.

What this chapter shows — The objects of Part 19 can be looked up from the book's notation to the names of Lean declarations, and from Lean names to the book's notation. Each row gives the anchor of the chapter where the definition is placed, and the parts that state theorems about the object.

Prerequisite chapters — None. Follow the anchor of each row to the defining chapter.

Said first — These tables list only the correspondence of definitions. The names of theorems are in the chapters of each part. Lean names are declaration names; locations (files) are not listed. Where the same object is defined separately in several lines (four: strong coupling, vortices, fermions, ultraviolet), the rows are split by line (the differences in convention are in 19-01 § 07).

The order of this chapter

1. How to read these tables — the meaning of the columns, and namespaces
2. Lattice, links, measures (19-01)
3. Twist, the vortex ratio, Polyakov loops (19-02)
4. Reflection, the vessel, infinite volume (19-03)
5. The block map and the multi-step family (19-04)
6. The fermion weight (19-05)
7. Correspondence between lines (bridges) — identifications closed in Lean
8. List of namespaces — finding the line from the head of a Lean name

---

01

How to read these tables

The columns of each table are "Symbol", "Meaning", "Lean declaration", "Defining chapter" and "Parts that use it". Symbols are those of the text; Lean declarations are written in the form `Namespace.name`. Arguments (`N`, `M`, `β` and so on) are omitted in places. "Parts that use it" are the parts that state theorems or premises about the object.

The Lean bundle is written in the four lines of 19-01, the Lean conventions (strong-coupling side, vortex side, fermion side, ultraviolet side). The convention for numbering directions is in 19-01 § 01 (20-01 to 20-05 use 0 to 3 with 0 as time; Parts 21 and 22 and 20-06 use 1 to 4). The lattice on the ultraviolet side is a box of side $2^m L$, and link values are in the closed unit ball (19-04 § 02). Even for the same mathematical object, different lines give different declarations. The bridges connecting the lines in Lean are gathered in 19-01, bridges.

The letter m means different things in different chapters: in 19-02 the side of a vortex block, in 19-04 the step number (the m of Lean's `stageCov m L` is also a step), and in 19-05 the bare mass.

02

Lattice, links, measures (19-01)

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
Links of $(\mathbb{Z}/N)^4$	Links of the torus of the same size in all four directions (point × direction)	`TorusRP.Lk`	19-01 #lattice	20
$(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$	Points of the torus with transverse size N and longitudinal size M	`TwistedWilson.Site`	19-01 #lattice, 19-02	20, 21
$U_\ell \in SU(2)$	Link variables. Unit quaternions	`OSGap.SU2`, `TwistedWilson.SU2`, `FermionSU2Config.SU2`	19-01 #su2	15, 20, 21, 22
$\{\lvert q\rvert \le 1\}$	The closed unit ball of quaternions (link values on the strong-coupling and ultraviolet sides)	`TorusRP.QBall`, `ChainBlockMap.Ball`	19-01 #conventions	15, 20

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
dU	The normalised Haar measure and its product	`OSGap.haarProb`, `TwistedWilson.haarProb`, `TorusRP.haarBall`, `TwistedWilson.haarCfg`	19-01 #haar	15, 20, 21, 22
U_p, Re U_p	Plaquette holonomy and its real part	`TorusRP.hol`, `TwistedWilson.hol`	19-01 #plaquette	15, 20, 21, 22
$\sum_p$ Re U_p	The action on the strong-coupling side (positive sign)	`TorusRP.action`	19-01 #wilson-measure	20, 22
$\tilde{\mu}_{N,\beta}$, $\mu_{N,\beta}$	The Wilson measure (unnormalised $\tilde{\mu}$) and the normalised μ. $\tilde{\mu}_{N,\beta} = Z_N(\beta)\mu_{N,\beta}$	`TorusRP.wilsonMeasure`, `TorusRP.wilsonProb`	19-01 #wilson-measure	20, 22
$Z_N(\beta)$	The partition function (total mass of $\tilde{\mu}_{N,\beta}$)	The value of `TorusRP.wilsonMeasure` on the whole space	19-01 #partition	20, 22

03

Twist, the vortex ratio, Polyakov loops (19-02)

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
n_{12}, n_{34}, z_p	Presence of twists, and the sign of each plaquette	`TwistedWilson.zt`	19-02 #twist	20, 21
Z_0, Z_1	Partition functions under the background $n_{12} = 1$ ($n_{34} = 0, 1$)	`TwistedWilson.ZW`	19-02 #twist	20, 21
θ_M	The vortex ratio $(Z_0 - Z_1)/(Z_0 + Z_1)$	`TwistBlocks.thetaM`	19-02 #theta	20, 21
$P_b(t)$	The Polyakov loop once around direction 3, and the expectation of a pair	`HalfSplit.polyLoop`, `PolyakovT.polyExp`	19-02 #polyakov	21
$S_{\mathrm{v}}(N, m)$, S_N	The infimum of the vortex action, and its infimum over m (the minimal action of a vortex)	`TwistBlocks.Svortex`, `TwistBlocks.SN`	19-02 #vortex-action	21

04

Reflection, the vessel, infinite volume (19-03)

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
Θ	Reflection (lattice-point planes, middle planes). The general form written as a pair of a map on link indices and a map on values	`LinkReflection.linkRefl`; concrete reflections `TorusRP.thL`, `TorusRP.sig` (lattice-point planes), `MidRP.thM` (middle planes), `HalfSplit.Th` (vortex side)	19-03 #reflection	20, 22
Positive side	Links on the positive side of the reflection (lattice-point planes, middle planes), and links within the mirror plane	`TorusRP.posP`, `TorusRP.fixP`, `MidRP.posM`	19-03 #positive-side	20
Pairing	A bilinear form of the form $\int F(\Theta\omega)G(\omega)\,d\mu$	`OrbitGrowth.pairingForm` (the field `OSGap.Datum.B` of the vessel; the vessel built from a measure, `OSGap.measureDatum`)	19-03 #pairing	20
T, Ω, P_Ω	The vessel of reconstruction (pairing form, time translation, constant), and the transfer operator, vacuum and projection onto the vacuum	`OSGap.Datum` (fields `B`, `τ`, `one`); objects built: `OSGap.Datum.Hilb`, `OSGap.Datum.T`, `OSGap.Datum.Ω`; projection `OSGap.vacProj`	19-03 #datum	20
Mass gap m	$\|T - P_\Omega\| \le e^{-m}$	`OSGap.Datum.HasMassGap`	19-03 #mass-gap-def	20, 28
ν_β	The periodic lift to $\mathbb{Z}^4$ of the normalised measure on $(\mathbb{Z}/2(n+1))^4$, and its limit	`WilsonLimit.liftProb`	19-03 #infinite-volume-space	20

05

The block map and the multi-step family (19-04)

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
Coarse link $b = (y, \mu)$ of Λ_m	Links of the torus of side $2^m L$. To the fine lattice by $y \mapsto 2y$	`BoxWalk.BoxLk`, `BoxWalk.double`, `BoxWalk.base`	19-04 § 02	15

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
$\gamma_{o,A}(b)$	The family of paths (order o, transverse offset A)	`WalkCast.walk`, `BoxWalk.boxPathsIdx`, `BoxWalk.boxPaths`	19-04 #paths	15
$w(o,A)$	Path weights $\frac{1}{6}\prod_t \mathrm{wt}(d_t)$, $\mathrm{wt} = (1/8, 3/4, 1/8)$	`ChainBlockMap.wt`, `ChainBlockMap.sixWeight`, `BoxWalk.boxW`	19-04 #paths, #weights	15, 28
$U(\gamma)$, $q_b(U)$	The product along a path, and its weighted average	`ChainBlockMap.pathProd`, `ChainBlockMap.sixAvg`, `ChainBlockMap.coarseAvg`	19-04 #block-map	15
ρ_{r_0}	The retract with threshold r_0, $q/\max(\lvert q\rvert, r_0)$	`ChainBlockMap.retract`	19-04 #block-map	15
B	The non-linear block map, and the composed map over steps	`ChainBlockMap.blockMap`, `ChainBlockMap.down`	19-04 #block-map	15, 28
C	The path kernel (the linear part of B about the identity), and its coefficients and operator	`BlockLinear.sixSgn`, `LatticeTorus.pathKernel`, `TorusFourier.Cop`, `PushCov.blockLin`	19-04 #path-kernel	15
$e^{\varepsilon a}$	The exponential configuration of a field of imaginary quaternions	`BlockLinearKernel.expCfg`	19-04 #path-kernel	15
$B_*\mu$, $\nu_{n,m}$	The push-forward measure, and the multi-step push-forward	`Measure.map`, `ChainBlockMap.vP`	19-04 #pushforward	15, 28
cov_μ	The covariance form	`PushCov.covForm`	19-04 #pushforward	15
$\mathrm{freeCov}_N$, $\mathrm{stageCov}_{k,N}$	The covariance of the free field (Feynman gauge), and the covariance at a step, pushed k times by C	`LatticePush.freeCov`, `LatticePush.stepOp`, `LatticePush.pushOp`, `LatticePush.stageCov`	19-04 #family	15
curl, plaquette covariance	The plaquette field, and its covariance	`LatticeFace.curl`, `LatticeFace.faceCov`	19-04 #family	15

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
$\omega(q)$, $P(q)$	$\sum_\nu 4\sin^2(q_\nu/2)$, and the projection onto the physical part	`OneStepET.omF`, `OneStepBridge.Pfam`	19-04 #family	15
Momenta with $\omega > 0$, $r_\zeta(q)$	The domain (coordinates $\theta = q/4$) and the 16 aliases	`OneStepFinal.Qpos`, `OneStepBridge.thR`, `OneStepFinal.rqPos`	19-04 #family	15
$\mathcal{M}$, A_ζ	The one-step map for each momentum, and its matrices	`OneStepBridge.Mfam`, `OneStepBridge.AM`	19-04 #family	15
G_k	$\mathcal{M}^k(P/\omega)$	`TauSplit.Gs`, `TorusLam.Gst`	19-04 #family	15

06

The fermion weight (19-05)

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
$\mathcal{L}_{N,h}$	Physical links of time circle $2h \times$ space $(\mathbb{Z}/N)^3$	`FermionSU2Config.PhysLink`	19-05 § 02	20
SW	$\sum_p(1 - \frac{1}{2}\operatorname{Re}\operatorname{tr}U_p)$ (negative-sign convention)	`WilsonGauge.wilsonAction`, `WilsonGauge.plaqE`	19-05 § 03	20
$D_m(U)$	The Wilson–Dirac operator ($r = 1$, antiperiodic in all four directions)	`WilsonGauge.physDirac`, `FermionSliceBlock.std4`	19-05 #wilson-dirac	20
γ_μ	γ_4 and γ_i	`FermionSliceBlock.gammaT`, `FermionSliceBlock.gammaSp`	19-05 #wilson-dirac	20
$F_{m,j}$	$\operatorname{Re}(\det D_m)^{2j}$	`WilsonGauge.fermWeight`	19-05 § 05	20
$W_{\beta,m,j}$, μ^{wf}	The density, and the Wilson–fermion measure (unnormalised, normalised)	`WilsonGauge.wfWeight`, `WilsonGauge.wfMeasure`, `WilsonGauge.wfProb`	19-05 #fermion-measure	15, 20
Pure-gauge measure	The measure with density $e^{-\beta SW}$ (a definition without j, $N = 2h$)	`WilsonGauge.gaugeMeasure`	19-01 (bridges), 19-05 § 08	20

Symbol	Meaning	Lean declaration	Defining chapter	Parts that use it
Θ (fermion side)	The action of the time reflection $t \mapsto -t$ on configurations	`WilsonGauge.thetaPhys`	19-03 #reflection	20, 22

07

Correspondence between lines (bridges)

Declarations showing in Lean that two definitions from different lines are the same object. The explanation is in 19-01, bridges.

What it connects	What it says	Lean declaration	Range
Strong-coupling side ↔ vortex side (measures)	$\tilde{\mu}_{N,\beta}$ (`TorusRP.wilsonMeasure N β`) equals the measure given by the product of Haar measures on the vortex side times the weight, transported by a one-to-one correspondence given by definition. No constant factor	`WilsonBridge.wilsonMeasure_eq_map`	Only for $M = N$ with no twist. There is no bridge for twisted measures (background $n_{12} = 1$)
Same (expectations, total mass)	The expectations of measurable observables, and the total mass $Z_N(\beta)$, agree on the two sides	`WilsonBridge.integral_wilsonMeasure`, `WilsonBridge.wilsonMeasure_univ`	
Same (correspondence aligning time)	Under the correspondence that overlays time on the strong-coupling side (index 0) with index 3 on the vortex side, the measures also agree, and the reflections through lattice-point planes on the two sides become the same map	`WilsonBridgeT.wilsonMeasure_eq_mapT`, `WilsonBridgeT.refl_toBallT`	
Same (vortex ratio)	Writes the vortex ratio with no background twist ($n_{12} = 0$) as an expectation under the probability measure of the strong-coupling side. It is not the book's θ_M ($n_{12} = 1$)	`WilsonBridgeV.vortex_ratio_eq`	

What it connects	What it says	Lean declaration	Range
Strong-coupling side ↔ fermion side	$\tilde{\mu}_{2h,\beta}$ is $e^{6(2h)^4\beta}$ times the pure-gauge measure `WilsonGauge.gaugeMeasure` transported by re-indexing	`WilsonGauge.wilsonMeasure_eq_map`	Spatial side $N = 2h$, $2h > 1$

Declarations connecting the ultraviolet side with the other lines by a single theorem are not included in this table (for re-indexing of measure types, see 19-04 § 06).

08

List of namespaces

From the head of a Lean name (its namespace), one can find which line the declaration belongs to.

Namespace	Line	Main objects
`TorusRP`, `OSGap`, `LinkReflection`, `MidRP`, `OrbitGrowth`, `WilsonLimit`	Strong-coupling side	The Wilson measure on $(\mathbb{Z}/N)^4$, the vessel, infinite volume
`TwistedWilson`, `TwistBlocks`, `HalfSplit`, `PolyakovT`	Vortex side	Twisted tori, θ_M, vortex action, Polyakov loops
`WilsonBridge`, `WilsonBridgeT`, `WilsonBridgeV`	Bridges between the strong-coupling and vortex sides	Agreement of measures for $M = N$ with no twist
`WalkCast`, `ChainBlockMap`, `BoxWalk`	Ultraviolet side (non-linear)	The family of paths, the block map, push-forward
`BlockLinear`, `BlockLinearKernel`, `LatticeTorus`, `TorusFourier`, `PushCov`	Ultraviolet side (linear part)	The path kernel, the covariance form
`LatticePush`, `LatticeFace`, `OneStepBridge`, `OneStepET`, `OneStepFinal`, `TauSplit`, `TorusLam`	Ultraviolet side (free field)	Covariances at steps, families over momenta
`WilsonGauge`, `FermionSliceBlock`, `FermionSU2Config`, `FermionSliceReflection`	Fermion side	Physical links, the Wilson–Dirac operator, the Wilson–fermion measure

What this chapter can say

Can say	Cannot say
Proved here The correspondence between the objects of Part 19 and the names of Lean declarations (with anchors to the defining chapters)	Identification between lines only within the range of the bridges of § 07 (there is no bridge for twisted measures)

Sources and reproduction

Item	Kind	Source / tools
Names of Lean declarations and namespaces	Lean	Copied by reading the source of the Lean bundle of this book's investigation. The definition and explanation of each object are in 19-01 to 19-05

Words used in this chapter — object, declaration, namespace, line, bridge. Their meanings are in the A-02 Glossary.

Next chapter to read: 19-07 The statements to be shown — a list of the statements to be shown, written with only the objects defined here.

The statements to be shown — written with defined objects only

> This chapter is this book's own investigation. The reading of the problem statement in § 01 and § 08 arranges established knowledge.

What this chapter shows — Statements of "what would have to be shown" towards the continuum limit and the mass gap, written with only the objects defined in Part 19. First we fix how the sequence β_n of bare couplings is chosen (matching), and then write five statements about that sequence: convergence of the full sequence, non-degeneracy, equicontinuity, the mass gap (uniform decay), and the band. Each can be written as a one-line formula, and none uses undefined quantities (effective couplings, activities and so on). Finally, we tabulate the gap to the problem statement and the nearby forms that are already theorems.

Prerequisite chapters — The definitions of the objects are in 19-01 The Wilson measure, 19-02 The vortex ratio, 19-03 The definition of the mass gap and 19-04 The push-forward measure. The problem statement is in 0-03, and the definition of the mass gap in 4-11.

Said first — Every statement in this chapter is set down without a proof Assumption . This book shows none of them. The first four (matching, convergence of the full sequence, non-degeneracy, equicontinuity) are statements on the ultraviolet side, written for this book's design (the measure pushed forward by a fixed block map). The existence of four-dimensional Yang–Mills theory was shown, with a different design, by the construction published on 2026-11-10, and the committee's assessment is that it is proved in Lean (Volume 2; a comparison of the two designs is in Part 14, and the record of this book's ultraviolet attempts in Part 15). The first four are therefore kept as a record of the statements to be shown in this book's design. The last two (uniform decay, with the mass gap as its consequence, and the band) are statements on the infrared side and remain open. They are the main subject of Volume 3. The five statements have content only when read for the sequence β_n fixed by matching. Read in a form where the sequence can be chosen freely, the mass-gap and band statements hold just by setting the coupling to 0 (§ 01). Choices remain in how the matching is done. Of the requirements of the problem statement, fine observables and rotation invariance do not yet have the objects needed to write statements (§ 08).

The order of this chapter

1. Setting — one box, and a sequence of finer lattices
2. Matching — how the sequence of bare couplings is fixed
3. Convergence of the full sequence — for the matched sequence, without passing to subsequences
4. Non-degeneracy — the coarse field stays in small fields
5. Equicontinuity — uniformly in physical position
6. Uniform decay — uniformly in lattice spacing and box (the consequence is the mass gap)
7. The band — the vortex ratio becoming small exponentially in the area
8. The gap to the problem statement — separate stages, and stages whose objects do not yet exist
9. Nearby forms that are already theorems (Table 2)

01

Setting — one box, and a sequence of finer lattices

What the problem statement asks for is a theory on infinitely extended continuous four-dimensional space (0-03 § 03). In this chapter, as a stage before that, we consider bringing the lattice spacing towards 0 on **one box of fixed size**. The objects used in the statements are only those defined in Part 19.

Let the size of the box be a positive integer L. Only the matching of § 02 is done on a box of one fixed **reference size** L_{ref}. The statements of § 03 to § 05 are about a box of one fixed size L (not limited to $L = L_{\mathrm{ref}}$), and in § 06 and § 07 the sizes L and L_0 vary. The lattice at step $n \geq 0$ is

$$\Lambda_n = (\mathbb{Z}/2^n L)^4 \quad (1)$$

and the lattice spacing at step n is read as $a_n = 2^{-n}$. Read this way, the lattice at every step subdivides the same box of side L. The larger the step number, the finer the lattice (the same direction as in 19-04 § 02). The direction playing the role of time is direction 0 in the numbering of Part 20 in 19-01 (direction 1 in the numbering 1 to 4 of 19-04; 19-04 itself does not specify a time direction).

Four objects are used.

Symbol	Contents	Definition
μ_n^β	The normalised Wilson measure on Λ_n (coupling β). Once the sequence of couplings (β_n) is fixed, $\mu_n := \mu_n^{\beta_n}$	19-01. Lean: `TorusRP.wilsonProb`
$\nu_{n,m}$	The measure μ_n pushed by the block map down to step $m \le n$. A probability measure on configurations of the coarse lattice Λ_m	19-04. Lean: `ChainBlockMap.vP`
$\theta_{N,M}(\beta)$	The ratio $(Z_0 - Z_1)/(Z_0 + Z_1)$ of the partition functions without and with the (3,4) twist, on the torus with transverse size N and longitudinal size M, with the background twist $n_{12} = 1$ fixed	19-02. Lean: `TwistBlocks.thetaM`
The vessel and the mass gap	The Hilbert space, transfer operator T and vacuum Ω built from a measure. $\|T - P_\Omega\| \le e^{-m}$ is called a gap of mass m	19-03. Lean: `OSGap.Datum.HasMassGap`

$\nu_{n,m}$ is the theory on the fine lattice of step n, viewed at the fixed resolution of step m. Holding step m fixed and letting $n \to \infty$, we see the limit in which the lattice spacing a_n approaches 0, on the same coarse lattice. The push-forward is a rule for making coarse fields; no decomposition (representation) into an effective action is used.

The space of configurations is compact (a finite product of balls). So at each step m, $\nu_{n,m}$ converges weakly along a subsequence, and by the diagonal argument a subsequence common to all steps can be taken Proved here . **Subsequential limits exist without any premise**, so the statements to be shown have meaning only in forms stronger than that. The following six are all of that form.

Read together with the matching. Each of the five statements of § 03 to § 07 involves the sequence of couplings (β_n). Read in a form where the sequence can be chosen freely, the statements lose their content.

- Setting $\beta_n \equiv 0$, the fine measure is the product of Haar measures. Since the block map is local, coarse variables separated in time are independent and their covariance is 0. So the mass-gap statement (§ 06) holds for this sequence Proved here . Also, at $\beta = 0$ the partition function does not change with or without the twist, $Z_0 = Z_1$, so $\theta = 0$, and the band statement (§ 07) holds too Proved here .
- Taking β_n large pushes the fine measure towards flat configurations, and the non-degeneracy statement (§ 04) is expected to become easier to satisfy.

Conversely, read as "for every sequence", there are expected to be sequences for which they are false (for instance, for a sequence alternating between the strong-coupling end and the weak-coupling end, convergence of the full sequence cannot be expected). So in this chapter we first fix one sequence (β_n) by **matching** in § 02, and write the five of § 03 to § 07 **for that sequence**. Note also that the theorems in the strong-coupling window (§ 09) lie in the direction on which the mass-gap statement holds trivially.

02

Matching — how the sequence of bare couplings is fixed

The coupling β on the lattice is, in the continuum limit, not an "input" but a number adjusted to calibrate the lattice spacing (introduction in 5-05 § 02). Here we write that adjustment with defined objects only.

The matching rule. Choose a step m_0, a bounded continuous function Y_0 of the coarse configuration at step m_0 (for example, the average of $\mathrm{Re}\, U_p$ over coarse plaquettes), and a target value κ_0. For each step $n \ge m_0$, set

$$f_n(\beta) = \int Y_0 \, d\nu_{n,m_0}^{\beta}, \qquad \beta_n \text{ a solution of } f_n(\beta_n) = \kappa_0 \quad (2)$$

Here ν_{n,m_0}^{β} is the push-forward of the Wilson measure with coupling β on the box of reference size L_{ref}.

Existence of solutions. f_n is continuous in β Proved here . Reason: $f_n(\beta)$ is the ratio of two integrals with respect to the product of Haar measures, $\int (Y_0 \circ B)\, e^{\beta S}$ and $\int e^{\beta S}$ ($S = \sum_p \mathrm{Re}\, U_p$, B the composed map from step n to step m_0). The integrands are bounded and continuous in β, and the configuration space is compact, so both integrals are continuous by dominated convergence, and the denominator is positive. Hence if κ_0 lies between two values $f_n(\beta')$, $f_n(\beta'')$, there is a solution in $[\beta', \beta'']$ by the intermediate value theorem Proved here . Whether κ_0 falls in this range for every n depends on the choice of Y_0 and m_0.

Where choices remain. (i) How Y_0, m_0 and κ_0 are chosen. (ii) Since the solution is not necessarily unique, which solution is taken (for example, the largest solution in a fixed interval). These two are design choices, and are listed in the table of 28-05.

The statement to be shown. If solutions exist for every n, the matching rule fixes one sequence. The existence of solutions hinges on checking the end values, which has not yet been done. Beyond that, what must be shown is that the sequence so fixed falls within **a bracket on how the coupling runs**.

Assumption `Matching: there are` β_* `and` $0 < b_- \le b_+$ `such that` $\beta_* + b_- n \le \beta_n \le \beta_* + b_+ n$ `for every` n

It is the form in which β increases by roughly a fixed amount each time the lattice spacing is halved. It corresponds to the logarithmic running $\beta \sim \text{const} \times \log(1/a)$ predicted by one-loop asymptotic freedom, written in terms of $n = \log_2(1/a_n)$ (introduction in 5-05 § 03). In the conditional implication assembled in this book's study (weak ultraviolet existence in a small box), a bracket with $b_\pm$ taken as constant multiples of the one-loop coefficient (the matching bracket for the bare coupling) was placed in a form that follows from an assumption on the effective coupling (the one-step bracket assumption for the coupling) (28-01).

The treatment of the sequence of couplings differs between that implication and Lean. The implication defines and uses the fine measure as "the Wilson measure at the β_n chosen by the matching bracket for the bare coupling" (the implication's β_n is chosen by matching the effective coupling to a target value, a different matching from the rule (2) of this section). The Lean theorems take an arbitrary sequence of bare couplings and do not tie it to that choice.

The convention from here on. The matching is done once, on the box of reference size L_{ref}, and the resulting sequence β_n (the coupling at lattice spacing $a_n = 2^{-n}$ of step n) is used for boxes of every size. In § 03 to § 07, β_n is this sequence, $\mu_n = \mu_n^{\beta_n}$ is the Wilson measure of the box of the size under consideration, and $\nu_{n,m}$ is its push-forward. When the size is varied in § 06 and § 07, the sequence is the same.

03

Convergence of the full sequence — without passing to subsequences

Assumption `Convergence of the full sequence: for the sequence $\beta_n$ fixed by matching, for every step $m$ and every bounded cont`

In other words, at each step m, $\nu_{n,m}$ converges weakly to some measure ν_m without passing to subsequences. Then, since the block map is continuous, push-forward and limit commute, and ν_m satisfies the consistency relation $(B_m)_*\nu_{m+1} = \nu_m$ Proved here . The consistent family (ν_m) gives the "continuum-limit theory" on the box of size L at all resolutions at once.

As in § 01, subsequential limits exist without any premise. The content of this statement is that "every subsequence gives the same limit". If the limit depended on the subsequence, the theory would not be determined uniquely.

This statement does not constrain the sequence of couplings, so it is read for the sequence fixed by the matching of § 02. Without a fixed matching, it is not determined what theory the limit is the limit of.

The conclusion of the conditional implication assembled in this book's study goes only as far as convergence along a subsequence (28-01). That implication has an assumption related to convergence of the full sequence (the summability-of-increments assumption), but it is **not the same as this statement**. The summability-of-increments assumption says that, for a countable dense family of gauge-invariant functions, the step-by-step increments of the values of observables are summable. Being summable, it is stronger than this statement, and the family of functions is also different. The step from gauge-invariant functions to all bounded continuous functions is an argument on paper, going through the invariance of the limiting measure under gauge transformations (28-02).

04

Non-degeneracy — the coarse field stays in small fields

Choose a fixed finite region R_m of the coarse lattice at step m (not the whole box, but a region of fixed physical size). The set of configurations in which the coarse links in R_m are close to unit length and the coarse plaquettes are nearly flat is called the **small-field set** C_m. For example, choosing a threshold $y_m > 0$,

$$C_m = \{U : \ |U_b| \geq 1 - \epsilon_m \text{ for every coarse link } b \text{ of } R_m, \ \ \beta_m (1 - \operatorname{Re} U_p) \leq y_m \text{ for every coarse plaquette } p \text{ of } R_m\} \quad (3)$$

(a closed set). β_m is the m-th term of the sequence fixed by matching ($m \geq m_0$). $\epsilon_m < 1$ and y_m are fixed **before the statement** to be as small as later stages (perturbative expansion) can use (for example, for a fixed angle φ_c setting the small-field threshold, below the floor $y_m \leq \beta_m(1 - \cos\varphi_c)$ at which the angle of plaquette values is at most φ_c). Coarse link values lie in the closed unit ball and $1 - \operatorname{Re} U_p \leq 2$, so taking $\epsilon_m \geq 1$, $y_m \geq 2\beta_m$ makes C_m the whole configuration space, and the statement holds trivially Proved here . How R_m is taken is also a choice. Written for the whole box, η_m could approach 1 with the volume, so it is written in the form of a region.

Assumption `Non-degeneracy: for the sequence $\beta_n$ fixed by matching and $(R_m, \epsilon_m, y_m)$ fixed beforehand, for every step $m$ there is`

Meaning: however fine the lattice pushed from, the coarse field at step m stays in the small-field region with at least a fixed probability. The same lower bound remains for the limit ν_m (C_m is closed), so the limiting measure gives positive weight to the small-field region Proved here . It is an entrance condition for entering later stages (the range where perturbative expansion can be used).

$\eta_m < 1$ is the content of the statement. Allowing $\eta_m = 1$, it holds for any measure. Also, this statement is expected to be of the kind that becomes easier to satisfy the larger the coupling is taken (§ 01). That is why it is read for the sequence fixed by matching.

05

Equicontinuity — uniformly in physical position

The continuum-limit theory should have observables not only at lattice points but at any position in the box. This is the statement for that.

Choose one family of observables. Let D be the countable dense set of positions x in the box $(\mathbb{R}/L\mathbb{Z})^4$ that are lattice points at some step $\mathrm{lev}(x)$ (dyadic rational points), and to each $x \in D$ assign a bounded continuous function G_x of the coarse configuration at step $\mathrm{lev}(x)$ (a fixed, non-constant local observable G placed at position x). The statement is needed for every local observable G. Taking G constant makes the statement hold trivially, so a single G alone has no content.

$$s_n(x) = \int G_x \, d\nu_{n,\mathrm{lev}(x)} \qquad (n \geq \mathrm{lev}(x)) \quad (4)$$

Assumption Equicontinuity: for the sequence β_n fixed by matching, there are $\tau_n \to 0$ and a function $\Omega(r)$ tending to 0 as $r \to 0$ s

Meaning: the expectations of observables have a modulus of continuity in position that is uniform in n (apart from the error τ_n coming from the lattice subdivision). Combined with convergence of the full sequence, the limit $s(x) = \lim_n s_n(x)$ is uniformly continuous on D, and extends continuously to every position in the box Proved here .

The choice of the family of observables (D, G) follows the form of the conditional implication assembled in this book's study; a cross-check of the definition and statement by another pair of eyes has not yet been done (the family of observables and small-field set in 28-04).

06

Uniform decay — uniformly in lattice spacing and box (the consequence is the mass gap)

We write τ_t for the translation by t steps in the time direction of the lattice at step m (the convention of § 01: direction 0 in the numbering of Part 20 in 19-01). Since the box is periodic, τ_t is defined as a map on coarse configurations. In physical time it is a shift of $a_m t$.

Assumption Uniform decay: for the sequence β_n fixed by matching, there is $m_* > 0$ such that, for every size L, every step m,

The time difference t is limited to half the period. In a periodic box, τ_t returns to the identity with period $2^m L$, and when t equals the period the covariance returns to $\mathrm{Var}(F)$ Proved here . The constants are taken in the form $C_F = c_F \|F\|_\infty$, where c_F is determined only by the number of links F depends on, and does not depend on n or L. m_* is a mass in physical units, depending neither on the lattice spacing nor on the box size. This is the core of the statement.

There are choices in the form of the statement. Whether to take constants for each observable (the form of this chapter), or one constant C uniformly as $C\|F\|_\infty\|G\|_\infty$. Whether observables depend on links near time 0, or on links at exactly time 0 (whose number grows with the volume). For obtaining the mass gap of the vessel, either form suffices Proved here .

The implication that this decay gives the mass gap ($\|T - P\Omega\| \leq e^{-m}$ in 19-03) in the vessel of reconstruction of the limiting measure is written in 28-03. Building the vessel also needs reflection positivity and symmetries of the limiting measure. Reflection positivity of the fine lattice is a theorem of Part 20, but carrying it over to the push-forward measure is on the side of the premises (reflection positivity at the coarse level in 28-04, symmetries of the measure).

The mass gap of the problem statement (4-11 § 01) is a gap in the spectrum of the Hamiltonian of the infinite-volume theory. This statement takes, among the steps toward it, the part "in a box of fixed size, uniformly in the lattice spacing" and makes it uniform in the size of the box as well. The step to infinite volume is a separate row of the table in § 08.

In this chapter the statement is written with this book's push-forward measure, but the core of the question (that correlations of observables on the renormalised lattice decay at an exponential rate, in physical units, uniformly in the cutoff and the volume) is open independently of the design. If it were obtained, the mass gap and the uniqueness of the vacuum of the limiting theory would follow from known general theory. What the published construction has goes only as far as estimates at a polynomial rate at long distances (16-03).

07

The band — the vortex ratio becoming small exponentially in the area

The vortex ratio $\theta_{N,M}(\beta)$ (19-02) is the relative difference of the partition functions when one twist is inserted. Since $Z_1 > 0$, $\theta_{N,M} \leq 1$ Proved here . If M is even, $0 \leq \theta_{N,M}$ also holds (a theorem of 21-06). In the convention of 19-02, the free energy of the vortex (flux) is $\Delta F = \ln(Z_0/Z_1)$, and $\theta = \tanh(\Delta F/2)$. So when θ is small, $-\ln\theta$ is nearly equal to minus the logarithm of ΔF, $-\ln(\Delta F/2)$ (introduction in 25-01).

Subdividing a square box of physical size L_0 at the lattice spacing of step n, the number of lattice points on a side is $2^n L_0$ (even for $n \geq 1$). For the coupling, the sequence β_n matched on the reference box in § 02 is used in the same way for every L_0.

Assumption `Band: for the sequence` β_n `fixed by matching, there is` $c > 0$ `such that, for every` L_0 `and all sufficiently large` n`,`

It is written without the logarithm $-\ln\theta$ so that the statement does not break at $\theta = 0$ (the best case). Lowering c slightly, it is the same as the form $\liminf_n(-\ln\theta) \geq c\,L_0^2$.

Meaning: in the continuum limit, the vortex free energy ΔF becomes small exponentially in the area of the box ($-\ln\theta$ grows in proportion to the area). This is the form of confinement in the language of vortices (an exponential in the area); that writing the band in the naive form "θ stays uniformly away from 1" is not enough is in 26-01 § 04. Crossing the transition between the weak-coupling side (small boxes) and the strong-coupling side (large boxes) with a single c is the content of this statement.

The band statement can be written with θ and Z alone, and does not use the push-forward measure. The present book has no arrow from this statement to the mass gap (28-03, 28-06).

08

The gap to the problem statement — separate stages, and stages whose objects do not yet exist

Between what the problem statement (0-03) asks for and the six statements of § 02 to § 07, there are still stages.

Table 1 The requirements of the problem statement and their relation to the statements of this chapter (as of 2026-11-13)

Requirement of the problem statement	Relation to the statements of this chapter	Objects for writing the statement
On $\mathbb{R}^4$ (0-03 § 03)	This chapter uses a box of size L. Enlarging the box is a separate stage	Can be written by adding one definition (restriction to a window in the box, or periodic extension). In the strong-coupling window it can be written with the periodic lift, and is a theorem (20-03)
Local fields, Schwinger functions (4-10 § 02)	The observables of this chapter are functions of coarse configurations at step m, not point fields	**Not yet available**. Definitions of a lattice gradient flow and of flowed observables are needed
Rotation invariance (the Euclidean group)	The symmetries of the lattice are only the hypercubic group	**Not yet available**. Observables on which rotations finer than the hypercubic ones act, or a block map from a rotated lattice to the standard lattice, are needed
Non-triviality (0-03 § 05)	Not in this chapter	Can be written, but in terms of which quantity is undecided (example: when matched at step m_0, the limiting value of the same observable at another step m_1)
Mass gap (0-03 § 06)	The uniform decay of § 06 is the form on a box, uniform in lattice spacing and box	Available (the vessel is in 19-03)
Agreement at short distances (0-03 § 07)	The bracket of § 02 is only about how the coupling runs, and says nothing about the short-distance form of correlations	—
Any compact simple group (0-03 § 02)	This chapter is $SU(2)$ only	—

For the two of fine observables and rotations, the objects must be defined before the form of the statement can be discussed. The list is in 28-06.

09

Nearby forms that are already theorems

The theorems of Parts 20 to 22 are forms close to one of the six statements (forms at another scale, or for another object). None is literally a special case. All are theorems at **a single scale with the lattice spacing fixed** (or for one linearised step), and do not reach the six statements themselves. The right-hand column of each row says where they fall short.

Table 2 The six statements, and the forms that are already theorems (as of 2026-11-13)

Statement	Form that is a theorem	Chapter, Lean	Where it falls short of the statement
Uniform decay	Cited In the strong-coupling window $0 < \beta$, $18 \tanh \beta < 1$: a gap of mass $-\frac{1}{2}\log(18 \tanh \beta)$ in the vessel of reconstruction of the infinite-volume limit measure, and clustering in the four directions. A formalisation of results of a known type	20-04. `InfMain2.wilson_infvol_main2`	β stays inside a small window, not a matched sequence $\beta_n \to \infty$. The lattice spacing is fixed at 1. The mass is in lattice units, and only a lower bound. Strong coupling is the direction on the side where things hold trivially (§ 01); it is an example in which the statement can be satisfied, not a check of its content
Convergence of the full sequence	Cited In the same window, the lifts of the Wilson measures on periodic boxes converge weakly to the same measure without a subsequence, for every sequence of box sizes. A formalisation of results of a known type	20-03. `AllN.wilson_infvol_allN`, `InfVol.wilson_infvol_unique`	What moves is the size of the box, not the lattice spacing (not the direction of n in this chapter). Only inside the window
The band	Cited The thin-vortex floor: for all real β and $N, M \geq 1$, $\theta_{N,M}(\beta) \leq \tanh(N^2\lvert\beta\rvert)^{M^2}$. A formalisation of one side of a known picture	21-02. `TwistedWilson.twisted_vortex_bound`	The form with the lattice spacing and the transverse size N held fixed and M made large. The exponent $-\ln\tanh(N^2\lvert\beta\rvert)$ goes to 0 as $N \to \infty$, and does not reach the form $N = M = 2^n L_0$
The band	Cited The thick-vortex floor: for any $\varepsilon > 0$, for every sufficiently large β and sufficiently large M, $\lvert\theta_{N,M+1}(\beta)\rvert \leq \exp\bigl(-(M+1)^2 e^{-\beta(S_N+\varepsilon)}\bigr)$ (S_N is the minimal action of a vortex, 19-02). A formalisation of one side of a known picture	21-03. `TwistBlocks.thick_vortex_floor`	Likewise the form with N and the lattice spacing held fixed. The thresholds in β and M are not explicit. The exponent goes to 0 as $\beta \to \infty$
The band	Cited The vortex floor at strong coupling (an upper bound on the vortex free energy): inside the strong-coupling window, on a torus of transverse size N and longitudinal size M, the difference of the twisted partition functions is exponentially small in the area of the longitudinal plane, and the rate per unit area depends neither on the transverse size nor on the longitudinal size. The prefactor (the transverse area) remains. A formalisation of a known type	20-06. `VortexStrongMN.vortex_floor_MN_sharp`	The coupling stays inside the strong-coupling window, while matched sequences leave the window. The lattice spacing is fixed at 1. Strong coupling is the direction on the side where things hold trivially (§ 01); it is an example in which the statement can be satisfied, not a check of its content
Non-degeneracy (a nearby form)	Cited Rarity at one scale: for $\beta \geq 81$, on every torus with even side ≥ 4 and for every set X of plaquettes, the probability that all plaquettes of X have $\mathrm{Re}\, U_p < 0$ is $\leq q_1^{\lfloor\lvert X\rvert/6\rfloor}$, with $q_1 < 1$ independent of the volume. A formalisation of the Chessboard Estimate	22-01. `FoldCap.rarity_explicit`	An estimate for the measure of the fine lattice itself (no push-forward, $m = n$), with the threshold fixed at $\mathrm{Re}\, U_p < 0$. It is not an estimate about the coarse plaquettes of $\nu_{n,m}$ ($m < n$), and is not a special case of non-degeneracy either
(none of the statements)	One step of the free field: for the field obtained by pushing the Gaussian free field m times by the linearised blocking, an estimate of the covariance of the field strength (ratio $\leq 640/9$), and a contraction $< 1/170$ over 17 steps, uniform in the step. Machine-checked in Lean	15-12. `LatticeFace.lattice_face_T1h`, `TorusLam.stage_tau_17`	The free field rather than the Wilson measure, and the linear part rather than the nonlinear block map. Depends on the weights $(1/8, 3/4, 1/8)$. Material, for the free field, toward a sufficient condition for the six statements (the premise of ultraviolet stability in 28-04)

The right-hand column of Table 2 says the same one thing in every row. **The theorems are in forms with the lattice spacing held fixed, or in free-field or linearised forms; there is not a single theorem of the form in which $n \to \infty$ under a matched sequence of couplings β_n.** The distance from the six statements to theorems is visible in the list of premises (28-04), as which premise carries which label.

What this chapter can say

Can say	Cannot say
Assumption The matching bracket, and five statements about the sequence fixed by matching (convergence of the full sequence, non-degeneracy, equicontinuity, uniform decay, the band), have been written with the objects of Part 19 only	None of the statements is shown
Proved here If the sequence is chosen freely, the uniform-decay and band statements hold for $\beta_n \equiv 0$	Whether they hold for the sequence fixed by matching
Proved here Limits along subsequences exist by compactness of the configuration space alone	That the limit does not depend on the subsequence (convergence of the full sequence)
Proved here The matching function $f_n(\beta)$ is continuous in β, and if the target value lies between the end values there is a solution	Whether the target value falls in the range for every n. Uniqueness of the solution. That the matched sequence falls within the bracket
Proved here Under convergence of the full sequence, the family of limits is consistent under push-forward	Non-triviality of the limit. How the limit depends on the choices in matching

Can say	Cannot say
Table 2: the strong-coupling window, the vortex floors with lattice spacing and transverse size fixed, rarity at one scale, and one step of the free field are theorems machine-checked in Lean	None is one of the six statements itself (they are forms with the lattice spacing fixed, or free-field or linearised forms)
The gap to the problem statement (Table 1)	For fine observables and rotation invariance, the objects for writing statements do not yet exist. Statements for the stages of infinite volume and non-triviality are not in this chapter

Words used in this chapter — statement to be shown, matching, bare coupling, bracket on how the coupling runs, push-forward measure, convergence of the full sequence, subsequential limit, non-degeneracy, small-field set, equicontinuity, uniform decay, vortex ratio, exponential in the area, band. Their meanings are in the A-02 Glossary.

Next chapter to read: 20-00 Entrance — what can be said at one lattice spacing — reads the theorems of Table 2 in order, from the definitions. To go to the list of premises first, see 28-00.

Entrance — what can be said at one lattice spacing

This chapter is a guide (the entrance to this part).

What this chapter shows — The list of theorems of Part 20 (one line per chapter) and the scope that applies to the whole part. The theorems of this part are statements on a finite lattice with the lattice spacing fixed, or on its infinite-volume limit: the parts that set up the vessel of reconstruction (the Hilbert space, the transfer operator, the vacuum), and the mass gap inside the strong-coupling window.

Prerequisite chapters — 19-00 (how to read objects, firm theorems and premises), and 19-01 and 19-03 (the lattice, the Wilson measure, reflection, the vessel of reconstruction).

Said first — The lattice spacing is fixed. The strong-coupling theorems hold only inside the window $18 \tanh |\beta| < 1$ or $24(1 - e^{-4|\beta|}) < 1$, and say nothing about the continuum limit or weak coupling. Every theorem is a Lean formalisation of a result of a known type.

The order of this chapter

1. The theorems of this part — one line per chapter (Table 1)
2. The scope that applies to the whole part
3. Reading order

01

The theorems of this part — one line per chapter (Table 1)

Chapter	What is said (one line)	Main Lean names
20-01 Reflection positivity	Reflection positivity of the Wilson measure on $(\mathbb{Z}/2M)^4$. For the plane through lattice sites, for all real β; for the plane through the middle of links, for gauge-invariant functions with $\beta \geq 0$, $M \geq 2$; for the planes through lattice sites in all four directions, also for all β. The reflection pairing is symmetric	`TorusRP.wilson_rp`, `MidRP.wilson_rp_mid`, `PeierlsPerm.wilson_rp_dir`, `TorusRP.wilson_refl_symm`
20-02 Decay of correlations at strong coupling	On $(\mathbb{Z}/N)^4$, the covariance of functions separated in the time direction is exponentially small. Windows $18 \tanh \lvert\beta\rvert < 1$ (the form measured by the change link by link) and $24(1 - e^{-4\lvert\beta\rvert}) < 1$ (the form with separated supports). The constants contain no N	`LinkSpec.wilson_cov_dist`, `TorusRP.wilson_strong_coupling`
20-03 The infinite-volume limit	In the window $18 \tanh \lvert\beta\rvert < 1$ ($\beta \neq 0$), the periodic lifts of the normalised Wilson measures on $(\mathbb{Z}/2(n+1))^4$ converge weakly, without passing to a subsequence, to a single probability measure ν_β on $\mathbb{Z}^4$ (the sequence over all sizes $(\mathbb{Z}/(m+1))^4$ has the same limit), and ν_β is invariant under unit translations in the four directions. At limit points, clustering in the four directions when $e^{\lambda} \cdot 18 \tanh \lvert\beta\rvert < 1$	`InfVol.wilson_infvol_unique`, `AllN.wilson_infvol_allN`, `TransI.wilson_infvol_translation`, `WilsonLimit.cluster_limit`

Chapter	What is said (one line)	Main Lean names
20-04 Reconstruction and the mass gap	In the reconstruction of the limit measure in the window $18\tanh\lvert\beta\rvert < 1$: $\lVert T - P\Omega\rVert \le (18\tanh\lvert\beta\rvert)^{1/2}$ (a lower bound on the mass) and the complement of the vacuum is not 0 ($\beta \neq 0$; the same form also in the gauge-invariant sector), and $T \ge 0$ ($\beta \ge 0$). A statement bundling these into one for $0 < \beta$. That the range of T lies in the gauge-invariant sector is a separate theorem	`InfMain2.wilson_infvol_main2`, `WilsonLimit.wilson_massGap_dob_exists`, `GaugeZ.wilson_massGap_gauge_exists`, `FullT.wilson_Tpos_full`, `Bind.T_range_gauge_all`
20-05 The vessel with fermions	On space $(\mathbb{Z}/N)^3$ with a time circle $\mathbb{Z}/2h$, the measure whose weight is the product of the Wilson gauge weight and the Wilson–Dirac determinant weight $\mathrm{Re}[(\det D)^{2j}]$ is positive under reflection in a time plane through lattice sites (all β, mass $m > -1$); the partition function is positive (all β, m, j); the determinant is invariant under global gauge transformations; and the normalised measure is invariant under the generators of the lattice symmetries	`WilsonGauge.site_reflection_positive_wilson_full`, `WilsonGauge.partition_pos_wilson_full`, `GaugeDet.physDirac_det_conj`, `CubicSym.wfProb_lattice_generators`

Chapter	What is said (one line)	Main Lean names
20-06 The area law at strong coupling, and an upper bound on the vortex free energy	On a torus with the same size in all four directions, inside the strong-coupling window, the expectation of the Wilson loop on the boundary of a rectangle is exponentially small in the area (in a finite box, and for the infinite-volume limit measure). On a torus of transverse size N and longitudinal size M, the difference of the twisted partition functions is exponentially small in the area of the longitudinal plane, and the rate per unit area does not depend on the transverse size (the transverse area in the prefactor remains)	`AreaLaw.area_law_wilson`, `AreaLaw.area_law_infvol`, `VortexStrong.vortex_floor`, `VortexStrongMN.vortex_floor_MN_sharp`
20-07 What this part says, and what it does not	The scope of the theorems of this part, and a table of what is not said	—

Table 1. The theorems of Part 20. All the assumptions of each row's statement are in the corresponding chapter. Every row is a formalisation of a result of a known type Cited (reflection positivity, strong-coupling decay and the mass gap: Osterwalder–Seiler; the infinite-volume limit (convergence without a subsequence): of Dobrushin's comparison type; the area law: Osterwalder–Seiler; the upper bound on the vortex free energy: of the type of 't Hooft and Münster).

02

The scope that applies to the whole part

- **The lattice spacing is fixed.** Every theorem is a statement at one lattice spacing (taken to be 1). About the limit in which the lattice spacing goes to 0 (the continuum limit), this part says nothing.
- **Only inside the strong-coupling window.** The theorems on decay, the infinite-volume limit and the mass gap hold only inside the window $18 \tanh |\beta| < 1$ ($|\beta| < 0.0556$ Reading) or $24(1 - e^{-4|\beta|}) < 1$ ($|\beta| < 0.0106$ Reading) (the windows for the area law and for the upper bound on the vortex free energy are in 20-06, for each version of the constants). Depending on the theorem, $\beta \neq 0$ or $0 < \beta$ is added, and $T \geq 0$ needs $\beta \geq 0$. Outside the window we say neither that they hold nor that they fail.

- **The area law is a statement about lattice Wilson loops.** Continuum Wilson loops are present neither in this part nor in the published construction (14-06). The strong-coupling theorems of this part are statements at the opposite end (strong coupling, lattice spacing fixed) from the question the published construction left open.
- **Nothing is said about weak coupling.** What the continuum limit needs is the side $\beta \to \infty$ (weak coupling), the opposite end from the window. The mass gap of this part is the gap of the lattice transfer operator inside the strong-coupling window; it is not a claim about the mass gap of four-dimensional Yang–Mills.
- **Reflection positivity and the vessel with fermions do not depend on the window.** The positivity in 20-01 and 20-05 holds for all real β (the middle plane for $\beta \geq 0$; 20-05 for mass $m > -1$), and is a statement for each finite torus.
- **Only a lower bound on the mass.** The upper bound on $\|T - P\Omega\|$ is a lower bound on the mass; neither the true value of the mass nor an upper bound on it is stated.
- **Formalisations of results of known types.** Every theorem is a result of a type known in the literature, machine-checked in Lean 4 on this book's objects (19-01). We do not present them as new mathematical results.

03

Reading order

The vessel rests on three pillars, read in this order. Reflection positivity (20-01) turns the pairing into an inner product (the middle-plane form, with a gauge average in between, is also used for $T \geq 0$); strong-coupling decay (20-02) makes distant correlations small; and the infinite-volume limit (20-03) produces a single measure independent of the volume. 20-04 assembles these three into the vessel of reconstruction and obtains the mass gap inside the window. 20-05 is the part that sets up the same vessel with a measure carrying a fermion weight, and can be read with only 20-01 as a prerequisite. 20-06 gives the area law and the upper bound on the vortex free energy inside the strong-coupling window, and can be read after 20-03. 20-07 is a chapter of tables only.

After this part, Part 21 gives theorems on a lattice with twisted boundary conditions, and Part 22 theorems on the rarity of large plaquettes at weak coupling; both are likewise statements at one lattice spacing. What would need to be said to reach the mass gap in the continuum limit is in Part 28 (28-00).

Reflection positivity — three forms

> This chapter is this book's own investigation. § 01 is a summary of established knowledge.

What this chapter shows — For the SU(2) Wilson measure on the finite torus $(\mathbb{Z}/2M)^4$, the fact that the integral of a function times its mirror image is never negative (reflection positivity) has been machine-checked in Lean in three forms. It holds for all real β for the plane through sites, for $\beta \geq 0$ and gauge-invariant functions for the plane through the middle of links, and for all β for the site planes in the four directions. In addition, the reflection pairing is symmetric. This chapter gives the four statements, the route of proof (split the action into three parts; fixing the variables on the plane turns the integral into a square), and when to use which.

Prerequisite chapters — 19-01 (the lattice, the Wilson measure) and 19-03 (reflection, the positive side, the pairing). For an introduction, 5-03 (reflection positivity and the transfer matrix) and 4-10.

Said first — Each is a statement on one finite torus, with the lattice spacing fixed. Nothing is said about the continuum limit. Positivity for the infinite-volume limit measure, and the positivity $T \geq 0$ of the transfer operator of the vessel, are in 20-04; the middle-plane statement, with an average over gauge transformations in between, is the source of $T \geq 0$. Each is a formalisation of a result of a known type (reflection positivity: Osterwalder–Seiler).

01

Why reflection positivity is needed — from the pairing to a Hilbert space

For an introduction, see 5-03 § 01 and 4-10. A theory on the lattice is written only as a probability measure; there is no Hilbert space and no operator that advances time. If the pairing $\langle F, G\rangle := \int F(\Theta U)\, G(U)\, d\mu$ of functions depending only on the positive side of the mirror is symmetric and $\langle F, F\rangle \geq 0$, then one can set up the Hilbert space obtained by dividing out the null functions and completing, the transfer operator T coming from time translation, and the vacuum Ω. That this positivity holds in lattice gauge theory is due to Osterwalder–Seiler Cited . This book's definitions of the pairing, the vessel and the mass gap are in 19-03, the pairing and the vessel of reconstruction.

Reflection positivity is the first pillar of the vessel, and the four statements of this chapter establish it in Lean for the Wilson measure on a finite torus. The remaining pillars and the assembly are in 20-02–20-04.

02

Two mirrors and the closed positive half (Figure 1)

The lattice is $(\mathbb{Z}/N)^4$ with $N = 2M$. In this part the directions are $\mu = 0, 1, 2, 3$, with 0 as time. This follows the index convention of Lean on the strong-coupling side and shifts the indices relative to the directions 1–4 of the text of 19-01 (the conventions of 19-01). A link $\ell = (x, \mu)$ goes from x to $x + e_\mu$, and $U_\ell \in SU(2)$ is a unit quaternion (19-01). The weight is $w_\beta(U) = \exp\bigl(\beta \sum_p \operatorname{Re} U_p\bigr)$, and the statements of this chapter are written with the unnormalised Wilson measure $w_\beta \prod_\ell dU_\ell$ (the $\tilde{\mu}_{N,\beta}$ of 19-01). It differs from the normalised measure $\mu_{N,\beta}$ only by the positive constant factor $Z_N(\beta)$, so the sign of the inequalities is the same (19-01).

The reflection in the plane through sites Θ is $x_0 \mapsto -x_0$. Setting $\vartheta x := (-x_0, x_1, x_2, x_3)$,

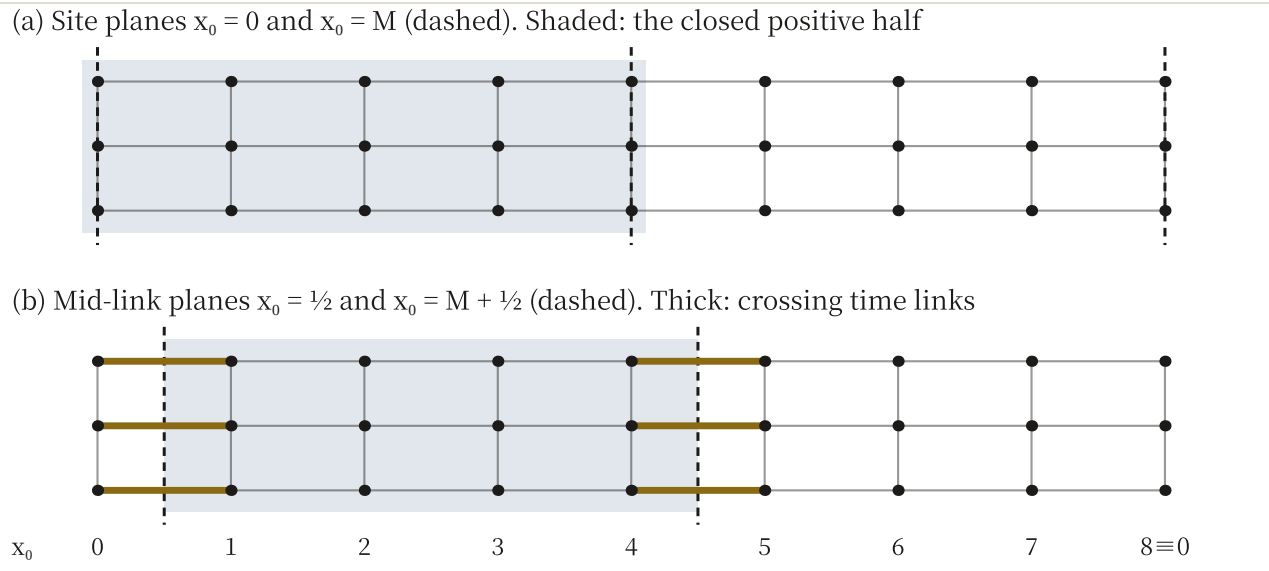
$$(\Theta U)_{(x,\mu)} = \begin{cases} U^{*}_{(\vartheta x - e_0,\, 0)} & (\mu = 0) \\ U_{(\vartheta x,\, \mu)} & (\mu \neq 0) \end{cases} \tag{1}$$

Time links reverse their direction, so they acquire an inverse (the quaternion conjugate $*$). Since $-M \equiv M$, the planes $x_0 = 0$ and $x_0 = M$ stay fixed. The **closed**

positive half Λ_+ consists of the spatial links at times $0, \dots, M$ and the time links whose base time is $0, \dots, M-1$.

The reflection in the plane through the middle of links Θ' is $x_0 \mapsto 1 - x_0$; its planes are $x_0 = \frac{1}{2}$ and $x_0 = M + \frac{1}{2}$. Time links with base time 0 or M **cross** the plane. The closed positive half Λ'_+ consists of the crossing links, the spatial links at times $1, \dots, M$, and the time links with base time $1, \dots, M-1$ (the positive side in 19-03).

Figure 1 A torus with $N = 8$ ($M = 4$) in the time direction, cut along time (horizontal) and one spatial direction (vertical, only 3 points). The shaded region is the closed positive half. (a) The spatial links on the plane belong to the positive half. (b) The thick crossing links straddle the plane; the spatial links at times 0 and 5 are on the negative side.



Proved here The figure draws (1) and the definitions in the text as they stand. Time 8 is the same point as 0 by periodicity.

03

Reflection positivity for the plane through sites — the statement

Statement (reflection positivity for the plane through sites)

Let $N = 2M$ and let β be any real number. If a bounded measurable real-valued function f depends only on the variables of the links of Λ_+, then

$$0 \;\le\; \int f(\Theta U)\, f(U)\, w_\beta(U) \prod_\ell dU_\ell . \qquad (2)$$

Cited A formalisation of Osterwalder–Seiler's reflection positivity for the plane through sites. Lean: `TorusRP.wilson_rp` (hypotheses: $N = 2M$; f measurable, bounded and depending only on Λ_+. β is any real number).

Meaning. The sign of β does not matter, because the sign is used nowhere in the proof (§ 04).

Example. Let C be a closed path in Λ_+, and take the real part of the Wilson loop, $f(U) = \operatorname{Re}\prod_{\ell\in C} U_\ell^{\pm 1}$ $(= \frac{1}{2}\operatorname{tr})$. f depends only on the links of Λ_+, satisfies $|f| \le 1$ and is continuous, so it meets the hypotheses. $f(\Theta U)$ is the real part of the Wilson loop of the mirrored path ϑC. Hence

$$\left\langle \operatorname{Re} W_{\vartheta C} \cdot \operatorname{Re} W_C \right\rangle_{N,\beta} \;\ge\; 0 \qquad (\text{all real } \beta) \quad (3)$$

Proved here (an application of (2); $\langle\cdot\rangle_{N,\beta}$ is the expectation of 19-01).

04

The route of proof — split the action, fix the plane, and get a square

The idea is the same as the "site reflection" of 5-03 § 04; in Lean it is divided into an abstract lemma and a concrete count.

Step 1: split the action into the positive side, the negative side and the plane

Give each plaquette p a weight $w(p)$: 1 for time plaquettes (plaquettes containing direction 0) with base time $0,\dots,M-1$ and for spatial plaquettes at times $1,\dots,M-1$; $\frac{1}{2}$ for spatial plaquettes at time 0 or M (plaquettes lying on the mirror plane); and 0 for the rest. Setting $S_+(U) := \sum_p w(p)\operatorname{Re} U_p$,

$$\sum_p \operatorname{Re} U_p \;=\; S_+(U) + S_+(\Theta U). \quad (4)$$

The mirror maps plaquettes to plaquettes, and the holonomy of a mapped plaquette is a cyclic shift of the conjugate, so its real part does not change. Plaquettes on the positive side are counted once, those on the negative side once as images, and those on the plane twice with a half each. Lean: `TorusRP.weight_factor` ($w_\beta = a(U)\,a(\Theta U)$, $a = e^{\beta S_+}$).

Step 2: make the integrand a pairing of a single function

$g := a\cdot f$ depends only on Λ_+ and is bounded. By (4), $f(\Theta U)\,f(U)\,w_\beta(U) = g(\Theta U)\,g(U)$; the weight disappears and only the product Haar measure remains. The sign of β has not been used so far.

Step 3: fixing the variables on the plane gives a perfect square

Divide the variables into the links on the plane U_0, the interior of the positive side $U_>$, and the negative side $U_<$. Writing $g(U) = G(U_0, U_>)$, we have $g(\Theta U) = G(U_0, V)$, where V is the negative-side variables carried to the positive side by (1). Haar measure is invariant under inversion, so V has the same distribution as $U_>$ and is independent of $U_>$. Therefore

$$\int g(\Theta U)\, g(U) \prod_{\ell} dU_\ell \;=\; \int dU_0 \left(\int G(U_0, U_>)\, dU_> \right)^2 \;\geq\; 0. \quad (5)$$

Lean: `LinkReflection.rp_core` (the abstract form) and `LinkReflection.rp_weighted` (the form with the weight factorised).

Detour: the six conditions of the abstract lemma

May be skipped. `rp_core` assumes the following about an involution θ on the index set, value maps σ_ℓ, and two predicates "on the plane" and "positive". (i) θ is an involution. (ii) Links on the plane are fixed by θ, and σ is the identity on them. (iii) Positive links are not on the plane. (iv) The image of a positive link is not positive. (v) The image of a link that is neither on the plane nor positive is positive. (vi) σ_ℓ preserves the measure on values. From these six, the space of variables is measure-preservingly isomorphic to "on the plane $\times$ positive $\times$ positive (images)", and (5) follows. On the torus, (ii), (iv) and (v) are where $N = 2M$ is used, and (vi) is the invariance of the Haar measure of SU(2) under inversion.

05

The plane through the middle of links — the roles of gauge invariance and β ≥ 0

Gauge transformations g and gauge-invariant functions are as in gauge transformations in 19-01 ($g(x) \in SU(2)$ at each site, $(gU)_{(x,\mu)} = g(x)\, U_{(x,\mu)}\, g(x + e_\mu)^*$).

Statement (reflection positivity for the plane through the middle of links)

Let $N = 2M$, $M \geq 2$ and $\beta \geq 0$. If a bounded measurable real-valued function F depends only on the variables of the links of Λ'_+ and is gauge invariant, then

$$0 \;\leq\; \int F(U)\, F(\Theta' U)\, w_\beta(U) \prod_{\ell} dU_\ell. \quad (6)$$

Cited A formalisation, in the form for gauge-invariant functions, of Osterwalder–Seiler's reflection positivity for link planes. Lean: `MidRP.wilson_rp_mid`

(hypotheses: $N = 2M$, $M \geq 2$, $\beta \geq 0$; F measurable, bounded, depending only on Λ'_+, and invariant under every g with unit values).

The proof has four steps.

Step 1: set the crossing links to 1 by a gauge transformation. The crossing links enter mutually distinct points at times 1 and $M+1$, and no crossing link leaves those points. Taking $g(x)$ to be the value of the crossing link entering that point makes every crossing link 1. For gauge-invariant H, $\int H(U) \prod dU = \int H(U^\circ) \prod dU$ (U° is the configuration with the crossing links set to 1). The change of variables is a skew product, and it preserves the measure because $V \mapsto aVb^*$ (a, b units) preserves Haar on each link. $M \geq 2$ is needed so that the starting points of the crossing links (times $0, M$) and the receiving points (times $1, M+1$) do not overlap. Lean: `GaugeFix.integral_gaugeFix`, `TorusGauge.wilson_gaugeFix`. This is applied to $H = F \cdot (F \circ \Theta') \cdot w\beta$ (Θ' carries gauge transformations to gauge transformations of a different form, and $w\beta$ is gauge invariant).

Step 2: split the action into three parts. $\sum_p \operatorname{Re} U_p = A(U) + A(\Theta' U) + C(U)$, where A is the sum over plaquettes on the positive side and C the sum over crossing plaquettes (time plaquettes having a crossing link as an edge).

Step 3: put the crossing plaquettes in kernel form. If the crossing links are 1, the holonomy of a crossing plaquette with base time 0 is VW^*, involving only the spatial link V at time 1 (positive side) and the spatial link W at time 0 (at the position of the image of V). For a crossing plaquette with base time M, it has the same form with the link at time M (positive side) and the link at time $M+1$. Viewing unit quaternions as points of $\mathbb{R}^4$, $\operatorname{Re}(VW^*) = \sum_{c=0}^{3} V_c W_c$, so

$$C(U^\circ) \;=\; \sum_j \psi_j(U)\, \psi_j(\Theta' U) \tag{7}$$

can be written as a sum of pairs of positive-side coordinates ψ_j (the quaternion components of the spatial links at times 1 and M).

Step 4: a positive-definite kernel. If $\beta \geq 0$, then

$$e^{\beta \sum_j \psi_j(U)\psi_j(\Theta' U)} \;=\; \sum_{n \geq 0} \frac{\beta^n}{n!} \Big(\sum_j \psi_j(U)\psi_j(\Theta' U) \Big)^n \tag{8}$$

is a sum, with coefficients ≥ 0, of terms of the form $h(U)\, h(\Theta' U)$, and each term becomes the integral of a square as in (5) of § 04. Lean: `LinkReflection.rp_kernel`

(abstract reflection positivity with a kernel, $\beta \geq 0$).

The role of gauge invariance. It is for Step 1. A crossing link is mapped to itself by the mirror, so it cannot be fixed and squared as in § 04; instead it is removed by setting it to 1 with a gauge transformation. For a function that does not depend on the crossing links (a function depending only on the interior of the positive side), averaging over two independent gauge transformations and then applying (6) gives a form that does not require gauge invariance (Lean `FullT.full_rp_torus`: normalised measure, $\beta \geq 0$, $M \geq 2$).

The role of $\beta \geq 0$. Step 4 uses that the coefficients $\beta^n/n!$ are ≥ 0. For $\beta < 0$ the kernel $e^{\beta\langle V,W\rangle}$ is not positive definite on S^3: the matrix $\begin{pmatrix} e^{\beta} & e^{-\beta} \\ e^{-\beta} & e^{\beta} \end{pmatrix}$ built from the two points V, $-V$ has determinant $e^{2\beta} - e^{-2\beta}$, which is negative Proved here . This means the tool of the proof cannot be used; (6) says neither that the statement holds nor that it fails for $\beta < 0$.

06

Reflection positivity in four directions, and the symmetry of the pairing

Four directions. Let τ be the swap of directions 0 and ρ, and consider the relabelling of configurations $(P_\tau U)_{(x,\mu)} := U_{(x\circ\tau,\ \tau\mu)}$. The weight w_β is invariant under P_τ (for plaquettes whose orientation is reversed the holonomy is conjugated, and the real part is the same). $\Theta_\rho := P_\tau\,\Theta\,P_\tau$ is the reflection $x_\rho \mapsto -x_\rho$ in the site plane of direction ρ.

Statement (reflection positivity for site planes in four directions)

Let $N = 2M$, $\rho \in \{0,1,2,3\}$, and let β be any real number. If a bounded measurable real-valued f depends only on the closed positive half of direction ρ (links of direction ρ whose base has x_ρ in $0,\dots,M-1$, and links of other directions with x_ρ in $0,\dots,M$), then

$$0 \;\leq\; \int f(\Theta_\rho U)\, f(U)\, w_\beta(U) \prod_\ell dU_\ell\,. \qquad (9)$$

Cited A formalisation, extended to four directions, of reflection positivity for the plane through sites (of Osterwalder–Seiler type). Lean: `PeierlsPerm.wilson_rp_dir` (all ρ, all real β; the invariance of the measure is `PeierlsPerm.wilson_perm_invariant`).

The proof just applies (2) to $f \circ P_T$ and returns by the invariance of the measure. Four directions are needed for the chessboard estimate, which carries a function of one block to all blocks by the mirrors of the four directions and stacks Cauchy–Schwarz direction by direction (22-01).

Statement (symmetry of the reflection pairing)

Let $N = 2M$, let β be any real number, and let f, g be measurable real-valued functions.

$$\int f(\Theta U)\, g(U)\, w_\beta(U) \prod_\ell dU_\ell \;=\; \int g(\Theta U)\, f(U)\, w_\beta(U) \prod_\ell dU_\ell . \quad (10)$$

Cited A formalisation of a known identity following from reflection invariance. Lean: `TorusRP.wilson_refl_symm` (neither boundedness nor a support condition is needed; when not integrable, both sides are 0 by Lean's convention).

There are three ingredients: Θ is an involution, Θ preserves the product Haar measure, and w_β is invariant under Θ (using (4) twice). (10) is the symmetry of the pairing and corresponds to a field of the vessel of reconstruction (19-03).

07

When to use which of the three forms

Form	Range	Class of functions	What it is used for
Plane through sites (time)	All real β, $N = 2M$	Bounded measurable functions on Λ_+	Positive semi-definiteness of the pairing → a Hilbert space. The source of positivity for the infinite-volume limit measure and of the assembly of the vessel (20-04)
Plane through the middle of links	$\beta \geq 0$, $M \geq 2$	Gauge-invariant bounded measurable functions on Λ'_+	The source of the positivity $T \geq 0$ of the transfer operator (20-04; with a gauge average in between)
Site planes in four directions	All real β, all directions	Functions on the closed positive half of direction ρ	The chessboard estimate (22-01)
Symmetry of the pairing	All real β	Measurable functions	Symmetry of the pairing (a field of the vessel)

The site-plane form has the lightest conditions and cares about neither the sign of β nor gauge invariance. In exchange, on its own it gets the transfer operator only as far as the type $T^2 \geq 0$, and cannot give positivity of T itself (the two kinds of “positive” in 5-03 § 03). The middle-plane form pays with $\beta \geq 0$ and gauge invariance and gives

positivity of the type $T \geq 0$. The $T \geq 0$ inside the vessel (20-04, Lean `FullT.wilson_Tpos_full`) is obtained by inserting into (6) the Haar average over all gauge transformations of the torus, extending it to functions on the positive side that do not depend on the crossing links and need not be gauge invariant (`FullT.full_rp_torus`), and passing to the limit.

On the lattice with twisted boundary conditions, the same type of splitting (fix the plane and take a square) is used with the plane through sites (21-06). In Part 21 the role of time is played by direction 4, and that is a separate statement on the lattice of Part 21.

08

What is not said

- **The lattice spacing is fixed and the volume is finite.** Every statement is an equality or inequality on one $(\mathbb{Z}/2M)^4$. Positivity is a property that holds exactly at each volume, and no form uniform in the volume is needed. Nothing is said about the continuum limit.
- **Unnormalised measure.** It differs by a positive constant factor, so the sign is the same. Positivity for the infinite-volume limit measure is in the bundled statement of 20-04 and in the axioms of the vessel (20-04).
- **Real-valued functions only.** Complex-valued functions are outside the statements.
- **Middle plane:** nothing is said about $\beta < 0$, $M = 1$, or F that depends on the crossing links and is not gauge invariant.
- **Lean's convention for values.** In Lean the link values are taken in the closed unit ball of the quaternions, and the reference measure is the image of the Haar measure of SU(2) (the unit sphere). As statements about bounded measurable functions they are the same as statements on SU(2) (the conventions of 19-01).
- **Not a new result.** Reflection positivity of lattice gauge theory is a result of Osterwalder–Seiler; this chapter is its formalisation for the Wilson measure on a finite torus.

Decay of correlations at strong coupling

This chapter is this book's own investigation.

What this chapter shows — When $|\beta|$ is small enough (strong coupling), the covariance of two functions separated in the time direction, under the SU(2) Wilson measure on the torus $(\mathbb{Z}/N)^4$, becomes exponentially small with the distance. This estimate is machine-checked in Lean in two ways, and in neither do the constants contain the volume N. One is the Dobrushin window $18\tanh|\beta| < 1$, which comes from how much the conditional distribution of one link depends on the surrounding links (coefficient $\tanh|\beta|$, row sum at most $18\tanh|\beta|$). The other is the window $24(1 - e^{-4|\beta|}) < 1$, obtained by counting chains of connected plaquettes.

Prerequisite chapters — 19-01 (the Wilson measure), 20-01 (notation). For an introduction, 5-02 (strong coupling) and 5-04 (infinite volume and clustering).

Said first — The lattice spacing is fixed, and the statements hold only inside the strong-coupling windows. The windows are $|\beta| < 0.0556$ Reading and $|\beta| < 0.0106$ Reading, the opposite end from the weak coupling ($\beta \to \infty$) that the continuum limit needs. Nothing is said outside the windows (not even that there is no decay). The distance is only the distance in the time direction, and the statements are in finite volume for each N. Each is a formalisation of a known result of Osterwalder–Seiler or Dobrushin type.

The order of this chapter

1. Two windows, two statements — an overview
2. Expectations and the time distance — the setting
3. The influence one link receives from its surroundings — the coefficient tanh|β| and the count 18
4. Decay with distance in the Dobrushin window — the statement
5. The route of proof — washing out the oscillation of G with heat-bath sweeps
6. The other window — swapping two replicas, and chains of plaquettes
7. Comparing the two windows (Table 1)

8. What is not said

01

Two windows, two statements — an overview

For an introduction, see 5-02 § 01 and 5-04. At $\beta = 0$ the Wilson measure is a product of Haar measures, and different links are independent. When $|\beta|$ is small, the coupling between links is weak, and the correlation of distant links pays a small factor each time it "crosses one coupling", so it decreases exponentially with the distance. This is the decay of correlations at strong coupling; in lattice gauge theory it is a result of Osterwalder–Seiler via the cluster expansion Cited .

The two statements of this chapter give this picture form through two different accountings.

- **Decay with distance** (§ 04): count how much the conditional distribution of one link moves when one surrounding link is changed (Dobrushin's influence coefficients). The window is $18 \tanh |\beta| < 1$.
- **Finite-volume decay** (§ 06): prepare two independent replicas, expand the plaquette weights, and count chains of plaquettes connecting the two supports. The window is $24(1 - e^{-4|\beta|}) < 1$.

Both are finite-volume statements for each N, and the constants on the right-hand side do not contain N. This form, uniform in the volume, is the source of the infinite-volume limit (20-03) and of the mass gap of the vessel of reconstruction (20-04).

02

Expectations and the time distance — the setting

The lattice is the torus $(\mathbb{Z}/N)^4$ ($N \geq 1$); the link variables $U_\ell \in SU(2)$, the weight w_β and the normalised measure $\mu_{N,\beta}$ are as in 19-01. This chapter uses the expectation of 19-01,

$$\langle H \rangle_{N,\beta} := \int H \, d\mu_{N,\beta} = \frac{\int H \, w_\beta \prod_\ell dU_\ell}{\int w_\beta \prod_\ell dU_\ell} \quad (1)$$

and writes the covariance as $\mathrm{Cov}(F, G) := \langle FG \rangle_{N,\beta} - \langle F \rangle_{N,\beta} \langle G \rangle_{N,\beta}$. β is real and its sign does not matter (the windows are written in terms of $|\beta|$).

Time distance. Fix a time $t_0 \in \mathbb{Z}/N$, and use the cyclic distance between the base time x_0 of a link $\ell = (x, \mu)$ and t_0,

$$d(\ell) := \min_{k \in \mathbb{Z}} \left| x_0 - t_0 + kN \right| \qquad (0 \le d(\ell) \le N/2) \tag{2}$$

However far apart things are in the spatial directions, this does not enter d. Two links sharing a plaquette differ in d by at most 1 (because the base times of the four links of a plaquette fit in two consecutive times). This fact, that "the distance changes by at most 1 between neighbours", is where both proofs turn distance into an exponent.

Support of a function. A function F depends only on the links of a finite set A if F takes equal values on any two configurations that agree on A.

03

The influence one link receives from its surroundings — the coefficient tanh|β| and the count 18

With all links other than x fixed at a configuration ω, the conditional distribution of x (the heat-bath kernel of one link) is

$$\gamma_x(dU \mid \omega) = \frac{\exp\left(\beta \sum_{p \ni x} \operatorname{Re} U_p(\omega[x \mapsto U])\right) dU}{\int \exp\left(\beta \sum_{p \ni x} \operatorname{Re} U_p(\omega[x \mapsto U'])\right) dU'} \tag{3}$$

The sum runs only over plaquettes containing x. In four dimensions one link is contained in 6 plaquettes (two, one on each side, for each of the remaining three directions).

Influence coefficients. For two configurations ω, ω' differing only at another link y, measure the difference of the conditional distributions of x. Let n_{xy} be the number of plaquettes containing both x and y. The difference of the local actions $h(U)$ satisfies $|h| \le 2|\beta|\, n_{xy}$, and the difference of two probability measures whose densities are tilted by e^h is bounded by

$$\sup_S \left| \gamma_x(S \mid \omega') - \gamma_x(S \mid \omega) \right| \;\le\; \tanh\left(|\beta|\, n_{xy}\right) \tag{4}$$

Lean: `LinkSpec.spec_coeff` ($\tanh$ in the form $(e^{2a}-1)/(e^{2a}+1)$).

The count 18. From $\tanh(na) \le n \tanh a$ ($a \ge 0$, Lean `LinkSpec.tanhForm_le`) and the fact that each of the 6 plaquettes containing x has 3 links other than x, $\sum_{y \,/=\, x} n_{xy} \le 18$. Hence the row sum satisfies

$$\alpha_0 := \sum_{y \not= x} \sup\bigl|\gamma_x(\cdot \mid \omega') - \gamma_x(\cdot \mid \omega)\bigr| \;\le\; 18 \tanh|\beta| \quad (5)$$

for every x and every N. Lean: `LinkSpec.dobrushin_row`. For $N \ge 3$ there are 18 neighbours, all with $n_{xy} = 1$; for $N = 2$ there are 15 neighbours with $\sum n_{xy} = 18$ Reading (a check of the count).

Meaning. $\alpha_0 < 1$ says that "the distribution of one link is moved, by all the surrounding links together, by less than 1 in total variation". This is the form of Dobrushin's uniqueness condition, and the window $18 \tanh|\beta| < 1$ is $|\beta| < \operatorname{artanh}(1/18) \approx 0.0556$ Reading . As an explicit sufficient condition, $|\beta| < 1/19$ is in Lean (`WilsonLimit.dob_window_strict`).

04

Decay with distance in the Dobrushin window — the statement

Statement (Dobrushin decay of covariance with distance)

Let $N \ge 1$, β real, and $\lambda \ge 0$ with $e^{\lambda} \cdot 18 \tanh|\beta| < 1$. Let $t_0 \in \mathbb{Z}/N$, $r \in \mathbb{N}$, and let the finite set of links A satisfy $d(\ell) \le r$ for all its links. Let F be bounded ($|F| \le c_F$), measurable and depending only on A, and G bounded and measurable. Let $\delta_y \ge 0$ be an upper bound on "the change in G when only link y is changed", that is, $|G(\omega) - G(\omega')| \le \delta_y$ for all ω, ω' agreeing outside y. Then

$$\bigl|\operatorname{Cov}(F, G)\bigr| \;\le\; 2\, c_F\, e^{\lambda r} \sum_{y} e^{-\lambda\, d(y)}\, \delta_y. \quad (6)$$

Cited A formalisation, in sweep form, of Dobrushin's comparison type. Lean: `LinkSpec.wilson_cov_dist` (hypotheses as above; the constants on the right-hand side do not contain N).

Two functions with separated supports. If G depends only on the links of a finite set A', $|G| \le c_G$, and $d \ge r + 2 + k$ for all links of A', one can take $\delta_y = 2c_G$ ($y \in A'$) and $\delta_y = 0$ (otherwise), and

$$\bigl|\operatorname{Cov}(F, G)\bigr| \;\le\; 4\, c_F\, c_G\, |A'|\, e^{-\lambda(k+2)} \quad (7)$$

Proved here (an application of (6); an application of the same type is inside Lean's `TorusRP.wilson_hdec_torus_dob`). Any λ below $-\ln(18 \tanh|\beta|)$ will do; for example, for $\beta = 0.001,\ 0.005,\ 0.01$ that upper limit is $4.02,\ 2.41,\ 1.71$ Reading .

Points to note in the statement. δ is constrained by hypothesis to be at least the true change of G, so it cannot be taken small to make a false claim. If G is constant, $\delta \equiv 0$ and both sides are 0. On the right-hand side, N appears only in the range of the sum and inside the cyclic distance; if the support of δ does not depend on N, the estimate is uniform in N.

05

The route of proof — washing out the oscillation of G with heat-bath sweeps

The idea is "flatten G without touching F". It is divided into five steps.

Step 1: the heat bath preserves the measure. For the heat-bath operator $P_x H(\omega) := \int H(\omega[x \mapsto U])\, \gamma_x(dU \mid \omega)$, $\langle P_x H\rangle_{N,\beta} = \langle H\rangle_{N,\beta}$ (because the conditional distribution of one link is (3); Lean `LinkSpec.hbSweep_invariant` and its iteration `LinkSpec.iter_invariant`).

Step 2: sweep while avoiding A. Let L be a sequence listing every link outside A once, and let $Q := \prod_{x \in L} P_x$ (a sweep). Since F depends only on A, P_x ($x \notin A$) passes through with F still multiplied, and for all K

$$\langle F \cdot Q^K G\rangle_{N,\beta} = \langle FG\rangle_{N,\beta}, \qquad \langle Q^K G\rangle_{N,\beta} = \langle G\rangle_{N,\beta}. \tag{8}$$

Lean: `LinkSpec.iter_mul_invariant`, `iter_invariant`.

Step 3: the flow of oscillation. The upper bounds δ on the link-by-link change of H move, under one application of P_x, as $\delta_x \mapsto 0$, $\delta_y \mapsto \delta_y + \delta_x C_{xy}$ (C_{xy} is the coefficient of (4)). Attaching the weights $\rho_y := e^{-\lambda d(y)}$, since d differs by only 1 between neighbours,

$$\sum_{y \neq x} \rho_y\, C_{xy} \;\le\; \left(e^{\lambda} \cdot 18 \tanh|\beta|\right) \rho_x =: \alpha\, \rho_x \tag{9}$$

(Lean `LinkSpec.row_weighted`). With $a := \sum_{y \in A} \rho_y \delta_y$ and $b := \sum_{y \notin A} \rho_y \delta_y$, one sweep shrinks b by a factor of at most α, and δ on A does not decrease. After K sweeps, $b_K \le \alpha^K b_0$ (Lean `Sweep.iter_bound`). The key point is to start the sweep with A treated as "already processed"; then b does shrink even though a grows by what flows into A.

Step 4: from oscillation to covariance. If $|H - c| \le S$ and $|F| \le c_F$, then $|\operatorname{Cov}(F,H)| \le 2 c_F S$ (Lean `LinkSpec.cov_le`). The total oscillation of $H = Q^K G$ is bounded by $\sum_y \delta_y^{(K)}$, and $\rho \ge e^{-\lambda r}$ on A, so

$$\sum_y \delta_y^{(K)} \;\le\; e^{\lambda r} \sum_y \rho_y \delta_y \;+\; \Big(\sum_y \rho_y^{-1}\Big)\, \alpha^K b_0 . \tag{10}$$

Step 5: $K \to \infty$. Since $\alpha < 1$ and N is fixed, the second term goes to 0, and together with (8) this gives (6). $\sum_y \rho_y^{-1}$ depends on N, but it vanishes in the limit and does not remain on the right-hand side.

Dobrushin's uniqueness theorem itself is not used as a tool. The heat-bath sweeps follow its comparison argument on the finite torus.

A numerical check Reading On a two-dimensional torus of Z_2 gauge theory (time $6 \times$ space 2, sum over all configurations), the ratio of the covariance of pairs of spatial Polyakov loops to the estimate of the form (6) was 6.2×10^{-4} (separation 1) to 3.1×10^{-8} (separation 3) at $\beta = 0.03$, and 3.1×10^{-3} to 3.8×10^{-6} at $\beta = 0.15$, all within the estimate (the numerical record of this book's study). This is not a check on four-dimensional SU(2) itself, and whether the estimate is sharp was not examined.

06

The other window — swapping two replicas, and chains of plaquettes

Statement (finite-volume decay of correlations at strong coupling)

Let $N \ge 1$ and $c := 1 - e^{-4|\beta|}$ with $24c < 1$. Let $t_0 \in \mathbb{Z}/N$, $r, k \in \mathbb{N}$, and let the finite sets of links A, A' satisfy $d \le r$ for all links of A and $d \ge r + 2 + k$ for all links of A'. Let F ($|F| \le c_F$) depend only on A and G ($|G| \le c_G$) only on A', both measurable. Then

$$\big|\mathrm{Cov}(F, G)\big| \;\le\; 2\, c_F\, c_G \cdot 6|A| \cdot \frac{c\,(24c)^k}{1 - 24c} . \tag{11}$$

Cited A formalisation of the type of Osterwalder–Seiler's strong-coupling cluster expansion. Lean: `TorusRP.wilson_strong_coupling` (the window literally as $24(1 - (e^{2|\beta|})^{-2}) < 1$; the constants $2c_F c_G$, $6|A|$, $c/(1 - 24c)$ and the rate $24c$ do not contain N).

The window is $|\beta| < \frac{1}{4} \ln \frac{24}{23} \approx 0.0106$ Reading . The proof has four steps.

Step 1: shift the plaquette weights to be at least 1. With $w_p := e^{\beta \,\mathrm{Re}\, U_p + |\beta|} \in [1, e^{2|\beta|}]$, $\prod_p w_p$ is a positive constant multiple of the Wilson weight, and the expectation (1) does not change.

Step 2: two replicas. Taking two independent configurations U, V, $2Z^2\,\mathrm{Cov}(F,G) = \iint (F(U)-F(V))(G(U)-G(V))\,W(U)W(V)$. Expand $W(U)W(V) = \prod_p (1+\sigma_p)$, $\sigma_p := w_p(U)w_p(V) - 1 \geq 0$, into a sum over sets of plaquettes Γ.

Step 3: separable sets vanish. Γ is called separable if there is a set of links T containing A and disjoint from A' such that every plaquette of Γ lies either inside T or outside T (does not straddle the edge of T). Then swapping the two replicas on T reverses the sign of that term, and these cancel in the sum. What remains are terms containing a minimal set of plaquettes π connecting A and A', and from $\sigma_p/(1+\sigma_p) \leq 1 - e^{-4|\beta|} = c$,

$$\left|\mathrm{Cov}(F,G)\right| \;\leq\; 2c_F c_G \sum_{\pi} c^{|\pi|} \tag{12}$$

This step holds for all β and all N (Lean `SwapDecay.covBound_minimal`, applied in `TorusRP.wilson_covariance`). The sum on the right is not uniform in the volume from this step alone; making it uniform is the counting of the next step.

Step 4: count the chains. A minimal π contains a sequence of plaquettes, consecutive ones sharing a link, from a plaquette touching A to a plaquette touching A' (the counting lemma derives an upper bound from the length of this sequence and the degree of plaquettes). Since 6 plaquettes contain a given link, at most 24 plaquettes (including itself) share support with a given plaquette, and at most $6|A|$ plaquettes touch A. The time distance of neighbouring plaquettes differs by only 1, so a chain has at least $k+1$ plaquettes. There are at most $6|A|\cdot 24^m$ chains of length $m+1$, so $\sum_\pi c^{|\pi|} \leq 6|A| \sum_{m\geq k} c^{m+1} 24^m = 6|A|\, c(24c)^k/(1-24c)$, which is (11) (Lean `TorusRP.card_link_plaqs`, `plaq_degree`, `card_touch_le`, `height_lip`, `SwapDecay.minimalNonsep_sum_le`).

The number 4 comes from twice (two replicas) the range $2|\beta|$ of $\beta\,\mathrm{Re}\,U_p$, and 24 from 4×6. 24 is an upper bound; the true maximum number of plaquettes sharing support with one plaquette is 21 for $N \geq 3$ and 19 for $N = 2$ Reading .

07

Comparing the two windows (Table 1)

	Decay with distance (6)	Finite-volume decay (11)
Window	$e^{\lambda} \cdot 18 \tanh|\beta| < 1$ ($\lvert\beta\rvert < 0.0556$ as $\lambda \to 0$ Reading)	$24(1-e^{-4\lvert\beta\rvert}) < 1$ ($\lvert\beta\rvert < 0.0106$ Reading)
Basis of the accounting	Row sum of one link's influence, $18 \tanh\lvert\beta\rvert$	Number of chains of plaquettes 24^m and weight c^{m+1}

	Decay with distance (6)	Finite-volume decay (11)
Assumption on G	Link-by-link change δ_y (no support needed)	Support A' at time distance at least $r + 2 + k$
Rate (per unit of separation)	Any λ below $-\ln(18 \tanh \lvert\beta\rvert)$	$-\ln(24c)$
Rate at $\beta = 0.001$ Reading	Upper limit 4.02	2.35
Rate at $\beta = 0.005$ Reading	Upper limit 2.41	0.74
Rate at $\beta = 0.01$ Reading	Upper limit 1.71	0.061
Lean	`LinkSpec.wilson_cov_dist`	`TorusRP.wilson_strong_coupling`

Table 1 Comparison of the two statements. The rates are floating-point computations.

The window is about 5.2 times wider on the Dobrushin side Reading , and the upper limit of the rate at the same β is also larger. The advantage of the finite-volume decay is that it handles two functions with separated supports directly, without measuring the link-by-link change of G.

A sense of strength Reading : (11) becomes smaller than the trivial upper bound $c_F c_G$ (Cauchy–Schwarz), with $|A| = 1$, for $k \geq 2$ at $\beta = 0.008$ and for $k \geq 35$ at $\beta = 0.01$. At the edge of the window the estimate has almost no content. On small Z_2 lattices, the true covariance was 10^8 to 10^{22} times smaller than (11) (the numerical record of this book's study).

In the later chapters of this part, the infinite-volume limit (20-03) and the mass gap (20-04) mainly use the Dobrushin window.

08

What is not said

- **Nothing is said outside the windows.** Not even that the decay stops. The windows are only the small end of $|\beta|$, the opposite of the weak coupling ($\beta \to \infty$) needed for the continuum limit. The lattice spacing is fixed.
- **Only distance in the time direction.** The d in (6) and (11) is the cyclic distance of the time coordinate. Clustering in four directions is a separate statement about the infinite-volume limit measure (20-03).
- **Finite volume for each N.** We say that the constants do not contain N, but the infinite-volume measure itself is not in this chapter.

- **The estimates are not sharp.** (11) contains $|A|$ and is almost trivial at the edge of the window. In (6) one supplies δ oneself.
- **This is not the mass gap itself.** Going from decay of covariance to the mass gap of the vessel of reconstruction needs reflection positivity (20-01) and the assembly of the limit (20-04).
- **Not a new result.** Decay of correlations at strong coupling is a known result of the type of Osterwalder–Seiler's cluster expansion and Dobrushin's uniqueness; this chapter is its formalisation for the SU(2) Wilson measure on a finite torus.

The infinite-volume limit — no subsequence, translation invariance, clustering

> This chapter is this book's own investigation. The explanation of Dobrushin's condition in § 03 introduces established knowledge.

What this chapter shows — In the strong-coupling window $18 \tanh |\beta| < 1$, $\beta \neq 0$: the sequence of Wilson measures on the tori $(\mathbb{Z}/2(n+1))^4$, lifted periodically to $\mathbb{Z}^4$, converges weakly to a single probability measure ν_β without passing to a subsequence. The sequence of all sizes $(\mathbb{Z}/(m+1))^4$ has the same limit. ν_β is invariant under unit translations in the four directions. The limit measure has the clustering property in the four directions (correlations of distant observables decrease exponentially). Each is a formalisation, machine-checked in Lean, of a result of a known type.

Prerequisite chapters — 19-01 The Wilson measure, 19-03 The infinite-volume configuration space and lifts, 20-02 Decay of correlations at strong coupling. The infinite-volume limit and the cluster expansion as established knowledge are in 5-04.

Said first — The lattice spacing is fixed at 1. The window is only $|\beta| < 0.0556$ Reading , and nothing is said about the continuum limit or weak coupling. The limit is a statement about “the sequence of periodic lifts”; nothing is said about other boundary conditions or about uniqueness of the Gibbs measure in the DLR sense. The “unique” part of the statement is trivial from the topology; the content is the convergence without a subsequence.

The order of this chapter

1. The setting — configuration space, periodic lifts, weak convergence: which sequence converges, and in what sense.
2. Four theorems: the theorem on the limit without a subsequence, the theorem on the limit independent of size, translation invariance of the limit, clustering at limit points.
3. Dobrushin's condition — the influence of one link on its neighbours: where the number 18 and the tanh come from.

4. Comparing two sizes — the difference is exponentially small in the distance to the boundary: the core of the proof.
5. From a Cauchy sequence to the limit: cylinder functions determine the measure, and compactness.
6. Translation invariance and clustering: carrying properties of finite boxes over to the limit.
7. Detour: what “unique” says: the uniqueness of $\exists!$, and the content of the convergence.
8. What is not said: the window, boundary conditions, the continuum limit.

01

The setting — configuration space, periodic lifts, weak convergence

The objects are those defined in 19-03. Only the main points are repeated here.

Configuration space. Let $\Lambda = \mathbb{Z}^4 \times \{0,1,2,3\}$ be the set of all links of $\mathbb{Z}^4$; placing one element of SU(2) (a unit quaternion) on each link gives a configuration. The configuration space $\mathcal{C}$ carries the product topology. Each factor is compact, so $\mathcal{C}$ is compact and metrisable. On the Lean side the values are taken in the closed ball $\{q : |q| \le 1\}$, but the measures live on the unit sphere (SU(2)) (the conventions of 19-01).

Periodic lift. From a configuration ω on the torus $(\mathbb{Z}/N)^4$, build the configuration $x_\ell = \omega_{\ell \bmod N}$ on $\mathbb{Z}^4$. Write the probability measure obtained by pushing the normalised Wilson measure (19-01) forward by this map as

$$\mu_n = \mathrm{lift}_*\, P_{N_n,\beta}, \qquad N_n = 2(n+1) \qquad (n = 0,1,2,\dots) \tag{1}$$

Its Lean name is `liftProb β n`. We also use the lift of the torus of every size $m+1$, `liftS β m`.

Weak convergence. A sequence of probability measures μ_n converges weakly to ν if $\int F\,d\mu_n \to \int F\,d\nu$ for every bounded continuous function F on $\mathcal{C}$. In Lean this corresponds to `Tendsto … atTop (𝓝 ν)` in the topology of Mathlib's space of probability measures.

Cylinder functions and supports. A function determined only by the values on a finite set of links S is called a cylinder function with support S. The proof is first carried out for cylinder functions and is finally transferred to measures.

The window and the constant. Throughout this chapter we set

$$q(\beta) = 18 \tanh |\beta| \qquad (\text{in Lean, } \texttt{dobConst}\ \beta)$$ (2)

The window $q(\beta) < 1$ is the same as $|\beta| < \operatorname{artanh}(1/18) = 0.055613$ Reading . The explicit sufficient condition $|\beta| < 1/19 \Rightarrow q(\beta) < 1$ is in Lean as `WilsonLimit.dob_window_strict`.

02

Four theorems

The theorem on the limit without a subsequence

Cited A formalisation of a result of Dobrushin-uniqueness type. Lean: `InfVol.wilson_infvol_unique` ($\beta \neq 0$, $q(\beta) < 1$).

Let $\beta \neq 0$ and $18 \tanh |\beta| < 1$. Then there is a unique probability measure $\nu\beta$ such that the sequence μ_n (all n, without passing to a subsequence) converges weakly to $\nu\beta$.

The theorem on the limit independent of size

Cited A formalisation of a result of the same type. Lean: `AllN.wilson_infvol_allN` ($\beta \neq 0$, $q(\beta) < 1$).

Under the same hypotheses, the limit ν of the sequence μ_n of even sizes is also the limit of the sequence of all sizes `liftS β m` (the tori $(\mathbb{Z}/(m+1))^4$). Moreover, for any sequence of natural numbers s with $s(k) \to \infty$, `liftS β (s k)` also converges weakly to the same ν.

Translation invariance of the limit

Cited A formalisation. Lean: `TransI.wilson_infvol_translation` ($\beta \neq 0$, $q(\beta) < 1$).

The $\nu\beta$ above is invariant under the unit translations $x \mapsto x(\cdot + e_i)$ in the four directions $i = 0, 1, 2, 3$: for every bounded continuous F,

$$\int F(x(\cdot + e_i))\, d\nu\beta(x) = \int F\, d\nu\beta.$$ (3)

Clustering at limit points

Cited A formalisation of a result of the type of exponential mixing under Dobrushin's condition. Lean: `WilsonLimit.cluster_limit` ($\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$; ν is the weak limit of some subsequence of μ_n).

Fix a direction i. Let F, G be bounded continuous cylinder functions such that, for every link of the supports S_F, S_G, the i-th coordinate of its base point lies in $[0, R]$ (the other coordinates are arbitrary). Let G_k be G shifted by k in direction i, $G_k(x) = G(x(\cdot + k e_i))$. Then for $k \geq R$

$$\left| \int F\, G_k \, d\nu - \int F \, d\nu \int G_k \, d\nu \right| \;\leq\; 4 \, \|F\|_\infty \|G\|_\infty \, |S_G| \, e^{-\lambda (k - R)}. \tag{4}$$

The constants do not depend on k, ν, or the other coordinates. The form with $\lambda = -\frac{1}{2}\log q(\beta)$ for ν_β is included in the bundled statement (20-04).

03

Dobrushin's condition — the influence of one link on its neighbours

For an introduction, see 5-04. On a compact configuration space, a sequence of measures always has a convergent subsequence. But the limit need not be unique. To pin it down, one must say that distant influences are weak. Dobrushin's condition measures this “one link at a time”.

Influence coefficients. The conditional distribution of a link x (the distribution of x when all other links are fixed) is determined only by the weights $e^{\beta \operatorname{Re} U_p}$ of the plaquettes containing x. Let C_{xy} be an upper bound on how much the conditional distribution of x moves in total variation when the value of another link y is changed. When x and y share n_{xy} plaquettes, Lean takes

$$C_{xy} = \tanh\bigl(|\beta| \, n_{xy}\bigr) \tag{5}$$

(`coef`). This is because the difference in the local action of x when y is changed lies in $[-2|\beta|, 2|\beta|]$ per shared plaquette (width $4|\beta|$), and tilting an exponential weight by a width w moves the total variation by at most $\tanh(w/4)$ Proved here .

Row sum. In four dimensions one link lies in 6 plaquettes, and each plaquette has 3 other links. So $\sum_y n_{xy} = 18$, and from $\tanh(|\beta| n) \leq n \tanh|\beta|$

$$\sum_{y \neq x} C_{xy} \;\leq\; 18 \tanh|\beta| = q(\beta) \tag{6}$$

holds for every size of torus Proved here . Dobrushin's condition is that this row sum is less than 1, and the window $q(\beta) < 1$ reads directly as “the total influence of one link on all its neighbours is less than 1”.

Weighted form. The proof uses the row sum with weights $\rho_y = e^{\lambda d(y)}$ in the distance d, $\sum_{y \neq x} \rho_y C_{xy} \leq \alpha \rho_x$, $\alpha = e^{\lambda} q(\beta)$. Since d differs by only 1 between two links sharing a plaquette, the weight changes by at most a factor e^{λ} Proved here . The role of the window is that one can take $\lambda > 0$ while keeping $\alpha < 1$.

04

Comparing two sizes — the difference is exponentially small in the distance to the boundary

The core of the proof is that "the expectations on two tori of different sizes are both close to a single number independent of N". We divide it into steps.

Step 1: heat-bath sweeps. On the torus, the operation of redrawing the value of link x from its conditional distribution is called the heat bath P_x. The Wilson measure is invariant under each P_x. Let Q be the operation of redrawing, one at a time in order, the links of a box A around the origin (links whose base point has every coordinate $|\cdot| \leq L$), and repeat Q K times. The oscillation vector δ_y of a function f (the upper bound on the change in f when only y is changed) is carried by the influence coefficients C at each sweep. Measured with the weight $e^{\lambda d(y)}$ (d is the maximum cyclic distance from the origin), the part inside the box shrinks by a factor of at most α each time, and the part leaking outside the box is divided by the weight $e^{\lambda(L+1)}$. The conclusion is that for every configuration ω

$$\left| E_N f - (Q^K f)(\omega) \right| \;\leq\; \left(\alpha^K + e^{-\lambda(L+1)} \right) \sum_y e^{\lambda d(y)} \delta_y \qquad (7)$$

(`LinkSpec.torus_box`). N does not enter the right-hand side.

Step 2: inside the box it is the same as $\mathbb{Z}^4$. If $2(L+1) < N$, the links inside the box $L+1$ map one-to-one under projection to the torus, and plaquettes containing links inside the box do not wrap around. So for F depending only on the links of the box $L+1$, the lift of the sweep on the torus agrees with the same sweep on $\mathbb{Z}^4$: $Q_N^K (F \circ \mathrm{lift}) = (Q_{\mathbb{Z}}^K F) \circ \mathrm{lift}$ (`ZHeat.iter_lift`). The function $Q_{\mathbb{Z}}^K F$ on the right does not depend on N.

Step 3: comparison with a number independent of N. Apply Steps 1 and 2 to a bounded continuous cylinder function F whose support S lies in the box R_0. If $L \geq R_0$ and $n \geq L+1$, then

$$\left| \int F \, d\mu_n - c_{K,L}(F) \right| \;\leq\; \left(\alpha^K + e^{-\lambda(L+1)} \right) \cdot 2 \|F\|_\infty \, |S| \, e^{\lambda R_0} \qquad (8)$$

holds (`InfVol.lift_close`; $\lambda \geq 0$, $\alpha \leq 1$, $\beta \neq 0$). The number compared with, $c_{K,L}(F) = (Q^K_{\mathbb{Z}} F)(\mathbf{0})$, does not depend on n. $\mathbf{0}$ is the configuration in which every link has value 0 (the centre of the closed ball). Any comparison point would do; all that is needed is that it does not depend on n. It need not even be an SU(2) configuration.

Step 4: the difference between two sizes. Applying (8) to two values $n, n' \geq L+1$, subtracting, and letting $K \to \infty$ ($\alpha < 1$) gives

$$\left| \int F \, d\mu_n - \int F \, d\mu_{n'} \right| \;\leq\; 4\|F\|_\infty \, |S| \, e^{\lambda R_0} \, e^{-\lambda(L+1)} \qquad (L \geq R_0,\ L+1 \leq \min(n, n'))$$

Proved here . L is "the distance from the support to where the two tori begin to look different". The difference is exponentially small in this distance; this is what the heading means. This step is a corollary for reading and is not in the Lean chain. The proof of convergence (Step 5) goes directly from (8).

05

From a Cauchy sequence to the limit

Step 5: a Cauchy sequence. Taking $\lambda = -\frac{1}{2}\log q(\beta)$ gives $\alpha = q(\beta)^{1/2} < 1$. For a given ε, make α^K and $e^{-\lambda j}$ small and set $L = \max(R_0, j)$; then by (8) the sequence of expectations $\int F \, d\mu_n$ of a cylinder function is a Cauchy sequence (`InfVol.cauchy_cyl`). The real numbers are complete, so each cylinder function has a limit.

Step 6: cylinder functions determine the measure. If two finite measures on $\mathcal{C}$ give the same integral for every bounded continuous cylinder function, they are equal (`CylDet.ext_of_cyl`). The marginals on finitely many links agree, and by the uniqueness of projective limits (Mathlib) the whole measures agree.

Step 7: convergence without a subsequence. $\mathcal{C}$ is compact and metrisable, so the space of probability measures is also compact. Every subsequence has a convergent subsequence, whose limit agrees with the limit of Step 5 on cylinder functions, and so is the same measure by Step 6. Since every subsequence has a sub-subsequence converging to the same limit, the sequence itself converges (`CylDet.tendsto_of_cyl_cauchy`).

All sizes. The estimate (8) does not use the parity of the size, and holds for the lifts of every size $m+1$ with the same number $c_{K,L}(F)$ in between (`AllN.lift_closeS`). So the sequence of all sizes, and any partial sequence of sizes, have the same limit Proved here .

Step	What it says	Lean name
1	The estimate for box sweeps (7), no N in the constants	`LinkSpec.torus_box`

Step	What it says	Lean name
2	For $2(L+1) < N$, the sweep inside the box agrees with $\mathbb{Z}^4$	`ZHeat.iter_lift`
3	Comparison with a number independent of N (8)	`InfVol.lift_close`
5	Expectations of cylinder functions are Cauchy	`InfVol.cauchy_cyl`
6	Cylinder functions determine the measure	`CylDet.ext_of_cyl`
7	From Cauchy to convergence of the sequence	`CylDet.tendsto_of_cyl_cauchy`

As an example showing that the hypotheses can be met, the case $\beta = 1/20$ is in Lean as `InfVol.infvol_example` ($18 \tanh(1/20) = 0.8993$ Reading).

06

Translation invariance and clustering

Translation invariance. The Wilson measure on each torus is invariant under unit translations of the torus. The lift commutes with translations, so each μ_n is invariant under unit translations of $\mathbb{Z}^4$ (`TransI.lift_shiftI_invariant`). If F is bounded continuous, so is $F(x(\cdot + e_i))$, and taking the limit of both sides under weak convergence gives (3) (`TransI.limit_shiftI_invariant`). The reverse translations are also bijections, so ν_β is invariant under all translations of $\mathbb{Z}^4$ Proved here .

Clustering. The covariance estimate on the torus (the Dobrushin distance form of 20-02) uses about the distance d only that "it changes by at most 1 between two links sharing a plaquette". So replace d by the cyclic distance of the i-th coordinate of the base point (`LinkSpec.coordLip`). The support of F is in $d \le R$ and that of the shifted G_k in $d \ge k$, and if the torus is large enough ($n \ge k + R$)

$$\left|\mathrm{Cov}_{P_N}(F, G_k)\right| \;\le\; 2\|F\|\, e^{\lambda R}\, |S_G|\, e^{-\lambda k} \cdot 2\|G\|$$

Since $F \cdot G_k$, F and G_k are all bounded continuous, the estimate passes to the weak limit and becomes (4) Proved here . Whether the limit point is unique is not used.

Example. For $\beta = 1/20$, $q = 0.8993$ and $\lambda = -\frac{1}{2}\log q = 0.0531$ Reading . The exponential factor $e^{-\lambda(k-R)}$ on the right-hand side of (4) becomes 0.1 when $k - R \approx 43$ Reading . The closer to the edge of the window, the slower the decrease. There is no record of the ratio to the true decrease of correlations.

Detour: what "unique" says

May be skipped. The Lean statement has the form $\exists!\, \nu,\ \mu_n \to \nu$. The topology of weak convergence on the space of probability measures is Hausdorff, so the limit of one sequence, if it exists, is always unique. So the "unique" part is trivial from the topology and adds no

information. The content of the statement is that “the sequence itself converges, without passing to a subsequence”.
Compactness alone only gives “there is a convergent subsequence”. In that case different subsequences could have different limits. The theorem on the limit without a subsequence closes off that possibility for this sequence (if the sequence converges, the limit of every subsequence is the same ν_β; Lean's `CylDet.subseq_limit_eq`).
The sequence is not constant. The lift for $n = 0$ (the 2^4 torus) has period 2, and $x_{\ell+2e_1} = x_\ell$ in every configuration. For $n = 1$ (4^4) these two are different links, and the probability that they agree is 0 Proved here . So $\mu_0 \neq \mu_1$.
Do not read “unique” as uniqueness of the Gibbs measure including limits coming from other boundary conditions. That is outside this theorem (§ 07).

07

What is not said

- **The lattice spacing is fixed at 1.** Nothing is said about the continuum limit, the operation of sending the lattice spacing to 0.
- **The window is narrow.** Only $|\beta| < 0.0556$ Reading . Nothing is said about weak coupling.
- $\beta = 0$ **is outside the statement.** The hypothesis is $\beta \neq 0$ ($\beta = 0$ is the product of Haar measures, and its limit is trivial).
- **Periodic boundary conditions only.** This is convergence of the sequence of periodic lifts; nothing is said about sequences with free or fixed boundary conditions, or about uniqueness of measures satisfying the DLR equations.
- **Translations are the generators, the unit translations.** Invariance under rotations and other lattice symmetries is not in the theorems of this chapter. The invariance under generators in 20-05 is a theorem about a different measure (the measure with fermions on a finite lattice).
- **The clustering estimate is an upper bound only.** (4) is an upper bound on the correlations (a lower bound on the rate of decrease) and does not say how fast the true correlations decrease. λ is chosen within $e^\lambda q(\beta) < 1$, and the $\frac{1}{2}$ in $-\frac{1}{2}\log q$ is a matter of choice.
- **Not a new result.** These are known results of Dobrushin-uniqueness type and Osterwalder–Seiler strong-coupling type, written in Lean on the concrete SU(2) Wilson measure.

What this chapter can say

What is said	What is not said
Cited The theorem on the limit without a subsequence: for $\beta \neq 0$, $18 \tanh \lvert\beta\rvert < 1$, μ_n (size $2(n+1)$) converges weakly, as a sequence, to a single ν_β (`InfVol.wilson_infvol_unique`)	Outside the window, $\beta = 0$, other boundary conditions, uniqueness of the Gibbs measure. "Unique" is trivial from the topology
Cited The theorem on the limit independent of size: the same limit for all sizes $m+1$ and for any $s(k) \to \infty$ (`AllN.wilson_infvol_allN`)	An explicit form of the rate of convergence (an estimate of the form (9) exists, but is not in the statement)
Cited Translation invariance of the limit: invariant under unit translations in four directions (`TransI.wilson_infvol_translation`)	Invariance under rotations and reflections
Cited Clustering at limit points: (4), four directions, at every limit point (`WilsonLimit.cluster_limit`, $\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$)	The true rate of decay, outside the window
Proved here The estimate (9) of the difference between two sizes (a one-line consequence of (8) in Lean)	(9) itself is not a Lean declaration
Reading The window $\lvert\beta\rvert < 0.055613$; for $\beta = 1/20$, $q = 0.8993$ and $\lambda = 0.0531$	Floating-point values (not interval estimates)

Reconstruction and the mass gap — inside the strong-coupling window

> This chapter is this book's own investigation.

What this chapter shows — In the strong-coupling window: the transfer operator T on the Hilbert space reconstructed from the infinite-volume measure ν_β satisfies $\|T\| \leq (18 \tanh|\beta|)^{1/2}$ on the orthogonal complement of the vacuum. That complement is not 0 (non-degeneracy). The same holds in the sector of gauge-invariant observables. For $\beta \geq 0$, $T \geq 0$. The range of T lies in the gauge-invariant sector. And a statement bundling these into one. Each is a formalisation, machine-checked in Lean, of a result of a known type.

Prerequisite chapters — 19-03 The vessel of reconstruction, the definition of the mass gap, 20-03 The infinite-volume limit, 20-01 Reflection positivity. Reconstruction and the definition of the mass gap as established knowledge are in 4-10 and 4-11.

Said first — The "mass gap" here is only the upper bound $\|T - P_\Omega\| \leq e^{-m}$, that is, a **lower bound** on the mass. It does not say that the mass is finite ($T \neq P_\Omega$). The lattice spacing is fixed at 1, the window is only $|\beta| < 0.0556$ Reading , and nothing is shown about a mass gap in the continuum limit.

The order of this chapter

1. The vessel — building the Hilbert space and T from the pairing, the translation and the constant: the three data the statements pin down.
2. The mass gap with non-degeneracy: two theorems for two windows.
3. Why non-degeneracy is put in the statement: avoiding a form that holds even for a one-point model.
4. The route of proof: from decay of correlations to the operator norm.
5. The gauge-invariant sector and the range of T: the plaquette observable, and F_0 falling into the kernel.
6. T ≥ 0: reflection in the middle plane and the gauge average.
7. The bundled statement: $0 < \beta$, everything inside the window.

8. What is not said: lower bound only, the window, the lattice spacing.

01

The vessel — building the Hilbert space and T from the pairing, the translation and the constant

The definition of the vessel is in 19-03. For an introduction, see 4-10. Here we write only the form we use.

The space of observables W. The set of bounded continuous functions depending only on finitely many links whose base points have time coordinate from 0 to R (R finite for each function). Equivalently, the cylinder functions on the closed positive half. Its Lean name is `Wsub`.

Three data. Let ν be a probability measure, and set

$$B(F,G)=\int F(\Theta x)\,G(x)\,d\nu(x),\qquad (\tau F)(x)=F(x(\cdot+e_0)),\qquad \mathbf{1}=\text{the constant 1}\ \text{(1)}$$

Θ is the time reflection $x_0\mapsto -x_0$ (time links are shifted by one and reversed in direction; 19-03). When B is positive semi-definite and symmetric, τ is symmetric with respect to B, $\tau\mathbf{1}=\mathbf{1}$, $B(\mathbf{1},\mathbf{1})=1$, and the orbits under translation are bounded, the triple $(B,\tau,\mathbf{1})$ is called a **vessel of reconstruction** (Lean's `OSGap.Datum`).

What is built. Put the semi-inner product B on W, divide out the null elements and complete to get $\mathcal{H}$; write $[F]$ for the image of an element of W, the vacuum $\Omega=[\mathbf{1}]$, T for the continuous extension of τ, and $P_\Omega v=\langle\Omega,v\rangle\Omega$ for the projection onto the vacuum.

Definition of the mass gap. The definition is in 19-03.

$$\texttt{HasMassGap}\ m\quad:\Longleftrightarrow\quad \|T-P_\Omega\|\le e^{-m}.\ \text{(2)}$$

Since $T\Omega=\Omega$ and T is symmetric, this is the same as "$\|T\|\le e^{-m}$ on the orthogonal complement of Ω" Proved here . In one time step, the components other than the vacuum shrink by a factor of at least e^{-m}. m is a lower bound on the mass (the energy gap).

The statements pin down the data. All the theorems below have the form "there is a vessel D such that the B of D is the integral (1), its τ is the translation by one time step, its $\mathbf{1}$ is the constant 1, and ...". All three data fields are fixed in the conclusion, so D is determined by ν Proved here . One cannot satisfy the conclusion by swapping T for an arbitrary operator.

02

The mass gap with non-degeneracy

Set $F_0(x) = \operatorname{Re} x\ell_0$, where ℓ_0 is the link of direction 1 (spatial) based at the origin; $F_0 \in W$. Write $q(\beta) = 18 \tanh|\beta|$ (20-03).

The mass gap with non-degeneracy — the Dobrushin window

Cited A formalisation of results of Dobrushin and Osterwalder–Seiler strong-coupling type. Lean: `WilsonLimit.wilson_massGap_dob_exists` ($\beta \neq 0$, $q(\beta) < 1$).

Let $\beta \neq 0$ and $18 \tanh|\beta| < 1$. Then there are a weak limit ν of some subsequence of μ_n and a vessel D built from ν by (1) such that

$$\|T - P_\Omega\| \le \big(18 \tanh|\beta|\big)^{1/2}, \qquad B(F_0, F_0) - B(\mathbf{1}, F_0)^2 \;\ge\; \tfrac{1}{4} e^{-12|\beta|}, \qquad \exists\, v \perp \Omega,\ \|v\| =$$

The first is **HasMassGap** with $m = -\frac{1}{2}\log q(\beta)$; the second and third are non-degeneracy.

The mass gap with non-degeneracy — at every limit point

Cited A formalisation of a result of the same type. Lean: `WilsonLimit.wilson_massGap_nondegenerate` ($\beta \neq 0$, $24(1 - e^{-4|\beta|}) < 1$; ν is the weak limit of any subsequence of μ_n).

In the window $24(1 - e^{-4|\beta|}) < 1$ ($|\beta| < 0.0106$ Reading), for **every** limit point ν, the vessel D satisfies **HasMassGap**$\big(-\log 24(1 - e^{-4|\beta|})\big)$ and the two non-degeneracy conditions of (3). The estimate in this window comes from the finite-volume decay of 20-02.

The two theorems differ in window and rate. The Dobrushin-window form picks one limit point in its statement, but the same estimate holds at every limit point (`WilsonLimit.wilson_massGap_dob`, § 04 Step 4). Moreover, inside the window the limit point is unique, ν_β (20-03). The narrow-window form reaches a conclusion of the same type by a different route, from the finite-volume decay (20-02), with rate $-\log 24(1 - e^{-4|\beta|})$. § 07 bundles the Dobrushin-window form for the limit ν_β without a subsequence. The narrow-window rate is not in § 07.

An example. For $\beta = 1/20$, $q = 0.8993$, $\|T - P_\Omega\| \le 0.948$, and the lower bound on the mass is $m = 0.053$ Reading. The lower bound for non-degeneracy is $\frac{1}{4}e^{-0.6} = 0.137$ Reading. The closer to the edge of the window, the closer the lower bound on the gap gets to 0.

03

Why non-degeneracy is put in the statement

(2) alone can have thin content. If $\mathcal{H}$ is the one-dimensional space spanned by Ω, then $T = P_\Omega$ and $\|T - P_\Omega\| = 0$. Then (2) holds for every m. This happens, for example, if ν is a point mass. So unless "there is a gap" is paired with "there are states outside the vacuum", it is a statement that holds even for a one-point model. For this reason, this book does not present theorems in the form without non-degeneracy.

Two forms of non-degeneracy. The second item of (3) is "the variance of F_0 measured by the reflection pairing is positive"; the third is "there is a unit vector orthogonal to Ω". The third follows from the second: $y = F_0 - B(\mathbf{1}, F_0)\mathbf{1}$ has $B(\mathbf{1}, y) = 0$ and $B(y, y) > 0$, so $v = [y]/\|[y]\|$ is a unit vector (`OSGap.Datum.exists_unit_orth`). The third rules out a one-dimensional $\mathcal{H}$ at the level of types.

Where the lower bound on the variance comes from. In steps:

1. ℓ_0 is a spatial link at time 0, so it is fixed by Θ, and $F_0 \circ \Theta = F_0$. Hence $B(F_0, F_0) - B(\mathbf{1}, F_0)^2 = \mathrm{Var}_\nu(F_0)$ Proved here .
2. For the Haar measure on SU(2), left invariance under $q \mapsto -q,\ iq,\ jq,\ kq$ gives $E\,\mathrm{Re}\,U = 0$ and $E(\mathrm{Re}\,U)^2 = \frac{1}{4}$. Hence $E(\mathrm{Re}\,U - c)^2 \geq \frac{1}{4}$ for every c (`HaarRe.integral_sq_sub_ge`).
3. The density of the conditional distribution of one link is given by the weights of the 6 plaquettes containing that link, and lies between $e^{\pm 6|\beta|}$. So the conditional variance is at least $\frac{1}{4}e^{-12|\beta|}$, and integrating gives $\mathrm{Var}(F_0) \geq \frac{1}{4}e^{-12|\beta|}$ on every torus (`LinkSpec.wilsonProb_sq_sub_ge`).
4. F_0 and F_0^2 are bounded continuous, so the lower bound passes to the weak limit (`WilsonLimit.var_limit_ge`).

04

The route of proof

The mass-gap part combines a general lemma that turns decay of correlations into an operator norm with the decay estimate for the Wilson measure.

Step 1: the axioms of the vessel. Positive semi-definiteness of B comes from carrying reflection positivity for the plane through sites on each torus (20-01) over to the weak limit. Symmetry of τ comes from translation invariance and its relation to Θ; boundedness of orbits from $|F| \leq \|F\|_\infty$.

Step 2: from decay to the operator norm. On the vessel, if for every $F \in W$ there is a constant C_F with

$$B(\tau^k F, \tau^k F) - B(\mathbf{1}, F)^2 \;\le\; C_F\, r^{2k} \qquad (k = 0, 1, 2, \dots) \tag{4}$$

then $\|T - P_\Omega\| \le r$ (`OSGap.Datum.opNorm_gap`). The left-hand side is $\|T^k[F] - P_\Omega[F]\|^2$ Proved here, so this is an argument that turns an estimate on a dense set into a spectral estimate for a symmetric operator.

Step 3: decay for the Wilson measure. $B(\tau^k F, \tau^k F) = \int F(\Theta\tau^k x) F(\tau^k x)\, d\nu$ is the correlation of two observables about $2k$ apart in time. Applying the Dobrushin distance covariance estimate on the torus (20-02, `LinkSpec.wilson_cov_dist`) gives $C_F\, e^{-2\lambda k}$ with a constant independent of N (`TorusRP.wilson_hdec_torus_dob`). λ is any number with $\lambda \ge 0$ and $e^{\lambda} q(\beta) < 1$ (in Step 4, $\lambda > 0$). Decay of this form is `WilsonLimit.dec_eventually_dob`. The estimate passes to limit points.

Step 4: choice of rate. Applying Step 2 with $r = e^{-\lambda}$ gives `HasMassGap` λ (`WilsonLimit.wilson_massGap_dob`). The $\lambda = -\frac{1}{2}\log q(\beta)$ in (3) is one choice satisfying $e^{\lambda} q = q^{1/2} < 1$, and the $\frac{1}{2}$ has no physical meaning. From the same theorem one can take a rate arbitrarily close to $-\log q(\beta)$.

Step 5: non-degeneracy. The four steps of § 03.

05

The gauge-invariant sector and the range of T

For an introduction, see 4-11. A gauge transformation $g : \mathbb{Z}^4 \to SU(2)$ acts as $(g \cdot x)_\ell = g(b)\, x_\ell\, g(b + e_\mu)^*$ (b the base point of ℓ, μ its direction). Let W_{gi} be the set of elements of W invariant under every g. $F_p = \mathrm{Re}\, U_p$ (the real part of the holonomy of the $(1,2)$ plaquette at the origin) belongs to W_{gi}.

The mass gap in the gauge-invariant sector

Cited A formalisation. Lean: `GaugeZ.wilson_massGap_gauge_exists` ($\beta \neq 0$, $q(\beta) < 1$).

The same form as (3) holds with W replaced by W_{gi} and F_0 by F_p. For some limit point ν, on the vessel over W_{gi}, $\|T - P_\Omega\| \le q(\beta)^{1/2}$, $\mathrm{Var}_\nu(F_p) \ge \frac{1}{4} e^{-12|\beta|}$, and there is a unit vector orthogonal to the vacuum. The lower bound on the variance comes from the fact that when one link U of the plaquette is varied, $U_p = UV$ (V, the product of the other three, is a unit), and the Haar variance of $\mathrm{Re}(UV)$ is the same as that of $\mathrm{Re}\, U$.

Why separate the sector. The witness F_0 of non-degeneracy for the whole W is not gauge invariant. The bundled statement (§ 07) contains $T[F_0] = 0$. That is, $[F_0]$ is a nonzero vector orthogonal to the vacuum, but it is killed by T. This is because a gauge

transformation placing the central element -1 at the site e_0 gives $\int G(\Theta x) F_0(\tau x)\, d\nu = 0$ for every $G \in W$ Proved here . This is the same mechanism as Elitzur's theorem (local gauge symmetry cannot be broken) Cited . Non-degeneracy in the gauge-invariant sector (witness F_p) is the non-degeneracy with content. F_p is not a vector known to be killed by T. However, $T[F_p] \;/= 0$ (that T is not 0 on the complement in this sector) is not in the Lean statement either.

The range of T lies in the gauge-invariant sector

Cited A formalisation. Lean: `Bind.T_range_gauge_all` ($\lambda > 0$, $e^{\lambda} q(\beta) < 1$; ν any limit point).

For the vessel D over W and the vessel D' over W_{gi} (both with data pinned down by (1)), both satisfy **HasMassGap** λ, and there is an isometric linear map $\iota : \mathcal{H}' \to \mathcal{H}$ with

$$\iota \Omega' = \Omega, \qquad \iota T' = T \iota, \qquad T u \in \iota(\mathcal{H}') \text{ for all } u \in \mathcal{H}. \quad (5)$$

The gauge-invariant sector embeds isometrically into the whole Hilbert space, commutes with T, and the range of T lies entirely inside it. The proof uses that taking the Haar average of gauge transformations over the end points of the support of τF gives an element of W_{gi} without changing the values of the pairing. The image of ι is closed and T is continuous, so the statement extends from a dense set to all u.

06

T ≥ 0

Cited A formalisation. Lean: `FullT.wilson_Tpos_full` ($\beta \geq 0$, $\lambda > 0$, $e^{\lambda} q(\beta) < 1$; ν any limit point).

Let $\beta \geq 0$. There is a vessel D over W (with data pinned down by (1)) for which **HasMassGap** λ, the two non-degeneracy conditions of (3), and

$$\langle v, T v \rangle \;\geq\; 0 \qquad (\text{for all } v \in \mathcal{H}) \quad (6)$$

all hold.

Route. $\langle [F], T[F] \rangle = B(F, \tau F) = \int F(\Theta x) F(\tau x)\, d\nu$. Since $\tau \circ \Theta' = \Theta$ (Θ' is the reflection $x_0 \mapsto 1 - x_0$ in the plane through the middle of links), this is the pairing for reflection in the middle plane. Reflection positivity for the middle plane (20-01) is about gauge-invariant functions and uses $\beta \geq 0$. So we insert the Haar average A over gauge transformations on all sites of the torus (G is a bounded measurable function depending only on the positive side). The measure is invariant under gauge

transformations, so $\int G(\Theta'\omega)G(\omega) = \int (AG)(\Theta'\omega)(AG)(\omega)$, and AG is gauge invariant. Thus it is positive on each torus, positive in the limit, and extends from a dense set to all v.

Reading. Combining $T \geq 0$, $T\Omega = \Omega$ and $\|T - P\Omega\| \leq e^{-m}$, the spectrum of T on the complement of Ω lies in $[0, e^{-m}]$ Proved here . Writing $-\log T$, we have $-\log T \geq m$ on the complement (read as $+\infty$ on the kernel of T). Nothing is said about $\beta < 0$.

07

The bundled statement

Cited A formalisation of results of Dobrushin-uniqueness type and Osterwalder–Seiler strong-coupling type. Lean: `InfMain2.wilson_infvol_main2` ($0 < \beta$, $18 \tanh \beta < 1$).

Let $0 < \beta$ and $18 \tanh \beta < 1$, and set $m = -\frac{1}{2} \log(18 \tanh \beta)$. There is a unique probability measure ν_β for which all of the following hold.

1. $\mu_n \to \nu_\beta$ (weak convergence without a subsequence; 20-03).
2. ν_β is invariant under unit translations in the four directions.
3. $\int F(\Theta x) F(x)\, d\nu_\beta \geq 0$ for every $F \in W$ (reflection positivity).
4. On the vessel over W (data pinned down by (1)): $\mathtt{HasMassGap}\ m$, $\mathrm{Var}(F_0) \geq \frac{1}{4} e^{-12\beta}$, existence of a unit vector orthogonal to Ω, $T[F_0] = 0$, and $T \geq 0$.
5. On the vessel over W_{gi} (pinned down likewise): $\mathtt{HasMassGap}\ m$, $\mathrm{Var}(F_p) \geq \frac{1}{4} e^{-12\beta}$, existence of a unit vector orthogonal to Ω, and $T \geq 0$.
6. Clustering in four directions: (4) of 20-03 with rate m.

The “unique” part is trivial from the topology; the content is the convergence in item 1 (the detour in 20-03). That the range of T lies in the gauge-invariant sector ((5) of § 05) is not in this statement. It is the separate theorem `Bind.T_range_gauge_all`.

08

What is not said

- **Only a lower bound on the mass.** $\|T - P\Omega\| \leq e^{-m}$ also holds if T is 0 on the complement (“infinite mass”). It is not said that the mass is finite, or that $T \neq P\Omega$. The number $-\frac{1}{2} \log(18 \tanh \beta)$ is a lower bound, and the $\frac{1}{2}$ is a matter of choice. There is no record of its ratio to the true mass.

- **The window is narrow.** $|\beta| < 0.0556$ Reading (the form for every limit point: $|\beta| < 0.0106$ Reading). Nothing is said about weak coupling or the physical range of couplings.
- **The lattice spacing is fixed at 1.** This is a lower bound on the mass measured in lattice units. Whether a mass gap survives in the continuum limit is outside the theorems of this part.
- **Sign.** The bundled statement needs $0 < \beta$, and $T \geq 0$ needs $\beta \geq 0$. The gap and non-degeneracy alone hold for $\beta \neq 0$ of either sign.
- **Reading of the sector.** W_{gi} is the set of functions that are "cylinder functions and gauge invariant". Whether its closure coincides with the physical space of gauge-invariant states is not said.
- **Not a new result.** These are known results of Osterwalder–Seiler strong-coupling type, written in Lean on the concrete SU(2) Wilson measure.

What this chapter can say

What is said	What is not said
Cited The mass gap with non-degeneracy (Dobrushin window, some limit point): (3) (`WilsonLimit.wilson_massGap_dob_exists`, $\beta \neq 0$)	That the mass is finite; outside the window
Cited The mass gap with non-degeneracy (every limit point, window $24(1 - e^{-4\|\beta\|}) < 1$) (`WilsonLimit.wilson_massGap_nondegenerate`)	As above; the window is narrower still
Cited The mass gap and non-degeneracy in the gauge-invariant sector (witness F_p) (`GaugeZ.wilson_massGap_gauge_exists`)	That the closure of W_{gi} coincides with the physical space of states
Cited $T \geq 0$ (on the whole W) (`FullT.wilson_Tpos_full`, $\beta \geq 0$)	$\beta < 0$
Cited The range of T lies in the gauge-invariant sector, (5) (`Bind.T_range_gauge_all`)	Not included in the bundled statement
Cited The bundled statement (`InfMain2.wilson_infvol_main2`, $0 < \beta$, $18 \tanh \beta < 1$)	The continuum limit, changing the lattice spacing, an upper bound on the mass
Proved here The reading, from $T \geq 0$ and the gap, that the spectrum on the complement lies in $[0, e^{-m}]$	The reading itself is not a Lean declaration
Reading For $\beta = 1/20$: $\|T - P_\Omega\| \leq 0.948$, $m = 0.053$, lower bound for non-degeneracy 0.137	Floating-point values

Words used in this chapter — vessel of reconstruction, transfer operator, vacuum, mass gap (lower bound), non-degeneracy, gauge-invariant sector, Elitzur's theorem, reflection positivity, strong-coupling window. Their meanings are in the A-02 Glossary.

Next chapter to read: 20-05 The vessel with fermions — on a finite lattice whose weight includes the Wilson–Dirac determinant, it reads reflection positivity, Z > 0 and the symmetries.

The vessel with fermions

This chapter is this book's own investigation.

What this chapter shows — On the finite lattice $(\mathbb{Z}/N)^3 \times \mathbb{Z}/2h$, the measure given by the Wilson gauge weight $e^{-\beta S_W}$ multiplied by the determinant of the Wilson–Dirac operator, $\mathrm{Re}\left[(\det D)^{2j}\right]$, is positive with respect to reflection in a time plane through sites (mass $m > -1$, all β). The partition function is positive (all β, m, j). $\det D$ is invariant under global gauge transformations. The normalised measure is invariant under the generators of the lattice symmetries. Each is a formalisation, machine-checked in Lean, of a result of a known type.

Prerequisite chapters — 19-05 The Wilson–Dirac operator, the measure with fermions, 20-01 Reflection positivity. Reflection positivity on the lattice and the transfer matrix as established knowledge are in 5-03.

Said first — All are statements on one finite lattice. Nothing is said about the infinite-volume limit, the continuum limit, chiral symmetry, or mass renormalisation. The symmetries are invariance under each generator; closure as a group is outside the statements. There is no mass gap with fermions in this chapter either.

The order of this chapter

1. The objects — the lattice, the action, the determinant weight: which measure.
2. Reflection positivity for the plane through sites: $m > -1$, all β.
3. The route of proof of reflection positivity: how the action splits, and positivity of the plane matrix.
4. Positivity of the partition function: normalisation can be defined.
5. Global gauge invariance of the determinant: conjugation by a constant g.
6. Invariance under the generators of the lattice symmetries: translations, rotations, reflections, time reflection.
7. What is not said: a finite lattice, the continuum limit, chiral symmetry.

01

The objects — the lattice, the action, the determinant weight

The definitions are in 19-05. Here we write only what is needed to read the theorems.

Lattice and links. Space is the three-dimensional torus $(\mathbb{Z}/N)^3$, and time is the circle $\mathbb{Z}/2h$ ($h \geq 1$). The links are the spatial links $x \to x + e_i$ ($i = 1, 2, 3$) at time t, and the time links $t \to t + 1$. Placing an element of SU(2) on each link gives a configuration ω, and the configuration space carries the product of Haar measures over links.

Gauge action. Counting unoriented plaquettes once each, set

$$S_W(\omega) = \sum_p \left(1 - \tfrac{1}{2} \operatorname{Re} \operatorname{tr} U_p\right) \quad (1)$$

and take the weight $e^{-\beta S_W}$. Since $\frac{1}{2} \operatorname{tr} U$ equals the real part of the quaternion, this is a constant multiple of the weight $e^{\beta \sum_p \operatorname{Re} U_p}$ of 19-01 Proved here. The orientation of β is also the same.

The Wilson–Dirac operator. $D = D(\omega)$ is the operator with Wilson-term coefficient $r = 1$ and mass m, with antiperiodic boundary conditions in all four directions (Lean's `WilsonGauge.physDirac`).

$$D = (4 + m)\,\delta - \tfrac{1}{2} \sum_\mu \left[(1 - \gamma_\mu)\, U_\mu(x)\, \delta_{x+\hat{\mu}} + (1 + \gamma_\mu)\, U_\mu(x - \hat{\mu})^\dagger\, \delta_{x-\hat{\mu}}\right] \quad (2)$$

The weight with fermions. Fix a natural number j, and set

$$w(\omega) = e^{-\beta S_W(\omega)} \cdot \operatorname{Re}\left[(\det D(\omega))^{2j}\right] \quad (3)$$

(`wfWeight`). As in 19-05, $(\det D)^{2j}$ is a non-negative real number, and Re is a notational convention. $\det D^{2j}$ corresponds to integrating out, with Grassmann variables, $2j$ flavours of fermions of the same mass. In Lean no Grassmann variables are introduced; the determinant itself is defined as the weight. The normalised measure $P = w\, d\omega / Z$, $Z = \int w\, d\omega$, is `wfProb` (19-05).

02

Reflection positivity for the plane through sites

For an introduction, see 5-03. The time reflection $\Theta : t \mapsto -t \pmod{2h}$ fixes the two site planes at times $t = 0$ and $t = h$. Divide the configuration into three parts: the spatial links on the two planes, c; the positive side a_+ (spatial links with $0 < t < h$, and time

links leaving $0 \le t < h$); and the negative side a_- (the rest, carried by Θ into the form of the positive side, with time links inverted).

Reflection positivity of the Wilson–fermion weight

Cited A formalisation of a result of Osterwalder–Seiler type. Lean: `WilsonGauge.site_reflection_positive_wilson_full` ($h > 0$, $m > -1$, all $\beta \in \mathbb{R}$, all j).

If φ is a bounded measurable real-valued function of (c, a_+), then

$$\int \varphi(c, a_+)\, \varphi(c, a_-)\, e^{-\beta S_W(\omega)}\, \mathrm{Re}\big[(\det D(\omega))^{2j}\big]\, d\omega \;\ge\; 0. \quad (4)$$

$\varphi(c, a_-)$ is φ read on the reflected configuration, that is, $(\Theta\varphi)$. (4) is reflection positivity of the form "$\langle \Theta\varphi \cdot \varphi \rangle \ge 0$", stated for the unnormalised measure. In Lean the integral is written in the split coordinates (c, a_+, a_-), and `WilsonGauge.physDirac_eq_split` says that the operator assembled in those coordinates is the same as the D of the physical configuration. Since $Z > 0$ (§ 04), the sign is the same after normalisation Proved here .

Why the sign of β does not matter. For reflection in the plane through sites, no plaquette straddles the plane. Every plaquette lies on one of the two fixed planes, on the positive side, or on the negative side. So $e^{-\beta S_W}$ splits as "a factor on the planes only $\times$ a factor on the positive side $\times$ a factor on the negative side", and no sign condition on the factors is needed Proved here . For reflection in the plane through the middle of links, $\beta \ge 0$ is needed to expand the factor of the straddling plaquettes as a positive kernel. The theorems of this chapter do not treat that case.

Why $m > -1$. On the fermion side, we use that the block of the operator on the fixed planes (the plane matrix) is positive definite (`FermionSliceBlock.wilsonPlane_posDef`). The plane matrix has the form $(m+1) + \sum_i (1 - \frac{1}{2}(T_i + T_i^\dagger))$ (T_i unitary hops), and each term $1 - \frac{1}{2}(T_i + T_i^\dagger)$ is positive semi-definite, so it is at least $m + 1$ Proved here . $m > -1$ is a sufficient condition for this. Whether it is necessary cannot be told from this theorem.

03 The route of proof of reflection positivity

Step 1: how the action splits. $S_W(\omega) = K(c) + H(c, a_+) + H(c, a_-)$, where H is **the same function** on the positive and negative sides (`WilsonGauge.wilsonAction_split`). A time plaquette on the negative side takes the form of one on the positive side when its time links are inverted and its two times are swapped, and $\mathrm{Re}\,\mathrm{tr}$ is unchanged by the cyclicity of tr and $\mathrm{tr}\, M^\dagger = \mathrm{tr}\, M$ (`WilsonGauge.plaqE_reflect`).

Step 2: abstract reflection positivity. If the weight has the form $k(c)\,w_+(c,a_+)\,w_+(c,a_-)$ ($k \geq 0$, w_+ real and bounded), and the fermion determinant side satisfies operator conditions such as positivity of the plane matrix, then an integral of the form (4) is non-negative (`FermionSliceReflection.site_reflection_positive_phys`). By Step 1 the gauge weight fits the form $k = e^{-\beta K}$, $w_+ = e^{-\beta H}$.

Step 3: the operators agree. The D written in the physical configuration (equation (2)) agrees with the operator assembled in the split configuration (`WilsonGauge.physDirac_eq_split`). This lets the operator conditions of Step 2 be discharged for the concrete D.

An example showing the hypotheses can be met: with $h = 1$, $m = 0$, $\varphi = 1$, all hypotheses hold. The statement is not vacuous.

04

Positivity of the partition function

Cited A formalisation. Lean: `WilsonGauge.partition_pos_wilson_full` ($h > 0$, all β, m, j).

$$Z = \int e^{-\beta S W(\omega)}\ \mathrm{Re}\big[(\det D(\omega))^{2j}\big]\,d\omega\ >\ 0. \tag{5}$$

There is no condition on the mass m. Since $Z > 0$, the normalised probability measure `wfProb` can be defined. $Z > 0$ is not trivial: it contains the content that $\mathrm{Re}\big[(\det D)^{2j}\big]$ does not vanish on every configuration.

05

Global gauge invariance of the determinant

Proved here A Lean formalisation of a known fact (the proof is the sentence below). Lean: `GaugeDet.physDirac_det_conj` (all N, h, m, g, ω; no hypotheses).

For the configuration $(g\cdot\omega)_\ell = g\,\omega_\ell\,g^{-1}$ obtained by conjugating every link by a constant $g \in SU(2)$,

$$\det D(g\cdot\omega) = \det D(\omega). \tag{6}$$

$D(g\cdot\omega)$ is similar to $D(\omega)$, sandwiched by the matrix that multiplies the colour index by the constant g, so the determinant does not change. g is a constant independent of the site. Local gauge transformations, which take a different $g(x)$ at each site, are outside this declaration.

06

Invariance under the generators of the lattice symmetries

Proved here A Lean formalisation of known facts (the route of proof is below). Lean: `CubicSym.wfProb_lattice_generators` ($h > 0$, all N, j, m, β).

The normalised measure P (`wfProb`) is invariant under push-forward by each of the following generators R: $R_* P = P$.

Generator	Action on configurations	Lean name
Global gauge transformation	Conjugate every link by a constant g	`conjPhys g`
Spatial unit translation (three directions)	$x \mapsto x + e_k$	`transPhys k`
Time unit translation	$t \mapsto t + 1$	`tshiftPhys`
90° rotation in a spatial plane	$e_a \mapsto e_b \mapsto -e_a$ ($a \neq b$, six oriented cases)	`rotPhys a b`
Reflection of a spatial axis	$x_k \mapsto N - 1 - x_k$	`reflPhys k`
Time reflection	$t \mapsto 2h - 1 - t$, time links inverted (the reversal about the mid-link plane $t = h - \frac{1}{2}$, different from the site-plane Θ of § 02. What Lean has is invariance of the measure under this reversal, not reflection positivity)	`treflPhys`

Proved here Likewise a formalisation. Lean: `CubicSym.wfProb_hypercubic_generators` (isotropic lattice $N = 2h$, $h > 0$). On a lattice whose spatial and time sizes are equal, in addition to all the above, the measure is also invariant under 90° rotations in a (space, time) plane (`trotPhys a`).

Route. For every generator, invariance of the measure splits into three parts. (i) The product of Haar measures over links is preserved by relabelling links and by inverting some links, $g \mapsto g^{-1}$. (ii) S_W is invariant. (iii) $\det D$ is invariant. (iii) is shown in Clifford form. Write D as $1 \otimes M + \sum_\mu \gamma_\mu \otimes A_\mu$; with a lattice permutation W and a spin matrix S (for rotations $S = 1 + \gamma_b \gamma_a$; for the reflection of axis k, the product of the other three γ), it follows from $(S \otimes W)\, D(\omega)\, (S \otimes W)^{-1} = D(R\omega)$ (`CubicSym.cliffOp_conj`, `CubicSym.det_cliffOp_perm`).

Time reflection and the determinant. For the time reflection too, the determinant itself is invariant: $\det D(\Theta_t \omega) = \det D(\omega)$ (`CubicSym.physDirac_det_trefl`; all N, h, m, ω; isotropy not needed). The spin matrix is $\gamma_1\gamma_2\gamma_3$ Proved here .

The antiperiodic seam. If the coordinate reversal is taken as $z \mapsto N - 1 - z$, the link carrying the antiperiodic sign ($N - 1 \to 0$) is mapped to itself (with its direction reversed). So the lattice permutation W needs no sign correction Proved here . If it is taken as $z \mapsto -z$, the seam moves and a signed permutation is needed.

07

What is not said

- **One finite lattice.** All theorems are statements on fixed N and h. Neither the infinite-volume limit nor reflection positivity there is in this chapter.
- **No continuum limit.** The lattice spacing is fixed. Nothing is said about the continuum limit or mass renormalisation (how to tune m).
- **No chiral symmetry.** The Wilson term breaks chiral symmetry explicitly. Nothing is said about its restoration or the treatment of fermion doubling.
- **Symmetries generator by generator.** Closure as the cubic or hypercubic group (that every element of the group arises as a product of generators) is outside the statements. Rotations involving time are only for the isotropic lattice $N = 2h$. Gauge invariance is for a global constant g; invariance of $\det D$ under local gauge transformations is not among the declarations.
- **Reflection in site planes only.** Reflection positivity for the plane through the middle of links (with fermions) is not in Lean. $m \leq -1$ is outside the range.
- **No gap.** A mass gap for the transfer operator of the measure with fermions is not among the theorems of this chapter.
- **Not a new result.** This writes, in Lean on the concrete operator, reflection positivity of Osterwalder–Seiler type and known facts about lattice symmetries.

Words used in this chapter — Wilson–Dirac operator, Wilson term, antiperiodic boundary conditions, reflection in a site plane, reflection positivity, partition function, global gauge transformation, hypercubic group, generator, chiral symmetry. Their meanings are in the A-02 Glossary.

Next chapter to read: 20-06 The area law at strong coupling, and an upper bound on the vortex free energy — estimates of Wilson loops and of the twisted partition function inside the strong-coupling window.

The area law at strong coupling, and an upper bound on the vortex free energy

This chapter is this book's study.

What this chapter shows — In the window where the coupling $\beta \geq 0$ is small (strong coupling), we read two estimates for the SU(2) Wilson measure on the four-dimensional torus $(\mathbb{Z}/N)^4$ that are machine-checked in Lean. (i) **The area law**: the expectation of the Wilson loop along the boundary of a rectangle with sides R, T is $\leq C\,(Kq)^{\mathrm{area}}$ ($Kq < 1$, K is 441 or 4096, $q = 1 - e^{-2\beta}$), and the constants contain no N, R or T. It holds for rectangles with any corner and orientation, and for the standard rectangle it also holds for the infinite-volume limit measure. (ii) **An upper bound on the vortex free energy**: the difference between the partition function Z_1 with a 't Hooft twist by the centre element -1 and the untwisted Z_0 is small at a rate per unit area independent of N. The prefactor N^2 remains. The proof is made of four parts: the positive mixture, the terms that vanish under reversal of the central sign, the domination lemma, and the connectedness, area lower bound and counting of minimal sets of plaquettes.

Prerequisite chapters — 19-01 The Wilson measure, plaquettes and holonomy, the product of Haar measures; 19-02 the sign of the twist, the vortex ratio; 20-03 The infinite-volume limit. The introductions are 5-02 (strong coupling and the area law) and 25-01 (twisted tori and flux).

Said first — The lattice spacing is fixed at 1, and these are statements only inside the strong-coupling window. Depending on the version of the constants, the window is $\beta < 1.22 \cdot 10^{-4}$ or $\beta < 1.135 \cdot 10^{-3}$ Reading . Nothing is said about the continuum limit, weak coupling ($\beta \to \infty$) or the band. These are statements on the lattice, distinct from "continuum Wilson loops and the area law" Assessment , which the assessment of the published construction lists as an open question. The constants are coarse, and the rates are on the side much smaller than the true values. Each is a formalisation of known results of the type of Osterwalder–Seiler (area law) and of 't Hooft and Münster (vortex free energy) Cited .

The order of this chapter

1. Setting — Wilson loops and the twisted partition function — the closed path on the boundary of a rectangle, q and the window
2. Statement (i) — the area law in finite volume — five versions (Table 1)
3. Statement (ii) — for the infinite-volume limit measure — the limit of the whole sequence, and every limit point
4. Statement (iii) — an upper bound on the vortex free energy — the rate per unit area does not depend on the transverse size
5. Route of the proof — four parts and one sum — the overall flow
6. Parts of the proof (1) — the positive mixture and the domination lemma — a one-step inequality that needs no positivity
7. Parts of the proof (2) — terms that vanish under reversal of the central sign — spanning sets, good sets and bad sets
8. Parts of the proof (3) — connectedness, area lower bound and counting of minimal sets of plaquettes — root, $R\min(T, N-T)$, N^2, $\Delta^{2(n-1)}$
9. Detour: from the parity of row cochains to the area lower bound — a difference equation column by column
10. In numbers — the window, the non-trivial range, comparison with the thin-vortex floor
11. What is said, and what is not

Labels — Source = we read the source of the published construction; Inferred = this book's inference; Assessment = from the committee's assessment (details in "Labels" in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are the labels of the whole book; Reading is a numerical reading of this book, and Lean a Lean theorem of this book. The names of Lean declarations are written outside the labels, on the same line as the scope.

01

Setting — Wilson loops and the twisted partition function

The introduction is 5-02. At strong coupling (small β), the expectation of a Wilson loop starts from terms that tile a surface bounded by the loop one plaquette at a time, and is exponentially small in the area. This is the strong-coupling area law, the starting point of the picture of confinement in lattice gauge theory Cited . This chapter reads that estimate as a theorem about the SU(2) Wilson measure on a finite torus.

The measure. The lattice is $(\mathbb{Z}/N)^4$; the link variables $U_\ell \in SU(2)$ (unit quaternions), the plaquette holonomy U_p and its real part $s_p := \operatorname{Re} U_p = \frac{1}{2}\operatorname{tr} U_p \in [-1,1]$ are as in 19-01. The plaquettes are the $6N^4$ unoriented ones with $i<j$. The Wilson measure is the product of Haar probability measures multiplied by the density $e^{\beta\sum_p s_p}$, and expectations are

$$\langle F\rangle_{N,\beta} := \frac{\int F\, d\mu_{\mathrm{W}}}{\int 1\, d\mu_{\mathrm{W}}}, \qquad d\mu_{\mathrm{W}} = e^{\beta\sum_p s_p}\prod_\ell dU_\ell \tag{1}$$

(the ratio of Lean's `wilsonMeasure N β` to its total mass). β follows the same convention as the standard SU(2) $\beta = 4/g^2$.

The boundary of a rectangle. Fix two directions $i \neq j$, a corner a and sides R, T ($1 \le R, T < N$), and let C be the closed path that goes from a R steps in direction i, T steps in direction j, then back R steps in direction i and T steps in direction j. $W(C)$ is the ordered product of the links along this path (links traversed backwards are conjugated), and $\operatorname{Re} W(C) = \frac{1}{2}\operatorname{tr} W(C)$ is gauge invariant. The standard rectangle has its corner at the origin and lies in the plane spanned by directions 1 and 2 (0 and 1 in the Lean indices). Like Parts 21 and 22, this chapter numbers the directions 1 to 4. 20-01 to 20-05 write the directions 0 to 3 as in the Lean indices, and their directions 0 and 1 are directions 1 and 2 of this chapter. Lean: `AreaLaw.rectWord` (standard), `AreaLaw.rectWordG` (general); the product is `wordHol`. For $R = T = 1$ it coincides literally with the boundary of a single plaquette (`AreaLaw.rectWord_one_one`). Since R, $T < N$, the path does not wind around the torus.

The twisted partition function. Write Z_D for the total mass of the weight $e^{\beta\sum_p \eta_p s_p}$ in which the sign of s_p is reversed on a set D of plaquettes ($\eta_p = -1$ for $p \in D$, $\eta_p = 1$ otherwise). On $(\mathbb{Z}/N)^4$, take D to be "the plaquettes of orientation 1, 2 with $x_1 = x_2 = 0$" (x_3, x_4 arbitrary, N^2 plaquettes), and set $Z_0 := Z_\varnothing$ (the ordinary partition function) and $Z_1 := Z_D$. This is the partition function with one 't Hooft twist by the centre element -1 (the same placement of plaquettes as the twist in 19-02). Lean: `VortexStrong.Ztw`, `VortexStrong.twist`.

The window. Throughout this chapter we set

$$q := 1 - e^{-2\beta} \qquad (\beta \ge 0) \tag{2}$$

so $q \approx 2\beta$. The window has the form $Kq < 1$: for $K = 4096$ it is $\beta < 1.22085\cdot 10^{-4}$, and for $K = 441$ it is $\beta < 1.13507\cdot 10^{-3}$ Reading .

02

Statement (i) — the area law in finite volume

Statement (the strong-coupling area law, finite volume)

Let $N \geq 2$, $\beta \geq 0$ and $4096q < 1$. For the boundary C of a standard rectangle with $1 \leq R, T < N$,

$$\left|\langle \operatorname{Re} W(C)\rangle_{N,\beta}\right| \;\leq\; 16\,\frac{(4096\,q)^{R\cdot\min(T,\,N-T)}}{4096\,(1-4096\,q)}. \tag{3}$$

Lean A formalisation of the type of the Osterwalder–Seiler strong-coupling area law. Lean: `AreaLaw.area_law_wilson` (the only assumptions are $\beta \geq 0$, $1 \leq R, T < N$, $4096q < 1$; the constants 16 and 4096 do not depend on N, R, T).

If $2T \leq N$, then $\min(T, N-T) = T$ and the exponent is the area RT (`AreaLaw.area_law_wilson_area`). There are four more versions of the same form (Table 1).

Version	Rectangle	Window	Right-hand side	Lean
Basic	Standard	$4096q < 1$	$16\,(4096q)^{R\min(T,N-T)}/(4096(1-4096q))$	`AreaLaw.area_law_wilson`
Position and orientation	Any corner a, any $i \neq j$	$4096q < 1$	Same	`AreaLaw.area_law_wilson_general`
Tightened constants	Standard	$441q < 1$	$6\,(441q)^{R\min(T,N-T)}/(441(1-441q))$	`AreaLaw.area_law_wilson_sharp`
Tightened, position and orientation	Any corner and orientation	$441q < 1$	Same	`AreaLaw.area_law_wilson_general_sharp`
Maximum of exponents	Standard	$441q < 1$	$6\,(441q)^{\max(R\min(T,N-T),\,T\min(R,N-R))}/(441(1-441q))$	`AreaLaw.area_law_wilson_max_sharp`

Table 1. Five versions of the area law. $\langle\cdot\rangle$ is the normalised expectation of (1). All with $\beta \geq 0$, $1 \leq R, T < N$.

Meaning. The expectation of a Wilson loop is exponentially small in the area enclosed by the loop, at a rate of at least $-\ln(441q)$. The rate and the prefactor depend neither on the lattice size N nor on the size of the rectangle. The versions with position and orientation are corollaries of the invariance of the Wilson measure under translations and permutations of directions (`AreaLaw.wilson_cfgShift_invariant`, `expect_perm`).

On the exponent. If $R \le N/2$ or $T \le N/2$, the exponent of the maximum version is the area RT. When R and T both exceed $N/2$, the exponent is $\max(R(N-T), T(N-R))$, smaller than RT. In this case the $N^2 - RT$ plaquettes of the whole plane of directions 1, 2 with the rectangle removed also have the same boundary mod 2, so the number of plaquettes truly needed can also be smaller than RT (7 plaquettes on two- and three-dimensional lattices with $N = 4$, $R = T = 3$ Reading ; a record of integer programming; not checked on the four-dimensional 4^4). The exponent of the theorem does not exceed that number, and a gap remains. The $N - T$ in $\min(T, N-T)$ is a weakness coming from the tool of the proof (the detour in § 08); it does not mean that $R \times (N - T)$ plaquettes span the boundary C.

03

Statement (ii) — for the infinite-volume limit measure

The space of infinite-volume configurations, the sequence of periodic lifts μ_n (the Wilson measure on the torus $(\mathbb{Z}/2(n+1))^4$ lifted to $\mathbb{Z}^4$, Lean's `liftProb β n`) and weak convergence are as in 20-03. Write $C_{R,T}$ for the boundary of the standard rectangle in $\mathbb{Z}^4$ (Lean's `zRectWord`).

Statement (the strong-coupling area law, infinite volume)

Let $\beta > 0$, $18 \tanh\beta < 1$, $4096q < 1$. Then there is a probability measure ν_β such that the whole sequence μ_n converges weakly to ν_β, and for all $R, T \ge 1$

$$\left| \int \operatorname{Re} W(C_{R,T}) \, d\nu_\beta \right| \;\le\; 16 \, \frac{(4096\,q)^{RT}}{4096\,(1 - 4096\,q)} \cdot \tag{4}$$

Lean A formalisation of the type of the strong-coupling area law. Lean: `AreaLaw.area_law_infvol` (the existence of ν_β is taken from the strong-coupling infinite-volume theorem `InfMain2.wilson_infvol_main2` of 20-03 and 20-04).

The intersection of the two windows is $0 < \beta < 1.22085 \cdot 10^{-4}$, and the window of the area law lies entirely inside the Dobrushin window ($\beta < 0.0556$) Reading .

At every limit point. There is also a form that does not use the existence of the limit. If $\beta \ge 0$, $4096q < 1$, and $\mu_{\varphi(n)} \to \nu$ (weakly) for a strictly increasing φ, then (4) holds for ν (`AreaLaw.area_law_limit_sub`; the case $\varphi = \mathrm{id}$ of the whole sequence is `AreaLaw.area_law_limit`). The proof uses, for $n \ge R + T$, the $2T \le N$ version of the finite-volume (3), and simply keeps the inequality in the limit of the integrals of the bounded continuous function $\operatorname{Re} W(C_{R,T})$.

The infinite-volume version is stated only with the constants 16 and 4096 and the standard rectangle (origin, directions 1, 2). The versions with tightened constants or with arbitrary corner and orientation are in finite volume only.

04

Statement (iii) — an upper bound on the vortex free energy

Statement (the vortex floor at strong coupling, isotropic torus)

Let $N \geq 1$, $\beta \geq 0$, $4096q < 1$. For Z_0, Z_1 on $(\mathbb{Z}/N)^4$ (§ 01),

$$|Z_0 - Z_1| \;\leq\; N^2 \,\frac{(4096\,q)^{N^4}}{4096\,(1-4096\,q)}\,(Z_0 + Z_1). \quad (5)$$

Lean A formalisation of the type of the strong-coupling estimate of 't Hooft's vortex free energy (Münster and others). Lean: `VortexStrong.vortex_floor` (the only assumptions are $\beta \geq 0$, $4096q < 1$). The version with tightened constants `VortexStrong.vortex_floor_sharp` (with $441q < 1$, 4096 replaced by 441); the 441 version with the denominator written as the total mass of the Wilson measure, `VortexStrong.vortex_floor_wilson` ($441q < 1$).

If the coefficient on the right-hand side is ε and $\varepsilon < 1$, then $|Z_0 - Z_1| \leq \frac{2\varepsilon}{1-\varepsilon} Z_0$ (`VortexStrong.vortex_floor_rel`; an arithmetic rewriting).

The same form also exists on the lattice of Part 21 (the torus of transverse size N and longitudinal size M, 19-02), and deals with the same quantity as the vortex ratio θ_M (19-02).

Statement (the vortex floor at strong coupling, torus of transverse size N and longitudinal size M)

Let $N, M \geq 1$, $\beta \geq 0$, $441q < 1$, and let the background twist $n_{12} \in \{0, 1\}$ be arbitrary. For $Z_k := Z_{N,M}(\beta; n_{12}, k)$ $(k = 0, 1)$,

$$|Z_0 - Z_1| \;\leq\; N^2 \,\frac{(441\,q)^{M^4}}{441\,(1-441\,q)}\,(Z_0 + Z_1). \quad (6)$$

Lean A formalisation of the same type. Lean: `VortexStrongMN.vortex_floor_MN_sharp` (the version with constant 9216 is `VortexStrongMN.vortex_floor_MN`).

Since $|Z_0 - Z_1|/(Z_0 + Z_1) = |\theta_M^{(n12)}|$, (6) is the same as

$$|\theta_M^{(n12)}| \;\le\; N^2\, \frac{(441\,q)^{M^2}}{441\,(1 - 441\,q)} \qquad (7)$$

Proved here .

Meaning. Inserting one vortex hardly changes the partition function, and the difference is exponentially small in the area M^2 of the longitudinal plane. **The rate per unit area $-\ln(441q)$ depends neither on the transverse size N nor on the longitudinal size M.** The prefactor N^2 (the number of plaquettes of the twist) remains. The thin-vortex floor (21-02), $|\theta_M| \le \tanh(N^2|\beta|)^{M^2}$, holds for all β, but its rate per unit area $-\ln\tanh(N^2|\beta|)$ approaches 0 as $N \to \infty$. (7) holds only inside the strong-coupling window, but differs in that its rate does not depend on N (comparison in § 09).

The statements of this section are upper bounds on the difference $|Z_0 - Z_1|$, and do not give the direction $Z_1 \le Z_0$ ($\theta_M \ge 0$). That direction is a separate theorem for even longitudinal size M (21-06).

05

Route of the proof — four parts and one sum

The area law (3) and the vortex floors (5), (6) are shown along the same line. We write it for the area law.

1. **Positive mixture (§ 06).** Write the plaquette weight as $e^{\beta s_p} = e^{-\beta}(1 + \sigma_p)$ with $0 \le \sigma_p \le t := e^{2\beta} - 1$, and expand $\prod_p(1 + \sigma_p)$ as a sum $\sum_X \prod_{p\in X} \sigma_p$ over sets X of plaquettes. Numerator and denominator become sums over all X, $\sum_X \int W \prod_X \sigma$ and $\sum_X Z_X$ ($Z_X := \int \prod_{p\in X} \sigma_p\, dU \ge 0$).
2. **Vanishing terms (§ 07).** The transformation that reverses the sign $U_\ell \mapsto -U_\ell$ on a set of links preserves the product of Haar measures. A term in which the boundaries of the plaquettes of X do not span C mod 2 changes sign under this transformation, and is 0.
3. **Domination (§ 06).** From $Z_{X\cup\{p\}} \le t\, Z_X$, the sum of the weights of the X containing a set Y of plaquettes is at most $q^{|Y|} \sum_X Z_X$.
4. **One sum.** Since $|W| \le 1$, the remaining terms are bounded by $q^{|Y|}$ for each "minimal set Y of plaquettes spanning C", giving

$$\big|\langle \operatorname{Re} W(C)\rangle\big| \;\le\; \sum_{Y\colon C\text{-spanning minimal set}} q^{|Y|} \qquad (8)$$

This holds for all $\beta \ge 0$ and all N (Lean `AreaLaw.abs_wordExpect_le`; the family of minimal sets `minSpanC` is placed concretely inside the definition, and is not an assumption).

5. **Geometry of minimal sets of plaquettes (§ 08).** A minimal Y is connected in the sense of sharing links, contains a plaquette touching a fixed link, and has $|Y| \ge R \min(T, N-T)$. The number of connected sets of size n touching the root is at most $16 \cdot 64^{2(n-1)}$, so the right-hand side of (8) is at most $16 \sum_{n \ge A} 4096^{n-1} q^n$ ($A = R \min(T, N-T)$), and summing the geometric series gives (3).

For the vortex floor, step 2 is replaced by "on good sets the twisted and untwisted weights coincide", step 4 by "the sum over bad sets", and the area lower bound of step 5 by "a bad set has at least N^2 plaquettes" (§ 07, § 08).

This line does not use the many-body sums of the cluster expansion. The only inequalities used are $0 \le \sigma_p \le t$ at each point and induction over finite sets. It is accounting of the same family as the "two copies and chains of plaquettes" of strong-coupling decay of correlations (20-02 § 06).

06

Parts of the proof (1) — the positive mixture and the domination lemma

Positive mixture. For $s \in [-1, 1]$,

$$e^{\beta s} = e^{-\beta}\big(1 + \sigma\big), \qquad \sigma := e^{\beta(s+1)} - 1 \in [0,\, e^{2\beta} - 1] \qquad (9)$$

($\beta \ge 0$). Lean: `AreaLaw.exp_eq_mix`, `mixVar_mem`. A product over a finite set is $\prod_p (1 + a_p) = \sum_X \prod_{p \in X} a_p$ (`AreaLaw.prod_one_add_univ`), and the form expanded inside an integral is `AreaLaw.integral_mul_prod_one_add`. That each σ in the expanded terms is at least 0 is the source of treating the weights, in the domination lemma below, as quantities that "increase as more are added".

The one-step inequality. For $Z_X := \int \prod_{p \in X} \sigma_p \prod_\ell dU_\ell$, using $\sigma_p \le t$ pointwise gives

$$Z_{X \cup \{p\}} \;\le\; t\, Z_X \qquad (p \notin X) \qquad (10)$$

(`AreaLaw.ZX_insert_le`).

The domination lemma (Lean: `AreaLaw.sum_superset_le`). If a real-valued function Z on the subsets of a finite set P and $t \geq 0$ satisfy $Z(S \cup \{p\}) \leq t\, Z(S)$ for all S and $p \notin S$, then for all Y

$$\sum_{X \supseteq Y} Z_X \;\leq\; \Big(\frac{t}{1+t}\Big)^{|Y|} \sum_{X} Z_X \qquad (11)$$

Here $t/(1+t) = 1 - e^{-2\beta} = q$ (`AreaLaw.q_eq`).

The core of the proof is one line. Let $a_Y := \sum_{X \supseteq Y} Z_X$; for $p \notin Y$, splitting a_Y into "X containing p" and "X not containing it" gives $a_Y = a_{Y \cup \{p\}} + b$ (b the side not containing it), and using (10) term by term gives $a_{Y \cup \{p\}} \leq t\, b$. Together, $(1+t)\, a_{Y \cup \{p\}} \leq t\, a_Y$, that is, $a_{Y \cup \{p\}} \leq q\, a_Y$. Induction on the size of Y gives (11). $Z \geq 0$ **is not used.** It follows from the splitting and the one-step inequality alone.

07

Parts of the proof (2) — terms that vanish under reversal of the central sign

Reversal. For an $\mathbb{F}_2$-valued function (cochain) T on links, let flip_T be the transformation $U_\ell \mapsto -U_\ell$ on the links with $T_\ell = 1$. -1 is in the centre of SU(2), and $-U$ has the same distribution as U, so flip_T is a measurable involution preserving the product of Haar measures (`AreaLaw.flipZ_preserving`). The product along a path w changes as

$$W(\mathrm{flip}_T\, U) = (-1)^{\langle T,\, \partial w \rangle}\, W(U) \qquad (12)$$

where ∂w is the number of times the path w passes each link, mod 2, and $\langle T, \partial w \rangle$ is its sum (`AreaLaw.wordHol_flip`; no condition on the lattice size is needed). The plaquette holonomy is the product along the path once around the boundary of the plaquette (`hol_eq_wordHol`), so s_p is also multiplied by $(-1)^{\langle T, \partial p \rangle}$.

Vanishing terms (Lean: `AreaLaw.integral_word_mul_prod_eq_zero_of_not_mem_span`). If ∂C is not in the $\mathbb{F}_2$-span of $\{\partial p : p \in X\}$, then for any function g

$$\int \mathrm{Re}\, W(C) \prod_{p \in X} g(s_p) \prod_{\ell} dU_\ell \;=\; 0. \qquad (13)$$

By duality in $\mathbb{F}_2$ linear algebra (`AreaLaw.not_mem_span_iff_exists_sep`), not being in the span is equivalent to "there is a T with $\langle T, \partial p \rangle = 0$ on every plaquette of X and $\langle T, \partial C \rangle = 1$ on C". Reversing by that T, the factor $\prod g(s_p)$ of the integrand is unchanged

and only W changes sign, so the integral equals its own negative and is 0. g is arbitrary, and not even measurability is needed.

The correct criterion is "lies in the span", not "X contains the plaquettes of C". For example, on a periodic torus the boundary of one plaquette can equal, mod 2, the sum of the boundaries of all the remaining plaquettes. For the quaternion group Q_8, summing over all configurations of a two-dimensional 2×2 torus, the terms of the 7 non-spanning X were exactly 0, those of the 9 spanning ones were not 0, and $\{1, 2, 3\}$, which does not contain plaquette 0, was not 0 either Reading .

On the vortex-floor side: good sets and bad sets. The twisted weight can be written $e^{\beta \sum_p (-1)^{m_p} s_p}$ using a mask of signs per plaquette $m : \text{plaquettes} \to \mathbb{F}_2$ (1 on D). The reversal flip_T changes the mask as $m \mapsto m + \delta T$ (δT the coboundary of T, $(\delta T)_p = \langle T, \partial p \rangle$) (`VortexStrong.ZM_gauge`). When there is a T for which the mask equals a coboundary on the set X of plaquettes, that is $m_p = \langle T, \partial p \rangle$ ($p \in X$), we call X a **good** set (Lean `VortexStrong.Good`). On good sets a single reversal makes the twisted and untwisted terms coincide (`VortexStrong.ZM_good`), and only the terms of **bad** sets remain in $Z_0 - Z_1$. Using the domination lemma for both weights,

$$|Z_0 - Z_1| \;\le\; \Big(\sum_{Y\text{: minimal bad set}} q^{|Y|} \Big) (Z_0 + Z_1) \qquad (14)$$

(`VortexStrong.abs_Z_sub_le`). The vortex floor does not use duality, because the definition of good and bad is itself written in terms of the existence of a coboundary.

08

Parts of the proof (3) — connectedness, area lower bound and counting of minimal sets of plaquettes

Connectedness (area law). Call two plaquettes neighbours when they share a link. Split a minimal set Y spanning C into two parts and suppose there is no pair of neighbours between them; then the sum of the boundaries of one part is closed ($\partial\partial = 0$, `AreaLaw.div_plaqBd`) and its support lies in the boundary of the rectangle. The boundary of the rectangle is a simple closed cycle, so such a closed chain is only 0 or ∂C itself (`AreaLaw.rect_closed_cases`, $1 \le R, T < N$). Either contradicts the minimality of Y, so a minimal Y is connected (`AreaLaw.minSpan_rect_conn`). Moreover Y contains a plaquette touching a fixed link of the rectangle (the root).

Connectedness (vortex floor). If a minimal bad set splits into two parts sharing no neighbours, one can glue the cochains of the two sides, "on the support of one" and "outside it", into a cochain for the whole, making the whole good, a contradiction (`VortexStrong.minBad_conn`).

Area lower bound (area law). A set of plaquettes spanning C has at least $R \min(T, N - T)$ plaquettes (`AreaLaw.card_ge_of_spans_rect`). The proof is placed in the detour. The same argument with directions 1 and 2 exchanged gives $T \min(R, N - R)$ as a lower bound too (`AreaLaw.wordBd_swap_rect`), and their maximum is the last version in Table 1.

Area lower bound (vortex floor). The mask of the translate $D_{a,b}$ of D (plaquettes of orientation 1, 2 with $x_1 = a$, $x_2 = b$) differs from the mask of D only by the coboundary of row and column cochains (`VortexStrong.good_twist_iff`). Hence a bad set meets every one of the N^2 mutually disjoint $D_{a,b}$, and has at least N^2 plaquettes (`VortexStrong.card_bad_ge`). The lower bound is attained: the plane $x_3 = x_4 = 0$ of directions 1, 2 (N^2 plaquettes) is a bad set (`VortexStrong.plane_bad`). A bad set contains a plaquette of D, so the roots are the N^2 plaquettes of D. This is the prefactor N^2 in (5).

Counting. If, for a symmetric neighbour relation, each point has at most Δ neighbours, then the number of connected sets of size n containing a fixed root is at most $\Delta^{2(n-1)}$ (`AreaLaw.card_conn_le`). It follows by an induction that inserts "go to a neighbour and come back" detours into a closed walk, without building a spanning tree. In the coarse count there are at most 64 neighbours and at most 16 roots, and $64^2 = 4096$. In the tightened count, the plaquettes containing a given link number 6, the plaquettes sharing a link with a given plaquette number at most 21 including itself ($1 + 4 \cdot 5$), so $21^2 = 441$, and there are 6 roots (`AreaLaw.card_rootP_le`, `card_nbQ_le`). The geometric series

$$\sum_{n \geq A} c_0 \, \Delta^{2(n-1)} q^n = \frac{c_0}{\Delta^2} \cdot \frac{(\Delta^2 q)^A}{1 - \Delta^2 q} \qquad (\Delta^2 q < 1) \tag{15}$$

gives the right-hand sides of (3), (5) and (6) (c_0 is the number of roots).

Detour: from the parity of row cochains to the area lower bound

May be skipped. For the standard rectangle (plaquettes of orientation 1, 2), for a column $0 \leq a < R$ and a row $y \in \mathbb{Z}/N$, consider the cochain $\rho_{a,y}$ that is 1 on "the links of direction 1 whose coordinates in directions 1, 2 are (a, y)" (all values of the other coordinates). Its pairing with plaquette boundaries is $\langle \rho_{a,y}, \partial p \rangle = [p \in Q(a,y)] + [p \in Q(a, y-1)]$ ($Q(a,y)$ is the class of plaquettes of orientation 1, 2 at coordinates (a, y); plaquettes of orientation 1, 3 or 1, 4 are hit twice and cancel), and its pairing with the boundary of the rectangle is $\langle \rho_{a,y}, \partial C \rangle = [y = 0] + [y = T]$. If X spans C, then, with $n(y)$ the number of plaquettes of X in $Q(a,y)$, $n(y) + n(y-1) = [y = 0] + [y = T]$ holds mod 2 for every y. Solving this difference equation, n is odd on all of $[0, T)$ or odd on all of $[T, N)$. Either way column a needs at least $\min(T, N - T)$ plaquettes, and R

columns need at least $R \min(T, N-T)$ Proved here . The solution on the $[T, N)$ side is a solution of the parity equation; it does not mean that the plaquettes on that side span the boundary C.

09

In numbers

Quantity	Value	Label
Window $4096q < 1$	$\beta < 1.22085 \cdot 10^{-4}$	Reading
Window $441q < 1$	$\beta < 1.13507 \cdot 10^{-3}$	Reading
Window of the infinite-volume version (intersection with $18 \tanh \beta < 1$)	$0 < \beta < 1.22085 \cdot 10^{-4}$	Reading
Range in which (3) is non-trivial (right-hand side < 1) for every area ≥ 1	$\beta < 1.2161 \cdot 10^{-4}$	Reading
Range in which the coefficient of (5) is < 1 for every N (4096 version / 441 version)	$\beta < 1.2093 \cdot 10^{-4}$ / $\beta < 1.1025 \cdot 10^{-3}$	Reading
Rate per unit area $-\ln(441q)$: $\beta = 10^{-5}, 10^{-4}, 10^{-3}$	`4.73, 2.43, 0.127`	Reading
Rate of the leading term at small β, $-\ln(\beta/4)$: same β	`12.9, 10.6, 8.29`	Reading

Table 2. Windows and rates. Floating-point calculations. The rate of the leading term is a rough guide read from the average of a single plaquette, $I_2(\beta)/I_1(\beta) = \beta/4 + O(\beta^3)$, not an estimate.

The rates of the upper bounds are much smaller than the rates of the leading term. The constant 441 (or 4096) comes from the coarseness of the count of connected sets, and also determines the width of the window.

Comparison with the thin-vortex floor Reading . With $N = M$, comparing the common logarithms of the upper bounds (7) and the thin-vortex floor $\tanh(N^2\beta)^{N^2}$, (7) becomes smaller (stronger) for $N \geq 30$ at $\beta = 10^{-5}$ and 10^{-4}, and for $N \geq 38$ at $\beta = 10^{-3}$. For example, at $\beta = 10^{-5}$, $N = 100$, the thin floor gives $-1.00 \cdot 10^4$ against $-2.05 \cdot 10^4$ for (7); at $N = 10$, the thin floor gives -300 against -206 for (7). The thin floor holds for all β, whereas (7) holds only inside the window.

Checks on small lattices Reading . We looked at the minimum size of bad sets by exhaustive search and integer programming in a separate script copying the Lean definitions. It was 4 on the three-dimensional 2^3, 4 on the four-dimensional 2^4, and 9 on 3^4 (all N^2); on lattices of transverse size N and longitudinal size M with $(N, M) = (2, 3), (3, 2), (2, 4)$ it was 9, 4, 16 $(= M^2)$, the same values as the Lean lower bound.

10

What is said, and what is not

- **The lattice spacing is fixed at 1.** These are statements about finite tori and their infinite-volume limit measure. Nothing is said about the continuum limit or sequences sending the lattice spacing to 0.
- **Only the strong-coupling window.** $\beta < 1.135 \cdot 10^{-3}$ (tightened constants), and $\beta < 1.22 \cdot 10^{-4}$ for the infinite-volume version and the basic version of the vortex floor. Nothing is said outside the window (nor that the area law fails there). This is the end far from the β of physical interest (the band around 2 to 3).
- **Rectangles only.** Loops along general closed paths are not treated. The infinite-volume version is only for the standard rectangle with the coarse constants.
- **A gap in the exponent.** When R and T both exceed $N/2$, the exponent stays smaller than the number of plaquettes truly needed.
- **The rates are coarse.** The rate per unit area is much smaller than the rate of the leading term at small β, and is not an estimate of the value of the tension. Estimates from below (lower bounds on Wilson loops, upper bounds on the tension) are not said.
- **The prefactor of the vortex floor.** The rates of (5) and (6) do not depend on N or M, but the prefactor N^2 remains. The direction $Z_1 \leq Z_0$ is not said.
- **Reaches neither the band nor the mass gap.** The mass gap inside the strong-coupling window is a separate theorem in 20-04. The band statement continuing to weak coupling (19-07) does not follow from the theorems of this chapter.
- **Distinct from the open question of the assessment.** The question listed by the assessment of the published construction, "construct Wilson-loop observables, connect them to local observables, and show the area law" Assessment , is a question about the continuum theory. This chapter is a strong-coupling statement on the lattice and does not answer that question.
- **Not a new result.** It is a formalisation, for the SU(2) Wilson measure, of the type of the strong-coupling area law (Osterwalder–Seiler) and of the strong-coupling estimate of the vortex free energy ('t Hooft, Münster and others).

The scope of what this chapter says

Said	Not said
Lean The area law in finite volume (3): $\beta \geq 0$, $4096q < 1$, $1 \leq R, T < N$, no N, R, T in the constants. Any corner and orientation; the version with constants 6 and 441; the version with exponent $\max(R\min(T, N-T), T\min(R, N-R))$. Lean `AreaLaw.area_law_wilson`, `area_law_wilson_general`, `area_law_wilson_sharp`, `area_law_wilson_general_sharp`, `area_law_wilson_max_sharp`	Outside the window. General loops. The true exponent when both R, $T > N/2$. Lower bounds on Wilson loops
Lean The area law in infinite volume (4): $\beta > 0$, $18\tanh\beta < 1$, $4096q < 1$, the limit ν_β of the whole sequence. Also at every limit point ($\beta \geq 0$, $4096q < 1$). Lean `AreaLaw.area_law_infvol`, `area_law_limit`, `area_law_limit_sub`	Infinite-volume versions with tightened constants or with arbitrary corner and orientation
Lean The upper bound on the vortex free energy (5): $(\mathbb{Z}/N)^4$, $\beta \geq 0$, $4096q < 1$ (tightened version $441q < 1$), the rate per unit area does not depend on N. Lean `VortexStrong.vortex_floor`, `vortex_floor_sharp`, `vortex_floor_rel`, `vortex_floor_wilson` (the 441 version)	Removal of the prefactor N^2. The direction $Z_1 \leq Z_0$. Outside the window
Lean The version (6) with transverse size N and longitudinal size M: every background n_{12}. The tightened version `vortex_floor_MN_sharp` with $441q < 1$ (the 441 window), the untightened version `vortex_floor_MN` with 9216q < 1 (the 9216 window). Lean `VortexStrongMN.vortex_floor_MN_sharp`, `vortex_floor_MN`	The band statement. The continuum limit
Proved here (7): (6) written in terms of the vortex ratio. The parity argument of the detour	—
Reading Windows, non-trivial ranges, rates (Table 2), comparison with the thin-vortex floor (crossovers at $N = 30, 38$), minimal sets on small lattices	Not proofs of upper or lower bounds. The true rate for four-dimensional SU(2)

Windows, rates, non-trivial ranges, comparison with the thin-vortex floor	Reading	The numerical record of this book's study (floating point; recomputed with a separate script)
The spanning criterion (Q_8, 2×2); minimum sizes of bad sets and spanning sets	Reading	The numerical record of this book's study (sums over all configurations, exhaustive search, integer programming; no proof of optimality for the four-dimensional 4^4)

Terms used in this chapter — strong coupling, Wilson loop, area law, positive mixture, domination lemma, reversal of the central sign, spanning set, cochain, coboundary, good set, bad set, root, counting of connected sets, 't Hooft twist, vortex free energy. Their meanings are in A-02 Glossary.

Next chapter to read: 20-07 What this part says, and what it does not — the theorems of Part 20 in one table. Other forms of the vortex floor are in 21-02 and 21-07.

What this part says, and what it does not

> This chapter is this book's own investigation. It is a chapter of tables.

What this chapter shows — The theorems of Part 20 gathered into one table, with their scope (range of β, lattice size, window), what they do not say, and the names of their Lean declarations.

Prerequisite chapters — 20-00 Entrance. The content of each row is in 20-01 to 20-06.

Said first — All the theorems of this part are statements on a lattice with the lattice spacing fixed at 1, and are formalisations of results of known types. No row says anything about the continuum limit, weak coupling, or an upper bound on the mass.

The order of this chapter

1. How to read the tables: notation and columns.
2. Reflection positivity (20-01): the three forms and the symmetry of the pairing.
3. Strong-coupling decay (20-02): two estimates in finite volume.
4. The infinite-volume limit and reconstruction (20-03, 20-04): limit, translation, clustering, gap, non-degeneracy, $T \geq 0$.
5. The vessel with fermions (20-05): four theorems on a finite lattice.
6. The area law at strong coupling, and an upper bound on the vortex free energy (20-06): the area law in finite and infinite volume, and the upper bound on the vortex free energy.
7. What the part as a whole does not say: limits common to all rows.

01

How to read the tables

Each row is one theorem. “Scope” copies the hypotheses of the Lean statement and the main form of the conclusion; “What is not said” gives limits specific to that row. Every row is machine-checked in Lean 4. The rows from 20-01 to 20-05 (§ 02– § 05) carry the

label Cited (a formalisation of a result of a known type from the literature). The exception is the rows of § 05 on the determinant and the lattice symmetries, which carry Proved here (a formalisation of known facts whose proof is given in the text). The rows from 20-06 (§ 06) carry the label Lean (a Lean theorem of this book, as in the legend of 20-06). Notation follows Part 19.

- $q(\beta) = 18 \tanh |\beta|$. The window $q(\beta) < 1$ is $|\beta| < 0.0556$ Reading .
- The narrow window $24(1 - e^{-4|\beta|}) < 1$ is $|\beta| < 0.0106$ Reading .
- μ_n: the periodic lift to $\mathbb{Z}^4$ of the Wilson measure on the torus $(\mathbb{Z}/2(n+1))^4$. ν_β: its limit without a subsequence (20-03).
- "Limit point": the weak limit of some subsequence of μ_n.
- W: cylinder functions on the closed positive half. W_{gi}: the gauge-invariant ones among them (20-04).

02

Reflection positivity (20-01)

Theorem	Scope	What is not said	Lean declaration
Reflection positivity for the plane through sites	$(\mathbb{Z}/2M)^4$, all β, bounded measurable f depending only on the closed positive half	The plane through the middle of links; the time direction only	`TorusRP.wilson_rp`
Reflection positivity for the middle plane	$(\mathbb{Z}/2M)^4$, $M \geq 2$, $\beta \geq 0$, gauge-invariant bounded measurable F	F that is not gauge invariant; $\beta < 0$. This theorem alone does not enter the vessel (the $T \geq 0$ of the vessel is a separate theorem in 20-04)	`MidRP.wilson_rp_mid`
Reflection positivity for site planes in four directions	$(\mathbb{Z}/2M)^4$, all β, for each direction ρ	A four-direction form for the plane through the middle of links	`PeierlsPerm.wilson_rp_dir`
Symmetry of the reflection pairing	$(\mathbb{Z}/2M)^4$, all β, measurable f, g	—	`TorusRP.wilson_refl_symm`

03

Strong-coupling decay (20-02)

Theorem	Scope	What is not said	Lean declaration
Finite-volume decay of correlations at strong coupling	Narrow window, for each finite N, no N in the constants, time distance	Distance in spatial directions; outside the window	`TorusRP.wilson_strong_coupling`
Dobrushin decay of covariance with distance	$\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$, finite N, no N in the constants	Outside the window; the true rate of decay	`LinkSpec.wilson_cov_dist`

04

The infinite-volume limit and reconstruction (20-03, 20-04)

Theorem	Scope	What is not said	Lean declaration
The theorem on the limit without a subsequence	$\beta \neq 0$, $q(\beta) < 1$	Other boundary conditions; uniqueness of the Gibbs measure. "Unique" is trivial from the topology; the content is convergence of the sequence	`InfVol.wilson_infvol_unique`
The theorem on the limit independent of size	$\beta \neq 0$, $q(\beta) < 1$, all sizes $m+1$, any $s(k) \to \infty$	The rate of convergence (outside the statement)	`AllN.wilson_infvol_allN`
Translation invariance of the limit	$\beta \neq 0$, $q(\beta) < 1$, unit translations in four directions	Rotations and reflections	`TransI.wilson_infvol_translation`
Clustering at limit points	$\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$, at every limit point, four directions	The true rate of decay	`WilsonLimit.cluster_limit`
The mass gap with non-degeneracy (Dobrushin window)	$\beta \neq 0$, $q(\beta) < 1$; the statement picks one limit point (the same estimate at every limit point: `WilsonLimit.wilson_massGap_dob`); $\|T - P_\Omega\| \leq q(\beta)^{1/2}$, $\mathrm{Var}(F_0) \geq \frac{1}{4} e^{-12\|\beta\|}$	That the mass is finite (lower bound only); the $\frac{1}{2}$ is a matter of choice	`WilsonLimit.wilson_massGap_dob_exi`

Theorem	Scope	What is not said	Lean declaration
The mass gap with non-degeneracy (every limit point)	$\beta \neq 0$, narrow window, every limit point, rate $-\log 24(1-e^{-4\lvert\beta\rvert})$ (not included in the bundled statement)	As above	`WilsonLimit.wilson_massGap_nondege`
The mass gap in the gauge-invariant sector	$\beta \neq 0$, $q(\beta) < 1$; the statement picks one limit point; witness $F_p = \mathrm{Re}\, U_p$	That the closure of W_{gi} coincides with the physical space of states	`GaugeZ.wilson_massGap_gauge_exists`
$T \geq 0$ (on the whole W)	$\beta \geq 0$, $\lambda > 0$, $e^{\lambda} q(\beta) < 1$, every limit point	$\beta < 0$	`FullT.wilson_Tpos_full`
The range of T lies in the gauge-invariant sector	$\lambda > 0$, $e^{\lambda} q(\beta) < 1$, every limit point	Not included in the bundled statement	`Bind.T_range_gauge_all`
The bundled statement	$0 < \beta$, $18 \tanh \beta < 1$. Convergence, translation, reflection positivity, gap and non-degeneracy in both sectors, $T[F_0] = 0$, $T \geq 0$, clustering	The continuum limit; an upper bound on the mass; outside the window	`InfMain2.wilson_infvol_main2`

05

The vessel with fermions (20-05)

The lattice is $(\mathbb{Z}/N)^3 \times \mathbb{Z}/2h$ ($h > 0$), the weight is $e^{-\beta S_W}\, \mathrm{Re}\big[(\det D)^{2j}\big]$, and D is the Wilson–Dirac operator ($r = 1$, antiperiodic in four directions).

Theorem	Scope	What is not said	Lean declaration
Reflection positivity of the Wilson–fermion weight	$m > -1$, all β and j, time plane through sites	$m \leq -1$; the middle plane; infinite volume	`WilsonGauge.site_reflection_positive_wilson_full`
Positivity of the partition function	All β, m, j	The size of Z	`WilsonGauge.partition_pos_wilson_full`

Theorem	Scope	What is not said	Lean declaration
Global gauge invariance of the determinant	Unconditional; constant g	Local gauge transformations	`GaugeDet.physDirac_det_conj`
Invariance under the generators of the lattice symmetries	All N, j, m, β: global gauge, translations in four directions, spatial 90° rotations, reflections of spatial axes, time reflection	Closure as a group; lifting to the block level	`CubicSym.wfProb_lattice_generators`
Invariance under the hypercubic generators	Isotropic lattice $N = 2h$; the above plus (space, time) 90° rotations	Rotations involving time on anisotropic lattices	`CubicSym.wfProb_hypercubic_generators`
Invariance of the determinant under time reflection	Unconditional (all N, h, m, ω); the reversal $t \mapsto 2h - 1 - t$	Reflection positivity for this reversal	`CubicSym.physDirac_det_trefl`

06

The area law at strong coupling, and an upper bound on the vortex free energy (20-06)

Set $q = 1 - e^{-2\beta}$. The window differs for each version of the constants (details in 20-06).

Theorem	Scope	What is not said	Lean declaration
The area law in finite volume	$\beta \geq 0$, $4096q < 1$ (the tightened version: $441q < 1$), the Wilson loop on the boundary of a rectangle; the rate and the prefactor depend neither on the size of the lattice nor on the size of the rectangle	Outside the window, general loops, a lower bound on Wilson loops, continuum Wilson loops	`AreaLaw.area_law_wilson`, `AreaLaw.area_law_wilson_sharp`, `AreaLaw.area_law_wilson_max_shar`

Theorem	Scope	What is not said	Lean declaration
The area law in infinite volume	$\beta > 0$, the intersection of $18 \tanh \beta < 1$ and $4096q < 1$, the limit measure (also at every limit point)	Infinite-volume versions with the tightened constants, or with arbitrary corners and orientations	`AreaLaw.area_law_infvol`, `AreaLaw.area_law_limit_sub`
Upper bound on the vortex free energy	$\beta \geq 0$. On a torus of transverse size N and longitudinal size M, for every background, $441q < 1$ (`VortexStrongMN.vortex_floor_MN_sharp`). On an isotropic torus, $4096q < 1$ (`VortexStrong.vortex_floor`), and the tightened version $441q < 1$ (`VortexStrong.vortex_floor_sharp`). The difference is exponentially small in the area M^2 of the longitudinal plane, and the rate per unit area depends neither on the transverse size nor on the longitudinal size	Removal of the prefactor N^2 (the transverse area), the direction of the sign of the difference, outside the window, the band statement	`VortexStrongMN.vortex_floor_MN_s`, `VortexStrong.vortex_floor`, `VortexStrong.vortex_floor_sharp`

All of these are formalisations of known results of the type of Osterwalder–Seiler (area law) and of 't Hooft and Münster (vortex free energy)Cited . The area law is a statement about lattice Wilson loops; continuum Wilson loops are present neither in this part nor in the published construction.

07

What the part as a whole does not say

- **The lattice spacing is fixed at 1.** No row says anything about the continuum limit or about uniformity when the lattice spacing is changed.
- **Only the strong-coupling window.** The rows on the area law and the upper bound on the vortex free energy (§ 06) also hold only inside the strong-coupling window. The infinite-volume rows hold only for $|\beta| < 0.0556$Reading (the narrow window: $|\beta| < 0.0106$Reading), and nothing is said about weak coupling.
- **Only a lower bound on the mass.** The mass-gap rows are upper bounds on $\|T - P\Omega\|$. It is not said that the mass is finite, nor how it compares with the true mass.
- **Formalisations of known types.** These are known results of Osterwalder–Seiler strong-coupling type, of Dobrushin-uniqueness type, and of the type of the strong-coupling area law and the vortex free energy, written in Lean on the concrete SU(2) Wilson measure. They do not show anything about the mass gap problem for four-dimensional Yang–Mills. They are statements at the opposite end (strong coupling,

lattice spacing fixed) from the questions the published construction left open (convergence and uniqueness, a uniform mass gap, continuum Wilson loops and the area law) (14-06).

The next part treats the vortex floor and Polyakov loops on a twisted lattice, at the same level of “one lattice spacing”.

What this chapter can say

What is said	What is not said
Cited Each row of the tables of § 02– § 05, Lean each row of the table of § 06 (all machine-checked in Lean; scope as in each row)	Changing the lattice spacing, the continuum limit, outside the window, an upper bound on the mass
Reading The edges of the windows, $\lvert\beta\rvert < 0.055613$ and $\lvert\beta\rvert < 0.010640$	Floating-point values (not interval estimates)

Sources and reproduction

Item	Kind	Source / tools
Original sources for the type of each row	Cited	K. Osterwalder, E. Seiler, Ann. Phys. 110 (1978) 440 (abstract). The original source of Dobrushin's uniqueness condition: bibliographic data only, not checked. The source tables of each chapter
The declarations of each row	Lean	Machine-checked in Lean 4 (all pass the kernel re-check; the axioms are the three standard ones). A-04
The numbers at the edges of the windows	Reading	The numerical record of this book's study (double precision)

Words used in this chapter — strong-coupling window, limit point, mass gap (lower bound), non-degeneracy, gauge-invariant sector, reflection positivity, generator. Their meanings are in the A-02 Glossary.

Next chapter to read: 21-00 Entrance — vortices in a twisted box — on to Part 21, which treats the vortex floor and Polyakov loops on a twisted lattice.

Entrance — vortices in a twisted box

> This chapter is a guide.

What this chapter shows — a list of the theorems in the chapters of Part 21, the scope that applies to the whole part (what it does not say), and the direction of the word "floor".

Prerequisite chapters — 19-02 the torus of width N and length M, the vortex ratio, Polyakov loops.

Said first — every theorem in this part is a statement on a finite torus at a fixed lattice spacing. Inside the strong-coupling window there is a form whose rate does not depend on the transverse size (the prefactor, the transverse area, remains; 20-06). Outside the window, none of the rates of the floors of this part (upper bounds on θ) is uniform in the transverse size N. The lower bound on the deficit in 21-07 (1/2 in a symmetric box, independent of the transverse size) is a statement in the opposite direction from a floor (on the side of lower bounds on θ). None reaches the band or the mass gap (the statements to be shown are in 19-07). Each is a formalisation of one side of a known picture.

The order of this chapter

1. The theorems of this part
2. The scope that applies to the whole part
3. What a "floor" is
4. A guide to the record of the study

01

The theorems of this part

The objects throughout are the $SU(2)$ Wilson measure on the torus $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ of width N (directions 1 and 2) and length M (directions 3 and 4), its twisted partition

functions $Z_0,\ Z_1$, and the vortex ratio $\theta_M = (Z_0 - Z_1)/(Z_0 + Z_1)$ (definitions in 19-02).

Chapter	Theorem (one line)
21-01 Three results on sign systems	The covering inequality, $\mathbb{Z}_2$ monotonicity, and comparison with $\mathbb{Z}_2$ (abstract implications, with all assumptions shown), and their application to the $SU(2)$ Wilson measure. A representation of θ_M as an average of the sign η of the (3,4) plaquettes
21-02 The thin-vortex floor	For all real β and $N, M \geq 1$, $\lvert\theta_M\rvert \leq \tanh(N^2\lvert\beta\rvert)^{M^2}$. If $\beta \neq 0$, $\lvert\theta_M\rvert \leq e^{-\sigma_0 M^2}$ with $\sigma_0 = -\ln\tanh(N^2\lvert\beta\rvert) > 0$
21-03 The thick-vortex floor — statement and route	For all $N \geq 1$ and any $\varepsilon > 0$, for every sufficiently large β and sufficiently large M, $\lvert\theta_{M+1}\rvert \leq \exp\bigl(-(M+1)^2 e^{-\beta(S_N+\varepsilon)}\bigr)$ (S_N is the minimal action of a vortex; the thresholds are not explicit)
21-04 The thick-vortex floor — parts of the proof	The estimate $\lvert\theta_M\rvert \leq \tanh(K_{\mathrm{eff}})^{k^2}$ ($mk \leq M$) obtained by dividing the longitudinal directions into blocks of side m, and the parts that assemble the thick-vortex floor
21-05 The minimal action of a vortex	For all $N \geq 1$, $S_N > 0$ (a lower bound uniform in the block size m; the value is not explicit). For $N = 2, 3, 4$, $S_N < 2N^2$ (a computer certificate)
21-06 The sign of θ and pairs of Polyakov loops	If M is even, $\theta_M \geq 0$ for all real β ($Z_1 \leq Z_0$). Upper bounds on pairs of Polyakov loops, for example for $M \equiv 0 \pmod 4$, $\lvert\langle P_b(0) P_{b'}(T)\rangle_0\rvert \leq 2\tanh(N^2\lvert\beta\rvert)^{M\,\min(T, M-T)}$
21-07 The vortex ratio — continuity, limit, matching	With the size of the lattice held fixed, the vortex ratio is continuous in the coupling, is 0 at coupling 0, and approaches 1 as the coupling grows. For a chosen target value (at least 0 and less than 1) there is a coupling matched to it (the largest solution). A box with two twists has no flat configuration, and the deficit in a symmetric box is at least 1/2, independent of the transverse size
21-08 What this part says, and what it does not	A table of the scope of each theorem

Every theorem is machine-checked in Lean, and in addition the definitions and statements have been compared against the text by a separate pair of eyes (the computer certificates for $N = 2, 3, 4$ are compared on the side of the corollaries that use them). The names of the declarations and their scope are in each chapter.

02

The scope that applies to the whole part

- **The lattice spacing is fixed.** These are equalities and inequalities about unnormalised partition functions on a finite torus. The continuum limit is not treated.
- **Outside the window, the rate of the floor is not uniform in the transverse size N.** The rates ($\sigma_0 \approx 2e^{-2N^2\lvert\beta\rvert}$ and $e^{-\beta(S_N+\varepsilon)}$) approach 0 as N grows. These are

estimates for a slab with the transverse size held fixed, effectively two-dimensional. Inside the strong-coupling window there is a form whose rate does not depend on the transverse size (the prefactor, the transverse area, remains; 20-06). The lower bound on the deficit in 21-07 (1/2 in a symmetric box, independent of the transverse size) is a statement in the opposite direction from a floor (on the side of lower bounds on θ), not a rate of a floor.

- **Some thresholds are not explicit.** For the thick-vortex floor and the corollaries that rest on it, the thresholds in β and M are given only as existing; no values come out. The positive lower bound on the minimal action of a vortex also has no explicit value.
- **Reaches neither the band nor the mass gap.** Neither the statement of the band, nor the four-dimensional area law, nor the mass gap follows from the theorems of this part. The statements to be shown about the band and the mass gap are in 19-07.
- **A formalisation of one side of a known picture.** Of the known picture of a gas of vortices on a thin twisted slab (said to be the line of Mack–Petkova, Fröhlich and others; bibliography in the table at the end of the chapter, the texts not checked in this book), this part puts the side of the upper estimates into Lean as theorems about the concrete $SU(2)$ Wilson measure. The floor theorems of this part are on the side of the upper estimates; on the opposite side, 21-07 gives only one value, in the limit $\beta \to \infty$ with the lattice held fixed. This book claims no novelty.

03

What a "floor" is

The vortex ratio is tied to 't Hooft's flux free energy $\Delta F = \ln(Z_0/Z_1)$ (the same quantity as in 25-01 and 26-03; 26-03 also calls it the vortex free energy) by $\theta_M = \tanh(\Delta F/2)$. In the picture of confinement, ΔF approaches 0 exponentially in the (3,4) area M^2, and the speed (the rate) corresponds to the tension. The theorems of this part bound θ_M, and hence ΔF, **from above**. That is the same as bounding the rate **from below**, and this lower estimate is what we call a "floor". It is a statement in the direction "the rate is at least this much"; the floor theorems say nothing about an upper limit on the rate (a lower bound on ΔF). On the opposite side, 21-07 gives only one value, in the limit $\beta \to \infty$ with the lattice held fixed (that the slope of the flux free energy converges to the minimal deficit). "Thin" and "thick" differ in whether the rate of the floor is taken from the cost $2N^2$ of the configuration that gathers the vortex onto a single plane, or from the cost S_N of a cheaper thick vortex.

04

A guide to the record of the study

The record of the study of twisted tori, vortices and the band, up to the theorems of this part, is in Part 25 (from the direction of space — a small twisted T^2 and confinement) and Part 26 (the crossover band) of the present book. The view that tools built on structure alone yield no more than the floor is in 26-04. This part does not rewrite them; it points to the chapters where needed.

What this chapter can say

Can say	Cannot say
Proved here The theorems of this part (listed in § 01; statements, assumptions and routes of proof in each chapter)	Anything that moves the lattice spacing; rates of the floor uniform in N; explicit thresholds; the band; the mass gap
Computer-assisted $S_N < 2N^2$ for $N = 2, 3, 4$ (a computer certificate supporting the analytic proof, 21-05)	$S_N < 2N^2$ for general N

Sources and reproduction

Three results on sign systems — the covering inequality, monotonicity, comparison

This chapter is this book's own investigation. The abstract theorems of § 02– § 05 are written as conditional implications.

What this chapter shows — three abstract inequalities (the covering inequality, Z_2 monotonicity, comparison with Z_2) for bounding the SU(2) vortex ratio from above by the vortex ratio of a Z_2 sign system, and their application to the SU(2) Wilson measure. We also set out a representation that writes the vortex ratio θ_M as an average of the signs η of the (3,4) planes.

Prerequisite chapters — 19-01 the product of Haar measures, plaquettes and holonomy; 19-02 the twist, the vortex ratio. We use the language of group characters (homomorphisms, values ± 1).

Said first — § 02– § 05 are abstract theorems in "if ... then" form with every assumption shown. As concrete objects satisfying the assumptions, the only results this chapter counts are the application to the SU(2) Wilson measure (§ 06) and the η representation (§ 07). All three are one-sided comparisons "from the Z_2 side upward"; no lower bound on the SU(2) vortex ratio (no lower bound on the flux free energy) comes out. Nothing here shows monotonicity or a covering inequality for a non-abelian group. The lattice spacing is fixed.

The order of this chapter

1. What the three results are for — the direction of the floor
2. Sign systems — characters, partition functions, twists, base systems
3. The covering inequality
4. Z_2 monotonicity
5. Comparison with Z_2 — couplings of indefinite sign and invariant measures
6. Application to the SU(2) Wilson measure
7. Writing the vortex ratio as an average of signs — the η representation
8. What is not said

9. Detour: reading the covering inequality on the lattice

01

What the three results are for — the direction of the floor

The object of Part 21 is the $SU(2)$ Wilson measure on the torus $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ of width N and length M (19-02). From the ratio of the partition function Z_1 with a twist inserted in one column of (3,4) planes and the partition function Z_0 without it, we form the vortex ratio

$$\theta_M = \frac{Z_0 - Z_1}{Z_0 + Z_1} = \tanh \frac{\Delta F}{2}, \qquad \Delta F := -\ln \frac{Z_1}{Z_0} \quad (1)$$

(definition in 19-02). ΔF is 't Hooft's flux free energy (the same quantity as in 25-01 and 26-03; 26-03 also calls it the vortex free energy). In the picture of confinement, ΔF approaches 0 exponentially in the (3,4) area M^2, and its speed is the tension Cited (the framework of twisted boundary conditions of G. 't Hooft, Nucl. Phys. B 153 (1979) 141).

The three results of this chapter are tools for bounding the ratio Z_1/Z_0 of the $SU(2)$ system **from below** by the ratio of a $\mathbb{Z}_2$ system whose only variables are the signs of the plaquettes. Restated through (1), they bound θ_M and ΔF **from above**, and bound the speed (the rate) at which ΔF decreases in M^2 **from below**. In this part we call this lower estimate a "floor". The $\mathbb{Z}_2$ system we compare with is finally brought down to a system computable by a closed two-dimensional formula (21-02).

The roles of the three are as follows.

Name	What is compared	Use in this part
The covering inequality	A large $\mathbb{Z}_2$ system and a small (base) $\mathbb{Z}_2$ system mapped into it	The pattern for bringing a four-dimensional sign system down to a two-dimensional one
$\mathbb{Z}_2$ monotonicity	Two versions of the same $\mathbb{Z}_2$ system with couplings of different size	That increasing the coupling does not decrease the vortex ratio (a check of the comparison pattern)
Comparison with $\mathbb{Z}_2$	A system on a measure invariant under the action of the centre $\{\pm 1\}$ ($SU(2)$ and others), and a base $\mathbb{Z}_2$ system	Bounding the $SU(2)$ vortex ratio by the vortex ratio of a $\mathbb{Z}_2$ system (§ 05)

Each is a combination of well-known tools of the correlation-inequality type. The pattern of comparing $SU(2)$ with $\mathbb{Z}_2$ is said to be the line of Mack–Petkova Cited

(bibliography in the source table; the text not checked in this book). This book claims no novelty.

02

Sign systems — characters, partition functions, twists, base systems

The three results are written in an abstract form that forgets the lattice. Four things appear.

The group of configurations and the plaquette index. G is a finite group (on the lattice, "a field of signs, one per link", with pointwise product), and ι is a finite set (on the lattice, the plaquettes).

Sign characters. A function $\psi : G \to \mathbb{R}$ is a sign character if it is multiplicative, $\psi(gh) = \psi(g)\psi(h)$, and takes values ± 1 (Lean: `CoveringInequality.IsSignChar`). We take one per plaquette, a family of characters $\chi = (\chi_B)_{B \in \iota}$. On the lattice, $\chi_B(g)$ is the product of the signs of the four links of plaquette B.

Partition functions and twists. For a coupling $c : \iota \to \mathbb{R}$ we set

$$Z_\chi(c) = \sum_{g \in G} \exp\Big(\sum_{B \in \iota} c_B \, \chi_B(g) \Big) \quad (2)$$

(Lean: `CoveringInequality.Z`). A twist is $\zeta : \iota \to \{\pm 1\}$, which replaces the coupling c by $\zeta c = (\zeta_B c_B)_B$. The $-\ln$ of the twisted ratio $Z_\chi(\zeta K)/Z_\chi(K)$ plays the role of the flux free energy of this abstract system.

Base systems and pull-back. Another finite group G_0, a family of characters $\chi^0 = (\chi^0_B)_{B \in \iota}$ (with the **same** index ι), and a map $p : G_0 \to G$ satisfying

$$\chi_B\big(p(t)\big) = \chi^0_B(t) \qquad (\text{for all } B \in \iota,\ t \in G_0) \quad (3)$$

are together called a "base system". p need not be a homomorphism (the proof uses only the multiplicativity of χ_B). On the lattice, p is the map that carries a sign field on a small torus periodically onto a large torus.

The starting lemma is an inequality of the first Griffiths type. For a non-negative coupling $J \geq 0$ and a twist ζ, $Z_\chi(\zeta J) \leq Z_\chi(J)$ Proved here (Lean: `CoveringInequality.Z_flip_le`; the assumption fields are "each χ_B is a sign character", "$J_B \geq 0$", "$\zeta_B = \pm 1$"). The proof expands the product using $e^{c\chi} = \cosh c + \chi \sinh c$ ($\chi = \pm 1$) and shows, by induction on the set of plaquettes, that "the absolute value of the twisted sum does not exceed the untwisted sum". Underneath lies the fact that a sum of a sign character $\sum_g \psi(g)$ is 0 or $|G|$, and never negative.

03

The covering inequality

The covering inequality (Lean: `CoveringInequality.covering_ineq`). We assume the following five.

- (hχ) Each χ_B is a sign character on G.
- (hχ_0) Each χ^0_B is a sign character on G_0.
- (hp) $p : G_0 \to G$ satisfies (3).
- (hK) The coupling is non-negative: $K_B \geq 0$.
- (hζ) $\zeta_B = \pm 1$.

Then

$$Z_\chi(K)\, Z_{\chi^0}(\zeta K) \;\leq\; Z_\chi(\zeta K)\, Z_{\chi^0}(K) \quad (4)$$

The ratio form (`covering_ratio`) and the $-\ln$ form (`vfe_cover_le`) are

$$\frac{Z_{\chi^0}(\zeta K)}{Z_{\chi^0}(K)} \leq \frac{Z_\chi(\zeta K)}{Z_\chi(K)}, \qquad -\ln \frac{Z_\chi(\zeta K)}{Z_\chi(K)} \leq -\ln \frac{Z_{\chi^0}(\zeta K)}{Z_{\chi^0}(K)} \quad (5)$$

with the same five assumptions. Proved here The proof is the two steps below; all three are machine-checked in Lean, and the definitions and statements have been compared by a separate pair of eyes. The tools are of well-known types, Griffiths-type correlation inequalities and change of configuration variables; this book has not checked where in the literature a comparison of this form appears.

The route of proof. Two steps.

1. **The key identity** (Lean: `Z_mul_Z`). In the double sum $\sum_s \sum_t$, replace the configuration on the covering side by $s = u \cdot p(t)$. Since $\chi_B(u\,p(t)) = \chi_B(u)\chi^0_B(t)$, for arbitrary couplings J, J'

$$Z_\chi(J)\, Z_{\chi^0}(J') = \sum_{u \in G} Z_{\chi^0}\left(J\chi(u) + J'\right) \quad (6)$$

   The product of two systems becomes a sum, over u, of single base systems Proved here .

2. **Comparison for each u.** The left side of (4) is $(J, J') = (K, \zeta K)$, the right side $(\zeta K, K)$. The base couplings are $K\chi(u) + \zeta K = \zeta\, a(u)$ and $a(u)$ respectively, where $a_B(u) = \zeta_B K_B \chi_B(u) + K_B \geq 0$. Applying the first Griffiths-type inequality $Z_{\chi^0}(\zeta a) \leq Z_{\chi^0}(a)$ for each u and summing gives (4) Proved here .

No limits and no size conditions are used. It holds for every finite system and every non-negative coupling.

A lattice instance (Lean: `TwistedWilson.z2_four_covers_two`, ratio form `z2_four_ratio`; the only assumption is $K \geq 0$). Take as the covering side the four-dimensional $\mathbb{Z}_2$ gauge theory on the torus of width N and length M (uniform coupling K), and as the base the $\mathbb{Z}_2$ gauge theory on the two-dimensional torus of the length directions (on the (3,4) planes the base character is the sign of a two-dimensional plaquette, not identically 1). With ζ the (3,4) twist,

$$\frac{1-\tanh(N^2K)^{M^2}}{1+\tanh(N^2K)^{M^2}} \;\leq\; \frac{Z_\chi(\zeta K)}{Z_\chi(K)}$$

Proved here . This brings the four-dimensional sign system down to the two-dimensional system of the length directions; it is not itself the detour's "covering that stretches the width n-fold". It is read within the Lean chain, but the proof of the main theorem of the $SU(2)$ thin-vortex floor does not use it; it goes directly from the application of § 06 to the two-dimensional formula.

04

Z_2 monotonicity

$\mathbb{Z}_2$ monotonicity (Lean: `CoveringInequality.mon_ineq`). There are four assumptions.

- (hχ) Each χ_B is a sign character.
- (hK) $K_B \geq 0$.
- (hKK') $K_B \leq K'_B$ (a coupling larger term by term).
- (hζ) $\zeta_B = \pm 1$.

Then

$$Z_\chi(\zeta K')\,Z_\chi(K) \;\leq\; Z_\chi(K')\,Z_\chi(\zeta K), \qquad \text{i.e.} \quad \frac{Z_\chi(\zeta K')}{Z_\chi(K')} \leq \frac{Z_\chi(\zeta K)}{Z_\chi(K)} \quad (7)$$

(the ratio form is `mon_ratio`, with the same assumptions). Increasing the coupling term by term does not increase the twisted ratio, and does not decrease the flux free energy. Proved here The proof follows the route below; it is machine-checked in Lean, and the definitions and statements have been compared by a separate pair of eyes. The pattern is a correlation inequality for ferromagnetic sign systems.

The route of proof. Use (6) with base = cover ($G_0 = G$, p the identity). Bring the couplings that appear into the form $\chi(u)\cdot\big(K' + \zeta\chi(u)K\big)$, remove $\chi(u)$ by the character

shift $Z_\chi(\chi(u)c) = Z_\chi(c)$ (the change of configuration $g \mapsto gu$; Lean: `Z_char_shift`), and apply the first Griffiths-type inequality to $K'_B + \zeta_B \chi_B(u) K_B \geq 0$ Proved here .

This monotonicity is a statement about $\mathbb{Z}_2$ sign systems (non-negative couplings, no twisted background). Whether the same monotonicity in the coupling β holds for the $SU(2)$ Wilson measure is not shown in this chapter (§ 08).

05

Comparison with Z_2 — couplings of indefinite sign and invariant measures

Relaxing the assumption (hK) of the covering inequality, the same form comes out for couplings of indefinite sign.

The form with dominated couplings (Lean: `CoveringInequality.dominated_covering_ineq`). The assumptions are (hχ)(hχ_0)(hp)(hζ) and

- (hJ) $|J_B| \leq K_B$ (the sign of J is arbitrary).

Then

$$Z_\chi(J)\, Z_{\chi^0}(\zeta K) \;\leq\; Z_\chi(\zeta J)\, Z_{\chi^0}(K) \quad (8)$$

The proof is the same as in § 03; the only change is that the base coupling $K_B + \zeta_B J_B$ $\chi_B(u)$ is non-negative by (hJ) Proved here . $J = K$ is the covering inequality, and base = cover with $J = K \leq K'$ is $\mathbb{Z}_2$ monotonicity.

The form on an invariant measure (comparison with $\mathbb{Z}_2$) (Lean: `CoveringInequality.invariant_dominated`). For a configuration space Ω with a measure μ, an action $g \cdot \omega$ of the sign group G on Ω, and functions $J_B : \Omega \to \mathbb{R}$, one per plaquette, we assume the following.

- (hinv) The integral is invariant under the action: for all $g \in G$ and all $f : \Omega \to \mathbb{R}$, $\int f(g \cdot \omega)\, d\mu = \int f(\omega)\, d\mu$.
- (hχ)(hχ_0)(hp) as in § 03.
- (hJ) The coupling changes sign by the character: $J_B(g \cdot \omega) = \chi_B(g)\, J_B(\omega)$.
- (hK) $|J_B(\omega)| \leq K_B$ (for all ω).
- (hζ) $\zeta_B = \pm 1$.
- (hint) For all $c : \iota \to \mathbb{R}$, $\omega \mapsto \exp\left(\sum_B c_B J_B(\omega)\right)$ is μ-integrable.

Then

$$\left(\int e^{\sum_B J_B(\omega)}\, d\mu\right) Z_\chi^0(\zeta K) \;\le\; \left(\int e^{\sum_B \zeta_B J_B(\omega)}\, d\mu\right) Z_\chi^0(K) \quad (9)$$

Cited The pattern is a comparison of a system of a group with centre against a system of the centre group, said to be the line of Mack–Petkova (bibliography in the source table; the text not checked in this book). It is machine-checked in Lean, and the comparison by a separate pair of eyes judged it to hold as an implication.

The route of proof. The key is averaging over the centre (Lean: `card_mul_integral_exp`). From (hinv) and (hJ), for each g, $\int e^{\sum J(\omega)} d\mu = \int e^{\sum \chi(g) J(\omega)} d\mu$, so averaging over g gives

$$|G| \int e^{\sum_B J_B(\omega)}\, d\mu = \int Z_\chi\big(J(\omega)\big)\, d\mu \quad (10)$$

Proved here . The integrand on the right is the partition function of a **sign system** with the configuration ω held fixed, and the coupling $J(\omega)$ is bounded by (hK). So apply (8) for each ω and integrate to obtain (9) (integrability comes from (hint)). In other words, the system on the measure is "a superposition of $\mathbb{Z}_2$ systems with couplings of indefinite sign", and each member of the superposition can be compared with the base $\mathbb{Z}_2$ system.

06

Application to the SU(2) Wilson measure

$SU(2)$ lattice gauge theory satisfies the assumptions of § 05. The correspondence is as follows (notation in 19-01 and 19-02).

Abstract field	The $SU(2)$ Wilson measure	Lean lemma that discharges it
Ω, μ	Link configurations U : links $\to SU(2)$, the product of normalised Haar measures	—
G and its action	A sign per link $g_\ell \in \{\pm 1\}$, $(g \cdot U)_\ell = g_\ell U_\ell$ (multiplying by the centre ± 1)	`TwistedWilson.signAction`
(hinv)	Haar measure is invariant under left multiplication by an element of the centre	`TwistedWilson.haarCfg_inv`
χ_B, (hχ)	The product of the signs of the four links of plaquette B (overlaps kept as overlaps)	`TwistedWilson.chiB_isSignChar`
J_B, (hJ)	$J_B(U) = \beta_B \operatorname{Re} U_B$. Multiplying by signs multiplies $\operatorname{Re} U_B$ by $\chi_B(g)$	`TwistedWilson.hol_smul`
(hK)	$\lvert\operatorname{Re} U_B\rvert \le 1$, so $\lvert J_B\rvert \le \lvert\beta_B\rvert$	`TwistedWilson.abs_re_le_one`
(hint)	The integrand is continuous and bounded	`TwistedWilson.integrable_exp`

The only remaining assumptions are on the side of the base system.

Comparison with $\mathbb{Z}_2$ ($SU(2)$, couplings per plaquette, any base system) (Lean: `TwistedWilson.su2_dominated_general`). If $N, M \geq 1$, β_B are real couplings per plaquette (of arbitrary sign), $\zeta_B = \pm 1$, and the base system (G_0, χ^0, p) satisfies

- each χ^0_B is a sign character on G_0,
- $p : G_0 \to \{\pm 1\}^{\text{links}}$ satisfies $\chi_B(p(t)) = \chi^0_B(t)$,

then

$$\left(\int e^{\sum_B \beta_B \operatorname{Re} U_B}\, dU\right) Z_{\chi^0}\left(\zeta|\beta|\right) \;\leq\; \left(\int e^{\sum_B \zeta_B \beta_B \operatorname{Re} U_B}\, dU\right) Z_{\chi^0}\left(|\beta|\right) \quad (11)$$

(dU is the product of Haar measures, $|\beta| = (|\beta_B|)_B$). Cited This is a formalisation of the comparison said to be the line of Mack–Petkova (the text not checked in this book). It is machine-checked in Lean, and the comparison by a separate pair of eyes judged that it holds conditionally on the three fields of the base system (being characters, the pull-back formula, $\zeta = \pm 1$), and that instances satisfying them exist.

An instance (Lean: `TwistedWilson.su2_dominated_general_instance`, no assumption fields). Take as the base the $\mathbb{Z}_2$ gauge theory on the two-dimensional torus $(\mathbb{Z}/M)^2$ of the length directions. p is the map that sends a sign t of a two-dimensional link to the links in directions 3 and 4 at (x_3, x_4) (independently of the transverse position (x_1, x_2)), and puts $+1$ on the links in directions 1 and 2 (`TwistedWilson.pull`). Taking the coupling $\beta_B = \beta\, z_B$ (z is the sign of the background twist n_{12}) and ζ the sign of the (3,4) twist, the two integrals in (11) become exactly the partition functions $Z_{N,M}(\beta; n_{12}, 0)$ and $Z_{N,M}(\beta; n_{12}, 1)$ of 19-02 (the case $n_{12} = 1$ gives this part's Z_0, Z_1), and

$$Z_{N,M}(\beta; n_{12}, 0) \cdot Z_{\text{base}}\left(\zeta|\beta|\right) \;\leq\; Z_{N,M}(\beta; n_{12}, 1) \cdot Z_{\text{base}}\left(|\beta|\right) \qquad \text{(for all real } \beta,\ N, M \geq$$

follows (the Lean name of the same formula is `TwistedWilson.su2_dominated`). The ratio on the base side is computable by a closed two-dimensional formula, and the thin-vortex floor follows from it (21-02). The background twist n_{12} is absorbed into the sign of J, so the bound $|J_B| \leq |\beta|$ of (hK) is unchanged even with a background. This contrasts with the $\mathbb{Z}_2$ system itself, where the background twist becomes a negative coupling and (hK) of the covering inequality fails.

```
07
```

Writing the vortex ratio as an average of signs — the η representation

The twist $n34$ was "reverse the sign of one column of (3,4) planes". In fact neither the position of the reversed column nor the way of reversing carries any meaning; only the product of the signs does. The η representation puts this into a formula.

For $\eta : (\mathbb{Z}/M)^2 \to \mathbb{R}$, write $Z[\eta]$ for the partition function in which the coupling of the (3,4) plaquette $((x_1,x_2),(x_3,x_4))$ is multiplied by $\eta(x_3,x_4)$ (the same factor for all N^2 transverse copies; the background n_{12} is left as it is; Lean: `TwistedWilson.ZEta`).

Parity of η (Lean: `TwistedWilson.ZEta_parity`). The only assumption is $\eta_y = \pm 1$ (for all y). Then

$$Z[\eta] = \begin{cases} Z_0 & \prod_y \eta_y = 1 \\ Z_1 & \prod_y \eta_y = -1 \end{cases} \quad (13)$$

(for all real β and $N, M \geq 1$. Here we wrote it in the notation of this part's convention $n_{12} = 1$. For $n_{12} = 0$ the same formula holds with Z_0, Z_1 replaced by $Z_{N,M}(\beta;0,0)$, $Z_{N,M}(\beta;0,1)$. The same goes for (14), whose left side is then $\theta_M^{(n_{12})}$ of 19-02).

θ is the average of η (Lean: `TwistedWilson.theta_eq_eta_average`, no assumption fields).

$$\theta_M = \frac{Z_0 - Z_1}{Z_0 + Z_1} = \frac{\sum_\eta \left(\prod_y \eta_y\right) Z[\eta]}{\sum_\eta Z[\eta]} \quad (14)$$

The sum runs over all $\eta : (\mathbb{Z}/M)^2 \to \{\pm 1\}$ (2^{M^2} of them), and this is a ratio of unnormalised sums. The right side is the expectation of $\prod \eta$ under the joint weight $\exp\left(\beta \sum_B z_B\, \eta_B\, \mathrm{Re}\, U_B\right)$ of the configuration (U, η). Proved here The proof follows the route below; both are machine-checked in Lean, and the definitions and statements have been compared by a separate pair of eyes. That the twist is determined only by its centre class is a standard fact about twisted boundary conditions Cited (G. 't Hooft, Nucl. Phys. B 153 (1979) 141).

The route of proof. Three parts Proved here .

1. Centre gauge invariance (Lean: `ZEta_gauge`). Reversing the links in directions 3 and 4 by a two-dimensional sign field t leaves Haar measure unchanged, and $Z[\eta] = Z[\eta \cdot \chi^{2D}(t)]$ ($\chi^{2D}_y(t)$ is the sign of the two-dimensional plaquette y).
2. Realising plaquette signs (Lean: `TwistedPlane.exists_chi2_eq`). If $\eta = \pm 1$ and $\prod \eta = 1$, there is a t with $\chi^{2D}_y(t) = \eta_y$. Shown by counting.

3. The involution $\eta \mapsto \eta \cdot e_0$ (reverse only plaquette 0) shows that the cases $\prod \eta = 1$ and -1 are equal in number.

(13) follows from 1 and 2, and (14) from (13) and 3. Independence of the position of the reversal (for every position P, "reverse only plaquette P" gives Z_1: `ZEta_flip_any`) follows from the same parts. This representation is the starting point of the thick-vortex floor (21-03).

08

What is not said

- **One side only.** All three point in the direction of bounding the $SU(2)$ ratio Z_1/Z_0 from below, from the $\mathbb{Z}_2$ side. A lower bound on ΔF (a lower bound on θ_M) does not come out of comparisons of this type.
- **Not monotonicity or a covering inequality for a non-abelian group.** § 03 and § 04 are theorems about $\mathbb{Z}_2$ sign systems. For $SU(2)$, neither monotonicity in the coupling β nor a covering inequality across torus sizes is shown. For the finite non-abelian group Q_8, without a twisted background, there are points at weak coupling where both the covering inequality and monotonicity fail Reading (floating-point values of transfer matrices on small three-dimensional lattices. Example: covering number 3, $\beta = 1.25$, $\Delta F_3(1.25) = 1.29498 > \Delta F_1(3.75) = 1.28758$; two independent implementations agree). Q_8 is a finite subgroup of $SU(2)$; whether the same happens for $SU(2)$ is not known.
- **The lattice dictionary is on paper.** The Lean statements of § 03 and § 04 are in abstract form. The dictionary (the detour) that reads a four-dimensional $\mathbb{Z}_2$ torus with the transverse directions stretched n-fold as a pair of a large torus and a base torus is on paper. The only lattice instance in Lean with a non-trivial base is the form at the end of § 03, "bringing four-dimensional $\mathbb{Z}_2$ down to two-dimensional $\mathbb{Z}_2$ of the length directions". Abstract examples whose base character is identically 1 are not counted among the results of this chapter.
- **The ratio of the base system is needed separately.** (11) and (12) go only as far as the comparison with the base $\mathbb{Z}_2$ system; the value of the base ratio is a separate computation (21-02 uses the closed two-dimensional formula).
- **The lattice spacing is fixed.** All are inequalities for finite systems on finite tori; they say nothing about the continuum limit, infinite volume or the mass gap.

The view that tools of this type yield no more than the floor is in the record of the study in 26-04 and 26-06.

Detour: reading the covering inequality on the lattice

You may skip this. In four-dimensional $\mathbb{Z}_2$ gauge theory, suppose a torus Λ covers a small torus Λ_0 n times (stretching the transverse directions periodically). With G the link signs of Λ, G_0 the link signs of Λ_0, p the periodic copy and ι the plaquettes of Λ, (3) is the obvious fact that "the plaquette signs of the copied field equal the plaquette signs of the base". The coupling on the base side is counted by the plaquette index of the cover, so if n plaquettes lie over one plaquette of the base, their couplings add up to nK. The covering inequality (5) then reads

$$\Delta F_{\Lambda}(\beta) \;\leq\; \Delta F_{\Lambda_0}(n\beta)$$

Stretching both transverse directions n-fold gives n^2 plaquettes. This reading is on paper, and has been checked by exhaustive enumeration on small lattices Reading (floating point, with a negative control: a version that miscounts the plaquettes fails). The $SU(2)$ application (§ 06) does not go through this dictionary; it builds the base system on the same lattice (the two-dimensional torus of the length directions) directly in Lean.

What this chapter can say

Can say	Cannot say
Proved here The covering inequality (4)(5), under five assumptions (two sign characters, the pull-back formula, $K \geq 0$, $\zeta = \pm 1$). Lean: `covering_ineq`, `covering_ratio`, `vfe_cover_le`	The reading on the lattice (the dictionary) is on paper. No version for non-abelian groups
Proved here A lattice instance: bringing four-dimensional $\mathbb{Z}_2$ down to two-dimensional $\mathbb{Z}_2$ of the length directions ($K \geq 0$). Lean: `z2_four_covers_two`, `z2_four_ratio`	A Lean instance of the covering that stretches the width n-fold
Proved here $\mathbb{Z}_2$ monotonicity (7): $0 \leq K \leq K'$, $\zeta = \pm 1$. Lean: `mon_ineq`, `mon_ratio`	Monotonicity in β for $SU(2)$. $\mathbb{Z}_2$ systems with a twisted background
Proved here Comparison with $\mathbb{Z}_2$ (8)(9): $\lvert J\rvert \leq K$, invariant measure, integrability. Lean: `dominated_covering_ineq`, `invariant_dominated`	The reverse direction (a lower bound on ΔF)
Proved here The $SU(2)$ application (11), under the three fields of the base system. Lean: `su2_dominated_general`. Instance (12) (no fields): `su2_dominated_general_instance`, `su2_dominated`	The value of the base ratio (21-02). Lattice spacing fixed; no continuum limit
Proved here Parity of η (13) (field $\eta = \pm 1$) and θ as the average of η (14) (no fields). Lean: `ZEta_parity`, `theta_eq_eta_average`	An estimate of the average of η itself (the thick-vortex floor is 21-03)
Reading For Q_8 there are points where the covering inequality and monotonicity fail (no background, small three-dimensional lattices)	The general form of the failure. Floating-point values, not a theorem

The three results, the application, the η representation	Proved here	Machine-checked in Lean 4 (declarations in each section; only the three standard axioms, no sorry). The definitions and statements were compared by a separate pair of eyes, which judged the three abstract results "to hold as implications", the application "conditional on the fields of the base system, with satisfying instances", and the η representation "to hold"
The failure for Q_8	Reading	The numerical record of this book's study (transfer matrices on three-dimensional lattices cross-checked by exhaustive enumeration; two independent implementations agree to 4–7 digits. D_4 gives the same values)
The check of the lattice dictionary	Reading	The numerical record of this book's study (sums over all configurations of small four-dimensional $\mathbb{Z}_2$ lattices; fails in a negative control that miscounts the plaquettes)

Words used in this chapter — sign system, sign character, base system, pull-back, covering inequality, $\mathbb{Z}_2$ monotonicity, comparison with $\mathbb{Z}_2$, averaging over the centre, vortex ratio, flux free energy, floor, η representation. Their meanings are in A-02 Glossary.

Next chapter to read: 21-02 The thin-vortex floor — putting the closed two-dimensional formula into the comparison of § 06, we obtain $|\theta_M| \le \tanh(N^2|\beta|)^{M^2}$.

The thin-vortex floor

> This chapter is this book's own investigation.

What this chapter shows — that the vortex ratio of the $SU(2)$ Wilson measure satisfies $|\theta_M| \le \tanh(N^2|\beta|)^{M^2}$ for every real β and all $N, M \ge 1$; its exponential form $|\theta_M| \le e^{-\sigma_0 M^2}$ ($\sigma_0 = -\ln\tanh(N^2|\beta|)$); the meaning of "thin"; and the five steps of the proof.

Prerequisite chapters — 19-02 the torus of width N and length M, the twist, the vortex ratio; 21-01 Three results on sign systems (the application in § 06).

Said first — the lattice spacing is fixed. The rate $\sigma_0 \approx 2e^{-2N^2|\beta|}$ approaches 0 as the width N grows and is not uniform in N. The sign of θ_M ($Z_1 \le Z_0$) is not stated in this chapter (21-06). No rate as $M \to \infty$ (a limit) is defined. Neither the band nor the mass gap is reached (the statements to be shown are in 19-07). This is a formalisation of one side of a known picture.

The order of this chapter

1. Statement — the ratio form, the two-sided form, the exponential form
2. In numbers — the size of the right side, and the gap to the actual ratio
3. What "thin" means — the cost of a vortex gathered onto one sheet
4. The route of proof — five steps
5. Part: the closed two-dimensional Z_2 formula
6. Part: moving the base partition function to two dimensions
7. Arithmetic restatements — a lower bound on the ratio and an upper bound on the flux free energy
8. What is not said

01

Statement — the ratio form, the two-sided form, the exponential form

The object is the $SU(2)$ Wilson measure on the torus $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ of width N (directions 1 and 2) and length M (directions 3 and 4). The weight is $e^{\beta \sum_p z_p \operatorname{Re} U_p}$ ($z_p = \pm 1$ is the sign of the twist), the measure is the product of normalised Haar measures, and partition functions are not normalised (19-01). Write $Z_{N,M}(\beta; n_{12}, n_{34})$ for the partition function with background twist n_{12} and (3,4) twist n_{34}, and let the vortex ratio with background n_{12} be $\theta_M^{(n_{12})} = \big(Z_{N,M}(\beta; n_{12}, 0) - Z_{N,M}(\beta; n_{12}, 1)\big) / \big(Z_{N,M}(\beta; n_{12}, 0) + Z_{N,M}(\beta; n_{12}, 1)\big)$ (the notation of the detour in 19-02). Under this part's convention $n_{12} = 1$, these are Z_0, Z_1 and $\theta_M = \theta_M^{(1)}$. The theorems below also hold for $n_{12} = 0$.

The thin-vortex floor (ratio form) (Lean: `TwistedWilson.twisted_vortex_bound`). For every real β, all $N, M \geq 1$ and $n_{12} \in \{0, 1\}$,

$$\theta_M^{(n_{12})} \;\leq\; \tanh\big(N^2 |\beta|\big)^{M^{\angle}} \quad (1)$$

The only assumption field is $N, M \geq 1$.

The thin-vortex floor (two-sided form) (Lean: `TwistedWilson.twisted_vortex_bound_abs`). In the same range,

$$\big|\theta_M^{(n_{12})}\big| \;\leq\; \tanh\big(N^2 |\beta|\big)^{M^{\angle}} \quad (2)$$

For $\beta < 0$ there are cases with $\theta_M^{(n_{12})} < 0$ ($N = M = 1$, $\beta = -1.5$ in the table of § 02), and there it is (2) that has content.

The thin-vortex floor (exponential form) (Lean: `TwistedWilson.thin_vortex_floor`). If $\beta \neq 0$,

$$\sigma_0 := -\ln \tanh\big(N^2 |\beta|\big) > 0, \qquad \big|\theta_M^{(n_{12})}\big| \;\leq\; e^{-\sigma_0 M^{\angle}} \quad (\text{for all } M \geq 1) \quad (3)$$

The only assumption is $\beta \neq 0$ (at $\beta = 0$, $\tanh 0 = 0$ and σ_0 loses its meaning; in fact $\theta_M^{(n_{12})} = 0$).

Proved here For all three, the route of proof is in § 04– § 06; they are machine-checked in Lean as theorems about the concrete $SU(2)$ Wilson measure, and the definitions and statements have been compared by a separate pair of eyes. The pattern, bounding the $SU(2)$ system by a $\mathbb{Z}_2$ system, is said to be the line of Mack–Petkova Cited (bibliography in the source table; the text not checked in this book). In exhaustive sums over finite groups and $SU(2)$ Metropolis runs, written independently during the comparison, no violation was found Reading .

In the language of this part, (3) is a lower estimate of the rate, "θ_M decreases in M^2 at least at rate σ_0", that is, a **floor** (for the direction, see 21-01 § 01).

02

In numbers — the size of the right side, and the gap to the actual ratio

We list the right side $t = \tanh(N^2|\beta|)$ and the rate $\sigma_0 = -\ln t$ for several N, β Reading (floating-point values).

N	$\lvert\beta\rvert$	$t = \tanh(N^2\lvert\beta\rvert)$	$\sigma_0 = -\ln t$	$2e^{-2N^2\lvert\beta\rvert}$
1	0.25	0.2449	1.407	1.213
1	0.5	0.4621	0.7719	0.7358
1	1	0.7616	0.2723	0.2707
2	0.25	0.7616	0.2723	0.2707
2	0.5	0.9640	0.03664	0.03663
2	1	0.99933	6.709×10^{-4}	6.709×10^{-4}
3	0.25	0.97803	0.02222	0.02222
3	0.5	0.999753	2.468×10^{-4}	2.468×10^{-4}
3	1	$1 - 3.05 \times 10^{-8}$	3.05×10^{-8}	3.05×10^{-8}

Once $N^2|\beta|$ exceeds 1, the rate is almost the same as $2e^{-2N^2|\beta|}$, and it drops by orders of magnitude each time N increases by one. The right side is determined by $N^2|\beta|$ alone, so $(N, \beta) = (1, 1)$ and $(2, 0.25)$ give the same row.

The gap to the actual ratio on small lattices is as follows Reading (for $SU(2)$, Metropolis estimates, from an implementation written independently during the comparison).

(N, M)	$n12$	β	$\theta_M^{(n12)}$ (estimate)	Right side t^{M^2}
(1,1)	1	1.5	0.7033 ± 0.0018	0.9051
(1,1)	0	-1.5	-0.0785 ± 0.0026	0.9051
(2,1)	0	0.5	0.4856 ± 0.0012	0.9640
(1,2)	0	1.0	0.0061 ± 0.0013	0.3364

For the $\mathbb{Z}_2$ system (the same lattice with $SU(2)$ replaced by $\{\pm 1\}$), in the pairs tried with $N = 1$ or $M = 1$, $|\theta_M|$ coincides with the right side Reading (floating-point values of finite sums by variable elimination). Since the system we compare with is a $\mathbb{Z}_2$ system, the bound is nearly an equality where configurations close to $\mathbb{Z}_2$ dominate, and becomes loose where the continuous fluctuations of $SU(2)$ matter.

03

What "thin" means — the cost of a vortex gathered onto one sheet

In closed form the rate σ_0 is

$$\sigma_0 = -\ln\tanh x = \ln\frac{1+e^{-2x}}{1-e^{-2x}} = 2\,\mathrm{artanh}\big(e^{-2x}\big), \qquad x = N^2|\beta| \quad (4)$$

Hence $2e^{-2x} \le \sigma_0 \le 2e^{-2x}/(1-e^{-4x})$, and for large x, $\sigma_0 \approx 2e^{-2N^2|\beta|}$ Proved here (from the positivity of the coefficients of the power series of artanh).

The exponent $2N^2|\beta|$ has the following meaning. Among the (3,4) plaquettes, fix one longitudinal position (x_3, x_4) and consider the configuration in which the signs of all N^2 transverse copies are reversed at once. This is a configuration in which the vortex is gathered onto a single sheet spread out in the transverse directions; we call it a **thin vortex**. Since N^2 plaquettes have $\mathrm{Re}\,U_p$ change from 1 to -1, the cost in action is $2\beta \cdot N^2$.

In the proof, this picture appears directly as a formula. The base system (§ 04) is the $\mathbb{Z}_2$ gauge theory on the two-dimensional torus of the length directions, and the coupling of one of its plaquettes is the sum $N^2|\beta|$ of the couplings of the N^2 transverse plaquettes lying over it. In two-dimensional $\mathbb{Z}_2$ gauge theory, the plaquette signs on a torus are independent apart from a single constraint, "the product of all is 1". Converting (7) (§ 05) into the vortex ratio gives $\theta^{2D} = t^{M^2}$ with $t = \tanh(N^2|\beta|)$; this is the mean of the product of all plaquette signs when each plaquette sign is taken to be an independent ± 1 with mean t. From the probability $q = (1-t)/2 \approx e^{-2N^2|\beta|}$ that a plaquette is reversed, $t^{M^2} = (1-2q)^{M^2} \approx e^{-2qM^2}$ Proved here .

So the right side of (1) says only this much: that the $SU(2)$ vortex decreases in M^2 at least as fast as "a dilute gas of thin vortices, each gathered onto one sheet spanning the full width". An $SU(2)$ vortex can spread out within the continuous group and carry the twist in the length directions at a lower cost. When the cost S_N of such a thick vortex is less than $2N^2$, the rate can be taken larger. That is the thick-vortex floor (21-03; for S_N, see 19-02).

04

The route of proof — five steps

The proof has five steps. Steps 1 and 2 are the application of 21-01 § 06, steps 3 and 4 the computation of the base, and step 5 arithmetic. This section and § 06 are written in the notation Z_0, Z_1 of this part's convention $n_{12} = 1$, but the same steps go through for $n_{12} = 0$.

1. **Averaging over the centre.** Haar measure is invariant under multiplying each link by a sign ± 1, and $\operatorname{Re} U_p$ changes only by the factor of the product of the four signs of the plaquette (`haarCfg_inv`, `hol_smul`). So the $SU(2)$ partition function can be written as "an integral over U of $\mathbb{Z}_2$ sign systems with couplings $J_p(U) = \beta z_p \operatorname{Re} U_p$", with $|J_p| \le |\beta|$.
2. **Comparison with $\mathbb{Z}_2$.** Take as the base system the $\mathbb{Z}_2$ gauge theory on the two-dimensional torus $(\mathbb{Z}/M)^2$ of the length directions, linked by the map that sends the signs of two-dimensional links to the links in directions 3 and 4 independently of the transverse position (`pull`). From the comparison with $\mathbb{Z}_2$ in 21-01 § 05,

$$Z_0 \cdot Z_{\text{base}}(\zeta|\beta|) \le Z_1 \cdot Z_{\text{base}}(|\beta|) \quad (5)$$

   (`su2_dominated`). ζ is the sign of the (3,4) twist.
3. **The base to two dimensions.** Up to a constant factor, the partition function of the base system is that of two-dimensional $\mathbb{Z}_2$ gauge theory with coupling $N^2|\beta|$. The twisted one has the coupling with the sign of plaquette 0 alone changed (`Z_base_const`, `Z_base_flip`; § 06).
4. **The closed two-dimensional formula.** The partition function of two-dimensional $\mathbb{Z}_2$ gauge theory can be written in closed form as $|\text{configurations}| \cdot (\prod \cosh + \prod \sinh)$ (`Z_plane`; § 05).
5. **Arithmetic.** Setting $L = N^2|\beta|$, $C = \cosh(L)^{M^2}$, $S = \sinh(L)^{M^2}$, steps 3 and 4 turn (5) into $Z_0(C - S) \le Z_1(C + S)$, which rearranges to $(Z_0 - Z_1)C \le (Z_0 + Z_1)S$, that is, (1) (`bound_of_base`).

The two-sided form (2) uses step 2 with the roles swapped. Taking the twisted side $n_{34} = 1$ as the "original" system and using `su2_dominated_general` with couplings $\beta_p = \beta\, z_p^{(n_{12},1)}$, $\zeta^2 = 1$ gives $Z_1 \cdot Z_{\text{base}}(\zeta|\beta|) \le Z_0 \cdot Z_{\text{base}}(|\beta|)$ (`su2_dominated_swap`). Applying step 5 to both gives $|Z_0 - Z_1|/(Z_0 + Z_1) \le t^{M^2}$ Proved here. The exponential form (3) is a restatement using $t^{M^2} = e^{M^2 \ln t}$ and the fact that $0 < t < 1$ when $\beta \neq 0$ Proved here.

05

Part: the closed two-dimensional Z_2 formula

Consider $\mathbb{Z}_2$ gauge theory on the two-dimensional torus $(\mathbb{Z}/M)^2$ of the length directions: points y, links (y, d) $(d = 1, 2)$, a sign field on links t, and the sign $\chi_y^{2D}(t)$ of plaquette y (the product of four signs, overlaps kept as overlaps) (Lean: `TwistedPlane.chi2`).

The closed formula (Lean: `TwistedPlane.Z_plane`; the only assumption field is $M \geq 1$). For arbitrary couplings c_y, one per plaquette,

$$Z_\chi^{2D}(c) = \sum_t \exp\Big(\sum_y c_y \chi_y^{2D}(t)\Big) = |\text{configurations}| \cdot \Big(\prod_y \cosh c_y + \prod_y \sinh c_y\Big) \quad (6)$$

For a uniform coupling L and the coupling with the sign of plaquette 0 alone changed (`Z_plane_const`, `Z_plane_flip`),

$$\frac{Z_\chi^{2D}(L \text{ with plaquette 0 reversed})}{Z_\chi^{2D}(L)} = \frac{\cosh^{M^2} L - \sinh^{M^2} L}{\cosh^{M^2} L + \sinh^{M^2} L} = \frac{1 - \tanh(L)^{M^2}}{1 + \tanh(L)^{M^2}} \quad (7)$$

(`TwistedPlane.plane_flip_ratio`). Proved here That two-dimensional lattice gauge theory is solvable is a long-known fact; this is a machine check of its $\mathbb{Z}_2$ case.

Proof. Expanding the product with $e^{c\chi} = \cosh c + \chi \sinh c$,

$$Z_\chi^{2D}(c) = \sum_{A \subseteq \text{plaquettes}} \Big(\prod_{y \in A} \sinh c_y\Big)\Big(\prod_{y \notin A} \cosh c_y\Big) \sum_t \prod_{y \in A} \chi_y^{2D}(t)$$

Every link is an edge of exactly two plaquettes, so if A is neither empty nor everything, there is on the boundary of A a "link with only one side in A", and the change of variables that reverses the sign of that link changes the sign of the inner sum, which is therefore 0 (`sum_FA_eq_zero`). For $A = \emptyset$ the product is 1, and for $A =$ everything each link appears twice, so the product is again 1 (`prod_chi2_univ`). The two remaining terms are (6) Proved here .

06

Part: moving the base partition function to two dimensions

The base system of step 2 keeps the four-dimensional plaquette index and has the two-dimensional sign field t as its variable. Its plaquette character $\chi_B^0(t)$, the product of the signs pulled back to the four links of the four-dimensional plaquette B, is as follows (Lean: `TwistedWilson.chi0_eq`).

$$\chi_B^0(t) = \begin{cases} \chi^{2D}_{(x_3,x_4)}(t) & B \text{ a (3,4) plaquette at longitudinal position } (x_3, x_4) \\ 1 & \text{other plaquettes} \end{cases} \quad (8)$$

Links in directions 1 and 2 carry $+1$, and the signs of links in directions 3 and 4 do not depend on the transverse position, so on plaquettes other than (3,4) the link signs each appear twice and cancel. Hence, if the coupling on plaquettes other than (3,4) is a uniform K,

$$Z_\chi^0(c) = e^A \cdot Z_\chi^{2D}\Big(y \mapsto \sum_{(x_1,x_2)} c((x_1,x_2),y),(3,4)\Big), \qquad A = \sum_{B \in /(3,4)} K \quad (9)$$

(`Z_base`). The couplings of the N^2 transverse plaquettes lying over the longitudinal position y add up to the coupling of the two-dimensional plaquette y. For a uniform $K = |\beta|$ the two-dimensional coupling is $N^2|\beta|$ (`Z_base_const`), and multiplying by the (3,4) twist ζ gives the coupling $N^2|\beta|$ with the sign of plaquette 0 alone changed (`Z_base_flip`). The same constant e^A multiplies both, so it cancels in the ratio Proved here .

What matters here is that the set of plaquettes of the twist $n34$ (the (3,4) plaquettes at longitudinal position $(0,0)$, N^2 transverse copies) is exactly the N^2 plaquettes lying over the two-dimensional plaquette 0 (the definition of the twist in 19-02). The thin vortex of § 03 is this bundle of N^2 plaquettes.

07

Arithmetic restatements — a lower bound on the ratio and an upper bound on the flux free energy

Setting $s = \tanh(N^2|\beta|)^{M^2}$, (1) can also be written in the following two forms. In both, the only assumption field is $N, M \geq 1$, and they hold for every real β. We write them in the notation of this part's convention $n_{12} = 1$; for $n_{12} = 0$ the same formulas hold with Z_0, Z_1 replaced by $Z_{N,M}(\beta;0,0)$, $Z_{N,M}(\beta;0,1)$.

A lower bound on the ratio (Lean: `TwistedWilson.twisted_ratio_lower`).

$$\frac{Z_1}{Z_0} \;\geq\; \frac{1-s}{1+s} \quad (10)$$

This is equivalent to (1) Proved here .

An upper bound on the flux free energy (Lean: `TwistedWilson.vortex_free_energy_bound`).

$$\Delta F = -\ln\frac{Z_1}{Z_0} \;\leq\; \ln\frac{1+s}{1-s} \;\leq\; \frac{2s}{1-s} \quad (11)$$

ΔF is 't Hooft's flux free energy (the same quantity as in 25-01 and 26-03). This is arithmetic from $0 \leq s < 1$ and $\ln x \leq x - 1$; both (10) and (11) are machine-checked in Lean Proved here .

(11) is a form, for each finite M, that bounds ΔF from above by $2s/(1-s) \approx 2e^{-\sigma_0 M^2}$. It is an upper bound on ΔF, not a lower bound ($\Delta F \geq 0$ follows, when M is even, from

the sign in 21-06). The word floor is used in the direction of bounding the speed (the rate) at which ΔF decreases from below.

08

What is not said

- **The sign.** $Z_1 \le Z_0$ ($\theta_M \ge 0$) is not part of the theorems of this chapter. If M is even, $\theta_M \ge 0$ for every real β (21-06). Since there are examples with $\theta_M < 0$ at $\beta < 0$ (the table of § 02), for $\beta < 0$ it is the two-sided form (2) that has content.
- **No rate uniform in N.** $\sigma_0 \approx 2e^{-2N^2|\beta|}$ goes to 0 as $N \to \infty$. This is an estimate for a slab with the width held fixed, effectively two-dimensional, and not a positive lower bound on the four-dimensional tension.
- **The rate as $M \to \infty$ is not defined.** (3) is an inequality for each finite M. We do not have, as a Lean statement, "$\sigma_N(\beta) \ge \sigma_0$" for a tension $\sigma_N(\beta)$ defined by $\lim$ or $\liminf$ (what can be read from (3) is only the estimate for each M).
- **Weak at large $N^2|\beta|$.** The rate is the value for a thin vortex of cost $2N^2|\beta|$; the thick-vortex floor (21-03) can be better at large β ($S_N < 2N^2$ for $N = 2, 3, 4$: 21-05).
- **The lattice spacing is fixed.** Nothing is said about the continuum limit, infinite volume, the four-dimensional area law, the band or the mass gap (the statements to be shown about the band and the mass gap are in 19-07).

A discussion that places this inequality within the view "tools built on structure alone yield no more than the floor" is in the record of the study, 26-04.

What this chapter can say

Can say	Cannot say
Proved here The thin-vortex floor (1): $\theta_M^{(n_{12})} \le \tanh(N^2\|\beta\|)^{M^2}$, every real β, $N, M \ge 1$, $n_{12} \in \{0, 1\}$, no assumption fields. Lean: `TwistedWilson.twisted_vortex_bound`	$Z_1 \le Z_0$ (21-06). For $\beta < 0$ the one-sided form may have no content
Proved here The two-sided form (2): $\|\theta_M^{(n_{12})}\| \le \tanh(N^2\|\beta\|)^{M^2}$, same range. Lean: `TwistedWilson.twisted_vortex_bound_abs`	A lower bound on θ_M
Proved here The exponential form (3): for $\beta \neq 0$, $\sigma_0 > 0$ and $\|\theta_M^{(n_{12})}\| \le e^{-\sigma_0 M^2}$. Lean: `TwistedWilson.thin_vortex_floor`	A rate uniform in N. A definition of the rate as $M \to \infty$, and a statement of its lower bound

Can say	Cannot say
Proved here The lower bound on the ratio (10) and the upper bound on the flux free energy (11). Lean: `twisted_ratio_lower`, `vortex_free_energy_bound`	A lower bound on ΔF

Words used in this chapter — thin-vortex floor, thin vortex, vortex ratio, flux free energy, floor, rate, base system, closed two-dimensional Z_2 formula, averaging over the centre. Their meanings are in A-02 Glossary.

Next chapter to read: 21-03 The thick-vortex floor — statement and route — instead of gathering the vortex onto one sheet, we take the rate again from the cost S_N of a cheaper thick vortex.

The thick-vortex floor — statement and route

This chapter is this book's own investigation.

What this chapter shows — that for the SU(2) Wilson measure on a twisted torus of width N and length M, the upper bound on the vortex ratio θ_M, "for every $\varepsilon > 0$, for each sufficiently large β, for sufficiently large M, $|\theta_{M+1}(\beta)| \le \exp(-(M+1)^2 e^{-\beta(S_N+\varepsilon)})$" (the thick-vortex floor), is machine-checked in Lean for all $N \ge 1$ with no assumption fields. How to read the order of quantifiers, the difference from the thin-vortex floor (exponent $2N^2$), and the route of the seven steps of the proof.

Prerequisite chapters — 19-02 (the twisted torus, the vortex ratio θ, the minimal action of a vortex S_N), 19-01 (the Wilson measure), 21-02 The thin-vortex floor. We use the language of limits ("sufficiently large") and the minimum of a continuous function on a compact set.

Said first — this is an upper bound **at a fixed lattice spacing, with the width N held fixed**. Neither the threshold in β nor the threshold in M for each β is explicit. The value of S_N for general N is not in Lean. The reverse direction (a lower bound on the rate) is not shown. It does not reach the band (the statement of 19-07), the four-dimensional area law, the mass gap or the continuum limit. In form it is a formalisation of a result of a known type, belonging to the picture of vortices on a thin twisted slab (the line of Mack–Petkova; conditional independence of blocks with the frame held fixed).

The order of this chapter

1. The objects, restated — the twisted torus, θ_M, how action is counted, S_v(N,m) and S_N
2. Statement — the thick-vortex floor, and how to read the order of quantifiers
3. Meaning — thin vortices and thick vortices — the exponent $2N^2$ drops to S_N. Figure 1
4. A map of the route — the seven steps, and which chapter holds which step
5. First half — dividing into blocks, turning into differences of action — the block-by-block estimate and the Laplace step

6. Second half — swapping the vortex into a cheap window — pigeonhole, compactness, the local model, rigidity, transplanting
7. Assembly — where the order of quantifiers comes from — from ε to m, β, M. Detour: why the twisted background is needed
8. What is not said — thresholds, the value of S_N, the reverse direction, N = 1, the band

---

01

The objects, restated

The definitions are in Part 19. Here we restate, one line each, only what the statement needs.

- The lattice is $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$. Directions 1 and 2 are the width (side N), directions 3 and 4 the length (side M) (19-02).
- The background twist $n_{12} = 1$ is always present. Z_0 and Z_1 are the partition functions with twist $n_{34} = 0$ and 1 on the (3,4) planes (the sign of the twist). The measure is the unnormalised Wilson weight $e^{\beta \sum_p z_p \operatorname{Re} U_p}$ times the product of Haar measures.
- The vortex ratio is $\theta_M(\beta) = (Z_0 - Z_1)/(Z_0 + Z_1)$ (19-02). The denominator is positive.
- Action is counted in the form before multiplying by β: $S(U;\eta) = \sum_p \big(1 - z_p\, \eta_p \operatorname{Re} U_p\big) \geq 0$. $\eta_p = \pm 1$ is a sign that multiplies only the (3,4) plaquettes.
- The twisted vacuum V is the configuration with i on the direction-1 links at $x_1 = 0$, j on the direction-2 links at $x_2 = 0$, and 1 elsewhere. Since $ij\,i^{-1}j^{-1} = -1$, even on the twisted (1,2) plaquettes $z_p \operatorname{Re} U_p = 1$, and the action is 0.
- $S_{\mathrm{v}}(N,m)$ is the infimum of the action of the block when, on the lattice $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/2m)^2$, the frame of a block of side m is held fixed at V and the sign of the corner (3,4) plaquette (N^2 transverse copies) is reversed. $S_N = \inf_{m \geq 1} S_{\mathrm{v}}(N,m)$ (19-02).

Leaving the interior at V and reversing the corner plaquette raises the action of each of the N^2 transverse plaquettes from 0 to 2. So $S_{\mathrm{v}}(N,m) \leq 2N^2$ and $S_N \leq 2N^2$.
Proved here Lean: `TwistBlocks.SN_bounds` ($0 \leq S_N \leq 2N^2$, for all $N \geq 1$).

02

Statement

The thick-vortex floor. Fix $N \geq 1$. For any $\varepsilon > 0$, for all sufficiently large β, for all sufficiently large M,

$$|\theta_{M+1}(\beta)| \;\leq\; \exp\Big(-(M+1)^2\, e^{-\beta(S_N+\varepsilon)}\Big). \quad (1)$$

Lean: `TwistBlocks.thick_vortex_floor` (all $N \geq 1$, no assumption fields; the statement is `ThickVortexFloorAbs N`). The form with definitions unfolded is `TwistBlocks.thick_vortex_floor_unfolded`. It is a formalisation of a result of a known type; the type is said to be the line of Mack–Petkova Cited (bibliography in the table at the end of the chapter; the text not checked in this book).

In the language of filters, the Lean statement has the order $\forall \varepsilon > 0,\ \forall^{\mathrm{f}} \beta \in \mathrm{atTop},\ \forall^{\mathrm{f}} M \in \mathrm{atTop}$. Unfolded into quantifiers, the order is as follows.

$$\forall \varepsilon > 0 \;\; \exists \beta_0 \;\; \forall \beta \geq \beta_0 \;\; \exists M_0(\beta) \;\; \forall M \geq M_0(\beta) : \quad (1). \quad (2)$$

Four points to note when reading it.

1. It is of the form in which β_0 **may depend on** ε**, and** M_0 **on** ε **and** β. The values of neither threshold appear in the statement (§ 07).
2. It is **with absolute value**. It bounds $|\theta|$ from above without using the sign of θ. The sign ($\theta \geq 0$ for even M) is a separate theorem (21-06).
3. Writing $M+1$ is only to avoid $M = 0$. Reading it as "for all sufficiently large M" is the same.
4. Only the large side of β. Nothing is said about $\beta < 0$ or about finite β.

Rewriting (1) in terms of the rate, for M with $\theta_M \neq 0$, $-\frac{1}{M^2} \ln |\theta_M| \geq e^{-\beta(S_N+\varepsilon)}$. Setting the slab tension to $\sigma_N(\beta) = \liminf_M -\frac{1}{M^2} \ln |\theta_M|$, we get $\limsup_{\beta\to\infty} \frac{1}{\beta} \ln \frac{1}{\sigma_N(\beta)} \leq S_N$. Proved here This restatement is one line of arithmetic outside Lean.

03

Meaning — thin vortices and thick vortices

The thin-vortex floor (21-02) says $|\theta_M| \leq \tanh(N^2|\beta|)^{M^2}$ for every real β and all $N, M \geq 1$. For large β, $-\ln \tanh(N^2\beta) \approx 2e^{-2N^2\beta}$, so the rate in the exponent is of order $e^{-2N^2\beta}$. **The exponent of the rate is** $2N^2$.

In the thick-vortex floor (1), the rate is $e^{-\beta(S_N+\varepsilon)}$. **The exponent of the rate drops from** $2N^2$ **to** S_N. If $S_N < 2N^2$, the thick-vortex floor is the stronger upper bound

where β is large.

In pictures: a vortex is a single reversal of the sign η of a (3,4) plaquette, threaded through the whole transverse T^2_N.

- **A thin vortex**: the reversal is absorbed at the position of a single (3,4) plaquette. Each of the N^2 transverse plaquettes pays an action of 2, so the cost is $2N^2$.
- **A thick vortex**: the reversal is spread within a block of side m in the directions of the (3,4) planes, and also over the transverse T^2_N. The links are rotated little by little to thin out the burden on each plaquette. The minimal cost is $S_{\mathrm{v}}(N, m)$, and its infimum over $m \to \infty$ is S_N.

Precisely, S_N is the infimum of "the minimal action for threading one vortex through a block whose boundary is held at the twisted vacuum". It is not the minimal action over the whole torus.

Figure 1 Dividing the longitudinal (3,4) plane T^2_M into blocks of side m (left). A single block enlarged (right): the frame (thick lines) is held fixed, and the sign is reversed on the corner plaquette (dark square). The cost of the vortex is paid by spreading this one sheet within the block. Above each point sits the transverse T^2_N.

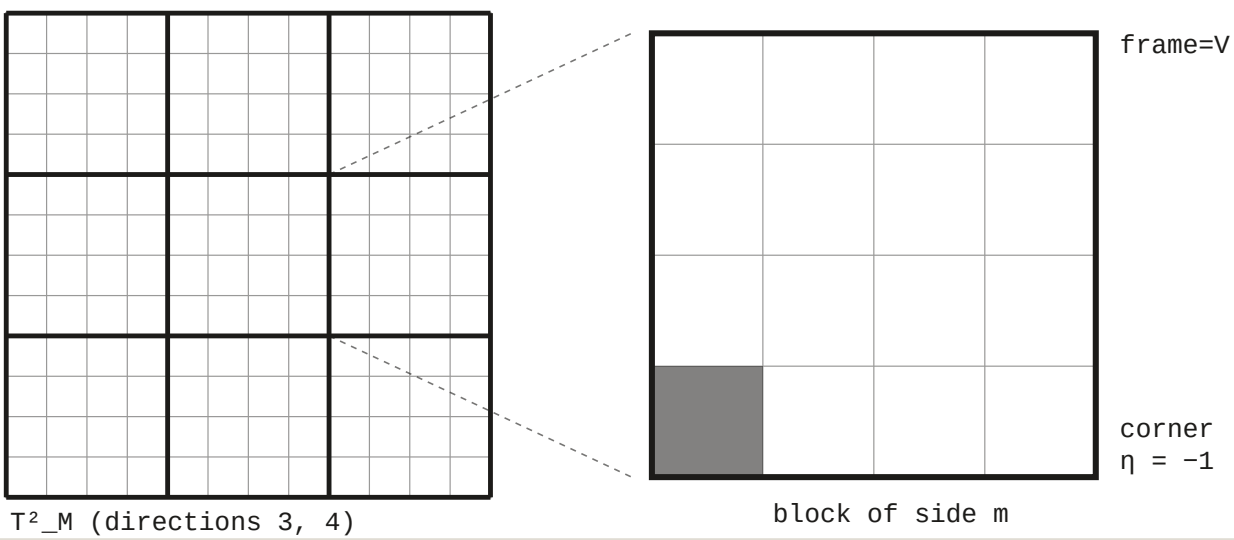

Figure 1 is schematic. No numbers are drawn.

The numbers for S_N are as follows.

N	Thin-vortex exponent $2N^2$	What can be said about S_N	Label / Lean
1	2	$S_1 = 2$ (numerical cooling). No gap	Reading Inside Lean only $S_1 \leq 2$

N	Thin-vortex exponent $2N^2$	What can be said about S_N	Label / Lean
2	8	$S_2 \le 6.67401$, $S_2 < 8$	Computer-assisted 21-05 (`VortexCert.SN_two_le`, `SN_two_lt`)
3	18	$S_3 < 18$ (upper bound 9.09321)	Computer-assisted 21-05 (`VortexCert.SN_three_lt`)
4	32	$S_4 < 32$ (upper bound 12.02057)	Computer-assisted 21-05 (`VortexCert.SN_four_lt`)
General	$2N^2$	$0 < S_N \le 2N^2$	Lean: `VortexPos.SN_pos`, `TwistBlocks.SN_bounds` (21-05)

$S_2 \le 6.67401$ for $N = 2$ is a computer certificate by a configuration with rational entries, checked in the Lean kernel. We use it as support for the analytic proof. For $N = 2$, the rate of the thick-vortex floor $e^{-6.675\beta}$ exceeds the rate of the thin-vortex floor $-\ln\tanh(4\beta)$ (the upper bound becomes smaller) from about $\beta > 0.523$, comparing down to the coefficients Reading . However, since the thresholds of the thick-vortex floor are not explicit, one cannot say that the thick upper bound is smaller at any concrete (β, M). Only the rates as $\beta \to \infty$ can be compared.

04

A map of the route

The proof splits into two halves: "bound $|\theta|$ by a quantity defined block by block, and bound the rate of that quantity as $\beta \to \infty$ by the minimal action of a vortex". Divided into steps, it is as follows.

```
Step 1 block-by-block estimate  |θ| ≤ tanh(K_eff)^{k²}            (first hal
  │                       K_eff = sup of log of the (+)/(−) ratio of a block
Step 2 Laplace step        K_eff ≤ ½(β(κ_c + 2δ) + D)             (first hal
  │                       κ_c = sup of the (+)/(−) difference of the block's
  │
Step 3 canonical signs     the block's sign field goes to a standard form, ac
Step 4 pigeonhole          the block contains a window of small action
Step 5 compactness         "small action" reduced to a claim about "action 0"
Step 6 local model, rigidity  action-0 configurations are gauge transforms of
Step 7 transplant          put a minimising configuration of S_v(N, m₀) into
  │                       ⇒ κ_c ≤ S_N + ε for sufficiently large m
  ▼
Assembly                   take the thresholds in the order ε → m → β₀ → M₀
```

The output of steps 3–7 is "for sufficiently large block side m, $\kappa_c \le S_N + \varepsilon$ for every frame". Inside Lean there is a named intermediate form of this, and from there to (1) is

arithmetic (21-04). The statements and scope of the parts are placed in 21-04. This chapter writes only the flow.

05

First half — dividing into blocks, turning into differences of action

Step 1: the block-by-block estimate

Divide the longitudinal plane T^2_M into $k \times k$ blocks of side m ($mk \le M$; only the last row and column are made wider). The links lying on the boundary lines of the blocks are called the **frame**. Every plaquette contains only frame links and interior links of at most one block. So once the frame is held fixed, the weight splits into a product over blocks.

In each block, compare the partition functions $Z^F_B(\pm)$ of the class where the product of the signs of the (3,4) plaquettes is $+1$ and the class where it is -1. Letting K_{eff} be half the supremum, over blocks and frames, of the logarithm of that ratio,

$$|\theta_M| \le \tanh(K_{\mathrm{eff}})^{k^2}. \quad (3)$$

Lean: `TwistBlocks.block_bound_abs` (every real β, $mk \le M$, arbitrary background n_{12}). The ratio lies within $e^{\pm 2N^2|\beta|}$, so $K_{\mathrm{eff}} \le N^2|\beta|$ (`TwistBlocks.Keff_le`). At $m = 1$ this returns to the form of the thin-vortex floor.

Step 2: the Laplace step

For large β, $Z^F_B(\pm)$ is nearly determined by the minimum $S^F_{\min}(\pm)$ of the block's action. From above it is trivially bounded by $e^{-\beta S_{\min}}$. From below it is bounded by the Haar measure of a small ball around the minimiser. In this way, for $\beta \ge 0$ and $\delta > 0$,

$$K_{\mathrm{eff}} \le \tfrac{1}{2}\big(\beta(\kappa_C + 2\delta) + D(\delta)\big), \qquad \kappa_C = \sup_{b,F} |S^F_{\min}(+) - S^F_{\min}(-)|. \quad (4)$$

Lean: `TwistBlocks.Keff_le_laplace` ($\beta \ge 0$, $\delta > 0$). $D(\delta)$ does not depend on β and is bounded above by a quantity determined by the block size alone (uniform in M). Combined with $-\ln\tanh K \ge e^{-2K}$, (3) and (4) give $|\theta_M| \le \exp(-k^2 e^{-\beta(\kappa_C + 2\delta) - D})$. What remains is to bring κ_C close to S_N.

06

Second half — swapping the vortex into a cheap window

What we want to show is that for sufficiently large m, **for every frame** F, $S^F_{\min}(-) \le S^F_{\min}(+) + S_N + \varepsilon$ (and the reverse) holds. That is, "from a configuration close to the minimum of (+), the class can be reversed at a cost of at most $S_N + \varepsilon$". We show it in five steps.

Step 3: canonical form of the signs

There are many sign fields η within a block. But applying reversals of links by the central $\mathbb{Z}_2$ in the interior, η can be moved to a standard form (all $+1$, or -1 on the corner plaquette alone) without changing the action. The class is determined by the product $\prod \eta$ alone. Lean: `TwistBlocks.canon_holds` (all $N, M \ge 1$, $mk \le M$).

Step 4: choosing a cheap window by pigeonhole

In either class, the block action of a configuration close to the minimum is at most $144N^2m$, since only the plaquettes touching the frame contribute. Inside the block, place T^2 windows of side $m_0 + 2$ so that they share no plaquettes. The sum of the actions of the windows is at most the action of the block, so some window has action at most $144N^2m/T^2$. Taking T large makes the action of this window as small as we like.

Step 5: compactness

The space of configurations around the window is compact, and the action is continuous. So if one can say "for configurations of action 0, the class can be reversed at a cost of at most c", then "for configurations of sufficiently small action, it can be reversed at a cost less than $c + \varepsilon$" follows. This is phrased in terms of cost, without using a distance. The smallness γ has no explicit value (it is a different quantity from the δ of step 2). Lean: `ThickFloor.small_action_cost`.

Step 6: the local model, and rigidity of the twisted torus

Lift the neighbourhood of the window to a single finite model independent of M (the transverse $T^2_N \times$ a square of side $m_0 + 2$). In this model, a configuration of action 0 is, **on the links that appear in plaquettes**, a gauge transform of the local twisted vacuum. The core is a problem on the transverse T^2_N. A flat configuration on T^2_N with one twisted plaquette is determined by two generators a, b, and the twist gives $ab = -ba$. A pair of anticommuting unit quaternions is mapped to (i, j) by conjugation. So the configuration is a gauge transform of the vacuum. Lean: `TwistBlocks.rigidT_all` (all $N \ge 1$), `ThickFloor.anticomm_conj`.

Step 7: transplanting the minimising configuration

Put a minimising configuration of $S_{\mathrm{v}}(N, m_0)$ into the window, matched by a gauge transformation. The plaquettes outside the window do not change. Inside the window the class is reversed once, at a cost of at most $S_{\mathrm{v}}(N, m_0)$. Choosing m_0 so that $S_{\mathrm{v}}(N, m_0) < S_N + \varepsilon/4$, the cost approaches S_N. Lean: `TwistBlocks.thick_vortex_floor_zero_of_rigid` (from rigidity to the zero-action claim; 21-04).

07

Assembly — where the order of quantifiers comes from

The thresholds are fixed in the following order.

1. Give ε.
2. Choose m_0 with $S_{\mathrm{v}}(N, m_0) < S_N + \varepsilon/4$ (existence only, from the definition of the infimum).
3. Obtain $\gamma > 0$ from the compactness of step 5. **Its value is not explicit**.
4. Take a natural number T with $\gamma T > 144 N^2 (m_0 + 3) + \varepsilon/4$, and set the block side to $m = (m_0 + 2)T + 1$. The action of the window of step 4 falls below γ, and for all $M \geq m$, κ_c comes within about ε of S_N.
5. Take β_0 large enough that D and $\ln(4m^2)$ can be absorbed by $\beta\varepsilon/2$. Since D contains the Haar measure of a small ball, **this too is not explicit**.
6. Take M_0. Within this proof $M \geq m$ suffices. But statement (2) is of the form in which M_0 may depend on β, and says no more than that.

So the statement takes the form "$\forall \varepsilon\ \exists \beta_0\ \forall \beta \geq \beta_0\ \exists M_0\ \forall M \geq M_0$", and none of the thresholds can be written as numbers.

Detour: why the twisted background is needed

You may skip this. The background twist $n_{12} = 1$ matters in one place, step 6. Because there is exactly one twisted plaquette, the two generators anticommute. Every pair of anticommuting unit quaternions is mapped to (i, j) by conjugation, and the zero-action configuration is unique up to gauge. Without the twist, the generators of a flat configuration may commute. For example, the configuration with every link equal to 1 and the flat configuration whose holonomy around the direction-1 loop is i have holonomies in different conjugacy classes, so they are not related by a gauge transformation. Proved here In that case the rigidity of step 6 fails, and this route does not go through as it stands.

08

What is not said

- **The thresholds are not explicit.** Neither $\beta_0(\varepsilon)$ nor $M_0(\varepsilon, \beta)$ can be written as numbers. They cannot be compared with numerical values at finite β and M.
- **The value of S_N for general N is not in Lean.** What Lean has is $0 < S_N \leq 2N^2$. $S_N < 2N^2$ exists only as certificates for $N = 2, 3, 4$ (21-05). No upper or lower bound uniform in N is shown.
- **For $N = 1$ it is no better than the thin-vortex floor.** $S_1 = 2 = 2N^2$ Reading , the same exponent as the thin-vortex floor.
- **No reverse direction.** A lower bound on $|\theta_M|$ (an upper bound on the rate, $\sigma_N \leq e^{-\beta(S_N - \varepsilon)}$) is not shown.
- **Only the rate as $\beta \to \infty$.** The prefactor affects β with a power of the order of the number of degrees of freedom of a block. It cannot be used for the band (the statement of 19-07).
- **The lattice spacing is fixed.** It does not reach the continuum limit, the area law for four-dimensional Wilson loops, or the mass gap.

Words used in this chapter — thick-vortex floor, thin-vortex floor, vortex ratio θ, twisted vacuum, minimal action of a vortex S_N, block, frame, window, effective coupling K_eff, rigidity, order of quantifiers. Their meanings are in A-02 Glossary.

Next chapter to read: 21-04 The thick-vortex floor — parts of the proof — the Lean statements and scope step by step, and theorems that show the limits of the method.

The thick-vortex floor — parts of the proof

> This chapter is this book's own investigation.

What this chapter shows — the statements and scope of the parts used in the proof of the thick-vortex floor (21-03): the block estimate and the effective coupling K_{eff}, the Laplace step, the lemma on the canonical form of signs, the compactness step, conjugation of anticommuting pairs and rigidity of the twisted torus. The form of the intermediate implications that link the parts, and the fact that all their assumptions are discharged in the final theorem. And a theorem showing that the rate of this method cannot be better than S_N.

Prerequisite chapters — 21-03 § 04 (the map of the route), 19-02 (the minimal action of a vortex), 19-01 (the product of Haar measures). We use the product of quaternions and the minimum of a continuous function on a compact set.

Said first — every part is a statement on a finite lattice with the lattice spacing and the width N held fixed. The intermediate implications are in "if ... then" form, with all assumptions shown. Those assumptions are discharged in the final theorem, but the intermediate implications themselves do not show content. The theorem on the limits of the method says only that an intermediate statement of this proof is false for $S < S_N$. It does not deny the floor itself, nor does it say that the true rate is S_N.

The order of this chapter

1. Blocks, frames, and the partition functions of classes — the conventions for dividing into blocks, and the definitions of $Z_B^F(\pm)$ and K_{eff}
2. The block estimate — $|\theta| \le \tanh(K_{\mathrm{eff}})^{k^2}$ and $K_{\mathrm{eff}} \le N^2|\beta|$
3. The Laplace step — the Haar measure of a small ball, and an upper bound on K_{eff} by κ_c
4. The lemma on the canonical form of signs — bringing a block's sign field to a standard form without changing the action
5. The compactness step — from "if the action is 0" to "if the action is small"
6. Rigidity — conjugation of anticommuting pairs, and zero-action configurations on the twisted torus

7. The form of the intermediate implications, and how the assumptions are discharged — the six links of the chain
8. A theorem showing the limits of the method — for $S < S_N$ the intermediate statement is false

---

01

Blocks, frames, and the partition functions of classes

The lattice is the twisted torus of width N and length M (19-02). Divide the longitudinal plane T^2_M into $k \times k$ blocks. The only condition is $mk \le M$. Blocks have side m; only the blocks in the last row and column have width $M - (k-1)m$.

- **Frame**: the links lying on the boundary lines of the blocks. A direction-3 link is in the frame if its $x4$ is on a line, a direction-4 link if its $x3$ is on a line, and a direction-1 or 2 link if either is on a line.
- **Interior**: the non-frame links belonging to the block.
- **Class**: whether the product $\prod \eta$ of the signs η of the (3,4) plaquettes in the block is $+1$ or -1.

Every plaquette contains only frame links and interior links of at most one block. So once the frame F is held fixed, the weight splits into a product over blocks. Write $Z^F_B(s)$ for the partition function of block b with frame F held fixed, summed over the class $s = \pm 1$ (integrating over the interior links with the product of Haar measures).

$$K_{\text{eff}} = \tfrac{1}{2} \sup_{b,\,F} \left| \ln \frac{Z^F_B(+)}{Z^F_B(-)} \right|. \quad (1)$$

The supremum is taken over all blocks b and all frame values F. Lean: `TwistBlocks.Keff`, `TwistBlocks.ZB`. In Lean, $Z^F_B(s)$ is the integral of the integrand $C_b + sS_b$ obtained by first summing over the signs plaquette by plaquette. It is the same as the sum within the class.

02

The block estimate

The block estimate. For $mk \le M$, every real β, and both backgrounds n_{12},

$$\left|\frac{Z_0 - Z_1}{Z_0 + Z_1}\right| \le \tanh(K_{\mathrm{eff}})^{k^2}, \qquad 0 \le K_{\mathrm{eff}} \le N^2|\beta|. \tag{2}$$

Proved here Lean: `TwistBlocks.block_bound_abs` (no assumption besides $mk \le M$), `TwistBlocks.Keff_le` ($mk \le M$), `TwistBlocks.Keff_nonneg`. This is the form of conditional independence of blocks with the frame held fixed, together with a product of block-by-block suprema.

Cited The type is a formalisation of conditional independence of blocks with the frame held fixed (the line of Mack–Petkova; sources in the table at the end of the chapter).

The proof runs in three lines. (i) With the frame held fixed, the weight of the sum over classes of η becomes a product over blocks. (ii) In each block, the ratio of the weights of classes $\pm$ lies within $e^{\pm 2K_{\mathrm{eff}}}$. Two positive numbers $Z_\pm$ whose ratio lies within $e^{\pm 2K}$ satisfy $|Z_+ - Z_-| \le \tanh K\,(Z_+ + Z_-)$. (iii) By the triangle inequality for integrals, $\tanh$ is multiplied in once for each of the k^2 blocks. $K_{\mathrm{eff}} \le N^2|\beta|$ holds because reversing one class changes only the signs of the N^2 transverse plaquettes.

From (2) and $-\ln\tanh K \ge e^{-2K}$ $(K > 0)$, $|\theta_M| \le \exp(-k^2 e^{-2K_{\mathrm{eff}}})$. Lean: `TwistBlocks.abs_block_bound_exp`.

What is not said. Since K_{eff} also takes the supremum over blocks, when block shapes are mixed it is weaker than the block-by-block product $\prod_b \tanh K_b$. For example, in a small $\mathbb{Z}_2$ model, the right side is $\tanh(1)^4 = 0.3364$ while the block-by-block product is 0.0862 Reading. It does not affect the rate.

03

The Laplace step

A coarse Laplace lower bound. Let ι be a finite set and ν the product of Haar probability measures on $SU(2)^\iota$. The distance is the maximum of the componentwise distances. If f is continuous and L-Lipschitz $(L > 0)$, then for all x_0, $\beta \ge 0$ and $\delta > 0$,

$$e^{-\beta(f(x_0)+\delta)}\,\mu_1(\delta/L)^{|\iota|} \le \int e^{-\beta f}\,d\nu, \qquad \mu_1(r) = \mathrm{Haar}\big(\{g : |g - 1| < r\}\big) > 0. \tag{3}$$

Proved here Lean: `CoarseLaplace.laplace_lower` ($\beta \ge 0$, $\delta > 0$, $L > 0$). The proof only uses $f \le f(x_0) + \delta$ on the ball of radius δ/L around x_0. The measure of the ball does not depend on its centre because left multiplication is an isometry and Haar measure is left-invariant. The prefactor does not depend on β. This is a weak form of Laplace's method that does not make the constants explicit.

We apply this to the action of a block. The action S_B is Lipschitz in the interior links, and from the number n_b of plaquettes in the block the constant can be taken as $L_b = 4n_b + 1$. Let $S^F_{\min}(\pm)$ be the infimum of the action over class $\pm$ and the interior, and set

$$\kappa_C = \sup_{b,F} \left| S^F_{\min}(+) - S^F_{\min}(-) \right|, \qquad D(\delta) = \max_b \Big(\ln \#\{\text{sign fields of block } b\} - \#\{\text{interior li}$$

Then, for $\beta \geq 0$ and $\delta > 0$,

$$K_{\text{eff}} \leq \tfrac{1}{2} \big(\beta(\kappa_C + 2\delta) + D(\delta) \big). \quad (4)$$

Proved here Lean: `TwistBlocks.Keff_le_laplace` ($mk \leq M$, $\beta \geq 0$, $\delta > 0$). When $M < (k+1)m$, $D(\delta)$ is bounded by a quantity $D^*(N, m, \delta)$ determined by N, m, δ alone (`TwistBlocks.Dmax_le`). That is, it is uniform in M. As a trivial upper bound on κ_C there is also $\kappa_C \leq 2N^2$ (`TwistBlocks.kappaC_le_two`, for all m).

What is not said. The value of $\mu_1(r)$ (that it is of order r^3) is not used, and D is not explicit. A sharp form of the prefactor (the degree of the power of β) is not treated. $\beta < 0$ is not treated.

04

The lemma on the canonical form of signs

The class infimum $S^F_{\min}(\pm)$ is the infimum over all sign fields σ in the class and all interior values. The following lemma makes it equal to "the infimum with η held at one value".

The lemma on the canonical form of signs. Let $mk \leq M$. For a block b, a frame F, interior values y, and a sign field σ of the block ($t = 0$ if $\prod \sigma = +1$, $t = 1$ if -1), there are interior values y' such that the action of the block in the standard field (all $+1$ if $t = 0$; -1 on the corner plaquette alone if $t = 1$) equals the action with σ.

Proved here Lean: `TwistBlocks.canon_holds` (statement `TwistBlocks.Canon N`; all $N, M \geq 1$ and $mk \leq M$; no condition on the shape of the block). The construction is a comb-shaped reversal. Let $\rho = \sigma \cdot (\text{standard field})$. In each column, accumulate the product of ρ from bottom to top to determine the signs κ_3 of the direction-3 links, and in the corner row only, accumulate the total product of each column from right to left to determine the direction-4 signs κ_4. Then on each plaquette the product of κ is ρ, and since the product of ρ within the block is 1, $\kappa = 1$ on the frame. On plaquettes spanning directions 1, 2 and directions 3, 4, the same κ appears twice and cancels.

With this lemma, Lean's κ_C equals the version κ with η held fixed (`TwistBlocks.kappaC_eq_kappa`, $mk \le M$).

05

The compactness step

Compactness in the form of cost. Let X be a compact space and $S, \Phi : X \to \mathbb{R}$ continuous. If $\Phi(x) \le c$ at points with $S(x) \le 0$, then for every $\varepsilon > 0$ there is $\gamma > 0$ such that $\Phi(x) < c + \varepsilon$ at points with $S(x) < \gamma$.

Proved here Lean: `ThickFloor.small_action_cost` (closes using Mathlib alone). Proof: $K = \{\Phi \ge c + \varepsilon\}$ is closed and hence compact. If it is empty, $\gamma = 1$ works. If not, S attains a minimum $S(x_0)$ on K, and by assumption $S(x_0) > 0$. Take $\gamma = S(x_0)$.

How it is used: let X be the configuration space of the local model around the window, S the local action, and Φ the infimum of "the action after replacing the interior and reversing one plaquette". There are finitely many positions for the reversal, so Φ is continuous. This reduces "in a window of sufficiently small action, the class can be reversed at cost $S_{\mathrm{V}} + \varepsilon$" to "for a local configuration of action 0, it can be reversed at cost S_{V}" (`TwistBlocks.localVortexL_of_zero`).

What is not said. The value of γ (a different quantity from the δ of § 03). γ depends only on N, m_0 and ε, but is not explicit. This is the main reason the thresholds of the thick-vortex floor are not explicit.

06

Rigidity

Conjugation of anticommuting pairs

Anticommuting pairs of unit quaternions. If unit quaternions A, B satisfy $AB = -BA$, there is a quaternion $g \neq 0$ with $gAg^{-1} = i$ and $gBg^{-1} = j$.

Proved here Lean: `ThickFloor.anticomm_conj`. First, $\mathrm{Re}\, A = \mathrm{Re}\, B = 0$ and the imaginary parts are orthogonal (`ThickFloor.anticomm_unit`). Next, setting $L(h) = h - ihA - jhB - kh(AB)$, from $A^2 = B^2 = -1$ and $AB = -BA$ alone, $L(h)A = iL(h)$ and $L(h)B = jL(h)$. For $e \in \{1, i, j, k\}$, $\sum_e \mathrm{Re}(\bar{e}\, L(e)) = 4$, so $L(e) \neq 0$ for some e. Take $g = L(e)$. Replacing g by $g/|g|$ gives conjugation by a unit quaternion.

Rigidity of the twisted torus

Consider configurations (A, B) on the transverse $T^2_N = (\mathbb{Z}/N)^2$ (A in direction 1, B in direction 2) whose plaquette products equal the sign of the twist (-1 at the origin, $+1$ elsewhere).

Rigidity of the twisted torus. For all $N \geq 1$, every such (A, B) is a gauge transform of the vacuum of T^2_N ($A = i$ at $a_1 = 0$, $B = j$ at $a_2 = 0$, 1 elsewhere). That is, there is $R : T^2_N \to SU(2)$ such that for all a, $R(a)A(a)R(a + e_1)^{-1}$ and $R(a)B(a)R(a + e_2)^{-1}$ equal the values of the vacuum.

Proved here Lean: `TwistBlocks.rigidT_all` (statement `TwistBlocks.RigidT N`, all $N \geq 1$). This is the form "a twisted flat connection is unique up to gauge". Proof: fixing the gauge on a tree of products taken from the front makes the tree links equal to 1. By induction on the flatness of plaquettes, the remaining links are determined by two generators $a = A(N-1, 0)$, $b = B(0, N-1)$ (`TwistBlocks.cfA`, `cfB`). Since there is exactly one twisted plaquette, $ab = -ba$ (`TwistBlocks.cf_comm`). Take the constant u that maps (a, b) to (i, j) by conjugation of anticommuting pairs, and compare with the vacuum gauge-fixed on the same tree (`TwistBlocks.uniqT`). $N = 1$ is a single point, so it is direct (`TwistBlocks.rigidT_one`).

Lifting to the local model

The local model around the window is the product of the transverse T^2_N and a square of side $V + 1$. This model has **links that appear in no plaquette** (the direction-3 and 4 links at the edges of the square, and the direction-1 and 2 links at the corners). They do not affect the action, so they can take arbitrary values even in a configuration of action 0. Local rigidity is therefore stated in the following scope.

Local rigidity. A configuration of local action 0 equals, **on all links that appear in plaquettes**, a gauge transform of the local twisted vacuum.

Proved here Lean: `TwistBlocks.rigidL_of_rigidT` (RigidT $N \Rightarrow$ RigidL N $(V + 1)$, for all V). Fixing the gauge on a maximal tree in directions 3 and 4 makes all direction-3 and 4 links equal to 1, and the direction-1 and 2 links no longer depend on the longitudinal position. What remains is the problem on T^2_N, which closes by the rigidity above. As an equality of functions on all links it is false, so restricting the scope to "links that appear in plaquettes" is the correct form.

```
07
```

The form of the intermediate implications, and how the assumptions are discharged

The Lean proof is built as a chain of implications that replaces the assumptions one by one with weaker claims. Each link has the form "if ... then the thick-vortex floor". Here we list them with all assumptions shown. $\mathrm{Floor}(S)$ is the statement (1) of 21-03 with S_N replaced by S.

Link	Lean	Assumption (if ...)	Conclusion
1	`thick_vortex_floor_abs_of_H4`	Upper bound on the flipping cost: for some S: for every $\varepsilon > 0$ there is m such that for all $M \geq m$, $\kappa_c(N, M, m, \lfloor M/m \rfloor) \leq S + \varepsilon$	$\mathrm{Floor}(S)$
2	`H4_of_local`	The lemma on the canonical form of signs (`Canon N`), and for all m_0, "if the action of the window is small, the class can be reversed at cost $S_{\mathrm{v}}(N, m_0) + \varepsilon$" (`LocalVortex`)	The upper bound on the flipping cost with $S = S_N$
1+2	`thick_vortex_floor_abs_of_local`	Of the assumptions of link 2, `LocalVortex` for all m_0 (`Canon N` is discharged inside by `canon_holds`)	$\mathrm{Floor}(S_N)$
3	`thick_vortex_floor_abs_of_localL`	The same claim, on the local model independent of M (`LocalVortexL`)	$\mathrm{Floor}(S_N)$
4	`thick_vortex_floor_abs_of_zero`	For all m_0, configurations of local action 0 can be reversed at cost at most $S_{\mathrm{v}}(N, m_0)$ (`ZeroVortexL`)	$\mathrm{Floor}(S_N)$
5	`thick_vortex_floor_abs_of_rigid`	Local rigidity for all m_0 (`RigidL N (m₀+2)`)	$\mathrm{Floor}(S_N)$
6	`thick_vortex_floor_abs_of_rigidT`	Rigidity of the twisted torus (`RigidT N`)	$\mathrm{Floor}(S_N)$

(All names are under `TwistBlocks.`. The `H4` remaining in the Lean names is the name from the source; in the text we call this intermediate statement the "upper bound on the flipping cost".) The theorems connecting the links are as follows.

- `Canon N` in 2 is discharged by `canon_holds` (§ 04). Pigeonhole (`exists_win_le`) is closed within the proof of 2.
- 3 → 1+2: write the answer on the local model back into the interior of the block (`localVortex_of_local`).
- 4 → 3: the compactness step (`localVortexL_of_zero`, § 05).
- 5 → 4: pull a minimising configuration of $S_{\mathrm{v}}(N, m_0)$ back to the local model and transplant it into the window using the rigidity gauge

(`thick_vortex_floor_zero_of_rigid`). The existence of a minimising configuration is `Svortex_attained`.

- $6 \to 5$: the lift to the local model (`rigidL_of_rigidT`, § 06).

The final theorem `TwistBlocks.thick_vortex_floor` is link 6 with `rigidT_all` put in. With this, every assumption of the chain is discharged and no assumption fields remain. As a sanity check of the machinery, we have also checked that the chain contains no intermediate theorem that is vacuous because its assumptions are false. The inner field "local action ≤ 0" of links 4 and 5 is satisfied by the local vacuum (`SL_vacL`), and the inner field "a flat configuration on T^2_N" of link 6 is satisfied by the vacuum of T^2_N (`flatT_nonempty`). These check that the fields are non-empty; they are examples of satisfaction without content.

> The intermediate links 1–6 do not, on their own, show content. For example, link 1 is easily satisfied if S is large. What has content is the pair of the final theorem with its assumptions discharged and the estimates of the value of S_N (21-05).

08

A theorem showing the limits of the method

Consider whether the S in the assumption of link 1 (the upper bound on the flipping cost) can be taken smaller than S_N. That it cannot is shown in Lean.

Comparison of a block with its frame at the vacuum. For all $m \geq 1$, $S_{\mathrm{v}}(N,m) \leq \kappa_c(N, 2m, m, 2)$. Proved here Lean: `TwistBlocks.kappaC_ge_Svortex`. With $M = 2m$, block $(0,0)$, and the frame at the twisted vacuum, the infimum for (+) is 0 and the infimum for (−) is $S_{\mathrm{v}}(N,m)$.

Negation of the intermediate statement. If $S < S_N$, the upper bound on the flipping cost is false. Proved here Lean: `TwistBlocks.H4_fails_below` (assumption $S < S_N$). Applying the upper bound on the flipping cost with $\varepsilon = (S_N - S)/2$ and $M = 2m$ contradicts the comparison above and $S_N \leq S_{\mathrm{v}}(N,m)$.

Three ways to read this.

1. This is **a limit of the method of this proof**. As long as one goes through the intermediate statement, the upper bound on the flipping cost (an upper bound on κ_c), the exponent of the rate obtained cannot be better than S_N.
2. This is **not a denial of the thick-vortex floor**. The floor (1) itself might hold with an S satisfying $S < S_N$; this theorem says nothing about that.

3. This **does not say that the true rate is S_N** either. A lower bound on the rate (the reverse direction) is still missing.

Words used in this chapter — block, frame, interior, class, effective coupling K_eff, coarse Laplace lower bound, lemma on the canonical form of signs, compactness in the form of cost, anticommuting pair, rigidity of the twisted torus, local rigidity, intermediate implication, limits of the method. Their meanings are in A-02 Glossary.

Next chapter to read: 21-05 The minimal action of a vortex — positivity, and a certificate for the upper bound — what can be said about the value of the exponent s_N of the floor.

The minimal action of a vortex — positivity, and a certificate for the upper bound

This chapter is this book's own investigation. The upper bounds of § 05 are computer-assisted certificates, placed as support for the analytic proof.

What this chapter shows — we read two facts, machine-checked in Lean, about the quantity S_N (the minimal action of a vortex) that appears in the exponent of the thick-vortex floor. One is that $S_N > 0$ for every $N \geq 1$, and moreover that there is a positive lower bound uniform in the block size m. The other is a certificate for an upper bound showing that, for $N = 2, 3, 4$, S_N is smaller than the thin-vortex value $2N^2$.

Prerequisite chapters — 19-02 the definition of the minimal action of a vortex, the vortex ratio θ_M; 21-02 The thin-vortex floor; 21-03 The thick-vortex floor

Said first — what we could say is only "positivity" and "upper bounds". The value of S_N is not known. The lower bound δ comes from compactness, so it is not an explicit number, nor is it uniform in the width N. The upper bounds are the action of a single configuration at $m = 8$ ($m = 4$ for $N = 4$), not the value of the infimum over m. The lattice spacing is fixed, and nothing is said about the continuum limit or the mass gap.

The order of this chapter

1. The minimal action of a vortex — the main points of the definition, and trivial bounds
2. S_N is positive — statement and meaning
3. The route to positivity — labels and a telescoping product
4. Detour: where the background twist matters
5. Upper bounds for N = 2, 3, 4 — statement
6. How the certificate is made — rational unit quaternions and rounding up
7. Comparison with the thin-vortex floor — comparing rates, and its limits
8. What is not said

01

The minimal action of a vortex — the main points of the definition, and trivial bounds

The definition is in 19-02. Here we repeat only the main points.

The lattice is the torus with transverse part $(\mathbb{Z}/N)^2$ and longitudinal part $(\mathbb{Z}/2m)^2$. In the longitudinal (3,4) plane take the block at the origin $b_0 = \{0,\dots,m-1\}^2$ (the set of longitudinal points at the roots of plaquettes), and consider its product with the transverse torus T^2_N (notation as in 19-02). The frame of the block (the links on the lines $x_3 \in \{0,m\}$ and $x_4 \in \{0,m\}$) is held at the **twisted vacuum** V. V is the configuration whose direction-1 links are the quaternion i at $x_1 = 0$, whose direction-2 links are j at $x_2 = 0$, and which is 1 everywhere else. Under the background twist $n_{12} = 1$, the action of V is 0.

Let $\Pi_{(0,0)}$ be the (3,4) plaquettes at the block corner $(x_3,x_4) = (0,0)$, collected over all N^2 transverse positions, and reverse their sign ($\eta_p = -1$ for $p \in \Pi_{(0,0)}$, $\eta_p = +1$ otherwise). The sum of the actions of all plaquettes whose root lies in b_0 is

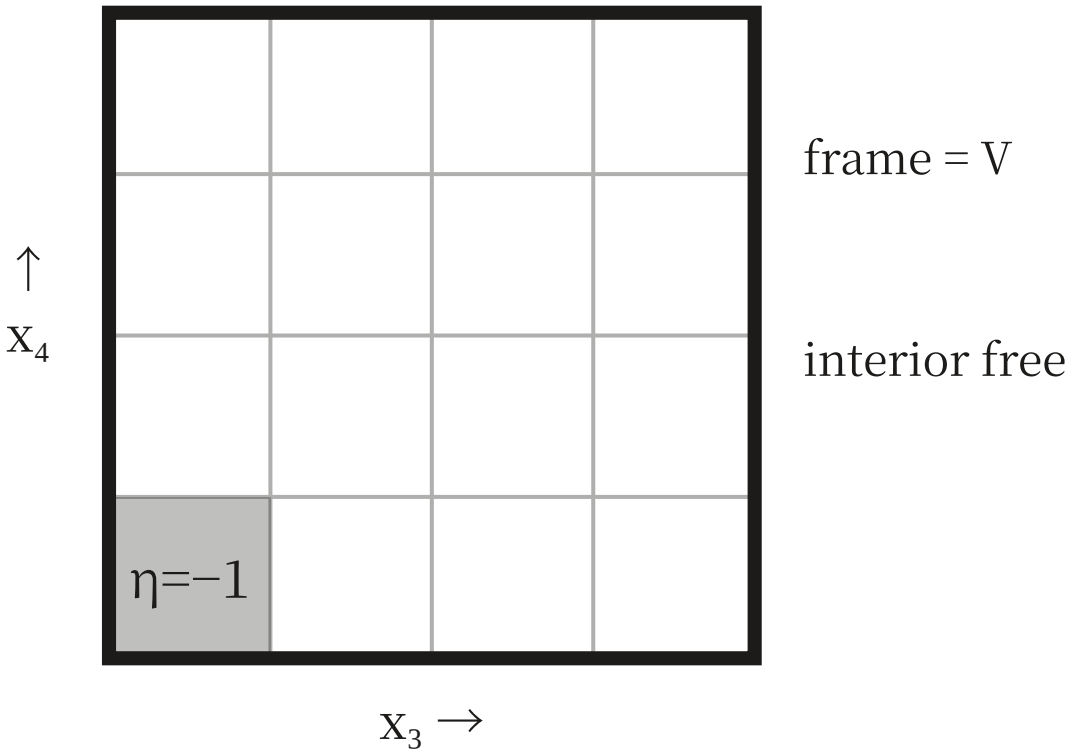
$$S(U;\eta) = \sum_{p:\ \mathrm{root}\in b_0} \left(1 - z_p\,\eta_p\,\mathrm{Re}\,U_p\right) \tag{1}$$

(the notation for action is as in 21-03). z_p is the sign of the background twist. β is not multiplied in. We write the infimum over all configurations of the interior links, and the infimum over block sizes, as

$$S_{\mathrm{v}}(N,m) = \inf_{\text{interior}} S(U;\eta), \qquad S_N = \inf_{m\ge 1} S_{\mathrm{v}}(N,m) \tag{2}$$

The Lean definitions are `TwistBlocks.Svortex` and `TwistBlocks.SN`. Since the frame is the vacuum while one corner sign is reversed, somewhere inside the block a vortex sheet must pass all the way around the transverse torus. $S_{\mathrm{v}}(N,m)$ is the minimal action for threading one such vortex.

Figure 1 A block in the (3,4) plane (example $m = 4$). On the squares of block b_0, the frame lines $x_3, x_4 \in \{0,m\}$ are drawn thick (fixed at the twisted vacuum). The shaded square is the position of the corner reversal $\Pi_{(0,0)}$. Above each point sits the transverse torus T^2_N



There are two trivial bounds. Proved here Since $|\operatorname{Re} U_p| \le 1$, each term of (1) is at least 0, and $S_{\mathrm{v}}(N,m) \ge 0$. Proved here In the configuration with the interior also at V, only the N^2 reversed plaquettes contribute, each $1-(-1)\cdot 1 = 2$, and the rest give 0, so the action is exactly $2N^2$. Hence $0 \le S_N \le 2N^2$ (Lean: `TwistBlocks.Svortex_le`, `TwistBlocks.SN_bounds`). This $2N^2$ is the value of the "thin vortex" that gathers the reversal onto one layer of plaquettes, and corresponds to the exponent of the thin-vortex floor. Reading For $N=1$, $S_1 = 2 = 2N^2$, and a thick vortex gains nothing (the numerical record of this book's study).

S_N appears in the exponent of the thick-vortex floor in the form $e^{-\beta(S_N+\varepsilon)}$. The two facts of this chapter are what can be said about the number in that exponent from below (positivity) and from above (the certificates for $N=2,3,4$). The Lean proof of the thick-vortex floor does not use the two facts of this chapter.

02

S_N is positive — statement and meaning

Positivity of the minimal action of a vortex. For every $N \ge 1$ there is $\delta > 0$, depending only on N, such that

$$\delta \le S_{\mathrm{v}}(N,m) \quad (\text{all } m \ge 1), \qquad \text{hence} \qquad S_N > 0. \ (3)$$

Lean: `VortexPos.Svortex_ge_unif` ($\exists\,\delta>0,\ \forall m\geq 1,\ \delta\leq S_{\mathrm{V}}(N,m)$; all $N\geq 1$, no assumption fields) and `VortexPos.SN_pos` ($0<S_N$).

The order of quantifiers is the point. δ is fixed first and does not depend on m. However large the block is made and however the vortex is spread out, the action does not fall below δ. If it were merely positive for each m, it might approach 0 as $m\to\infty$, and the infimum S_N could be 0.

The value of δ is not known. The proof uses the fact "if the action is small, the configuration is close to the gauge orbit of the vacuum" through **compactness**, not through an explicit estimate of distance. So we can say only that δ exists; no number comes out. Reading Numerically, $S_{\mathrm{V}}(2,m)$ is about 7.0 to 6.67 for $m=3$ to 8 (the numerical record of this book's study), and δ may be much smaller than that.

Cited This theorem is a formalisation, on the lattice, of the known picture that the action of a vortex (a fractional instanton) in a twisted box is positive ('t Hooft's twisted boundary conditions, 25-02) (Lean: `VortexPos.SN_pos`). The only tools are compactness and rigidity.

03

The route to positivity — labels and a telescoping product

We argue by contradiction. Take a configuration of very small action, and show that it is incompatible with the corner reversal.

Step 1 Split into parts. For each point $s=(i,j)$ ($0\leq i,j\leq m$) of the block's (3,4) plane, call the transverse torus T^2_N above it (the direction-1 and 2 links) the **fibre**. Split the action (1) into three kinds of parts.

- Fibre action a_s: the sum of the terms of the (1,2) plaquettes of the fibre.
- Link defect b_λ: how badly the direction-3 or 4 links joining two neighbouring points (N^2 of them) connect the two fibres. For unit quaternions $\|X-Y\|=\sqrt{2(1-\operatorname{Re}XY^*)}$, so $b_\lambda\leq 2N^2\sqrt{2S}$ (S is the action of the block) Proved here . This estimate is also used inside the Lean proof (`VortexPos.linkH_le`, `linkV_le`).
- Square part pP: the sum of the terms of the N^2 plaquettes over the square P of the (3,4) plane.

The fibre actions and square parts are partial sums of (1), so they are at most S.

Step 2 Fibres are close to the vacuum. On the twisted T^2_N, configurations of action 0 lie in the gauge orbit of the twisted vacuum (Lean: `TwistBlocks.rigidT_all`). By compactness, if the fibre action is small, the fibre is close to the gauge orbit of the

vacuum. The only gauge transformations fixing the vacuum are the constants ± 1, and this too is extended by compactness to "if it nearly fixes it, it is close to ± 1".

Step 3 Attach labels. At each point s, take a gauge g_s that brings the fibre to the vacuum. On the frame the fibre is exactly the vacuum, so take $g_s = 1$ there. For each link λ, $g_s^{-1} U_\lambda g_{s'}$ is close to a constant $+1$ or -1; let its sign be the label $c(\lambda) \in \{\pm 1\}$. Links on the frame lines are 1 in the vacuum, so $c = +1$ there.

Step 4 Compatibility square by square. The product around a plaquette over square P, sandwiched by gauges, has the form $h_1 h_2 h_3^* h_4^*$, whose value is close to $\prod_{\lambda \in \partial P} c(\lambda)$. If $\eta(P) \;/= \prod_{\partial P} c$, the plaquette term is at least $2 - 4\varepsilon$ ($3/2$ for $\varepsilon = 1/8$). If all parts are small, then $\eta(P) = \prod_{\partial P} c$ for every square.

Step 5 Telescoping product. Multiplying $\prod_{\partial P} c$ over all squares, each interior link appears twice and the frame links are 1, so the product is 1 Proved here . But η is -1 on exactly one square, the corner, so $\prod_P \eta(P) = -1$. Contradiction.

Step 6 Conclusion. So some part is at least a threshold δ_0. For a fibre or a square, $S \geq \delta_0$; for a link, $2N^2\sqrt{2S} \geq \delta_0$. Together,

$$S_{\mathrm{v}}(N, m) \;\geq\; \delta := \min\!\left(\delta_0,\; \frac{\delta_0^2}{32N^4 + 1}\right) \quad (4)$$

holds for all $m \geq 1$. δ_0 comes from the compactness of step 2, so it is not explicit. The Lean core is a lemma of the form `TwistBlocks.grid_vortex_floor`, and all its part fields are discharged inside `VortexPos.Svortex_ge_unif`.

Detour: where the background twist matters

You may skip this. In step 3 the labels fall into $\{\pm 1\}$ because the only gauge transformations fixing the twisted vacuum are the constants ± 1 (Lean: `TwistBlocks.stab_vacT`). i and j appear on the links of the twisted vacuum, and the only unit quaternions commuting with both i and j are ± 1 Proved here . So the "offset" of each link is close to an element of the centre $\{\pm 1\}$, and the argument rides on $\mathbb{Z}_2$ bookkeeping: compatibility square by square and a telescoping product. The core of the proof is that the corner reversal cannot be cancelled in $\mathbb{Z}_2$ bookkeeping.

04

Upper bounds for N = 2, 3, 4 — statement

The upper side can be stated by exhibiting a single concrete configuration. Since $S_{\mathrm{v}}(N, m)$ is an infimum, the action of any configuration is an upper bound for it. The upper bounds machine-checked in Lean are the following three Computer-assisted .

N	Block side m	Upper bound	Corollary	Lean declarations
2	8	$S_{\mathrm{v}}(2,8) \le 667401/100000$	$S_2 < 8 = 2 \cdot 2^2$	`VortexCert.Svortex_two_eight_le`, `SN_two_le`, `SN_two_lt`
3	8	$S_{\mathrm{v}}(3,8) \le 909321/100000$	$S_3 < 18 = 2 \cdot 3^2$	`VortexCert.Svortex_three_eight_le`, `SN_three_le`, `SN_three_lt`
4	4	$S_{\mathrm{v}}(4,4) \le 1202057/100000$	$S_4 < 32 = 2 \cdot 4^2$	`VortexCert.Svortex_four_four_le`, `SN_four_le`, `SN_four_lt`

None has assumption fields. $S_N \le S_{\mathrm{v}}(N,m)$ follows from the definition of the infimum (Lean: `VortexCert.SN_le_Svortex`).

Put into the thick-vortex floor, the exponent becomes an explicit number. Lean: `TwistBlocks.thick_vortex_floor_two` (no assumption fields) says that, for each sufficiently large β, for sufficiently large M,

$$|\theta_{M+1}(\beta)| \;\le\; \exp\!\left(-(M+1)^2\, e^{-6.675\,\beta}\right) \quad (5)$$

`TwistBlocks.thick_vortex_floor_three` has exponent number 9.094, and `TwistBlocks.thick_vortex_floor_four` has 12.021. The proof just takes the ε of the thick-vortex floor (21-03, `TwistBlocks.thick_vortex_floor`) to be "exponent number $-$ SN". The certificate for the upper bound gives $\varepsilon > 0$.

One caution in reading. What we could say is **only an upper bound**. One cannot write "$S_2 = 6.674$". Since it is a single configuration at $m = 8$ ($m = 4$ for $N = 4$), it is not the value of the infimum over m either. Reading The configuration for $N = 4$ comes from a numerical minimisation at $m = 4$ that has not fully converged, and the true value of S_4 may be smaller.

05

How the certificate is made — rational unit quaternions and rounding up

The certificate is computer-assisted Computer-assisted . It is not a pillar of the analytic proof; it is placed as support for "exhibiting one configuration that gives an upper bound". It is made in four stages.

(a) Make the configuration rational. The interior link values $q = (q_0, \underline{q})$ obtained by numerical minimisation (cooling) are converted to $\underline{\tau} = \underline{q}/(1+q_0)$ and then rounded to $t/2^{16}$ ($t \in \mathbb{Z}^3$). From this, quaternions are built in the Cayley form

$$q = \frac{\left(s^2 - |t|^2,\; 2s\,t\right)}{s^2 + |t|^2}, \qquad s = 2^{16} \quad (6)$$

Proved here Since $(s^2 - |t|^2)^2 + 4s^2|t|^2 = (s^2 + |t|^2)^2$, the norm is **exactly** 1. No square roots are needed (Lean: `VortexCert.normSq_cay`).

(b) Round up plaquette by plaquette. The plaquette term $1 - z_p \eta_p \operatorname{Re}(ABC^*D^*)$ is rational because the four links are rational. Round it **up** in units of 2^{-32} and add the resulting integers. Because the rounding is upward, the integer sum $/2^{32}$ is an upper bound on the action of the block.

(c) Count in the kernel. The integer inequality, for example for $N = 2$ "sum $\times 100000 \le 667401 \cdot 2^{32}$", is checked by a finite computation in the Lean kernel (`decide +kernel`) (Lean: `VortexCert.certN2`, `certN3`, `certN4`). The number of plaquettes is 1536 for $N = 2$, 3456 for $N = 3$, and 1536 for $N = 4$.

(d) Carry over to a real upper bound. The soundness theorem `VortexCert.Svortex_le_of_cert` derives $S_{\mathrm{v}}(N, m) \le b_n / b_d$ from the integer inequality. Its only assumptions are the integer inequality (and positivity of the denominator). Whatever the values in the table, each link is a unit quaternion because of the form (6), the frame values are fixed at V on the side of the definition, and it is shown inside Lean that the background and corner signs agree with the definition. So the configuration of the certificate belongs, **by construction**, to the set over which the infimum (2) is taken.

Reading The actions of the rational configurations are 6.6740076 for $N = 2$, 9.0932068 for $N = 3$ and 12.0205673 for $N = 4$, and the increase due to rounding is less than 4×10^{-7} (the numerical record of this book's study, computed exactly in fractions without rounding). The Lean upper bounds are, in each case, the smallest number on a 10^{-5} grid that passes.

What Lean checks is only the evaluation of integer polynomials. Where the configuration came from (whether the cooling is close to the minimum) has no bearing on the correctness of the upper bound.

06

Comparison with the thin-vortex floor — comparing rates, and its limits

The thin-vortex floor is $|\theta_M| \le \tanh(N^2|\beta|)^{M^2} = \exp(-M^2\sigma_0)$, $\sigma_0 = -\ln\tanh(N^2|\beta|)$. Proved here As $\beta \to \infty$, $\sigma_0 = 2e^{-2N^2\beta}(1 + o(1))$, so the rate at which the thin coefficient decreases is $2N^2$. The rate of the thick-vortex floor (5) is $S_N + \varepsilon$. For $N = 2$, $6.675 < 8$, and as a rate for $\beta \to \infty$, the thick coefficient becomes exponentially larger.

This comparison has three limits.

- **It is not a Lean theorem.** What Lean has is the numerical inequality $6675/1000 < 2 \cdot 2^2$ (`TwistBlocks.thick_vortex_floor_two_rate_lt`) and each of the two floors. "The thick-vortex floor is stronger than the thin-vortex floor" itself is a comparison of numbers set side by side by hand.
- **For small β it is the other way round.** Reading $e^{-6.675\beta}$ exceeds $-\ln\tanh 4\beta$ from $\beta > 0.523$. At $\beta = 1$ it is 1.26×10^{-3} versus 6.71×10^{-4}; at $\beta = 2$, 1.59×10^{-6} versus 2.25×10^{-7}.
- **The thresholds are not explicit.** β_0 and $M_0(\beta)$ of the thick-vortex floor are not explicit, so one cannot say "the thick bound is smaller at a concrete (β, M) with $\beta > 0.523$". What can be said is a comparison of rates as $\beta \to \infty$.

N	Thin-vortex rate $2N^2$	Upper bound on S_N (Lean)	Exponent number of the thick-vortex floor (Lean)
1	2	— (Reading $S_1 = 2$)	—
2	8	6.67401	6.675
3	18	9.09321	9.094
4	32	12.02057	12.021

$S_N < 2N^2$ for general N is not in Lean. For $N = 1$ there is no gain.

07

What is not said

- The value of S_N. What we could say is only $0 < S_N$ (with a non-explicit δ) and the upper bounds for $N = 2, 3, 4$.
- The number δ. It would need a quantitative estimate of rigidity (an explicit relation between action and distance from the vacuum).
- Lower or upper bounds uniform in N. Changing N changes the configuration space of the fibre, and this argument is for each N separately.
- The reverse direction of the thick-vortex floor (a lower bound on θ, an upper bound on the rate). There is no theorem in the reverse direction.
- The band (the statement that the vortex ratio θ becomes small exponentially in the area of the box, that is, that $-\ln\theta$ (corresponding to the slab tension times the area) grows in proportion to the area, stated with a single constant while moving the transverse and longitudinal sizes and the coupling together; 19-07). The quantities of this chapter are in a form with the lattice spacing and the width N held fixed. The distance is examined in 21-08.
- The lattice spacing is fixed; none of the continuum limit, the four-dimensional area law or the mass gap is said.

What this chapter can say

Can say	Cannot say
Lean `TwistBlocks.Svortex_le`, `TwistBlocks.SN_bounds`: $0 \le S_{\mathrm{v}}(N,m) \le 2N^2$, $0 \le S_N \le 2N^2$ (the configuration with the reversal put into the vacuum)	The value of S_N
Lean `VortexPos.Svortex_ge_unif`, `SN_pos`: for every $N \ge 1$ there is $\delta > 0$ uniform in m with $S_N \ge \delta > 0$	The number δ (it comes from compactness). A lower bound uniform in N
Computer-assisted $S_{\mathrm{v}}(2,8) \le 6.67401$, $S_{\mathrm{v}}(3,8) \le 9.09321$, $S_{\mathrm{v}}(4,4) \le 12.02057$, hence $S_N < 2N^2$ $(N = 2,3,4)$	The value of the infimum over m. $S_N < 2N^2$ for general N
Lean `TwistBlocks.thick_vortex_floor_two`, `_three`, `_four`: for each sufficiently large β, for sufficiently large M, floors with exponent numbers 6.675, 9.094, 12.021	The values of β_0 and $M_0(\beta)$
Reading For $N = 2$ the coefficient of the thick-vortex floor exceeds the thin one from $\beta > 0.523$	"The thick-vortex floor is stronger" itself is not a Lean theorem (a comparison of rates)

Words used in this chapter — minimal action of a vortex $S_{\mathrm{v}}(N, m)$, S_N, twisted vacuum, fibre, link defect, label, telescoping product, Cayley form, rounding up, certificate, comparison of rates. Their meanings are in A-02 Glossary.

Next chapter to read: 21-06 The sign of θ and pairs of Polyakov loops — that the vortex ratio θ is never negative, and that θ bounds correlations of Polyakov loops.

The sign of θ and pairs of Polyakov loops

> This chapter is this book's own investigation.

What this chapter shows — that on a torus of width N and length M, if M is even then $Z_1 \le Z_0$, that is, $\theta_M \ge 0$, for every real β. That with the same reflection tools, the correlation of two Polyakov loops winding around direction 3 is bounded by $2\sqrt{\theta}/(1+\theta)$ at distance $M/2$, and by $2\tanh(N^2|\beta|)^{M\,\min(T,M-T)}$ at a general time separation T. Each is a formalisation, machine-checked in Lean, of an estimate of known type.

Prerequisite chapters — 19-02 the twist, the vortex ratio, Polyakov loops; 19-03 reflection; 21-02 The thin-vortex floor; 21-03 The thick-vortex floor

Said first — the expectation $\langle\cdot\rangle_0$ is with respect to the Wilson measure on a finite lattice with the background twist $n_{12}=1$ and without the (3,4) twist. What can be said is a linear **lower bound** on the energy inside a transverse $N\times N$ tube, not uniform in N. The lattice spacing is fixed. Nothing is said about four-dimensional confinement, the area law or the mass gap. The case of odd M is not included.

The order of this chapter

1. The expectation $\langle\cdot\rangle_0$ and Polyakov loops
2. Splitting the lattice into two halves by a reflection in the time direction
3. θ ≥ 0 — statement and proof
4. Pairs of Polyakov loops at distance M/2, and θ
5. General time separation — repeating the reflection
6. Detour: the range in the parities of M, N and the sign of β
7. How to read it — a linear lower bound on the energy inside a tube
8. What is not said

01

The expectation $\langle\cdot\rangle_0$ and Polyakov loops

The lattice is the torus with transverse part $(\mathbb{Z}/N)^2$ (directions 1 and 2) and longitudinal part $(\mathbb{Z}/M)^2$ (directions 3 and 4). The definitions are in 19-02. Under the background twist $n_{12} = 1$, let Z_0 and Z_1 be the partition functions without and with the (3,4) twist, and write the vortex ratio as $\theta_M = (Z_0 - Z_1)/(Z_0 + Z_1)$ (19-02).

The expectation in this chapter is

$$\langle F\rangle_0 = \frac{1}{Z_0}\int F(U)\, w_0(U)\, dU, \qquad w_0(U) = \exp\Big(\beta \sum_p z_p^{(0)}\, \mathrm{Re}\, U_p\Big) \quad (1)$$

dU is the product of Haar measures, and $z_p^{(0)}$ is the sign of the background twist $n_{12} = 1$ only. **The (3,4) twist is not included.** In Lean the weight is `wE N M β (fun _ => 1)` and the divisor is `ZW N M β true false`.

A Polyakov loop is the real part of the product of the links going once around direction 3, at transverse position $b = (x_1, x_2)$ and direction-4 position t (19-02).

$$P_b(t) = \mathrm{Re} \prod_{k=0}^{M-1} U_3\big((b),(k,t)\big) \quad (2)$$

The real part of a quaternion is $\frac{1}{2}\,\mathrm{tr}$ in the fundamental representation, and $|P_b(t)| \le 1$. In Lean it is `HalfSplit.polyLoop`, and the expectation of a pair is `PolyakovT.polyExp`.

Proved here The expectation of a single loop $\langle P_b(t)\rangle_0$ is 0. Multiplying all direction-3 links at $x_3 = 0$ by -1, every plaquette contains 0 or 2 of the reversed links, so w_0 is unchanged, while $P_b(t)$ alone changes sign. The meaningful quantity is the pair correlation $\langle P_b(0) P_{b'}(T)\rangle_0$.

02

Splitting the lattice into two halves by a reflection in the time direction

When M is even, the reflection $\Theta:\ x_4 \mapsto -x_4$ fixes two planes of lattice points, $x_4 = 0$ and $x_4 = M/2$. Links in directions 1, 2 and 3 only have their positions mapped; links in direction 4 have their orientation reversed and their values inverted (the general form of reflection is in 19-03).

Since the planes pass through lattice points, no square crosses them. The squares on the two planes (those not containing direction 4) are shared half and half between the upper and lower halves. The **half weight** built in this way,

$$a_\eta(U) = \exp\Big(\beta \sum_p c_p \, z_p \, \eta_p \, \mathrm{Re}\, U_p\Big), \qquad c_p \in \{1, \tfrac{1}{2}, 0\} \tag{3}$$

(1 in the upper half, $\frac{1}{2}$ on the planes, 0 below), depends only on the links of the closed upper half. The whole weight then splits as

$$w_\eta(U) = a_{\eta 1}(U)\, a_{\eta 2}(\Theta U) \tag{4}$$

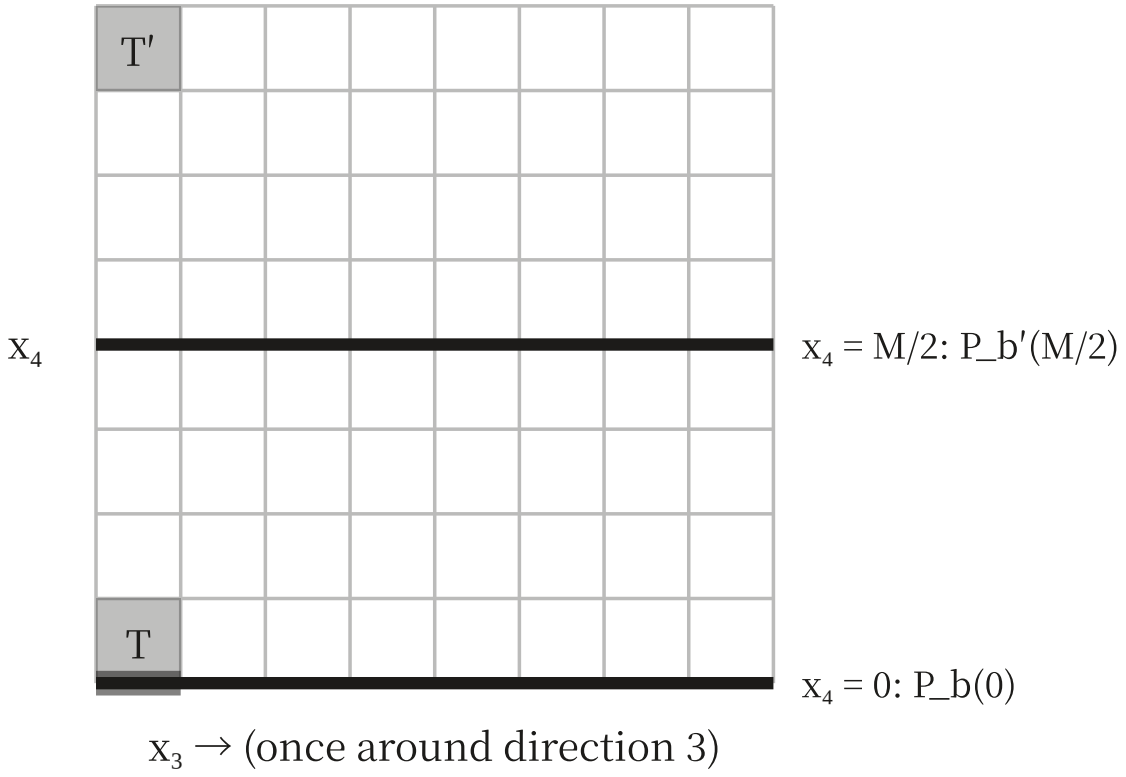
Here η gives the signs of the (3,4) plaquettes as $\eta 1$ in the upper half and as the mirror image of $\eta 2$ in the lower half (Lean: `HalfSplit.half_split`).

The product of Haar measures is invariant under the reflection, and for bounded measurable g depending only on the closed upper half,

$$\int g(\Theta U)\, g(U)\, dU \;\geq\; 0 \tag{5}$$

holds (reflection positivity; Lean: `HalfSplit.half_pairing_nonneg`). By (4) the weight is absorbed into g, so no condition on the sign of β is needed. Cited This form is of the type of Osterwalder–Seiler reflection positivity, and `HalfSplit.half_pairing_nonneg` is its formalisation on the twisted lattice (19-03).

Figure 1 The longitudinal (3,4) plane (example $M = 8$; the transverse T_N^2 omitted). The thick horizontal lines are the reflection planes $x_4 = 0$ and $x_4 = M/2$. Two Polyakov loops lie on them. The shaded squares are the reversal T ($(0,0)$) and its mirror image T' ($(0,-1) = (0, M-1)$). The marked link is the sign reversal c of § 04



The figure only shows the two planes and the positions of the reversals used in § 03 and § 04; it carries no numbers.

03

θ ≥ 0 — statement and proof

The sign of the vortex ratio. If M is even, then for every real β and all $N \geq 1$,

$$Z_1 \leq Z_0, \qquad \text{equivalently} \qquad 0 \leq \theta_M(\beta). \tag{6}$$

Lean: `HalfSplit.Z1_le_Z0` (M even, every real β), `TwistBlocks.theta_nonneg` ($0 \leq \theta_M$ in the same range).

Proof. Let T be the reversal of the sign of the corner (3,4) plaquette $(x_3, x_4) = (0, 0)$ at all transverse positions, and put $g = a_1 - a_T$ into (5). Expanding with (4),

$$0 \leq \int g(\Theta U) g(U)\, dU = Z[1] - Z[T] - Z[T'] + Z[TT'] \tag{7}$$

T' is the reversal at $(0, -1)$, the mirror position of T, and TT' is the two reversals together. Proved here The partition function does not depend on the positions of the reversals; it is determined only by the product of the reversals $\prod \eta$ (positions of reversals can be moved by a change of variables that changes the signs of the links on

a cut; Lean: `TwistedWilson.ZEta_flip_any`, `TwistedWilson.ZEta_parity`). Hence $Z[T] = Z[T'] = Z_1$ and $Z[TT'] = Z_0$, and (7) is $0 \le 2Z_0 - 2Z_1$. □

This estimate removes the absolute value from the thick-vortex floor. Lean: `TwistBlocks.thick_vortex_floor_signed` (all $N \ge 1$) says that for any $\varepsilon > 0$, for each sufficiently large β, for sufficiently large M, if $M+1$ is even,

$$0 \le \theta_{M+1}(\beta) \le \exp\bigl(-(M+1)^2 e^{-\beta(SN+\varepsilon)}\bigr) \quad (8)$$

The thresholds in β and M are not explicit.

Odd M is not included, because the second plane $x_4 = M/2$ does not fall on lattice points. Moreover, for odd M and $\beta < 0$, $\theta \ge 0$ can fail. Reading At $N = 1$, $M = 1$, $\beta = -1.5$ we found $\theta = -0.055 \pm 0.005$ (SU(2) Monte Carlo, the numerical record of this book's study). For $\beta \ge 0$ it is expected to hold regardless of parity, by positivity of the transfer matrix, but this book has not checked it. Proved here Note that $\theta_M < 1$ follows for all M from $Z_1 > 0$ (Lean: `TwistBlocks.theta_lt_one`).

04

Pairs of Polyakov loops at distance M/2, and θ

A bound on pairs of Polyakov loops by θ. If M is even, then for every real β and all transverse positions b, b',

$$\bigl|\langle P_b(0)\, P_{b'}(M/2)\rangle_0\bigr| \;\le\; \frac{2\sqrt{\theta_M}}{1+\theta_M}. \quad (9)$$

Lean: `HalfSplit.polyakov_pair_theta` (M even, every real β). The left side is the expectation (1), with divisor Z_0.

θ is the quantity determined from the flux free energy $\Delta F = \ln(Z_0/Z_1)$ by $\theta = \tanh(\Delta F/2)$ (19-02; 26-03 of the present book also calls ΔF the "vortex free energy"), and (9) says that it is **a quantity that bounds the correlation of loops at long distance from above**. Cited Estimates that bound long loops by ratios of twisted partition functions belong to the line of Tomboulis–Yaffe's argument on the flux free energy, and `HalfSplit.polyakov_pair_theta` is a formalisation, in that line, of the form for pairs of Polyakov loops at $T = M/2$ (the inequality in the original paper is about Wilson loops; the text not checked).

The route.

1. **The central sign reversal** c**.** Multiply the direction-3 links at $(x_3, x_4) = (0,0)$ (N^2 transverse links) by -1. The product of Haar measures is unchanged. The (1,3) and

(2,3) plaquettes contain two reversed links and are unchanged; among the (3,4) plaquettes only the two, T and T', change sign (the marked link in Figure 1). Hence $w_0(cU) = wTT'(U)$.

2. **Parity of the loops.** In $P_b(0)$ only the first link of the loop is reversed, so it changes sign; $P_{b'}(M/2)$ is unchanged. The product $\psi = P_b(0)P_{b'}(M/2)$ satisfies $\psi(cU) = -\psi(U)$, so $\int \psi w_0 = \frac{1}{2}\int \psi\,(w_0 - wTT')$.
3. **Write as sum and difference.** With $a_\pm = a_1 \pm a_T$, (4) gives $w_0 - wTT' = \frac{1}{2}\big[(a_+ \circ \Theta)a_- + (a_- \circ \Theta)a_+\big]$.
4. **Cauchy–Schwarz.** ψ depends only on the links on the two planes (Figure 1), is unchanged by Θ, and $|\psi| \le 1$. Using Cauchy–Schwarz for the reflection pairing with ψ inserted, and putting in $\langle a_\pm, a_\pm\rangle = 2(Z_0 \pm Z_1)$, gives $|\int \psi w_0| \le \sqrt{Z_0^2 - Z_1^2}$ (Lean: `HalfSplit.odd_fix_bound`).
5. **Divide.** $\sqrt{Z_0^2 - Z_1^2}/Z_0 = 2\sqrt{\theta}/(1+\theta)$ Proved here . □

Reading A guide to its strength: in the sum over all configurations for the $\mathbb{Z}_2$ subgroup, $N = 1$, $M = 2$, (9) is an equality. In SU(2) samples the right side was 3–6 times the left side (the numerical record of this book's study).

Putting a floor into (9) gives a floor for loop correlations. From $2\sqrt{\theta}/(1+\theta) \le 2\sqrt{\theta}$ and the thin-vortex floor $\theta \le \tanh(N^2|\beta|)^{M^2}$, $|\langle P_b(0)P_{b'}(M/2)\rangle_0| \le 2\tanh(N^2|\beta|)^{M^2/2}$ (M even, every real β; Lean: `PolyakovT.half_pair_tanh`). From the signed floor (8), Lean: `HalfSplit.polyakov_pair_floor` (all $N \ge 1$) gives, for any $\varepsilon > 0$, for each sufficiently large β, for sufficiently large M, if $M+1$ is even,

$$\left|\langle P_b(0)\,P_{b'}\left(\tfrac{M+1}{2}\right)\rangle_0\right| \;\le\; 2\exp\!\Big(-\tfrac{1}{2}(M+1)^2 e^{-\beta(S_N+\varepsilon)}\Big) \quad (10)$$

(the lattice has length $M+1$). The thresholds are not explicit, and the coefficient $e^{-\beta(S_N+\varepsilon)}$ becomes exponentially small as $\beta \to \infty$.

05

General time separation — repeating the reflection

Pairs of Polyakov loops at general time separation. If $M \equiv 0 \pmod 4$, then for every real β, all $0 \le T \le M$ and all b, b',

$$\left|\langle P_b(0)\,P_{b'}(T)\rangle_0\right| \;\le\; 2\,\tanh(N^2|\beta|)^{\,M\cdot\min(T,\,M-T)}. \quad (11)$$

Lean: `PolyakovT.polyakov_pair_all` ($M \equiv 0 \bmod 4$, every real β).

Cited Decay of correlations inside a tube of finite cross-section is an estimate of known type along the lines of Mack–Petkova and Tomboulis–Yaffe, and `PolyakovT.polyakov_pair_all` is its formalisation.

The case $T = M/2$ follows from § 04. For general T, we move the reflection plane and repeat Cauchy–Schwarz, reducing to convexity of the logarithm of the correlation. Write $G_{bb'}(T) = \int P_b(0) P_{b'}(T)\, w_0\, dU$ (unnormalised).

Step 1 Translation. The direction-4 translation $x_4 \mapsto x_4 + 1$ preserves the product of Haar measures and w_0, so $\int P_b(s) P_{b'}(t)\, w_0$ depends only on $t - s$ (Lean: `PolyakovT.corr_shiftZ`). So the reflection plane can be placed at any time. Also $G_{bb'}(T) = G_{b'b}(M - T)$ (`PolyakovT.Gc_swap`).

Step 2 The weighted reflection pairing. For bounded F, G depending only on the closed upper half, $\langle F, G\rangle_w = \int F(\Theta U) G(U)\, w_0\, dU$ is positive semidefinite because $w_0 = a_1 \cdot (a_1 \circ \Theta)$ by (4), and Cauchy–Schwarz holds (every real β; Lean: `PolyakovT.wpair_nonneg`, `PolyakovT.wpair_cs`).

Step 3 Midpoint convexity for even separations. Taking $F = P_b(u)$, $G = P_{b'}(v)$ and using $P_b(u) \circ \Theta = P_b(-u)$ and translation, for $2u, 2v \le M$,

$$G_{bb'}(u+v)^2 \;\le\; G_{bb}(2u)\, G_{b'b'}(2v), \qquad G_{bb}(2u) \ge 0 \quad (12)$$

(Lean: `PolyakovT.cs_even`; the non-negative side is `PolyakovT.Gc_even_nonneg`).

Step 4 The chord inequality. Proved here If $g \ge 0$ satisfies $g(k)^2 \le g(k-1) g(k+1)$ $(1 \le k \le m-1)$, then $g(k)^m \le g(0)^{m-k} g(m)^k$ (Lean: `LogChord.chord`). Applying this with $g(k) = G_{bb}(2k)$ and $m = M/4$, for $T = 2k \le M/2$, $G(T)$ is bounded by a weighted geometric mean of $G(0) \le Z_0$ and $G(M/2)$.

Step 5 Put in the ends. By § 04 and the thin-vortex floor, $G(M/2)$ is at most $2\, t^{M \cdot M/2}$ Z_0 $(t = \tanh(N^2|\beta|))$ (`PolyakovT.half_pair_tanh`). For even $T \le M/2$ with $b = b'$, this gives (11). For $b \neq b'$, use (12) with $u = v = T/2$ to return to $G_{bb'}(T)^2 \le G_{bb}(T) G_{b'b'}(T)$. For odd $T < M/2$, since $M/2$ is even, $T + 1 \le M/2$, and we use (12) with $u = (T-1)/2$, $v = (T+1)/2$. $T > M/2$ is brought back by the symmetry of step 1.

The constant 2 does not depend on β, N, M or T. Using the trace of the transfer matrix and Hölder's inequality, the θ form $(\theta^{T/M} + \theta^{1-T/M})/(1+\theta)$ is to be expected, but it is not in Lean. (11) is weaker than that in only two respects: the constant 2, and the replacement of θ by t^{M^2} from the thin-vortex floor.

Detour: the range in the parities of M, N and the sign of β

You may skip this. With reflections in planes of lattice points alone, odd separations are not covered when $M \equiv 2 \pmod 4$. Adding reflections in planes through the middle of links covers them, but such a plane crosses squares, so $\beta \geq 0$ is needed (Lean: `PolyakovT.link_rp`, M even ≥ 4, $\beta \geq 0$). If N and M are both even, a change of variables by staggered signs sends $\beta \mapsto -\beta$ without changing the expectation of a pair (`PolyakovT.polyExp_neg`).

Lean declaration	M	N	β
`PolyakovT.polyakov_pair_all`	$M \equiv 0 \bmod 4$	Any	All real numbers
`PolyakovT.polyakov_pair_evenM`	Even, $M \geq 4$	Any	$\beta \geq 0$
`PolyakovT.polyakov_pair_evenNM`	Even, $M \geq 4$	Even	All real numbers

All conclusions have the same form as (11). Not covered are the case of odd M, and the case $M \equiv 2 \pmod 4$ with N odd and $\beta < 0$.

06

How to read it — a linear lower bound on the energy inside a tube

Setting $V(T) = -\frac{1}{M} \ln |\langle P(0)P(T)\rangle_0|$, (11) becomes

$$V(T) \;\geq\; \sigma_0 \cdot \min(T, M-T) - \frac{\ln 2}{M}, \qquad \sigma_0 = -\ln \tanh(N^2|\beta|) \quad (13)$$

A pair of Polyakov loops is a pair of static charges when direction 3 is viewed as time, and $V(T)$ corresponds to the energy of separating the pair to distance T. (13) is **a linear lower bound on the energy inside a transverse $N \times N$ tube**.

- **Only a lower bound.** It says neither that V is linear nor anything about an upper bound.
- **Not uniform in N.** $\sigma_0 \approx 2e^{-2N^2|\beta|}$ goes to 0 as $N \to \infty$. The thicker the tube, the weaker the lower bound.
- **The lattice spacing is fixed.** With N held fixed the system is effectively two-dimensional, and Cited in two-dimensional lattice gauge theory an area law at every β is the usual outcome. This is not a claim about four-dimensional confinement, the area law or the mass gap.

A guide to the non-trivial range. $|\langle P(0)P(T)\rangle_0| \leq \langle P^2\rangle_0$ is trivial. Reading $\langle P^2\rangle_0$ is about 0.25–0.3 (1/4 at $\beta = 0$). The smallest exponent $X = M \min(T, M-T)$ needed for the right side of (11) to fall below 1/4 is as follows Reading .

N	β = 0.1	0.3	0.5	1	2
1	1	2	3	8	57
2	3	12	57	3100	$9.2\cdot10^{6}$
3	7	231	8425	$6.8\cdot10^{7}$	$4.48\cdot10^{15}$

Reading Since $X \le M^2/2$ (with equality at $T = M/2$), for example at $N = 2$, $\beta = 1$, $X \ge 3100$ requires $M \ge 78.74$; with $M \equiv 0 \pmod 4$ in fact $M \ge 80$, and even then the right side falls below 1/4 only for T near $M/2$. At large β and large N, (11) is loose, and that side is covered by forms of the thick-vortex floor such as (10).

07

What is not said

- $\theta \ge 0$ for odd M; pairs of Polyakov loops for odd M.
- The Hölder form itself ((11) is weaker by the constant 2 and by replacing θ with t^{M^2}).
- An upper bound on $V(T)$, the linearity of V, the value of the tension.
- Estimates uniform in the width N. The band (the statement that the vortex ratio θ becomes small exponentially in the area of the box, that is, that $-\ln\theta$ (corresponding to the slab tension times the area) grows in proportion to the area, stated with a single constant while moving the transverse and longitudinal sizes and the coupling together; 19-07) is not reached. The estimates of this chapter are in a form with the lattice spacing and the width held fixed (21-08).
- The values of the thresholds in β and M in (8) and (10).
- The continuum limit; four-dimensional confinement, the area law, the mass gap.

What this chapter can say

Can say	Cannot say
Lean `HalfSplit.Z1_le_Z0`, `TwistBlocks.theta_nonneg`: $0 \le \theta_M$ for even M and every real β	Odd M (Reading there is an example where it fails at $\beta < 0$)
Lean `TwistBlocks.thick_vortex_floor_signed`: at large β and large M ($M+1$ even), $0 \le \theta_{M+1} \le \exp(-(M+1)^2 e^{-\beta(S_N+\varepsilon)})$	The values of the thresholds
Lean `HalfSplit.polyakov_pair_theta`: for even M and every real β, $\lvert\langle P_b(0) P_b'(M/2)\rangle_0\rvert \le 2\sqrt{\theta}/(1+\theta)$	Distances other than $M/2$ (those are the next row)

Can say	Cannot say
Lean `PolyakovT.polyakov_pair_all`: for $M \equiv 0 \bmod 4$, every real β, $0 \le T \le M$, $\lvert\langle P_b(0)P_{b'}(T)\rangle_0\rvert \le 2\tanh(N^2\lvert\beta\rvert)^{M\,\min(T,M-T)}$. `_evenM` ($M$ even ≥ 4, $\beta \ge 0$), `_evenNM` (N, M even, every β)	The Hölder form (weaker by the constant 2 and by $\theta \to t^{M^2}$). Odd M. A tension uniform in N
Lean `HalfSplit.polyakov_pair_floor`: a floor at distance $(M+1)/2$, combined with the thick-vortex floor	The values of the thresholds. Four-dimensional confinement
Lean `PolyakovT.half_pair_tanh`: for even M (including $M = 2$) and every real β, $\lvert\langle P_b(0)P_{b'}(M/2)\rangle_0\rvert \le 2t^{M\cdot M/2}$	Other T for $M \equiv 2 \bmod 4$ (`_evenM` if $M \ge 4$)
Reading The non-trivial range (at $N = 2$, $\beta = 1$: $M \ge 80$, with T near $M/2$)	—

The example with $\theta < 0$ for odd M, the strength ratios, the table of the non-trivial range	Reading	The numerical record of this book's study (SU(2) Monte Carlo and weighted averages over uniform samples, sums over all $\mathbb{Z}_2$ configurations, floating-point computation of $2t^X < 1/4$)

Words used in this chapter — expectation $\langle\cdot\rangle_0$, Polyakov loop, vortex ratio θ_M, reflection positivity, half weight, central sign reversal, midpoint convexity for even separations, chord inequality, staggered signs, linear lower bound on the energy inside a tube. Their meanings are in A-02 Glossary.

Next chapter to read: 21-07 The vortex ratio — continuity, limit, matching — for the vortex ratio with the lattice held fixed, its continuity and limits in the coupling, and matching it to a chosen value.

The vortex ratio — continuity, limit, matching

This chapter is this book's study.

What this chapter shows — For the vortex ratio $\theta_{N,M}(\beta) = (Z_0 - Z_1)/(Z_0 + Z_1)$ of the SU(2) Wilson measure on a torus of transverse size N and longitudinal size M, we read five things that are machine-checked in Lean with the lattice held fixed. (1) $\beta \mapsto \theta$ is continuous and $\theta(0) = 0$. (2) A box with two twists has no configuration in which the holonomy of every plaquette equals the sign of the twist (no flat configuration). (3) The deficit (the loss of action) of that box has a positive lower bound, and in a symmetric box it is at least $1/2$, independent of N. (4) As $\beta \to \infty$, $\theta \to 1$, and the slope of the flux free energy converges to the minimal deficit. (5) For every κ_0 with $0 \le \kappa_0 < 1$ there is a $\beta \ge 0$ with $\theta(\beta) = \kappa_0$, and among the solutions there is a largest one (matching).

Prerequisite chapters — 19-02 the torus of transverse size N and longitudinal size M, the sign of the twist, the vortex ratio, the twisted vacuum; 21-02 The thin-vortex floor. The introduction is in 25-01.

Said first — The lattice spacing is fixed at 1, and nothing is said about the continuum limit. Every theorem is a statement **with the lattice sizes N, M held fixed**. The speed of $\theta \to 1$, the constants in the estimates coming from the lower bound on the deficit, and the matching solution β^* depend on N, M, and nothing is said about sequences in which N and β move together (matched sequences). Nor do we say anything about the monotonicity of θ, the uniqueness of the matching solution, the continuity of β^* in κ_0, or that the largest solution for $\kappa_0 = 0$ is 0. Nor do we compare the true value of the minimal deficit with the value in the continuum theory. Each is a formalisation of the lattice form of the known picture of 't Hooft's twisted box Cited .

The order of this chapter

1. Setting — the vortex ratio, the flux free energy, the deficit — the background with two twists, and its minimal deficit
2. Statement — continuity and the value at β = 0 — θ(0) = 0
3. Statement — a twisted box has no flat configuration — with only one twist there is one

4. Statement — a lower bound on the deficit — $2N^2M^2/(N^2+M^2)^2$, and $1/2$ in a symmetric box
5. Statement — $\theta \to 1$ as $\beta \to \infty$ — the form of the lower bound, and the slope of the free energy
6. Statement — the largest matching solution — every $\kappa_0 \in [0, 1)$, the lower envelope from the right
7. Route of the proof — discrete Stokes, anticommutation of quaternions, positivity of Haar measure on open sets, intermediate values
8. As questions — how things map when the lattice is doubled — what is not a theorem
9. What is said, and what is not

Labels — Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are the labels of the whole book (Reading is a numerical reading, Lean a Lean theorem of this book).

01

Setting — the vortex ratio, the flux free energy, the deficit

The lattice is the torus $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ ($N, M \geq 1$) of transverse size N (directions 1, 2) and longitudinal size M (directions 3, 4); the weight is $e^{\beta \sum_p z_p \operatorname{Re} U_p}$, and the reference measure is the product of normalised Haar measures (19-02). With the background twist $n_{12} = 1$, write the partition functions without and with the longitudinal twist n_{34} as

$$Z_0 = Z_{N,M}(\beta; 1, 0), \qquad Z_1 = Z_{N,M}(\beta; 1, 1) \quad (1)$$

and write the vortex ratio and the flux free energy as

$$\theta = \theta_{N,M}(\beta) = \frac{Z_0 - Z_1}{Z_0 + Z_1}, \qquad \Delta F = \ln \frac{Z_0}{Z_1} = \ln \frac{1+\theta}{1-\theta} \quad (2)$$

(19-02; the equality on the right is Lean `ThetaLimit.phi_theta_eq`). Lean: `TwistBlocks.thetaM N M β`; Z_0 and Z_1 are `ZW N M β true false` and `ZW N M β true true`. This chapter deals mainly with $\beta \geq 0$.

The deficit. In the background with two twists $(n_{12}, n_{34}) = (1, 1)$, define the deficit of a configuration ω as

$$D(\omega) := \sum_p \big(1 - z_p \operatorname{Re} U_p(\omega)\big) \ \geq 0 \quad (3)$$

(z_p is the sign of the twist of this background). It is the loss from the maximum of the action (the number of plaquettes) to the actual action. $D(\omega) = 0$ means $U_p = z_p$ on every plaquette, that is, a flat configuration matching the twist. Write the minimal deficit as

$$D_{\min}(N, M) := \inf_{\omega} D(\omega) \quad (4)$$

Lean: `TwistFlat.defect11`, `ThetaLimit.Smin`.

Caution. $D_{\min}$ is the minimal deficit over the whole twisted box. It is a different quantity from the minimal action of a vortex S_N (19-02, 21-05; the quantity in which the boundary of a block of side m is held at the twisted vacuum).

02

Statement — continuity and the value at β = 0

Statement (continuity of the vortex ratio)

Let $N, M \geq 1$. $\beta \mapsto Z_{N,M}(\beta; n_{12}, n_{34})$ is continuous on the whole real line, and $\beta \mapsto \theta_{N,M}(\beta)$ is continuous too. At $\beta = 0$, $Z = 1$ and $\theta = 0$.

Lean Continuity of a bounded exponential integral. Lean: `ThetaTuning.ZW_continuous`, `thetaM_continuous`, `ZW_zero`, `thetaM_zero` (the only assumption is $N, M \geq 1$).

The proof is by dominated convergence. In the range $|\beta| \leq |\beta_0| + 1$, the integrand is bounded by $\exp((|\beta_0| + 1) \cdot \text{number of plaquettes})$. The denominator $Z_0 + Z_1$ is positive, so θ is continuous too. At $\beta = 0$, the reference measure is a probability measure, so $Z = 1$.

The range of values is $-1 < \theta \leq 1$ (`ThetaLimit.theta_gt_neg_one`, `theta_le_one`), and if the longitudinal size M is even, $\theta \geq 0$ (21-06, `TwistBlocks.theta_nonneg`). That $\theta > 0$ for $\beta > 0$ is not in Lean.

03

Statement — a twisted box has no flat configuration

Statement (a box with two twists has no flat configuration)

Let $N, M \geq 1$ (including the degenerate lattices $N = 1$, $M = 1$). In the background $(n12, n34) = (1, 1)$, there is no SU(2) configuration with $z_p \operatorname{Re} U_p = 1$ on every plaquette.

Lean The lattice form of the known type ('t Hooft): "a box with one twist in directions 1, 2 and one in directions 3, 4 has no flat connection". Lean: `TwistFlat.no_flat_twist11` (no assumptions).

In the background $(1, 0)$ with only one twist, the statement of the same form is false. The twisted vacuum (19-02: the unit quaternion $\mathbf{i}$ on the links of direction 1 at $x_1 = 0$, $\mathbf{j}$ on the links of direction 2 at $x_2 = 0$, and 1 elsewhere) is a configuration with deficit 0 (`ThetaLimit.flat_exists_10`). Because of this contrast, the statement does not hold trivially merely because of how the signs of the twist are placed.

Meaning. In a box with two twists, every configuration contributing to the twisted partition function Z_1 pays a positive loss of action. On the other hand, Z_0 (one twist) has configurations with zero loss. This difference is the source of $Z_1/Z_0 \to 0$, that is $\theta \to 1$, as $\beta \to \infty$ (§ 05).

04

Statement — a lower bound on the deficit

Statement (the minimal deficit is positive and is attained)

Let $N, M \geq 1$. There is a configuration $\omega^\star$ with $0 < D(\omega^\star) \leq D(\omega)$ (for all ω). Hence $D_{\min}(N, M) > 0$.

Lean From compactness and § 03. Lean: `TwistFlat.defect11_floor`, `minDefect11_pos` (no assumptions).

Statement (a uniform lower bound on the deficit)

For all $N, M \geq 1$ and all configurations ω,

$$D(\omega) \;\geq\; \frac{2N^2M^2}{(N^2+M^2)^2}. \tag{5}$$

In particular, in a symmetric box $N = M$, $D(\omega) \geq 1/2$, and $D_{\min}(N, N) \geq 1/2$ holds independently of N.

Lean A coarse uniform version, on the lattice, of the known type of lower bound on the action of a twisted box. Lean: `TwistFloor.defect11_ge_two`, `defect11_sym_half`, `defect11_uniform_half`, `Smin_sym_half` (no assumptions).

In the background with one twist, there is no positive lower bound of the same form (`TwistFloor.no_floor_10`).

The core of (5) is an inequality for quaternions. For unit quaternions a, b, c, d,

$$\|ab + ba\| + \|cd + dc\| + \|ac - ca\| + \|bc - cb\| \;\geq\; 2 \quad (6)$$

(Lean `QuadFloor.quad_floor_two`). The left-hand side is the sum of the failures of four relations, "a, b anticommute, c, d anticommute, and c commutes with both a and b", and in SU(2) these four are incompatible. The constant 2 is attained, for example at $(a, b, c, d) = (\mathbf{i}, \mathbf{j}, 1, \mathbf{k})$, and cannot be raised.

In numbers Reading . The minimal deficit for $N = M = 1$ is numerically 2.000; for $N = M = 2$ and 4 the deficits of configurations found by cooling are 7.84 and 9.80, and these are upper bounds on the minimum. There is still a gap of a factor of 16 to 20 from the lower bound $1/2$. The lower limit of the action of the corresponding sector in the continuum theory is $\pi^2 \approx 9.87$ in units of $\beta = 4/g^2$, from the self-dual estimate and the fractional topological charge $1/2$ Cited . How $D_{\min}(N, N)$ changes with N is not known.

05

Statement — θ → 1 as β → ∞

Statement (the limit of the vortex ratio)

With $N, M \geq 1$ held fixed, $\theta_{N,M}(\beta) \to 1$ as $\beta \to \infty$. Moreover, for all $\beta \geq 0$,

$$\theta_{N,M}(\beta) \;\geq\; 1 - \frac{2}{v}\, e^{-D_{\min}\beta/2} \quad (7)$$

where $v > 0$ is the Haar volume of a certain open set containing the twisted vacuum in the background with one twist (it does not depend on β, depends on N, M, and has no explicit value).

Lean From the lower bound on the deficit and the positivity of Haar measure on open sets. Lean: `ThetaLimit.tendsto_theta_one`, `theta_lower`, `Z11_le`, `Z10_ge`,

`volV_pos`, `ratio_tendsto_zero`.

Statement (the slope of the flux free energy)

With $N, M \geq 1$ held fixed,

$$\frac{\Delta F}{\beta} = \frac{1}{\beta} \ln \frac{Z_0}{Z_1} \longrightarrow D_{\min}(N, M) \qquad (\beta \to \infty). \tag{8}$$

In a symmetric box, this limit is at least $1/2$, independent of N.

Lean Estimates from both sides using the same parts. Lean: `ThetaLimit.tendsto_logratio_div`, `TwistFloor.logratio_limit_half`.

Meaning. With the lattice held fixed and the coupling made weaker, the sector with two twists loses weight exponentially by the amount of the deficit, and the vortex ratio approaches 1. The slope of that exponent is exactly the minimal deficit. This is $\beta \to \infty$ with the lattice held fixed, not the continuum limit (the direction in which κ_0 is held fixed and the lattice is made finer).

06

Statement — the largest matching solution

Statement (matching the vortex ratio)

Fix $N, M \geq 1$. For every κ_0 with $0 \leq \kappa_0 < 1$ there is a $\beta \geq 0$ with $\theta_{N,M}(\beta) = \kappa_0$, and the set of these solutions has a largest element $\beta^*(\kappa_0; N, M)$ within $\beta \geq 0$. If $\kappa_0 > 0$, then $\beta^* > 0$.

Lean Continuity, the intermediate value theorem and compactness. Lean: `ThetaLimit.tuning_all`, `tuning_all_pos` (the only assumption is $0 \leq \kappa_0 < 1$). An example where the assumptions can be met: for $N = M = 2$, a positive solution for $\kappa_0 = 1/2$ (`ThetaLimit.sanity_half`).

As a weak form there is also the statement that if $0 \leq \kappa_0 \leq \theta(\beta_1)$, there are a solution and a largest solution in $[0, \beta_1]$ (`ThetaTuning.tuning_exists`, `tuning_max_exists`). By § 05 such a β_1 can be taken for every $\kappa_0 < 1$, which gives the full form above (`ThetaLimit.exists_theta_gt`).

The lower envelope from the right. Whether θ is monotone in β is not known. We therefore use $\theta(\beta) := \inf_{\beta' \geq \beta} \theta(\beta')$. θ is increasing; at the largest solution β^*, $\theta(\beta^*) = \kappa_0$; for $\beta > \beta^*$, $\theta(\beta) > \kappa_0$; and β^* is also the largest among the solutions of $\theta = \kappa_0$ (`ThetaLimit.thetaLow`, `thetaLow_mono`, `envelope_max_sol`). Even for a θ that is not monotone, the largest solution is characterised by this monotone function. We do not claim continuity of θ.

What the matching is for. The matching in the statements to be shown (19-07) is a statement about how to fix the bare coupling along a sequence of ever finer lattices. The matching in this chapter is the part, lattice by lattice, of one candidate for it, "on each lattice, match the vortex ratio to a chosen value κ_0": the existence on each lattice. What holds as a sequence (how β^* depends on N) is not said.

07

Route of the proof

No flat configuration (§ 03). In two steps.

1. **Discrete Stokes.** Suppose quaternion fields A, B on an additive group G satisfy at each point the exchange relation $A(x)B(x+e) = s(x)\, B(x)A(x+f)$ ($s(x)$ a sign), and $Le = 0$, $L'f = 0$. Then the product along a line going once around in direction e and the product along a line going once around in direction f commute up to the product of all the s on the cut (Lean `FlatStokes.torus_commutator`). This is shown by a two-stage induction, first column by column, then sheet by sheet. For a configuration with deficit 0, $U_p = z_p$ on each plaquette is precisely this exchange relation.
2. **A contradiction in the quaternions.** For the four loops W_1, W_2 (transverse) and W_3, W_4 (longitudinal) through the origin, the product of the signs on the cut is -1 for the cuts in directions 1, 2 and in directions 3, 4, and $+1$ for the cuts in directions 1, 3 and 2, 3. Hence $W_1W_2 = -W_2W_1$, $W_3W_4 = -W_4W_3$, and W_3 commutes with both W_1 and W_2. Only real numbers commute with an anticommuting pair (W_1, W_2) of unit quaternions, so $W_3 = \pm 1$, which contradicts $W_3W_4 = -W_4W_3$ (`FlatStokes.no_twisted_quadruple`). Only four pairs of directions are used.

The lower bound on the deficit (§ 04). Extend (6) to a quantitative form. If the fields are unit-valued and the failure of the exchange relation is at most $d(x)$ at each point, then the failure of the loops to commute is at most the sum of d over the cut (`FlatStokes.approx_torus_commutator`; each sheet peeled off adds one error). The failure on a plaquette is $\|U_p - z_p\| = \sqrt{2(1 - z_p \operatorname{Re} U_p)}$. Applying (6) to the four loops at each base point, summing over the base points, recounting by translation and using

Cauchy–Schwarz twice gives (5). When $N \neq M$, the weights of the cuts in directions 1, 2 (N^2 sheets) and in directions 3, 4 (M^2 sheets) do not balance, and the bound becomes $2/(\rho + 1/\rho)^2$ in the ratio $\rho = N/M$. We take its approach to 0 as $\rho \to 0$ or $\rho \to \infty$ to be a weakness of the method Assumption . The only grounds are small examples: on the degenerate lattice $N = 1$, the minimal deficit for $M = 1, 2, 3$ stays numerically at 2.000 and does not drop Reading .

$\theta \to 1$ **(§ 05).** For $\beta \geq 0$, action = number of plaquettes $-D$, so $Z_1 \leq e^{\beta(|P| - D_{\min})}$ ($|P|$ is the number of plaquettes). On the other hand, the action in the background with one twist is continuous and takes its maximum $|P|$ at the twisted vacuum, so the set of configurations whose action exceeds $|P| - D_{\min}/2$ is an open set containing the twisted vacuum. The product of Haar measures puts positive weight on non-empty open sets, so its volume v is positive, and $Z_0 \geq v\, e^{\beta(|P| - D_{\min}/2)}$. Taking the ratio, $Z_1/Z_0 \leq v^{-1} e^{-D_{\min}\beta/2}$, and $\theta = 1 - 2Z_1/(Z_0 + Z_1) \geq 1 - 2Z_1/Z_0$ gives (7). (8) uses the same parts from above and below, with an open set around the minimiser. No precise Laplace-type estimate is needed.

Matching (§ 06). Since $\theta(0) = 0$, θ is continuous and $\theta \to 1$, the intermediate value theorem gives a solution. The set of solutions is closed, and there are no solutions beyond some b_0 ($\theta > \kappa_0$), so as a bounded closed set it has a largest element.

08

As questions — how things map when the lattice is doubled

What follows is not a theorem; these are questions lying beyond the theorems of this chapter.

- **How doubling maps.** With the coupling matched to $\theta = \kappa_0$ in a symmetric box of side N (the largest solution $\beta^*(\kappa_0; N)$), measuring the vortex ratio of a box of side $2N$ determines a value $\Sigma(\kappa_0; N) := \theta_{2N}(\beta^*(\kappa_0; N))$. Whether $\Sigma(\cdot; N)$ approaches a single function as $N \to \infty$, and if so how that function behaves between 0 and 1, remains a question. For two-dimensional SU(2), the corresponding function can be written by a formula on the continuum side, and it behaves like κ_0^4 for small κ_0 Reading (a formula using Bessel coefficients, and numbers; no proof is given). The Monte Carlo numbers on small four-dimensional lattices have large errors and are not at a stage where anything can be said.
- **The limit of the fixed-lattice direction.** What § 05 gives is only that the slope of ΔF as $\beta \to \infty$ with the lattice held fixed is $D_{\min}(N, N)$, and that this is at least $1/2$. If $D_{\min}(N, N)$ and $D_{\min}(2N, 2N)$ differ, no statement bounding $\Delta F_N - \Delta F_{2N}$ uniformly can be made in the fixed-lattice form. Even if they are equal, a

comparison of the terms slower than linear in β remains. The cooling numbers are all upper bounds, so whether they differ is not known.

- **Relation to the band.** The band statement (19-07; the correct form is in 26-01) says that the vortex ratio becomes exponentially small in the longitudinal area, uniformly in the lattice spacing and the size of the box. The theorems of this chapter are all statements with the lattice held fixed, and do not reach the band statement.

09

What is said, and what is not

- **Statements with the lattice held fixed.** v, $D_{\min}$, β^* and the speed of convergence in (7) depend on N, M. What happens to θ along sequences in which N and β move together is not said.
- **The shape of θ.** Monotonicity, $\theta > 0$ for $\beta > 0$, uniqueness of the matching solution, continuity of β^* in κ_0, and that the largest solution for $\kappa_0 = 0$ is 0, are not said.
- **The value of the deficit.** The true value of $D_{\min}$, its comparison with π^2, and its dependence on N are not said. The lower bound $1/2$ is a coarse uniform version. For $N \neq M$, the lower bound approaches 0 when the aspect ratio becomes lopsided.
- **Reaches neither the band nor the mass gap.** The lattice spacing is fixed, and the continuum limit is not treated.
- **Not a new result.** That a twisted box has no flat connection, the lower bound on its action, and the behaviour of the vortex free energy at weak coupling are a known picture; this chapter is its formalisation on the lattice.

Numerical values of the minimal deficit, upper bounds from cooling, the doubling function in two dimensions	Reading	The numerical record of this book's study (quaternion minimisation, cooling, numerical values of the formula with Bessel coefficients; the cooling values are upper bounds)

Terms used in this chapter — vortex ratio, flux free energy, 't Hooft twist, deficit, flat configuration, twisted vacuum, discrete Stokes, anticommutation, positivity of Haar measure on open sets, matching, largest solution, lower envelope from the right. Their meanings are in A-02 Glossary.

Next chapter to read: 21-08 What this part says, and what it does not — the theorems of Part 21 in one table. The vortex floor in the strong-coupling window, with a rate independent of the transverse size (the prefactor N^2 remains), is in 20-06.

What this part says, and what it does not

> This chapter is this book's own investigation. The table of § 01 is a list of the theorems of Part 21.

What this chapter shows — the theorems of Part 21 in a single table, with their scope, what they do not say and their Lean declarations. After that, a short look at how far the floors of this part are from the band.

Prerequisite chapters — 21-00 Entrance and each chapter of Part 21. The definitions of the objects are in 19-02

Said first — apart from the first, abstract implication, every theorem of this part is an equality or inequality at a fixed lattice spacing on a finite lattice of transverse size N and longitudinal size M. Inside the strong-coupling window there is a form whose rate does not depend on the transverse size (the prefactor, the transverse area, remains; 20-06). Outside the window, none of the rates of the floors of this part (upper bounds on θ) is uniform in the transverse size N. The lower bound on the deficit in 21-07 (1/2 in a symmetric box, independent of the transverse size) is a statement in the opposite direction from a floor (on the side of lower bounds on θ). Nothing is said about the continuum limit, four-dimensional confinement or the mass gap.

The order of this chapter

1. The list of theorems — scope and what is not said
2. What depends on the width N
3. The distance from the floor to the band

01

The list of theorems — scope and what is not said

The object throughout is the SU(2) Wilson measure on the torus with transverse part $(\mathbb{Z}/N)^2$ and longitudinal part $(\mathbb{Z}/M)^2$, with background twist $n_{12} = 1$ (19-02). We write

$\theta_M = (Z_0 - Z_1)/(Z_0 + Z_1)$ and $t = \tanh(N^2|\beta|)$. Each is a formalisation of a result or picture of known type (the Cited rows of each chapter).

Only the first row is an abstract implication with assumption fields. The other rows are theorems about concrete objects, whose assumption fields are only the ranges written in the table.

Theorem	Scope	What is not said	Lean declarations
Three results on sign systems (the covering inequality, $\mathbb{Z}_2$ monotonicity, comparison with $\mathbb{Z}_2$)	Abstract groups and sign characters. Implications with a column of assumptions	On their own they are not estimates for a concrete measure (the application is inside the next row)	`CoveringInequality.covering_ineq`, `mon_ineq`, `dominated_covering_ineq`, `invariant_dominated`
The thin-vortex floor (ratio form)	All real β, $N, M \geq 1$, any background twist: `twisted_vortex_bound` is the signed form $(Z_0 - Z_1)/(Z_0 + Z_1) \leq t^{M^2}$, and `_abs` the absolute-value form $\lvert Z_0 - Z_1\rvert/(Z_0 + Z_1) \leq t^{M^2}$	The sign ($Z_1 \leq Z_0$ is a separate row). A rate uniform in N	`TwistedWilson.twisted_vortex_bound`, `twisted_vortex_bound_abs`
The thin-vortex floor (exponential form)	$\beta \neq 0$: $\sigma_0 = -\ln t > 0$, $\lvert\theta_M\rvert \leq e^{-\sigma_0 M^2}$	$\sigma_0 \to 0$ ($N \to \infty$)	`TwistedWilson.thin_vortex_floor`
The block estimate	$mk \leq M$, all real β: $\lvert\theta_M\rvert \leq \tanh(K_{\text{eff}})^{k^2}$	When blocks of different shapes are mixed, it is weaker than the product over blocks	`TwistBlocks.block_bound_abs`
The thick-vortex floor	All $N \geq 1$, any $\varepsilon > 0$, for every sufficiently large β and sufficiently large M: $\lvert\theta_{M+1}\rvert \leq \exp(-(M+1)^2 e^{-\beta(S_N+\varepsilon)})$	The values of the thresholds in β and M. The value of S_N. The opposite direction (a lower bound on the rate)	`TwistBlocks.thick_vortex_floor`

Theorem	Scope	What is not said	Lean declarations
Positivity of the minimal action of a vortex	All $N \geq 1$: $\delta \leq S_{\mathrm{v}}(N, m)$ with a $\delta > 0$ uniform in m, and $S_N > 0$	The number δ (not explicit). A lower bound uniform in N	`VortexPos.Svortex_ge_unif`, `VortexPos.SN_pos`
Certificates for the upper bounds Computer-assisted	$S_{\mathrm{v}}(2,8) \leq 6.67401$, $S_{\mathrm{v}}(3,8) \leq 9.09321$, $S_{\mathrm{v}}(4,4) \leq 12.02057$, hence $S_N < 2N^2$ $(N = 2,3,4)$	The value of S_N (only upper bounds, from a single configuration). General N	`VortexCert.Svortex_two_eight_le`, `Svortex_three_eight_le`, `Svortex_four_four_le`, `SN_two_lt`, `SN_three_lt`, `SN_four_lt` (soundness: `VortexCert.Svortex_le_of_cert`)
The thick-vortex floor with explicit exponents	$N = 2,3,4$, for every sufficiently large β and sufficiently large M: exponent numbers 6.675, 9.094, 12.021	The values of the thresholds. "Stronger than the thin-vortex floor" is a comparison of rates and not a Lean theorem (Reading from $\beta > 0.523$ for $N = 2$)	`TwistBlocks.thick_vortex_floor_two`, `_three`, `_four`
The sign of the vortex ratio	M even, all real β: $Z_1 \leq Z_0$, $\theta_M \geq 0$	M odd (Reading examples where it fails for $\beta < 0$)	`HalfSplit.Z1_le_Z0`, `TwistBlocks.theta_nonneg`
The signed thick-vortex floor	In the range of the thick-vortex floor, with $M+1$ even: $0 \leq \theta_{M+1} \leq \exp(-(M+1)2_e{-}\beta(S_N+\varepsilon))$	The values of the thresholds	`TwistBlocks.thick_vortex_floor_signed`
Continuity and matching of the vortex ratio	With the size of the lattice held fixed, for all real couplings: the vortex ratio is continuous in the coupling, is 0 at coupling 0, and approaches 1 as the coupling grows. For every target value at least 0 and less than 1 there is a coupling matched to it (the largest solution)	Monotonicity, uniqueness of the solution, sequences in which the transverse size and the coupling move together	`ThetaTuning.thetaM_continuous`, `ThetaLimit.tendsto_theta_one`, `ThetaLimit.tuning_all`

Theorem	Scope	What is not said	Lean declarations
A lower bound on the deficit of a twisted box	A box with twists in two orthogonal planes has no flat configuration. The deficit of a symmetric box is at least 1/2, independent of the transverse size	The true value of the minimal deficit	`TwistFlat.no_flat_twist11`, `TwistFloor.defect11_sym_half`
Estimate of pairs of Polyakov loops by θ	M even, all real β, all b, b': $\lvert\langle P_b(0)P_{b'}(M/2)\rangle_0\rvert \le 2\sqrt{\theta}/(1+\theta)$	Only the distance $M/2$	`HalfSplit.polyakov_pair_theta`
Pairs of Polyakov loops at a general time separation	$M \equiv 0 \bmod 4$, all real β, $0 \le T \le M$: $\lvert\langle P_b(0)P_{b'}(T)\rangle_0\rvert \le 2t^{M\min(T,M-T)}$	A Hölder form (weaker by the constant 2 and by replacing θ with t^{M^2}). M odd. Linearity; an upper bound	`PolyakovT.polyakov_pair_all`
The same (other parities)	M even ≥ 4 with $\beta \ge 0$ / N, M even ($M \ge 4$) with all β	M odd. $M = 2$ (only $T = M/2$, in the next row). $M \equiv 2 \bmod 4$ with N odd and $\beta < 0$	`PolyakovT.polyakov_pair_evenM`, `polyakov_pair_evenNM`
Pairs at distance $M/2$ and the thin-vortex floor	M even (including $M = 2$), all real β: $\lvert\langle P_b(0)P_{b'}(M/2)\rangle_0\rvert \le 2t^{M\cdot M/2}$	Other time separations (the two rows above)	`PolyakovT.half_pair_tanh`
Pairs of Polyakov loops combined with the thick-vortex floor	For every sufficiently large β and sufficiently large M, $M+1$ even: the pair at distance $(M+1)/2$ is $\le 2\exp(-\frac{1}{2}(M+1)^2 e^{-\beta(S_N+\varepsilon)})$	The values of the thresholds. Four-dimensional confinement	`HalfSplit.polyakov_pair_floor`

Common to all rows: the lattice spacing is fixed, and none of the continuum limit, the four-dimensional area law or the mass gap is said. The Polyakov-loop estimates are linear **lower bounds** on the energy inside a transverse $N \times N$ tube.

What depends on the width N

Every theorem of this part has the form of holding N fixed and moving M and β. We list how each depends on N.

Quantity	Dependence on N	What is known
The rate of the thin-vortex floor $\sigma_0 = -\ln\tanh(N^2\lvert\beta\rvert)$	Proved here $\approx 2e^{-2N^2\lvert\beta\rvert}$, 0 as $N \to \infty$	Explicit
The exponent of the thick-vortex floor S_N	$0 < S_N \leq 2N^2$ (`VortexPos.SN_pos`, `TwistBlocks.SN_bounds`)	Value unknown. Upper bounds only for $N = 2, 3, 4$
The thresholds of the thick-vortex floor $\beta_0(N)$, $M_0(\beta, N)$	Unknown	Not explicit
The positivity lower bound $\delta(N)$	Unknown	Not explicit
The rate of the vortex floor at strong coupling (20-06; a theorem of Part 20)	Independent of it (only inside the strong-coupling window; the transverse area in the prefactor remains)	Explicit. Nothing is said outside the window
The lower bound on the tension inside a tube ((13) of 21-06)	Same as σ_0; goes to 0 as $N \to \infty$	Explicit
The minimal deficit $D_{\min}(N, N)$ of a twisted box (21-07; not a floor, but on the side of lower bounds on θ)	The lower bound $1/2$ does not depend on N. v and β^* depend on N	The lower bound is explicit. The true value is unknown

Outside the strong-coupling window, the explicit quantities of the floors go to 0 with N. For the rate coming from S_N, the dependence on N is unknown, and the thresholds are not explicit either.

03

The distance from the floor to the band

The floors of this part are **upper bounds** on θ, for each width N. They bound the slab tension $\sigma_N(\beta) = \liminf_M -\frac{1}{M^2}\ln\lvert\theta_M\rvert$ (21-03) from below, for each N.

The statement of the band is in 19-07. Assumption For a sequence of bare couplings β_n fixed by matching, there is $c > 0$ such that for every L_0, for all sufficiently large n, $\theta_{2^n L_0, 2^n L_0}(\beta_n) \leq \exp(-c\,L_0^2)$. It is the form that refines the transverse and longitudinal sizes together, moves the coupling as well, and bounds the vortex ratio exponentially in the area with a single constant c.

The floors of this part concern holding the lattice spacing and the transverse size N fixed and moving the longitudinal size M, and do not reach this form. To state the

band, one needs estimates uniform in the transverse and longitudinal sizes and in the coupling. As the table of § 02 shows, every floor theorem of this part is for each N separately and contains no such uniformity (the lower bound on the deficit in 21-07 does not depend on the transverse size, but it is a statement on the side of lower bounds on θ, not a floor). The form in 20-06 inside the strong-coupling window has a rate independent of the transverse size, but since the coupling stays inside the window, it does not reach matched sequences on the side where the coupling grows large.

In this book, this uniform estimate is placed on the side of the premises. The list of premises and the form of the implications are in Part 28.

What this chapter can say

Can say	Cannot say
Each row of the table of § 01 (machine-checked in Lean; the first row is an abstract implication)	The "what is not said" column of each row
Proved here The rate of the thin-vortex floor and the lower bound on the tension inside a tube go to 0 as $N \to \infty$	Estimates uniform in N and in the coupling (the statement of the band, 19-07)

Sources and reproduction

Item	Kind	Source / tool
The theorems of each row	—	The "Sources and reproduction" table of each chapter (21-01–21-07). Lean declarations in the table of § 01
$\sigma_0 \approx 2e^{-2N^2\lvert\beta\rvert}$	Proved here	$\tanh x = 1 - 2e^{-2x} + O(e^{-4x})$ and $-\ln(1-y) = y + O(y^2)$

Words used in this chapter — vortex floor, vortex ratio θ_M, minimal action of a vortex S_N, Polyakov loop, band, estimate uniform in the width. Their meanings are in A-02 Glossary.

Next chapter to read: 22-00 Entrance — the rarity of large plaquettes — on to the theorem on rarity at one scale, on the weak-coupling side.

Entrance — the rarity of large plaquettes

> This chapter is a guide.

What this chapter shows — The list of theorems of Part 22, the scope that applies to the whole part, and the idea of the tool, the Chessboard Estimate. We also set side by side how the published construction uses the same Chessboard Estimate (as a seminorm measuring the size of observables) and how this part uses it (as an estimate of the probability of rare events).

Prerequisite chapters — 19-01 the Wilson measure, 20-01 Reflection positivity, 26-05 the Chessboard Estimate and simultaneous flips.

Said first — The theorems of this part are statements at one scale, about the Wilson measure itself on a fine lattice at a fixed lattice spacing. They are uniform in the volume (the size of the torus), but say nothing about the measure at a coarse scale after renormalisation. The threshold $\beta \geq 81$ is a value chosen for the convenience of the proof, far from the band of physical interest. Each is a formalisation of a known type, the chessboard Peierls argument from reflection positivity Cited .

The order of this chapter

1. List of the theorems of this part — Table 1
2. The Chessboard Estimate as a tool — uniform patterns and the geometric mean
3. Two uses — measuring size, or measuring rarity — the difference from the published construction
4. The scope that applies to the whole part
5. Order of reading

Labels — Source = we read the source of the published construction; Inferred = this book's inference; Assessment = from the committee's assessment (details in "Labels" in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are the labels of the whole book; Reading is a numerical reading of this book, and Lean a Lean theorem of this book.

01

List of the theorems of this part

Measure the "deviation" of a plaquette p by $1 - \operatorname{Re} U_p \in [0, 2]$, and call a plaquette exceeding a threshold y a **large plaquette** (for $y = 1$, $\operatorname{Re} U_p < 0$). The statement of this part is that the probability of configurations in which many large plaquettes appear at once is exponentially small in the number of plaquettes, with a rate that does not depend on the size of the torus.

Theorem	Scope	Gist of the statement	Lean
The Chessboard Estimate	Side $N = 2m$ ($m \geq 1$), all real β	The expectation of a product of functions placed block by block is at most the geometric mean of the expectations of the uniform patterns	`FoldWilson.wilson_chessboard_even`
Rarity uniform in the volume	$\beta \geq 81$, $m \geq 2$	The probability that $\operatorname{Re} U_p < 0$ on all of a set X of plaquettes is $\leq q_1^{\lfloor \lvert X \rvert / 6 \rfloor}$, with $q_1 < 1$ independent of N and X	`FoldCap.rarity_explicit`
The form with rate $1/4$	$0 < y \leq 2$, at or above some β_0, $m \geq 1$	Probability $\leq q_4^{\lfloor \lvert X \rvert / 24 \rfloor}$	`FoldQuarter.rarity_uniform4`

Table 1. The theorems of Part 22. Statements, proofs and numbers are in 22-01; the scope and what is not said are in 22-02.

02

The Chessboard Estimate as a tool

The introduction is in 26-05 and 20-01. For a reflection-positive measure, the expectation of the product of a function with its mirror image is at least 0, and from this follows an inequality of Cauchy–Schwarz form, the "folding inequality". Repeating

it for every mirror, one divides the torus into blocks, and for the expectation of a product with a function f_w placed in each block,

$$\left|\left\langle \prod_{w} f_w \right\rangle\right| \;\le\; \prod_{w} \left\langle \prod_{w'} f_w^{(w')} \right\rangle^{1/|\mathrm{blocks}|} \quad (1)$$

holds (the Chessboard Estimate of Fröhlich–Israel–Lieb–Simon Cited). The $\prod_{w'} f_w^{(w')}$ on the right is the "uniform pattern" in which the same function f_w is carried by reflections to every block. The point is that any placement on the left is bounded by the geometric mean of the expectations of uniform patterns.

Each factor on the right is a quantity determined by a single function f,

$$\|f\|_{\mathrm{cb}} := \left\langle \prod_{w'} f^{(w')} \right\rangle^{1/|\mathrm{blocks}|} \quad (2)$$

and we call it the **chessboard root**. Since it is a quantity per block, it takes a form independent of the volume even as the volume grows.

03

Two uses — measuring size, or measuring rarity

How the published construction uses it. From the reflection positivity of the Wilson measure, the published construction derives the chessboard inequality (`Cells.Tiling.tiles` , `YM/Cells/Chess.lean:80`) and the triangle inequality for the chessboard root, $\|F+P\|_{\mathrm{cb}} \le \|F\|_{\mathrm{cb}} + \|P\|_{\mathrm{cb}}$ (`Cells.Tiling.adds` , same file `:108`) Source . The root `rootTest` (`YM/Cells/Tiling.lean:226`) is a quantity of the form (2) Source . Because of the triangle inequality, the root can be used like a seminorm on the space of observables Inferred .

With this seminorm, one of the estimates placed at the interface between the ultraviolet side and the infrared side is written. Measured by the chessboard root, renormalised local observables are at most $A \cdot a_m^{-d-\varepsilon}$, uniformly in all volumes (`Extraction.Wcmain` , `YM/Extraction/Center.lean:38`) Source . This becomes the input of local boundedness and equicontinuity for taking an infinite-volume subsequence (12-02, 12-03) Source . This is not the only input received from the ultraviolet side Source .

How this part uses it. This part uses the same Chessboard Estimate to estimate **the probability of rare events**. If the function placed is the indicator of a plaquette, "this plaquette is large", the uniform pattern becomes the event "that plaquette is large at every location". Its weight is exponentially small compared with the partition function, because the action loses heavily (energy), and the partition function is bounded below

by the weight of configurations with every link near the identity (entropy). The $1/|\text{blocks}|$-th power of the ratio becomes the rate per plaquette. This is the chessboard Peierls argument Cited .

	Published construction	This part
Function placed	Renormalised local observables	Indicator that a plaquette is large
What the root measures	The size of observables (of order $a_m^{-d-\varepsilon}$)	The rarity of events (rate per plaquette < 1)
Where it is used	Local boundedness and equicontinuity → subsequential limits	That configurations with many large plaquettes are rare
Mirrors	For the original Wilson measure, planes through lattice sites and planes through midpoints of edges, four axes, $\beta \geq 0$ Source	The same two kinds (the middle plane for gauge-invariant functions, $\beta \geq 0$, $m \geq 2$)
Triangle inequality	Present Source	Not used

Table 2. Two uses of the Chessboard Estimate.

In the language of the root, the theorems of this part can presumably be restated in the form "the root of the indicator that a plaquette of one orientation is large is at most $q < 1$" Inferred (steps 2–5 of the proof in 22-01 bound this quantity). The published construction does not use the chessboard to estimate the probability of sets of large plaquettes Inferred (within the range of a search by name). Large fields are handled by another mechanism within each step of renormalisation (22-02).

04

The scope that applies to the whole part

- **One scale.** These are statements about the Wilson measure itself on a fine lattice at a fixed lattice spacing. Nothing is said about the measure at a coarse scale pushed forward by the block map (19-04).
- **Uniform in the volume, not uniform in the lattice spacing.** The rate does not depend on N, but β is the coupling of a single lattice and has nothing to do with sequences sending the lattice spacing to 0.
- **The weak-coupling side, with an explicit threshold.** $\beta \geq 81$ ($m \geq 2$). For the form with rate $1/4$, only the existence of the threshold is given. Nothing is said about the band of physical interest (β around 2 to 3).
- **Even sides, no twist.** Only even sides, and only the measure without a background twist.

- **A formalisation of a known type.** A formalisation of the chessboard Peierls argument (of Fröhlich–Israel–Lieb–Simon type) for the SU(2) Wilson measure. No novelty is claimed.

05

Order of reading

22-01 (statements, routes of proof, numbers) → 22-02 (what is said and what is not, and the relation to how the published construction handles large fields). How this rarity was planned to be used on the side of the premises is in 28-04.

The scope of what this chapter says

Said	Not said
Lean The three theorems of Table 1 (details in 22-01)	Coarse scales, $\beta < 81$, odd sides, measures with a twist
Source The published construction has the chessboard inequality and the triangle inequality for the root, and uses an estimate of the size of observables measured by the root as an input to the infinite-volume limit	Where that estimate enters the dependency chain of the published theorems (read in 12-03)
Inferred The published construction does not use the chessboard to estimate the probability of large plaquettes. The theorems of this part can presumably be restated in the language of the root	A Lean form of the restatement

Terms used in this chapter — large plaquette, Chessboard Estimate, uniform pattern, chessboard root, seminorm, Peierls argument, reflection positivity, uniform in the volume. Their meanings are in A-02 Glossary.

Next chapter to read: 22-01 Rarity of large plaquettes — the chessboard estimate — the statements and routes of proof of the three theorems of this part.

Rarity of large plaquettes — the chessboard estimate

This chapter is this book's own investigation. § 01 is established knowledge.

Scope — The theorems of this chapter are statements about the SU(2) Wilson measure itself at one scale (the fine lattice with the lattice spacing fixed). They say nothing about the blocked measure at a coarse scale, about fields with a background (such as twists), or about estimates uniform across steps. They are uniform in the volume (the size of the torus), but not in the lattice spacing. A summary of the scope of the whole part and of what is not said is in 22-02.

What this chapter shows — For the Wilson measure on the torus $(\mathbb{Z}/N)^4$ with even side $N = 2m$, we read three things: (1) a chessboard estimate for the expectation of products of functions of the links of a unit cube placed block by block (all β, all $m \geq 1$); (2) for $\beta \geq 81$ and $m \geq 2$, the probability that every plaquette of a set X of plaquettes has $\operatorname{Re} U_p < 0$ is $\leq q_1^{\lfloor |X|/6 \rfloor}$, with $q_1 < 1$ independent of N and X; (3) a form with rate $1/4$ that includes $m = 1$.

Prerequisite chapters — 22-00 Entrance (the list of theorems of this part, and the scope that applies to the whole part); 19-01 The Wilson measure, plaquettes and holonomy, the product of Haar measures; 20-01 Reflection positivity; 26-05 § The Chessboard Estimate.

Said first — The scope is as written directly under the title. There are three further points. (1) The q_1 of (4) is written with the true volume $h(1/20)$ of the cap, but what Lean pins down as a number goes only as far as $h(1/20) \geq 83^{-4}$, and the upper bound $e^{-0.88\beta} 83^{16}$ on q_1 is about $2.5 \cdot 10^{12}$ times the true q_1 Reading . The threshold 81 is determined by this upper bound; with the true h it would be about 48 Reading . (2) The threshold $\beta \geq 81$ is a value of convenience for the proof, far from the β of physical interest (the band 2–3). (3) The probability is a ratio to the partition function Z, not a ratio to any other quantity (such as a twisted partition function or a partition function restricted to small fields). Every theorem is a formalisation of a known type, the chessboard Peierls argument from reflection positivity Cited .

The order of this chapter

1. The chessboard and the Peierls argument — spreading an event into a uniform pattern by reflections, and comparing energy with entropy
2. Setting — large plaquettes and caps — the event $\mathrm{Re}\, U_p < 1 - y$, the volume $h(r)$ of a cap
3. The chessboard estimate — every even side, every β
4. Rarity uniform in the volume — $\beta \geq 81 - q_1^{\lfloor |X|/6 \rfloor}$, $q_1 < 1$
5. The route of the proof of rarity — reflection positivity → uniform pattern → an upper bound on the action and a lower bound on the partition function → pigeonhole
6. Detour: the bookkeeping behind $48r^2$ and $h(r)^4$ — the numbers of plaquettes and links per lattice site
7. The form with rate $1/4$ — including $m = 1$ — the threshold exists, nothing more
8. Strength — in numbers — the lower bound on the volume of the cap and its true value, the values of the thresholds
9. What is not said — coarse scales, backgrounds, $\beta < 81$, other ratios

---

01

The chessboard and the Peierls argument

The introduction is 26-05 § The chessboard estimate and 20-01. For a reflection-positive measure, the expectation of a product of functions placed block by block is bounded by the geometric mean of the expectations of the "uniform patterns" in which each function is carried by reflections to all the blocks (the chessboard estimate, Fröhlich–Israel–Lieb–Simon)Cited .

Using this to estimate rare events is the chessboard Peierls argumentCited . When the event to be estimated (a plaquette at some place is large) is carried by reflections to all the blocks, it becomes the event of a "uniform pattern" in which the plaquettes are large at every place. The weight of the uniform-pattern event loses a lot in the action, so it is exponentially small compared with the partition function Z. The $1/|\text{number of blocks}|$-th power of that ratio becomes the rate per plaquette. The key point of this argument is that the rate does not depend on the volume.

The theorems of this chapter formalise this argument for the SU(2) Wilson measure. They are not results of a new type.

02

Setting — large plaquettes and caps

The lattice is $(\mathbb{Z}/N)^4$, $N = 2m$. The measure is the Wilson measure of 19-01 (not normalised),

$$d\mu_W(U) = \prod_{\ell} dh(U_\ell)\ \exp\Big(\beta \sum_{p} \operatorname{Re} U_p\Big), \qquad Z = \mu_W(\text{whole space}), \tag{1}$$

where h is the Haar probability measure of $SU(2)$, and the sum over plaquettes is over the $6N^4$ unoriented plaquettes $(x; \mu < \nu)$. Lean: `TorusRP.wilsonMeasure`; Z is `FoldPeierls.Zw` (the total mass). This chapter numbers the directions 1 to 4 (the Lean indices 0 to 3 are directions 1 to 4; 19-01 § Numbering of directions).

Large plaquettes. For a threshold $y \in (0, 2]$, a plaquette p is called "large" when $1 - \operatorname{Re} U_p > y$. For $y = 1$ this is $\operatorname{Re} U_p < 0$. Lean: `FoldEntropy.bigP N y ω p` (an indicator function, strict inequality). $\operatorname{Re} U$ is $\frac{1}{2}\operatorname{tr} U$, and $1 - \operatorname{Re} U = |U - 1|^2/2$ (regarding U as a unit quaternion).

Caps. We write $h(r)$ for the Haar volume of the open cap $\{U \in SU(2) : |U - 1| < r\}$ around the identity ($|\cdot|$ is the quaternion norm). Lean: `FoldEntropy.ballQ r`; $h(r)$ is `haarBall.real (ballQ r)`.

For a set X of plaquettes, $\int \prod_{p \in X} \mathbf{1}[p \text{ is large}]\, d\mu_W / Z$ is the probability of the event "all plaquettes of X are large". No condition is put on plaquettes outside X.

03

The chessboard estimate

The blocks are unit cubes, one for each point w of $(\mathbb{Z}/N)^4$, N^4 in all. A bounded measurable function that depends only on the links inside the cube at the origin (links whose starting point has all coordinates 0 or 1 and whose coordinate in their own direction is 0) is called "a function of the block at the origin". Ψ_w is a map of configurations which, for each coordinate direction, composes a translation if the coordinate of w is even and a reflection if it is odd. For a function f of the block at the origin, $f \circ \Psi_w$ is the function carried to block w.

The chessboard estimate Lean: `FoldWilson.wilson_chessboard_even`. For $N = 2m$ ($m \geq 1$), every real β, a family (f_i) of functions of the block at the origin, and an assignment $F : (\mathbb{Z}/N)^4 \to I$,

$$V(F) = \int \prod_{w} f_{F(w)}\big(\Psi_w U\big)\, d\mu_W(U), \qquad |V(F)|^{N^4} \;\le\; \prod_{w} V\big(\text{the constant assignment } F(\cdot$$

Meaning. Whatever function is placed on whatever block, the expectation of the product is bounded by the geometric mean of the expectations of the uniform patterns in which each function is placed on all the blocks. The side need not be a power of 2. For $f \equiv 1$ both sides are Z^{N^4} and equality holds.

The route of the proof has three stages. (i) On a ring $\mathbb{Z}/2m$ in one direction, derive $|V(F)|^{2m} \le \prod_t V(\text{constant } F(t))$ from the "folding inequality" $V(F)^2 \le V(F^+)V(F^-)$ for reflections in all planes and from $V(\text{constant}) \ge 0$ (`FoldChess.chess_one`). To avoid being restricted to powers of 2, we use the argument of Fröhlich–Israel–Lieb–Simon, which takes the maximum of a ratio over a finite family of ranges and uses that folding preserves the maximum. In a model with a one-dimensional transfer kernel, the conclusion is not violated for reflection-positive kernels, and is violated for kernels that are not positive Reading . (ii) Apply it once in each of the four directions (`FoldChess.chess_four`). (iii) Derive the folding inequality from reflection positivity for planes through lattice sites in Cauchy–Schwarz form (20-01, every real β), and from the invariance of the measure under reflections and translations (`FoldChess.chess_data`; the concrete discharge is `FoldWilson.data`).

04

Rarity uniform in the volume — $\beta \ge 81$

Theorem of rarity uniform in the volume Lean: `FoldCap.rarity_explicit`. Set

$$q_1 = \frac{e^{\beta(48\cdot(1/20)^4 - 1)}}{h(1/20)^4} = \frac{e^{-0.88\,\beta}}{h(1/20)^4} \quad (3)$$

Then $q_1 < 1$ for every $\beta \ge 81$. Moreover, for every $m \ge 2$ ($N = 2m$) and every set X of unoriented plaquettes of $(\mathbb{Z}/N)^4$,

$$\int \prod_{p \in X} \mathbf{1}\big[\operatorname{Re} U_p < 0\big]\, d\mu_W \;\le\; Z \cdot q_1^{\lfloor |X|/6 \rfloor}. \quad (4)$$

The order of quantifiers is "for each β, there is a q_1 determined by β alone, and for all N and all X". q_1 depends neither on N nor on X.

Meaning. When the coupling is weak (β large), configurations in which many plaquettes are strongly twisted at once are exponentially unlikely in the number of twisted plaquettes, at a rate that does not depend on the size of the lattice. There is content from $|X| \ge 6$ onward (for $|X| < 6$ the right-hand side is Z). The event is not

empty. There is a configuration with $\mathrm{Re}\, U_p = -1$ on every plaquette (a fully frustrated $\mathbb{Z}_2$ configuration), and positive weight sits on an open set near it, so the left-hand side is positive for every X Proved here .

An intermediate form (also in Lean): for a general threshold $0 < y \le 2$, there exist $r > 0$ and β_0 (in the proof $r = y/20$) such that for $\beta \ge \beta_0$, $q1 = e^{\beta(48r^2 - y)}/h(r)^4 < 1$ and the form (4) holds (`FoldMix.rarity_uniform_all_mix`, $m \ge 2$). For plaquettes of a single orientation only, the rate is 1 per plaquette (`FoldMix.rarity_orient`).

05

The route of the proof of rarity

1. **Reflection positivity in four directions.** In directions 1 and 2 we use reflections in planes through lattice sites (every real β); in directions 3 and 4, reflections in planes through link midpoints (gauge-invariant functions, $\beta \ge 0$, $m \ge 2$) (20-01). Mixing in the midpoint planes makes the blocks lattice sites, and the carried plaquettes are distinct across all N^4 blocks. The indicator of a plaquette is gauge invariant ($\mathrm{Re}\, U_p$ is invariant). This builds the vessel of § 03 (`FoldMix.dataMix`). $m \ge 2$ is the condition of this stage.
2. **To a uniform pattern.** Place the block function "the plaquette of orientation $(1, 2)$ at the origin is large" on the blocks of a set S of lattice sites, place 1 elsewhere, and use (2): the probability is bounded by the $|S|/N^4$-th power of the weight of the event "all N^4 plaquettes of orientation $(1, 2)$ are large".
3. **The weight of the uniform pattern (energy).** On that event, $\mathrm{Re}\, U_p < 1 - y$ on N^4 plaquettes and $\mathrm{Re}\, U_p \le 1$ on the others, so the action is $\le 6N^4 - yN^4$ and the weight is $\le e^{\beta(6N^4 - yN^4)}$ (in the form of `FoldMix.action_le_mix`).
4. **A lower bound on the partition function (entropy).** If every link is placed in the cap $|U - 1| < r$, each plaquette is a product of four, so $|U_p - 1| \le 4r$ and hence $\mathrm{Re}\, U_p \ge 1 - 8r^2$. The Haar weight of this set of configurations is $h(r)^{4N^4}$, so $Z \ge e^{6N^4\beta(1-8r^2)} h(r)^{4N^4}$ (`FoldEntropy.Zw_ge`).
5. **Take the ratio.** Dividing 3 by 4 and taking the $1/N^4$-th power gives $q = e^{\beta(48r^2 - y)}/h(r)^4$ per plaquette.
6. **Align the orientations.** The measure is unchanged by involutions that map the six orientations to $(1, 2)$. A general X has at least $\lfloor |X|/6 \rfloor$ plaquettes of one of the six orientations (pigeonhole), and the indicator functions take values in $[0, 1]$, so we can drop to that subset (`FoldMix.rarity_all_mix`).

7. **An explicit threshold.** With $y = 1$ and $r = 1/20$, $48r^2 - 1 = -0.88$. The volume of the cap is bounded by $h(1/20) \geq 83^{-4}$ using a covering by the lattice $(1/41)\mathbb{Z}^4$ (`FoldCap.ballQ_ge`), and from $e^{71} > 2.718^{71} > 83^{16}$, $q_1 < 1$ for $\beta \geq 81$ (`FoldCap.q_lt_one_explicit`).

Detour: the bookkeeping behind $48r^2$ and $h(r)^4$

You may skip this. Per lattice site there are 6 plaquettes (the number of pairs of directions $\mu < \nu$) and 4 links. In the lower bound on the partition function, each plaquette loses at most $1 - \mathrm{Re}\, U_p \leq 8r^2$, so the loss of action per lattice site is $6 \cdot 8r^2 = 48r^2$, and the Haar weight is $h(r)^4$. On the side of the uniform-pattern event, one plaquette per lattice site loses at least y. Taking the ratio leaves $e^{\beta(48r^2 - y)}/h(r)^4$ per lattice site Proved here . Making r smaller makes $48r^2$ smaller, but $h(r)$ also shrinks at the rate r^3, so to get $q < 1$, β must be taken to be several times $\log(1/h(r))$. This is why the threshold is large.

06

The form with rate $1/4$ — including $m = 1$

Theorem of rarity with rate $1/4$ Lean: `FoldQuarter.rarity_uniform4`. For $0 < y \leq 2$, there exist $r > 0$ and β_0 such that for every $\beta \geq \beta_0$, $q_4 = e^{\beta(48r^2 - y/4)}/h(r)^4 < 1$, and for every $N = 2m$ ($m \geq 1$, in particular including $N = 2$) and every set X of plaquettes,

$$\int \prod_{p \in X} \mathbf{1}\left[1 - \mathrm{Re}\, U_p > y\right] d\mu_W \;\leq\; Z \cdot q_4^{\lfloor |X|/24 \rfloor}. \tag{5}$$

There are two differences. Since it is built only with reflections in planes through lattice sites, without those through link midpoints, the condition $m \geq 2$ is not needed; in exchange, the distinct plaquettes in a uniform pattern number $N^4/4$, and the rate becomes $1/4$. A general X is split into 24 classes (6 orientations $\times$ 4 parities of the outer directions) and pigeonhole is used.

The Lean statement asserts only the existence of r and β_0. In the proof, $r = y/1000$, and β_0 is taken as an expression containing $h(r)$; its numerical value is not in Lean. Putting in numbers with the formula for the volume of the cap gives $\beta_0 \approx 357$ at $y = 1$ Reading . The only explicit threshold held as a number inside Lean is the $\beta \geq 81$ of § 04 ($m \geq 2$).

07

Strength — in numbers

Quantity	Value	Label
True value of the volume $h(1/20)$ of the cap (formula $(\vartheta - \sin\vartheta\cos\vartheta)/\pi$, $\vartheta = 2\arcsin(1/40)$)	$2.652 \cdot 10^{-5}$	Reading
Lean's lower bound 83^{-4}	$2.107 \cdot 10^{-8}$	Reading
Ratio (true value / lower bound)	1259	Reading
Loss in the upper bound on q_1 (1259^4)	$\approx 2.5 \cdot 10^{12}$	Reading
q_1 at $\beta = 81$: Lean's upper bound / with the true h	0.56 / $2.2 \cdot 10^{-13}$	Reading
Threshold for $q_1 < 1$: with Lean's lower bound / with the true h	80.34 / 47.9	Reading
Threshold of the form with rate $1/4$ ($y = 1$, $r = y/1000$ as in the proof)	357	Reading

The upper bound should be far from the true probability, but there is no record comparing it numerically with the true probability at β above the threshold. What can be said goes only as far as the form of the rate and the threshold. A direct estimate without the chessboard diverges as $N \to \infty$ with X fixed, so it is not uniform in the volume. At small volumes the direct estimate can be the stronger one. The value of this chapter's estimate is that it is uniform in the volume, and in exchange the constants are weak.

08

What is not said

- **Coarse scales.** These are theorems at one scale (about the Wilson measure on the fine lattice itself). They do not reach estimates of large fields for the measure at a coarse scale pushed forward by the block map (19-04). Estimates of large fields across steps are on the side of the premises (28-04).
- **Lattice spacing.** They are uniform in the volume, but β is the coupling on a fixed lattice, and has nothing to do with the limit in which the lattice spacing is sent to 0.
- **Range of β.** § 04 covers only $\beta \geq 81$, and § 06 only couplings at or above a β_0 that is known only to exist. Nothing is said about the physical band (β between 2 and 3). 81 is a value of convenience for the proof.
- **Parity of the side.** Only even sides. § 04 needs $m \geq 2$; $m = 1$ ($N = 2$) is covered only by the form with rate $1/4$ of § 06.
- **What the ratio is taken against.** The probability is a ratio to Z. It is not a ratio to a partition function restricted to small-field events, nor to a twisted partition function.

- **Backgrounds.** Only the Wilson measure without twist (19-02).

What this chapter can say

Can say	Cannot say
Chessboard estimate: for $N = 2m$ ($m \geq 1$), every real β, and a family of functions of the links of a unit cube, $\lvert V(F)\rvert^{N^4} \leq \prod_w V(\text{constant})$. Lean: `FoldWilson.wilson_chessboard_even`	Odd sides. Measures with a twist
$\beta \geq 81$, $m \geq 2$: $P(X\text{: all its plaquettes have } \mathrm{Re}\, U_p < 0) \leq q_1^{\lfloor \lvert X\rvert/6 \rfloor}$, with $q_1 < 1$ independent of N and X. Lean: `FoldCap.rarity_explicit`	$\beta < 81$, $m = 1$. The measure at a coarse scale. The threshold 81 is a value fixed by a crude lower bound on the volume of the cap (with the true h about 48 Reading)
$0 < y \leq 2$, at or above some existing β_0, all $m \geq 1$: the form with rate $1/4$, $\leq q_4^{\lfloor \lvert X\rvert/24 \rfloor}$. Lean: `FoldQuarter.rarity_uniform4`	The value of β_0 (about 357 at $y = 1$ is Reading)
$Z \geq e^{6N^4\beta(1-8r^2)} h(r)^{4N^4}$ ($\beta \geq 0$). Lean: `FoldEntropy.Zw_ge`	—
$h(1/20) \geq 83^{-4}$. Lean: `FoldCap.ballQ_ge`	A Lean form of the true value of the volume of the cap

Terms used in this chapter — large plaquette, cap, chessboard estimate, uniform pattern, reflection positivity, plane through lattice sites, plane through link midpoints, Peierls argument, partition function, pigeonhole. Their meanings are in A-02 Glossary.

Next chapter to read: 22-02 What this part says, and what it does not — the theorems of Part 22 laid out in one table, checking the scope and what is not said.

What this part says, and what it does not

> This chapter is a guide. § 03 and § 04 are a map of open questions.

What this chapter shows — We lay out the theorems of Part 22 in one table and check their scope and what they do not say. We then describe what it means that this rarity is "a statement at one scale", how it relates to the published construction's handling of large fields by recounting them within each step of renormalisation, and the distance between statements of this type and the questions that remain (as an inference).

Prerequisite chapters — 22-00 Entrance, 22-01 Rarity of large plaquettes — the chessboard estimate. The published construction's handling of large fields is in 11-03 and 11-04.

Said first — This chapter adds no new theorem. The comparisons and assessments of § 03 and § 04 come from reading the statements in the source of the published construction Source and from inferences drawn from them Inferred . We do not say that the rarity of this part yields uniqueness of the infinite-volume limit or the mass gap.

The order of this chapter

1. List of theorems — scope and what is not said — Table 1
2. A statement at one scale — nothing is said about scales after renormalisation
3. Large fields in the published construction — recounting step by step — an inequality on the side of the action, and rarity on the side of the measure
4. Distance to the questions that remain — an estimate of the type that controls large fields (an inference)
5. What the part as a whole does not say

Labels — Source = we read the source of the published construction; Inferred = this book's inference; Assessment = from the committee's assessment (details in "Labels" in 6-00). Proved here, Cited, Computer-assisted, Reading, Assumption and Lean are the labels of the whole book; Reading is a numerical reading of this book, and Lean a Lean theorem of this book. Source: `yang-mills-group/OpenAI-YM-20261028` (Apache-2.0).

01

List of theorems — scope and what is not said

Theorem	Scope	What is not said	Lean
The Chessboard Estimate	$N = 2m$ ($m \geq 1$), all real β, families of functions of the links of a unit cube	Odd sides, measures with a twist, measures at a coarse scale	`FoldWilson.wilson_chessboard_even`
Rarity uniform in the volume	$\beta \geq 81$, $m \geq 2$, any set X of plaquettes: probability $\leq q_1^{\lfloor \lvert X\rvert/6\rfloor}$, with $q_1 < 1$ independent of N and X	$\beta < 81$, $m = 1$, coarse scales. 81 is a value fixed by a coarse lower bound on the volume of the cap (with the true volume it would be about 48 Reading)	`FoldCap.rarity_explicit`
The form with rate $1/4$	$0 < y \leq 2$, at or above some β_0, all $m \geq 1$: probability $\leq q_4^{\lfloor \lvert X\rvert/24\rfloor}$	The value of β_0 (about 357 for $y = 1$ is Reading)	`FoldQuarter.rarity_uniform4`
Lower bound on the partition function	$\beta \geq 0$: $Z \geq e^{6N^4\beta(1-8r^2)} h(r)^{4N^4}$	—	`FoldEntropy.Zw_ge`
Lower bound on the volume of the cap	For $K \geq 2$ and $2/K < r$, $h(r) \geq 1/(2K+1)^4$. With $K = 41$, $r = 1/20$, $h(1/20) \geq 83^{-4}$	A Lean form of the true value of the volume of the cap	`FoldCap.ballQ_ge`

Table 1. The theorems of Part 22. Each is a formalisation in this book's Lean of the type of the chessboard Peierls argument from reflection positivity Lean . Notation as in 22-01.

Probabilities are ratios to the partition function Z. They are not ratios to a partition function restricted to small-field events, nor to a twisted partition function. The upper bounds should be far from the true probabilities, but there is no record of a numerical

comparison with the true probabilities at β above the threshold. What can be said goes only as far as the form of the rate and the threshold (22-01 § 07).

02

A statement at one scale

The theorems of this part are statements about the Wilson measure itself on a fine lattice at a fixed lattice spacing. β is the coupling of that lattice, and no operation changing the lattice spacing is involved.

- **Nothing is said about scales after renormalisation.** Whether large coarse plaquettes are rare for the measure pushed forward to a coarse lattice by the block map (19-04) does not follow from the theorems of this part. The push-forward averages and composes the deviations of plaquettes, so there is no guarantee that the rarity of fine plaquettes becomes, as it stands, the rarity of coarse plaquettes Proved here .
- **Rarity uniform across steps is on the side of the premises.** Rarity of the same form at every step of renormalisation (with constants independent of the step and the lattice spacing) is placed as a premise in this book's study and is not shown (28-04, the large-field rarity condition).
- **Uniform in the volume, not uniform in the lattice spacing.** In the continuum limit β moves with the lattice spacing, so a statement at fixed β is not, as it stands, an estimate for any step of a continuum-limit sequence Proved here .

03

Large fields in the published construction — recounting step by step

The published construction too has to deal with large fields (places where the deviation of a plaquette exceeds a threshold). Its handling is of a different kind from the rarity of this part.

- **The form of the density.** The effective density at each step is carried in the form of a product of the exponential of an action truncated to be quadratic up to the threshold and linear beyond it, and a gas of large-field activities (forced activities) Source (11-01).
- **Recounting step by step.** The "seeds" of large fields are recounted at each step from the field of that step. It is not of the type in which a region that has once become a large field is fixed from then on Source . A persistent defect has its price paid again at each step Inferred .

- **Energy per seed.** The key of one step is a configuration-wise inequality: the difference of actions inside the halo is bounded below in proportion to the number of seeds (`Next.Fluctuations.grants`, `YM/Next/FLUCTUATIONS/Grants.lean:24`; with assumptions such as a gauge slice (`SliceSet`), regions (`Plot`) and `Funds`) Source . In the record of how declarations are used, this inequality is reached from one of the headline theorems (`SharpGram.habitat`) Source . How to read it is in 11-04. Where this inequality enters the dependency chain of the published theorems has not been checked.

The difference from the rarity of this part is as shown in Table 2 Inferred .

	Large fields in the published construction	Rarity in this part
Kind of statement	A configuration-wise inequality for the action (for all configurations, with conditions)	A statement about the measure (probabilities of events)
Scale	Each step of renormalisation, recounted step by step	One scale of the fine lattice
Coupling	Inside the weak-coupling band at every step	$\beta \geq 81$ (the coupling of one lattice)
Volume	The ledger of one step is a pointwise sum and does not depend on the volume. Estimates at the level of the density contain an exponential in the volume Source	The rate is uniform in the volume
Tools	Decomposition of the action, regions, partitions of unity, polymer sums	Reflection positivity, the chessboard, Peierls

Table 2. Two ways of handling large fields.

Neither follows from the other Inferred . The inequality of the published construction is a statement about the action within a step and says nothing about the rarity of a measure. The rarity of this part is a statement about the measure at one scale and says nothing about estimates across steps. What the published construction uses as estimates uniform in the volume are such things as the chessboard-root estimate on the side of the Wilson measure (22-00 § 03), and there too the chessboard is not used for the probability of large plaquettes Inferred (within the range of a search by name).

04

Distance to the questions that remain

This section is an inference Inferred .

One of the open questions in the assessment is the convergence and uniqueness of the infinite-volume limit (16-02). The published construction takes the infinite-volume

limit as a subsequence by compactness, and includes neither estimates of differences when the volume is changed nor material for uniqueness Source .

Arguments that show uniqueness usually take as a component some "lack of disorder" uniform in the volume. For uniqueness in the strong-coupling window (20-03), this was the Dobrushin condition (the smallness of the influence that one link receives from its surroundings). The rarity of this part provides, as a statement about the measure, a lack of disorder of the form "configurations with many large plaquettes are rare, at a rate independent of the volume" on the weak-coupling side. It is an estimate of the type that controls large fields and, like the Dobrushin condition in the strong-coupling window, has the form of a lack of disorder uniform in the volume. Its object, however, is the measure at one lattice spacing, which is different from the object of the assessment's question (the infinite-volume limit of the continuum theory).

For the following three reasons, the rarity of this part does not yield uniqueness.

1. Rarity alone says nothing about long-range correlations on the side of small fields (plaquettes that are not large). Uniqueness needs decay on that side, or an argument that replaces it.
2. It is a statement about one lattice with $\beta \geq 81$, a different object from the one for which the published construction takes infinite volume (correlation functions with the continuum limit taken first).
3. There is no rarity at renormalised scales (§ 02), so it is not in a form usable along a continuum-limit sequence.

Whether a statement of the same type can become a component of an argument for the mass gap (uniform decay) likewise remains open.

05

What the part as a whole does not say

- **Coarse scales.** Rarity of the pushed-forward measure and rarity uniform across steps are not said.
- **The range of β.** $\beta \geq 81$ (explicit), and at or above a β_0 whose existence only is given. Nothing is said about the physical band (β around 2 to 3).
- **Sides and background.** Only even sides and measures without a twist.
- **What the ratio is taken against.** Probabilities are ratios to Z.
- **Uniqueness, the mass gap, the continuum limit.** None of these follows from the theorems of this part.
- **Not a new result.** It is a formalisation of the chessboard Peierls argument for the SU(2) Wilson measure.

The scope of what this chapter says

Said	Not said
Lean The five items of Table 1 (the Chessboard Estimate, rarity uniform in the volume, the form with rate 1/4, the lower bound on the partition function, the lower bound on the volume of the cap). Details in 22-01	Coarse scales, $\beta < 81$, odd sides, measures with a twist
Source The published construction recounts large fields at each step and handles them by a configuration-wise inequality on the energy per seed	The path by which that inequality enters the chain of the published theorems (not checked)
Inferred Neither handling yields the other. The rarity of this part is an estimate of the type that controls large fields (in the form of a lack of disorder uniform in the volume)	A road to uniqueness or the mass gap

Entrance to Part 23 — the staircase, and the random walk, the ruler and the clock

> This chapter is a guide (the entrance to this part).

This part is a record of the study. The theorems that have been machine-checked are in Parts 20–22, and the current list of premises is in 28-04.

What this chapter shows — Part 23 is the part that examines a road to the mass gap with the diffusive-relaxation-time assumption (the time over which fluctuations are smoothed out grows as a power of the square of the correlation length) as its axis. The diffusive-relaxation-time assumption is one sentence that restates a quantity of the problem statement (the gap in Euclidean time) as a quantity that can be computed on the lattice and that machine checking can reach (the relaxation time of Langevin dynamics). This part divides that sentence into a staircase of four steps, and lays out how far the claim has been built on the first step (the path measure of the double well in 0+1 dimensions). In this chapter, after looking at the picture of the staircase and the map of the part, we set up quantities such as the correlation length ξ and the Poincaré constant C_P one by one, with the metaphors of the random walk, the ruler and the clock.

Prerequisite chapters — 2-10 (relaxation time and the dynamical exponent), 4-11 (definition of the mass gap and the correlation length), 2-07 (the path integral and imaginary time).

Said first — This chapter is an entrance that lines up quantities through metaphors, and proves nothing. The relaxation-time assumption is an unproved assumption. The precise definitions are placed in 23-01 (the side of the four-dimensional lattice) and 23-04 (the side of the double well).

The order of this chapter

1. A map of the part — the list of eighteen chapters, and how to read the labels
2. The four steps of the staircase — from the double well to the mass gap in the limit (Figure 1)
3. The ruler — the correlation length ξ — in how many steps correlations die out

4. The smearing time — the Poincaré constant C_P — L^2 steps to even out a length L (Table 3). Detour: why the random walk goes as a square
5. The scale and the clock — the remaining three quantities — the number of rescalings, the graduation of the clock, the clock that runs slow
6. The relaxation-time assumption in one sentence — smearing time $\asymp$ ruler^2. "Some f" and "every f"
7. How to walk through Part 23 — in which chapter each metaphor becomes a precise sentence

---

01

A map of the part — the list of eighteen chapters, and how to read the labels

This part is a study with the relaxation-time assumption (the time over which fluctuations are smoothed out grows as a power of the square of the correlation length) as its axis. The relaxation-time assumption is not the mass gap itself but a sentence that restates it as a quantity of a dynamics measurable on the lattice (23-01 § 05), and this part builds that sentence on the first step of a four-step staircase — the path measure of the double well in 0+1 dimensions. We split the claim of the first step into four conditions, and for each condition lay out in one table the rows where a proof is given, rows citing original sources, computer-assisted rows, rows of numerical reading, and assumption rows.

The eighteen chapters of Part 23

0. **23-00 Entrance — the staircase, and the random walk, the ruler and the clock** [Y2] (this chapter)
1. 23-01 The line of construction and the diffusive-relaxation-time assumption [Y2]–[Y3]
2. 23-02 Roads tried on the four-dimensional lattice, and walls [Y3]
3. 23-03 The four steps of the staircase — why we start from 0+1 dimensions [Y2]
4. 23-04 The path measure of the double well, and kinks [Y2]–[Y3]
5. 23-05 The statement of the first step — the four double-well conditions and the upper-bound proposition [Y3]
6. 23-06 The in-phase local Poincaré condition [Res]
7. 23-07 The map of the saddle-tube condition — seven routes and the seam of the ring [Y3]

8. 23-08 What computer-assisted means — the conditions on the chain inside the window [Y2]–[Y3]
9. 23-09 The sector framework and the three strands of the window log-Sobolev route [Res]
10. 23-10 The list of detour plans — types of breakage [Y3]–[Res]
11. 23-11 Box reduction and the gap inside the box — the constant of the core [Res]
12. 23-12 The integrated table and the dependency graph [Y3]
13. 23-13 Lean statements and the limits of machine checking [Y2]–[Y3]
14. 23-14 Reconciliation — the numbers of the record and the known numbers [Y3]
15. 23-15 What remains and its cost — the distance to a theorem [Y3]
16. 23-16 What is not claimed [Y2]
17. 23-17 Insights and small questions [Y2]–[Y3]

The chapters run: why this assumption (23-00 to 23-02), the statement of the first step (23-03 to 23-05), the four conditions (23-06 to 23-11), the overall tables (23-12, 23-13), and reconciliation and what remains (23-14 to 23-17). The marks [Y2], [Y3] and [Res] are reader levels: [Y2] is second-year, [Y3] third-year and above (using measures, operators and Poincaré inequalities), and [Res] is research level. This chapter is [Y2]. Viewpoints other than the relaxation-time assumption, and new views that take the relaxation-time assumption as a premise, are placed in Part 24 The first road, second half.

The labels of this part

In this part the strength of a claim is divided by five labels (the labels of 0-01 § 03, refined for the material of this part). Each sentence gets one label; a sentence needing two is split.

Table 1 The five labels of this part (Lean is a column outside the labels)

Label	Meaning	What it does not guarantee
Proved here	Elementary. The proof is placed in the text or at the end of the chapter	That it contains no error (it is placed in a form the reader can check)
Cited	A known theorem cited from the original source (or a secondary source whose statement was checked)	That it is a result of this book
Computer-assisted	Computer-assisted. Checked as an inequality by interval arithmetic (premises such as rounding conventions are written on the same row)	That it holds outside the range computed

Label	Meaning	What it does not guarantee
Reading	A reading. Floating-point numbers, Monte Carlo, fits. The kind (a point value, a lower bound over a family, etc.) is added	That it is a proof of an upper or lower bound
Assumption	An assumption. A row put down without a proof. It is given a name	That it holds

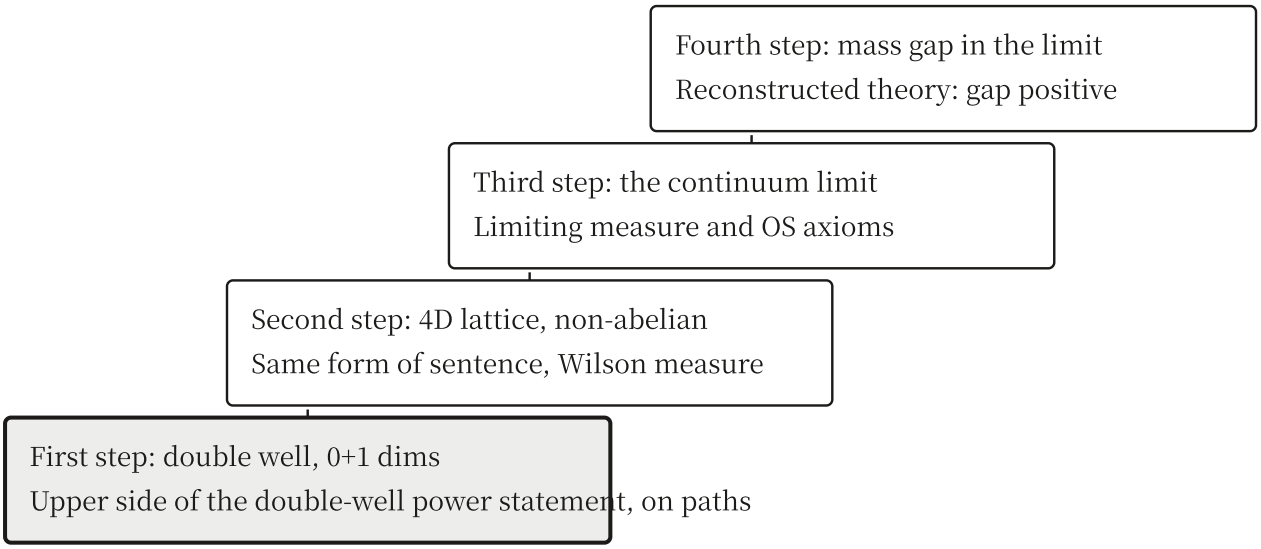
Lean is a column separate from the five labels. A Lean theorem is the "algebra from assumptions to conclusion" checked by machine, and the theorem name and the assumptions of that theorem are written on the same row. Whether the assumptions are true is outside the check (23-13).

02

The four steps of the staircase — from the double well to the mass gap in the limit

The relaxation-time assumption is the sentence "in some family of measures, the time over which fluctuations are smoothed out grows as a power of the square of the correlation length", and it can be stated independently of dimension. So we line up sentences of the same form in four steps, from easy places to hard ones.

Figure 1 The four steps of the staircase. This part deals with the inside of the first step; the arrows from the second step upwards stand for "a sentence of the same form", not for theorems of implication



Written out in words, Figure 1 is as follows. From the bottom: the first step = the double well in 0+1 dimensions (the path measure in imaginary time of a quantum-mechanical model); the second step = the non-abelian gauge theory on the four-dimensional lattice (the Wilson measure); the third step = the continuum limit with the lattice spacing taken to 0, and that limit satisfying the Osterwalder–Schrader axioms; the fourth step = the mass gap of the limiting theory.

Table 2 The objects of the four steps, and what can be called "closed" at each step

Step	Object	Form in which it can be called closed	State in this book

Step	Object	Form in which it can be called closed	State in this book
First step	The path measure of the double well in 0+1 dimensions (parameter $\hbar$)	Show the upper side of the double-well power statement (an upper bound on C_P), with a table of finitely many assumption rows	Split into the four double-well conditions, and up to the algebra on top of them (the Double-Well Relaxation-Time Upper-Bound Proposition). Every condition leaves Assumption rows
Second step	The Wilson measure on the four-dimensional lattice (parameter β)	A sentence of the same form, as $\beta \to \infty$	The relaxation-time assumption remains an assumption. Only estimates from below (23-02)
Third step	The limiting measure as the lattice spacing $a \to 0$	The limit exists and satisfies the OS axioms	Not dealt with. That a theory satisfying the Wightman axioms can be built as a limit of four-dimensional Wilson lattice gauge theory was proved in Lean by the construction published on 2026-11-10, according to the committee's assessment (Part 6). A probability measure for the continuum theory and uniqueness of the infinite-volume limit are not shown (6-04)
Fourth step	The reconstructed quantum field theory	The gap of the Hamiltonian is positive (4-11)	Not dealt with. The published construction does not show it either (6-04)

Even if the first step is closed, there is no guarantee that it lifts to the second step and beyond. What has a prospect of lifting is "the form of the sentence" and "the form of the tools"; constants and ranges of parameters do not lift. The reasons are given from both sides in 23-03 § 06.

03

The ruler — the correlation length ξ

Fluctuations are similar between nearby places and become unrelated when far apart. The length over which they become unrelated is the correlation length ξ. As a metaphor, it is the one ruler the measure carries.

As a formula, the correlation of two points (the expectation of the product with the mean subtracted) decreases exponentially with distance r, and the length of that decrease is ξ.

$$\langle O(0)\,O(r)\rangle - \langle O\rangle^2 \;\approx\; C\,e^{-r/\xi}, \qquad \xi = \frac{1}{m} \quad (1)$$

m is the gap of the transfer matrix (or transfer operator), that is, the difference between the lowest eigenvalue and the next, and r is the distance in the imaginary-time direction. That the decay of correlations and the gap are the same quantity is in 4-11 § 02, and the restatement as a correlation length is in 4-11 § 07 Cited .

Example 1 (free field). For the free field on a one-dimensional lattice (a Gaussian chain with neighbours joined by springs, mass m_0), correlations decrease exactly as $e^{-r/\xi}$, and ξ is determined by $m_0^2 = 2(\cosh(1/\xi) - 1)$. For $m_0 = 1$, $\xi \approx 1.04$; for $m_0 = 0.1$, $\xi \approx 10.0$ (18-03 § 05).

Example 2 (double well). In the quantum-mechanical double well (2-05 § 07), the gap is the tunnelling splitting Δ, determined by passing through between the two valleys, and it becomes exponentially small the higher the hill. Seen through paths in imaginary time, the correlation length is $\xi = \hbar/\Delta$, and as $\hbar$ is made smaller it grows at the rate $e^{S_0/\hbar}$ (S_0 is the action of the path that moves from valley to valley). This property, that the ruler grows exponentially, is one of the reasons for choosing the model of the first step (23-03 § 04, 23-04 § 03).

The ξ measurable on the lattice is a number in units of one graduation of the lattice (5-09 § 01). The physical length is ξ times the lattice spacing a, $a\xi$, and in the continuum limit $a\xi$ must remain finite while $a \to 0$. That is, ξ in lattice units must grow to infinity (5-09 § 05). The $\hbar \to 0$ of the double well is the smallest specimen of this regime, "the ruler becomes infinitely long compared with the graduations".

04

The smearing time — the Poincaré constant C_P

Drop a drop of ink on paper, and the ink gradually smears and spreads, and in the end becomes uniformly pale. What the smearing really is, is a random walk of the ink particles. Each particle moves one step left or right at random at each tick. After t steps the spread of the particles (the root-mean-square distance) is $\sqrt{t}$, and evening out a strip of length L takes on the order of L^2 steps.

The Poincaré constant C_P is this "longest time until evening out is finished", defined in general for fluctuations. As a metaphor, it is the reading of the one clock the measure carries: the smearing time.

We write it as a formula. Given a probability measure μ and the "size of the change from place to place" $\mathcal{E}(f)$ of a function f (the Dirichlet form),

$$\mathrm{Var}_\mu(f) \;\le\; C_P\,\mathcal{E}(f) \quad (\text{for every } f), \qquad C_P = \sup_f \frac{\mathrm{Var}_\mu(f)}{\mathcal{E}(f)} \;(2)$$

the best constant is C_P (1-10 § 07). If there is a function with large variance but small change, that is, "a large, slowly varying fluctuation", C_P becomes large. For the diffusion dynamics (Langevin dynamics) with μ as its equilibrium, $1/C_P$ is the gap of that dynamics, and the slowest fluctuation decreases by a factor $1/e$ every time C_P Cited .

Example: the random walk on a single road

Consider a single road of L cells in a row (reflecting at both ends). μ is the uniform distribution, and $\mathcal{E}(f) = \frac{1}{L}\sum_i (f_{i+1} - f_i)^2$. Then the C_P of (2) is the reciprocal of the eigenvalue next after 0 of the Laplacian matrix of the road, and can be written in closed form.

$$C_P(L) = \frac{1}{2\,(1-\cos(\pi/L))} \;\approx\; \frac{L^2}{\pi^2} \qquad (L \to \infty) \;(3)$$

Proved here Proof: $f_i = \cos(\pi(i-\frac{1}{2})/L)$ $(i = 1, \dots, L)$ is an eigenvector of the Laplacian matrix of the road reflecting at both ends, with eigenvalue $2(1-\cos(\pi/L))$ (use $\cos(A+B)+\cos(A-B) = 2\cos A \cos B$ on the sum of the two neighbouring terms, and check that at both ends the mirror conditions $f_0 = f_1$, $f_{L+1} = f_L$ hold). The other eigenvectors are $\cos(\pi k(i-\frac{1}{2})/L)$ $(k = 0, \dots, L-1)$, with eigenvalues increasing with k. Since μ is uniform, Var and $\mathcal{E}$ are divided by the same $1/L$, and the supremum of the ratio is the reciprocal of the eigenvalue next after 0. ∎

Proved here Table 3 C_P of the random walk on a single road (values of the closed formula (3)). C_P/L^2 approaches $1/\pi^2 \approx 0.10132$

L	Gap $2(1-\cos(\pi/L))$	C_P	C_P/L^2
16	0.0384294	26.02	0.10165
32	0.00963055	103.8	0.10140
64	0.00240909	415.1	0.10134
256	0.000150596	6640	0.10132

Doubling L makes the time until evening out is finished four times as long.

The C_P used in this part replaces this single road by "the space of configurations of whole paths". For the double well, the measure $e^{-S/\hbar}$ on the whole of the paths $x(\tau)$ in imaginary time is μ, $\mathcal{E}$ is the expected square of the change when a path is moved slightly, and Langevin dynamics diffuses whole paths along an "artificial time" s (23-04

§ 01). On the four-dimensional lattice, μ is the Wilson measure and what moves are the angles of the links (23-01, 7-09).

For the free field, the slowest fluctuation is in the direction of shifting the whole path uniformly, and its rate is the square of the mass, m_0^2. So $C_P = 1/m_0^2$, and from $m_0^2 = 2(\cosh(1/\xi) - 1)$ of Example 1, C_P/ξ^2 at $\xi = 1, 4, 16, 256$ is 0.921, 0.995, 0.9997, 0.999999, approaching 1 Proved here (values of the closed formula). The smearing time is the square of the ruler: that is the free field's answer.

Precisely, the C_P meant here is the Poincaré constant of "the distribution of configurations over the whole of spacetime (in 0+1 dimensions, imaginary time)" (the path measure). The Poincaré constant of the distribution at a single time (the $|\psi_0|^2$ of the ground state) is a different quantity, and it is tied to the gap of the Hamiltonian. The distinction among the three C_P is placed in 23-01. Known examples in which the power z (the dynamical exponent) with which C_P grows in ξ departs from 2 are in 2-10.

Detour: why the random walk goes as a square

A subsection you may skip. The position X_t after adding t independent steps ± 1 has mean 0, and its variance is t times the variance 1 of one step. This is because for sums of independent things, variances add (1-08).

$$\mathbb{E}[X_t^2] = \sum_{i=1}^{t} \mathbb{E}[\varepsilon_i^2] + \sum_{i \neq j} \mathbb{E}[\varepsilon i]\,\mathbb{E}[\varepsilon j] = t \quad (4)$$

The spread is $\sqrt{t}$, so reaching distance L takes $t \approx L^2$. A wave advances one step per tick, but a random walk goes back and forth, so reaching far is delayed by a square. The "square" of the relaxation-time assumption is this square of the random walk.

05

The scale and the clock — the remaining three quantities

Besides the ruler ξ and the smearing time C_P, there are three quantities that have been used in the record for the four-dimensional lattice. They are not the main players on the first step (the double well), but the reason for putting the relaxation-time assumption as a "power statement" lies here, so we only line up the metaphors.

The ruler	The smearing time	The number of rescalings	The graduation of the clock
The correlation length ξ	The Poincaré constant C_P		

the reciprocal of the gap m (§ 03)	L^2 steps to even out a length L (§ 04)	The bookkeeping length ξ_{RG} the number of steps that coarsen the map	The normalisation of $\mathcal{E}$ in what unit the same fluctuation is measured
`The clock that runs slow` Renormalisation of stochastic time the clock itself stretches with scale			

The number of rescalings. In four-dimensional lattice Yang–Mills there is no way to obtain ξ by formula as a function of the coupling β. So we coarsen the scale of the map one step at a time, and make separately a length that counts how many times it takes to reach a picture of fixed coarseness, the bookkeeping length ξ_{RG}. In the one-loop count, raising β just a little makes the bookkeeping length grow exponentially (4-07). That the bookkeeping length and ξ agree up to a constant factor is an assumption. The definitions and tables have been moved to 23-01 and 23-02.

The graduation of the clock. The C_P of (2) changes value depending on the unit in which $\mathcal{E}$ is measured. Multiplying $\mathcal{E}$ by c multiplies C_P by $1/c$. The same happens for the double well. Between the $\mathcal{E}$ that measures paths by the canonical field $x/\sqrt{\hbar}$ and the $\mathcal{E}_x = \mathcal{E}/\hbar$ that measures them by the position x as it is, $C_P^{(x)} = \hbar\, C_P$ Proved here Lean `ratioR_x_normalisation` (no assumptions; if $C_P^{(x)} = \hbar C_P$, the ratio is also multiplied by $\hbar$). The difference of graduation shows in "the width of a constant factor", but the factor of a power of $\hbar$ is small compared with $\ln \xi$, so it does not show in "the power".

The clock that runs slow. Langevin time itself stretches and shrinks when the scale is changed. In the perturbation theory of stochastic quantisation, the graduation of stochastic time also has to be renormalised (7-09) Cited (at the level of perturbation theory). On the four-dimensional lattice its effect is a factor of a fractional power of β, and this too does not show in the power. How to compare the four clocks is placed in a detour of 23-01.

Precisely, the three of them — the number of rescalings, the graduation of the clock and the clock that runs slow — move sentences stated in "the width of a constant

factor" (band statements), and do not move sentences stated in "a power". That is why the relaxation-time assumption in this part is a power statement.

06

The diffusive-relaxation-time assumption in one sentence — smearing time ≍ ruler²

With the quantities in place, we put the relaxation-time assumption into one sentence as a metaphor: "the smearing time grows with the same power as the square of the ruler". When a family of measures is lined up by one parameter, and moving the parameter makes the ruler grow without bound,

$$(\xi^2): \quad \frac{\ln C_P}{\ln \xi} \longrightarrow 2 \qquad (\xi \to \infty) \tag{5}$$

On the four-dimensional lattice the parameter is β with $\beta \to \infty$; for the double well the parameter is $\hbar$ with $\hbar \to 0$. For the free field it holds with $C_P/\xi^2 \to 1$, as in § 04. The question is whether it holds on the four-dimensional lattice with interaction, and the first step is to build the upper side on the double well, which is easier than that.

For the double well, the "width of a constant factor" sentence stronger than (5) ($C_P \le K\xi^2$) is read as being on the side that breaks. This is because the lower bound on the path C_P grows from 1 times to 6.5 times ξ^2 as $\hbar$ is lowered Reading (lower bound over a family, step $\varepsilon = 0.25$, $\hbar \in [0.07, 0.4]$, 23-04 § 04). In the count at the level of physics that counts kinks, the growth is first order in $S_0/\hbar \approx \ln \xi$ (the numbers in this range alone cannot distinguish it from exponential growth). If it is first order, the power statement (5) is kept. That is why the goal of the first step is not the band statement but the upper side of the power statement, $C_P \le K\xi^2 S_0/\hbar$ (23-03 § 05).

"Some f" and "every f"

The C_P of (2) is a supremum, so bounding it from below and from above differ in difficulty. To bound it from below (C_P is large), it is enough to show one test function with large $\mathrm{Var}(f)/\mathcal{E}(f)$. To bound it from above (C_P is not too large), the inequality must be shown for every f.

$$C_P \ge c\,\xi^2 \iff \exists f: \ \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} \ge c\,\xi^2, \qquad C_P \le C\,\xi^2 \iff \forall f: \ \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} \le C\,\xi^2 \tag{6}$$

As a metaphor, that smearing is slow can be said by showing one stain, but that it is not too slow must be said for every stain. What lies on the side of the mass gap is the upper side (C_P not too large), and test functions and numerics reach only the lower

side. The algebra that rereads the upper side as a lower bound on the mass, and the definitions of the upper and lower halves (the relaxation-time upper-bound assumption and the relaxation-time lower-bound assumption), are placed in 23-01.

Precisely, the lower bound $CP \geq \xi^2$ for the double well is a proposition of the form that a family of test functions local in time (functions of a single time summed over time) reaches up to equality (the One-Dimensional One-Sided Bridge Proposition in 23-04 § 04). On the upper side, even for the first step there are only conditional propositions.

07

How to walk through Part 23 — in which chapter each metaphor becomes a precise sentence

Each metaphor of this chapter is replaced once by a precise sentence somewhere in Part 23. Table 4 matches metaphors, symbols and the chapters that make them precise.

Table 4 Metaphors and the corresponding precise sentences

Metaphor	Symbol	Precise definition or sentence	State
The staircase	Four steps	23-03	The convention for how this part is built
The ruler	$\xi = 1/m$ (for the double well $\xi = \hbar/\Delta$)	4-11 § 07, 23-04 § 02	Cited Definition
The smearing time	CP (the path measure)	23-01, 23-04 § 01	Cited Definition. The value on the four-dimensional lattice is unknown
The number of rescalings	ξ_{RG}	23-01, 23-02	Convention (that it agrees with ξ is Assumption)
The graduation of the clock, the clock that runs slow	Normalisation of $\mathcal{E}$, stochastic time	23-01	Convention, level of perturbation theory
Smearing time $\asymp$ ruler^2	The relaxation-time assumption (power statement)	23-01, 23-03 § 05	Assumption
The upper side of the first step	$CP \leq K\xi^2 S_0/\hbar$ (the First-Step Upper-Bound Proposition)	23-05	Algebra on top of four conditions. The conditions leave Assumption rows

To follow the line first: 23-03 → 23-04 → 23-05 → 23-12 (the integrated table) → 23-15 (the distance to a theorem). To see the relation with the four-dimensional lattice first:

23-01 → 23-02. To see what is not claimed first, 23-16 is the shortcut. The Lean statements and assumptions are in 23-13, and how to read Lean is in A guide to Lean.

What this chapter can say

Said	Not said
Cited That the correlation length and the gap are the same quantity ((1)); the definition of the Poincaré constant, and that the gap of the diffusion dynamics is its reciprocal ((2))	That ξ diverges as $\beta \to \infty$ in four-dimensional lattice Yang–Mills; the value of C_P
Proved here The closed form (3) of C_P for the random walk on a single road; $C_P/\xi^2 \to 1$ for the one-dimensional free field; the mean-square distance $= t$ of the random walk ((4))	That the same ratio agrees in power in a model with interaction (the relaxation-time assumption)
Proved here That multiplying the normalisation by $\hbar$ also multiplies C_P by $\hbar$ (the graduation of the clock in § 05) Lean `ratioR_x_normalisation`	That the bookkeeping length ξ_{RG} of the four-dimensional lattice and the correlation length ξ agree up to a constant factor
Reading That the lower bound on the path C_P of the double well grows from 1 times to 6.5 times ξ^2 (lower bound over a family, $\varepsilon = 0.25$, $\hbar \in [0.07, 0.4]$)	An upper bound on C_P for the double well. The upper side of the first step is conditional on the four conditions (23-05)
The way of building it as a four-step staircase (a convention)	Implication from the first step to the second step and beyond. About the fourth step (the mass gap in the limit), this chapter shows nothing

The line of construction and the diffusive-relaxation-time assumption — eight statements, the direction of the lattice version of the mass gap, and the relaxation-time assumption in six stages

> This chapter is this book's own investigation. § 02 and § 08 are a map of open questions; § 03 is established knowledge.

What this chapter shows — We line up the Clay problem as a single line, "lattice → infinite volume → continuum limit → OS axioms → mass gap", and split it into the eight statements of construction. The mass gap on the lattice is not "the gap in lattice units is uniformly positive" but "the gap in physical units stays positive". The diffusive-relaxation-time assumption, the axis of this part (the time C_P over which fluctuations are smoothed out grows with the same power as the square of the correlation length), is explained in six stages, each with an example that can be checked by hand: what we want to measure; why we restate it as a quantity of a dynamics; the statement (band statement → power statement → upper and lower halves [the relaxation-time upper-bound assumption and the relaxation-time lower-bound assumption]); what the relaxation-time assumption gives; what it does not give; and analogous cases. On a lattice with continuous time the one-sided bridge $C_P \geq \kappa \xi^2$ can be shown, and together with the upper-bound assumption it gives a lower bound on the gap of the lattice in physical units. The converse does not hold in general; under the assumption of the bridge, the upper-bound assumption is a stronger sentence than the lattice mass gap in physical units.

Prerequisite chapters — 0-03 (the problem statement), 5-09 (what to hold fixed when taking the limit), 4-11 (the gap and the correlation length), 1-10 (the Poincaré constant), 23-00 (the five quantities and the labels of the five grades).

Said first — This chapter does not solve the problem. Along the line of this chapter (for each β, first make the volume infinite, then β→∞), what is in hand in four dimensions is only the theorems of the reflection-positivity preservation statement and the OS reconstruction statement, and the infinite-volume uniqueness statement at small β (for the relation to the published construction, see the note in § 02). The relaxation-time assumption, the upper-bound assumption, the lower-bound assumption and the three chains are all assumptions. The one-sided bridge is a proposition on a finite spatial lattice with continuous time; towards the Wilson measure with discretised time and towards infinite volume, assumption rows remain. What was checked in Lean is only the algebra from assumptions to conclusions.

The order of this chapter

1. The conventions of this chapter — symbols, and the unit of the ruler
2. From the problem to the line of construction — eight statements (Table 1) and how they connect
3. The direction of the lattice version of the mass gap — a uniform lattice gap is on the opposite side (Table 2)

4. Restating with the Poincaré constant — three C_P (Table 3) and the free field (Table 4)
5. The relaxation-time assumption — (1) what we want to measure, (2) why we restate it, (3) the band statement, the power statement, the upper and lower halves (Table 5)
6. What the relaxation-time assumption gives and what it does not — (4) the one-sided bridge (Table 6), (5) a counterexample to the converse (the Free-Particle-on-a-Circle Counterexample) and the strong-coupling side (Table 7), (6) analogous cases, classification and the dependency graph (Table 8)
7. Detour: the number of rescalings and four clocks — logarithms that do not show in the power (Tables 9 and 10)
8. What of the line is in hand — on to 23-02 and 23-03

01

The conventions of this chapter — symbols, and the unit of the ruler

This chapter is about the side of the four-dimensional lattice. The group is $SU(2)$, the Wilson action is $S_W = \beta \sum_P (1 - \frac{1}{2} \operatorname{tr} U_P)$ (5-01), and $\beta = 4/g^2$ is the inverse of the coupling, not an inverse temperature. All quantities are counted in lattice units (lattice spacing 1).

$m_{\mathrm{lat}}(\beta)$ is the gap of the transfer matrix on gauge-invariant states (the mass in lattice units), $\xi = 1/m_{\mathrm{lat}}$ the correlation length, and $a(\beta)$ the lattice spacing measured in physical units. The mass in physical units is

$$\xi = \frac{1}{m_{\mathrm{lat}}}, \qquad \Delta(\beta) = \frac{m_{\mathrm{lat}}(\beta)}{a(\beta)} \quad (1)$$

There is more than one way to fix $a(\beta)$. If the string tension σ is taken as the physical unit, $a\sqrt{\sigma}$ is the lattice spacing; in the four-dimensional record of this part, a is set to the reciprocal of a length fixed by counting the steps that coarsen the lattice, the bookkeeping length ξ_{RG} (§ 07). Which one is taken goes into the assumptions of the one-scale chain and the bookkeeping-length chain among the three chains of § 05.

Example: if $m_{\mathrm{lat}} = 0.514$ at $\beta = 2.60$ (a Monte Carlo value of Lucini–Teper), then $\xi = 1.95$ lattice spacings Reading . Δ is a quantity fixed only when this is divided by a; the numbers on the lattice alone do not fix it (5-09).

02

From the problem to the line of construction — eight statements

The problem statement (0-03) asks that a non-trivial quantum Yang–Mills theory exist on $\mathbb{R}^4$, and that the theory have a mass gap $\Delta > 0$. On the road entering from the lattice, we line this up as a single line.

Lattice	Infinite volume	Continuum limit	OS axioms	Mass gap
The Wilson measure on a finite box	Make the box infinite the infinite-volume uniqueness statement, the	$\beta \to \infty$ $(a \to 0)$ the Wilson-loop limit statement, the rotation-recovery statement	Hilbert space and Hamiltonian	The gap in physical units is positive

a probability measure for each β and each volume	reflection-positivity preservation statement		the OS reconstruction statement, the non-triviality statement	the physical-unit gap statement

The order is to make the volume infinite first for the measure at each β, and then take $\beta \to \infty$ (the order of Chatterjee 2018; there is also the order of taking $a \to 0$ first in a finite box, 16-07). Table 1 makes each stage of the line a statement, and the demand of the problem statement becomes the following overall picture.

$$\textbf{the demand of the problem statement} \impliedby (\mathrm{S1}) \wedge (\mathrm{S2}) \wedge (\mathrm{S3}) \wedge (\mathrm{S4}) \wedge (\mathrm{S6}) \wedge (\mathrm{S7}) \wedge (\mathrm{S8}) \quad (2)$$

(2) is an overall picture, not a theorem. The relaxation-time band at the bookkeeping length is not in (2); it is a restatement of the physical-unit gap statement (§ 04).

Table 1 The eight statements of construction and their current status in four dimensions (in formulas they are written with the labels (S1)–(S8))

Statement	Content	Current status in four dimensions	Chapter
Infinite-volume uniqueness statement ((S1) in formulas)	For each β, the infinite-volume limit measure is uniquely determined	Cited Limit points exist by compactness. At small β, existence of the limit (Osterwalder–Seiler 1978) and uniqueness (Shen–Zhu–Zhu 2023). At large β, 'in general unknown' (Chatterjee § 3)	5-04
Reflection-positivity preservation statement ((S2) in formulas)	A positive self-adjoint transfer operator. Preserved under weak limits	Cited Osterwalder–Seiler 1978, Lüscher 1977	5-03
Wilson-loop limit statement ((S3) in formulas)	As $a \to 0$, renormalised Wilson loops have a non-trivial limit	Unsolved (the continuum string-tension problem (Chatterjee's Problem 5.2))	5-09, 7-07
Physical-unit gap statement ((S4) in formulas)	$\Delta(\beta) \to \Delta_\infty \in (0, \infty)$	Unsolved (the half on the lattice side is the lattice correlation-length problem (Chatterjee's Problem 5.1))	4-11, 5-09
Relaxation-time band at the bookkeeping length (slowness of fluctuations) ((S5) in formulas)	$a^2 C_P \asymp 1$	Assumption The formulation of this part. There is no proof	§ 04, § 05
Rotation-recovery statement ((S6) in formulas)	In the limit, invariance under rotations and translations of $\mathbb{R}^4$ returns	Unsolved along this line (shown in two dimensions; for the side of the published construction, see the note below)	16-07
OS reconstruction statement ((S7) in formulas)	Build the Hilbert space and the Hamiltonian from the axioms	Cited A theorem (Osterwalder–Schrader). Along this line it remains that the limit satisfies the axioms (for the side of the published construction, see the note below)	4-10
Non-triviality statement ((S8) in formulas)	The limit is not Gaussian, and at short distances agrees with the predictions of asymptotic freedom	Unsolved. For four-dimensional ϕ^4 cut off by a lattice, the limit is Gaussian Cited	0-03, 7-08

Note (relation to the published construction). The "current status in four dimensions" of Table 1 is the status along the line of this chapter (for each β, first make the volume infinite, then β→∞). The construction published on 2026-11-10, with a different assembly (stacking steps of renormalisation to take the ultraviolet limit, and taking infinite volume along a subsequence), shows that a quantum field theory satisfying the Wightman axioms can be built as a limit of four-dimensional Wilson lattice gauge theory, and the committee's assessment is that it is proved in Lean (Part 6). In that construction,

Euclidean invariance (recovery of rotations) and the OS axioms and reconstruction are shown for the theory of each phase (6-03). What is not shown is the convergence and uniqueness of the infinite-volume limit, a probability measure for the continuum theory, a uniform mass gap, Wilson loops and the area law, and one-particle states (6-04). The physical-unit gap statement and the Wilson-loop limit statement are open under either assembly.

The eight are not independent. Written with arrows meaning "the source is a prerequisite of the target", they are as follows (this book's arrangement; the arrow labelled with the band form of the diffusive-relaxation-time assumption holds only under the band statement of § 05).

$$(\mathrm{S1}) \to (\mathrm{S3}) \to (\mathrm{S6}),\ (\mathrm{S8}); \qquad (\mathrm{S1}),(\mathrm{S2}) \to (\mathrm{S4}) \xleftarrow{(\xi')\text{band}} (\mathrm{S5}); \qquad (\mathrm{S2}),(\mathrm{S6}) \to (\mathrm{S7}) \quad (3)$$

Along the line of this chapter, what is in hand in four dimensions is the reflection-positivity preservation statement and the OS reconstruction statement (the part that is the reconstruction theorem). One is tempted to say "once the limit can be taken, the rest is automatic", but the footnote of the problem statement does not accept weak existence by compactness alone as a solution unless the properties of the limit ('such as the existence of a mass gap and the axioms') are shown separately (Jaffe–Witten) Cited .

$$\underbrace{\mu_{\beta_j} \to \mu \ \ (\text{subsequence})}_{\text{compactness only}} \implies (\mathrm{S2})\ \text{survives};\ \ (\mathrm{S4})\cdot(\mathrm{S6})\cdot(\mathrm{S8})\ \text{nothing can be said} \quad (4)$$

Example. Three arrows enter the physical-unit gap statement, and only the one from the relaxation-time band at the bookkeeping length is an arrow under the band statement. Only the infinite-volume uniqueness statement enters the Wilson-loop limit statement because the order is to make the volume infinite first.

03

The direction of the lattice version of the mass gap — a uniform lattice gap is on the opposite side

If the "mass gap" on the lattice is read as "the gap in lattice units $m_{\mathrm{lat}}(\beta)$ is at least a fixed value for every β", in the continuum limit it means the opposite. As in (1), the mass in physical units is the mass in lattice units divided by the lattice spacing.

$$\inf_{\beta} m_{\mathrm{lat}}(\beta) \geq c > 0 \implies \Delta(\beta) \geq \frac{c}{a(\beta)} \to \infty \qquad (a \to 0) \quad (5)$$

Proved here Just divide (1) by $a(\beta)$. As a metaphor, if the graduations of a ruler are made finer and finer but the thing measured is always a few graduations long, the actual length of the thing shrinks to 0. Precisely, under (5), ξ is bounded, and the correlation length in physical units $a\xi$ goes to 0. What the physical-unit gap statement asks for is the opposite: that m_{lat} goes to 0 at the same rate as a.

$$(\mathrm{S4}):\quad m_{\mathrm{lat}}(\beta) \sim \Delta_{\infty}\, a(\beta), \qquad \text{in particular}\ \ \xi(\beta) \to \infty \quad (\beta \to \infty) \quad (6)$$

This direction is exactly the lattice correlation-length problem of Chatterjee (2018): 'Show that for any β > 0, there exists some ξ(β) ∈ (0, ∞) such that ... Moreover, prove that $\lim_{\beta\to\infty} \xi(\beta) = \infty$.' Cited How to fix the scale is in 5-09.

Example: Table 2 takes the string tension σ as the physical unit and regards $a\sqrt{\sigma}$ as the lattice spacing. Over $\beta = 2.25 \to 2.60$, a becomes 1/3.16 and m_{lat} 1/2.70, while $\Delta/\sqrt{\sigma}$ stays at 3.3–3.8. The last column is the case where m_{lat} stops at its value at $\beta = 2.25$; it increases in inverse proportion to a.

Reading Table 2 Monte Carlo values from Table 1 of Lucini–Teper (2001) ($SU(2)$, lattices 8^4 to 24^4), and their ratios (errors propagated as independent)

β	$a\sqrt{\sigma}$	m_{lat}	$\Delta/\sqrt{\sigma}$	Case with m_{lat} held
2.25	0.4231(25)	1.390(30)	3.285(74)	3.29
2.30	0.3108(17)	1.090(33)	3.507(108)	4.47
2.40	0.2634(14)	0.953(19)	3.618(75)	5.28
2.475	0.2016(13)	0.754(10)	3.740(55)	6.89
2.55	0.15896(63)	0.586(10)	3.686(65)	8.74
2.60	0.13395(62)	0.514(8)	3.837(62)	10.38

$\Delta/\sqrt{\sigma}$ mostly increases and approaches the extrapolated value 3.844(61) of the original from below (it drops once, within errors, over $\beta = 2.475 \to 2.55$) Reading . The window is $\xi \lesssim 2$ lattice spacings, and it is not evidence that the limit exists (16-08).

04

Restating with the Poincaré constant — the statement of the slowness of fluctuations, and three C_P

We restate the physical-unit gap statement with the Poincaré constant C_P of the lattice measure μ_β. It is the supremum of the ratio of the variance of an observable to its sensitivity to the motion of the links (the Dirichlet form $\mathcal{E}$), and it is the time over which the slowest fluctuation is smoothed out in Langevin dynamics, which shakes the links while moving them towards lower action (1-10, 23-00 § 04).

$$C_P = \sup_f \frac{\mathrm{Var}_{\mu_\beta}(f)}{\mathcal{E}(f)}, \quad \mathcal{E}(f) = \mathbb{E}_{\mu_\beta}\Big[\sum_\ell |\nabla_\ell f|^2\Big], \qquad \text{(S5)}: \; a(\beta)^2\, C_P(\beta) \asymp 1 \quad (7)$$

∇_ℓ is the derivative in the direction of link ℓ (measured in the angle of the link), and $A \asymp B$ means that the ratio is bounded above and below by positive constants independent of β. Langevin time has the dimension of length squared (diffusion), so $a^2 C_P$ is the slowest relaxation measured in physical units, and the relaxation-time band at the bookkeeping length says it goes neither to 0 nor to infinity.

Three quantities are called by the same symbol C_P, so we distinguish them (Table 3). The C_P of this part is the path C_P, the Poincaré constant of the path measure (the distribution of all links in spacetime).

Table 3 Three C_P (the free-field column is for mass m with continuous time)

	Measure	Quantity it is tied to	Free field
Vacuum C_P	The vacuum distribution at a single time $\lvert\psi_0\rvert^2$	Gap of the Hamiltonian $\Delta = 1/(2C_P^{(\alpha)})$ Cited (ground-state transformation, 2-05, 1-10)	$1/(2m)$
Path C_P	The distribution of all fields in spacetime (paths)	The Langevin gap $\lambda_1 = 1/C_P$. Tied to m only through the relaxation chain	$1/m^2$
Path C_P measured in a graduation	The same measure as the path C_P	The graduation of $\mathcal{E}$. Multiplying $\mathcal{E}$ by c multiplies C_P by $1/c$	In angles $C_P^{(\vartheta)} = \frac{q^2}{4}\xi^2$, in fields $C_P^{(A)} = \xi^2$

For the free field $C_P^{(\beta)} = 4\,(C_P^{(\alpha)})^2$ Proved here (just square the free-field column of Table 3; on a time lattice of spacing 1 the right-hand side is multiplied by $1 + m^2/4$). The relaxation-time assumption is a sentence about the path C_P, so it can be reread as "the C_P of the paths agrees with the square of the C_P of the vacuum". In a gauge theory, however, the measure at a single time lives on the space of gauge orbits, and this rereading is an analogy from the form of the free field.

For the free field (with the graduation measured in field variables), C_P is the largest eigenvalue of the covariance $(-\Delta_{\text{lat}} + m_{\text{lat}}^2)^{-1}$ (1-10)Cited .

$$C_P = \frac{1}{m_{\text{lat}}^2} \quad \Longrightarrow \quad a^2 C_P = \frac{1}{\Delta^2} \ (8)$$

For the free field, the physical-unit gap statement and the relaxation-time band at the bookkeeping length say the same thing, and a uniform lattice gap $m_{\text{lat}} \geq c$ is $C_P \leq 1/c^2$, that is, the side of $a^2 C_P \to 0$. Table 4 is an example with $\Delta = 1$ held fixed and a made smaller.

Proved here Table 4 The free field on the four-dimensional lattice ($C_P = 1/m_{\text{lat}}^2$; ξ from $m_{\text{lat}}^2 = 2(\cosh(1/\xi) - 1)$. Values of the closed formulas)

a	m_{lat}	C_P	ξ	$a^2 C_P$	$a\xi$
1	1	1	1.0390	1	1.0390
1/4	0.25	16	4.0104	1	1.0026
1/16	0.0625	256	16.003	1	1.0002
2^{-k}	1 (held)	1	1.0390	4^{-k}	$1.039 \cdot 2^{-k}$

Each halving of a makes C_P four times and ξ twice as large, with $a^2 C_P = 1$ and $a\xi \to 1$. If the mass in lattice units is held at 1, $\Delta = 2^k$ diverges while $C_P = 1$ stays. Whether C_P and ξ^2 grow with the same power in a theory with interaction is the relaxation-time assumption of the next section.

Detour: two times

A subsection you may skip. For the free field the gap of the transfer matrix (Euclidean time) is $\approx m_{\text{lat}}$, and the gap $1/C_P$ of Langevin dynamics (the "fifth time") is m_{lat}^2. As a metaphor, it is the difference between the distance a wave reaches and the time ink takes to smear; precisely, Langevin dynamics is diffusion, and evening out a length ξ takes on the order of ξ^2 (18-03, the detour of 23-00).

05

The diffusive-relaxation-time assumption — what we want to measure, why we restate it, what it says

In one sentence, the relaxation-time assumption is the sentence "the time over which fluctuations are smoothed out grows with the same power as the square of the correlation length". In this section and the next we explain this sentence in six stages: (1) what we want to measure, (2) why we restate it as a quantity of a dynamics, (3) the statement, step by step, (4) what the relaxation-time assumption gives, (5) what the relaxation-time assumption does not give, (6) analogous cases. Each stage has a small example that can be checked by hand.

Its place in this part. The relaxation-time assumption is one restatement chosen in order to get a handle on the problem of the mass gap. It is neither the only road to the mass gap nor a road settled to be right. Viewpoints other than the relaxation-time assumption, and new ways of thinking that take the relaxation-time assumption as a premise, are dealt with in Part 24.

Why this part puts the relaxation-time assumption at the axis. The quantity the problem statement asks for is the gap in the direction of Euclidean time (the gap of the transfer matrix measured in physical units). The relaxation-time assumption replaces it with a quantity — the relaxation time C_P of Langevin dynamics and a power of the correlation length — that is fixed by the lattice measure alone, for which

tools exist to assemble inequalities "for every f" from local parts, and whose algebra of assembly can be checked by machine. As we see in § 06, this replacement can return to the side of the mass gap through the one-sided bridge; moreover, under the assumption of the one-sided bridge, the upper-bound assumption, the upper half of the relaxation-time assumption, is a stronger sentence than the gap in physical units on the lattice staying positive. Saying a stronger sentence in a language with more tools: this trade is the standpoint of this part, and all the chapters of Part 23 are built with the relaxation-time assumption at the axis. That is what the title of this part, a study taking the relaxation-time assumption as a handle, means.

(1) What we want to measure — the ruler and the smearing time

The part of the demand of the problem statement that can be stated on the lattice is (6): "the gap in physical units $\Delta = m_{\mathrm{lat}}/a$ stays positive as $\beta \to \infty$". Seen on the lattice, two things must happen at once: the ruler $\xi = 1/m_{\mathrm{lat}}$ grows without bound compared with the graduations of the lattice, and the way it grows matches the inverse of the lattice spacing ($a\xi$ goes neither to 0 nor to infinity). In terms of the five quantities of 23-00 § 05, the problem statement is a sentence asking about the relation between the ruler and the number of rescalings.

The ruler	The smearing time	The number of rescalings	The graduation of the clock	The clock that runs slow
The correlation length $\xi = 1/m$ lat the reciprocal of the gap in Euclidean time	The Poincaré constant C_P the reciprocal of the gap of Langevin dynamics	The bookkeeping length $\xi_{\mathrm{RG}} = 1/a$ the reciprocal of the lattice spacing (§ 07)	The normalisation of $\mathcal{E}$ the path C_P measured in a graduation, Table 3	Renormalisation of stochastic time the detour of § 07

The relaxation-time assumption brings the smearing time into this question. The time C_P over which the slowest fluctuation in the measure is smoothed out is a diffusion time, so evening out a length ξ should take on the order of ξ^2 (the detour of 23-00). So we make "the smearing time balances the square of the ruler" into one sentence, and state the relation between the ruler and the number of rescalings through the smearing time. That is the idea of the relaxation-time assumption.

Example 1 (counting the random walk on a single road by hand). On the single road of 23-00 § 04 (L cells, reflecting at both ends, uniform distribution, $\mathcal{E}(f) = \frac{1}{L}\sum_i (f_{i+1} - f_i)^2$), what corresponds to the ruler is the length of the road L. For $L = 2$, $f = (1, -1)$ is the slowest fluctuation, with $\mathrm{Var}(f) = 1$ and $\mathcal{E}(f) = \frac{1}{2} \cdot 2^2 = 2$, and the ratio is $\frac{1}{2}$. For $L = 3$, with $f = (1, 0, -1)$, $\mathrm{Var}(f) = \frac{2}{3}$ and $\mathcal{E}(f) = \frac{1}{3}(1 + 1) = \frac{2}{3}$, and the ratio is 1. Both agree with the values of $C_P(L) = 1/(2(1 - \cos(\pi/L)))$ from (3) of 23-00, and for $L = 4$ it is $1/(2 - \sqrt{2}) \approx 1.707$ Proved here . Doubling L makes C_P roughly four times as large, and for large L, $C_P \approx L^2/\pi^2$ (Table 3 of 23-00). This checks "the smearing time is the square of the ruler" on the smallest road.

Precisely, the L of the single road is a length given from outside, not a ruler the measure carries itself (a correlation length). The simplest example where the two agree is the free field: from $C_P = 1/m_0^2$ and $m_0^2 = 2(\cosh(1/\xi) - 1)$, $C_P/\xi^2 \to 1$ (23-00 § 04, Table 4 of this chapter). How the smearing time and the ruler balance in a measure with interaction is the question of the relaxation-time assumption.

(2) Why restate it as a quantity of a dynamics — measurable, with tools, within reach of checking

The quantity on the side of the ruler, m_{lat}, is the gap of the transfer matrix, a quantity of an operator on the Hilbert space of gauge-invariant states. Placing one trial state gives an upper bound on m_{lat} (a lower bound on ξ), but a lower bound needs all states. An upper bound on C_P also needs "every f", so the difficulty remains in the same direction. There are still three reasons to restate it.

(a) It can be measured from the lattice measure alone. As in (7), C_P is fixed by expectation values under μ_β alone: the variance and the Dirichlet form. It can be defined directly from the measure, without going through the Hilbert space or reconstruction; one test function gives a lower bound, and readings of lower bounds can also be taken from the autocorrelations of Langevin dynamics or Markov chains (23-02 § 04).

(b) There are tools to assemble "every f". For Poincaré inequalities, tools that assemble an upper bound on the whole from local parts are available in a form independent of dimension. With the conventions measure $\mu \propto e^{-S}$ and $\mathcal{E}(f) = \mathbb{E}|\nabla f|^2$,

$$\mathrm{Hess}\, S \geq \rho \;\Rightarrow\; C_P(\mu) \leq \frac{1}{\rho}; \qquad \mu' \propto e^{-W}\mu \;\Rightarrow\; C_P(\mu') \leq e^{\operatorname{osc} W}\, C_P(\mu); \qquad C_P(\mu_1 \otimes \mu_2) = \max\bigl(C_P(\mu_1),$$

The two on the left are Cited (the Bakry–Émery convexity criterion and the Holley–Stroock bounded perturbation; $\operatorname{osc} W = \sup W - \inf W$. Bibliographic data in the table of sources of 23-06), and the one on the right is Proved here (use the Poincaré inequality of each component on each term of the Efron–Stein inequality $\mathrm{Var}(f) \leq \mathbb{E}\,\mathrm{Var}_1(f) + \mathbb{E}\,\mathrm{Var}_2(f)$ to get $\leq \max$; equality for a function of one coordinate only). Adding to these the decomposition of the variance (the sum of the conditional variance and the variance of the conditional expectation, 23-05 § 01), these four are the parts from which the first step is assembled. The logarithmic Sobolev inequality (LSI) has tools of the same type, among them convexity criteria split by scale (23-02 § 05).

(c) Machine checking can reach it. The stage of combining the inequalities of the parts is algebra of real inequalities. The algebra can be checked in Lean, and numerical inequalities inside a finite window can be confirmed by interval arithmetic (computer-assisted). What is checked is the assembly from assumptions to conclusions, not the assumptions themselves (23-13).

Example 2 (where the tools work, for a Gaussian measure on two sites). Consider the measure $\mu \propto e^{-S}$ on $\mathbb{R}^2$, with $S(x_1, x_2) = \frac{1}{2}(x_1 - x_2)^2 + \frac{1}{2}m_0^2(x_1^2 + x_2^2)$. The Hessian is $\begin{pmatrix} 1+m_0^2 & -1 \\ -1 & 1+m_0^2 \end{pmatrix}$, with eigenvalues m_0^2 (direction $(1,1)$) and $m_0^2 + 2$ (direction $(1,-1)$). The criterion on the left of (9) gives $C_P \leq 1/m_0^2$. On the other hand, for $f = x_1 + x_2$, since the covariance is the inverse of the Hessian, $\mathrm{Var}(f) = 2/m_0^2$ and $\mathcal{E}(f) = |\nabla f|^2 = 2$, and the ratio is $1/m_0^2$. Upper and lower bounds agree, and $C_P = 1/m_0^2$ Proved here. For the single road (Example 1) we found C_P by diagonalising a matrix; in this example (9) gives the answer without diagonalisation. For the double well $V(x) = (x^2-1)^2/8$, at the top $V''(0) = -\frac{1}{2} < 0$, and the convexity criterion of (9) cannot be used on the whole. So one combines the decomposition of the variance, splitting valley by valley, with convexity and perturbation after the split (23-04 § 06, 23-05 § 04). That an upper bound can be assembled from parts for a measure with interaction that cannot be diagonalised — this is the first gain of the restatement.

(3) The statement of the relaxation-time assumption, step by step — the band statement, the power statement, the upper and lower halves

First step: the band statement. Written plainly, it becomes the sentence "C_P lies within the width of a constant factor of the square of the ruler". Comparing with the physical unit a and a width of constant

factors independent of β (a band),

$$\exists\,\beta_0,\ \exists\, 0<c\le C:\qquad c\le a(\beta)^2\,C_P(\beta)\le C\qquad(\beta\ge\beta_0)\ \text{(10)}$$

In numbers, it is the sentence that when $\xi_{\mathrm{RG}}=1/a=10$, C_P lies between $100c$ and $100C$, and if $\xi_{\mathrm{RG}}=1000$, between 10^6c and 10^6C. Langevin time has the dimension of length squared (diffusion), so a^2C_P is the slowest relaxation measured in physical units, and (10) says it goes neither to 0 nor to infinity.

Example 3 (the single road satisfies the band statement). Taking L as the ruler for the single road of Example 1 and setting $x=\pi/L$, $C_P(L)/L^2=\frac{1}{\pi^2}\cdot\frac{(x/2)^2}{\sin^2(x/2)}$. Since $t/\sin t$ increases on $(0,\pi/2]$, for $L\ge 2$

$$\frac{1}{\pi^2}\;<\;\frac{C_P(L)}{L^2}\;\le\;\frac{1}{8}\ \text{(11)}$$

(the equality on the right is $C_P=\frac12$ at $L=2$), and the band statement holds with $c=1/\pi^2\approx 0.101$, $C=1/8$ Proved here .

Inserting the correlation length, the band statement splits into three factors.

$$a^2C_P=\underbrace{(a\xi)^2}_{\text{chains (ii)(iii)}}\cdot\underbrace{\frac{C_P}{\xi^2}}_{\text{chain (i)}},\qquad (a\xi)^2=\frac{1}{m_{\mathrm{phys}}^2},\qquad \frac{C_P}{\xi^2}=\frac{m_{\mathrm{fat}}^2}{\lambda_1}\ \text{(12)}$$

The first factor is determined by the mass in physical units $m_{\mathrm{phys}}=m_{\mathrm{lat}}/a$, and the second is the factor of the relaxation chain, "the Langevin gap λ_1 agrees with the square of the mass". Further splitting the first factor into "the square of the mass agrees with the string tension" (the one-scale chain) and "the string tension agrees with the square of the lattice spacing" (the bookkeeping-length chain), the three ratios are the three chains (17-12). All three are assumptions Assumption . What the upper and lower halves of each chain need is seen in 23-02 § 05.

Second step: the power statement. The band statement is moved by the logarithmic factors brought in by the graduation of $\mathcal{E}$, the order of the bookkeeping and the renormalisation of stochastic time (the detour of § 07). Lowering it to a level that ignores not only constant factors but also factors of powers of $\ln\xi$ gives the relaxation-time assumption.

$$(\xi^2):\qquad \lim_{\beta\to\infty}\frac{\ln C_P(\beta)}{\ln\xi(\beta)}=2\ \text{(13)}$$

This sentence has the same form as (2) of the statement of the first step, 23-03 § 05, $\lim_{\hbar\to0}\ln C_P(\hbar)/\ln\xi(\hbar)=2$. Only the family of measures differs: here the Wilson measure μ_β with $\beta\to\infty$, on the first step the path measure of the double well with $\hbar\to0$. So in this part (13) is treated as a dimension-independent power statement, called "the diffusive-relaxation-time assumption" at the stage of the four-dimensional lattice and "the double-well relaxation-time power statement" on the first step. Being a power statement, it does not change when $\mathcal{E}$ is multiplied by a power of β ($\ln\beta/\ln\xi\to0$) Proved here Lean `exponent_invariant_of_slowly_varying` (assumptions: $X_n,\ell_n>0$, $\ln X_n/\ln a_n\to p$, $\ln\ell_n/\ln a_n\to0$. Conclusion: $\ln(X_n\ell_n)/\ln a_n\to p$. Algebra of sums of limits).

Example 4 (the difference between band and power, in numbers). Consider the family $C_P=\xi^2\ln\xi$. The ratio $C_P/\xi^2=\ln\xi$ keeps increasing, $2.30,\ 6.91,\ 13.8$ at $\xi=10,10^3,10^6$, so the band statement breaks. On the other hand $\ln C_P/\ln\xi=2+\ln\ln\xi/\ln\xi$ approaches 2 slowly, $2.362,\ 2.280,\ 2.190$, and the power statement holds Proved here (divide the values $0.834,\ 1.933,\ 2.626$ of $\ln\ln\xi$ by $\ln\xi=2.303,\ 6.908,\ 13.82$). Conversely the single road of Example 3 satisfies the band statement, but $\ln C_P/\ln L=2-(\ln\pi^2$

$+ o(1))/\ln L$ is $\ln 6640/\ln 256 \approx 1.587$ at $L = 256$, far from 2. The power statement says only "2 in the limit", and allows a slow approach by the amount of the constants. The band statement implies the power statement ($\ln c/\ln \xi \to 0$), and the converse fails, as $C_P = \xi^2 \ln \xi$ shows Proved here .

(10) is a sentence that combines the relaxation-time assumption with the one-scale chain and the bookkeeping-length chain, and in this book it is not called the relaxation-time assumption. The names are fixed as in Table 5.

Table 5 Readings and names of "C_P agrees with the square of a length" (eight detailed readings in A-06)

Level, length compared	Sentence	Name in this book	In the free approximation
Power, ξ	$\ln C_P/\ln \xi \to 2$	The diffusive-relaxation-time assumption	Holds
Power, bookkeeping length	$\ln C_P/\ln \xi_{\mathrm{RG}} \to 2$	The relaxation-time assumption with the one-scale chain and the bookkeeping-length chain (power)	Holds
Band, ξ	$C_P \asymp \xi^2$	$(\xi^2)_{\mathrm{band}}[\mathcal{E}_\vartheta]$, $(\xi^2)_{\mathrm{band}}[\mathcal{E}_A]$ (naming the graduation)	Equality in the field graduation; in the angle graduation the lower half breaks with ratio $g^2/4$
Band, bookkeeping length	$a^2 C_P \asymp 1$ ((10))	Band statement with the one-scale chain and the bookkeeping-length chain = the relaxation-time band at the bookkeeping length	Determined by the order of the bookkeeping (§ 07)

The two rows at the power level are moved neither by the choice of graduation nor by the logarithmic factors of § 07. That is why this part places the relaxation-time assumption as a power statement.

Third step: upper and lower halves. Separating the right and left of the band statement (10) gives the upper-bound assumption and the lower-bound assumption.

$$(\xi^2)\uparrow:\ a^2 C_P \le C\ \ (C_P \lesssim \xi_{\mathrm{RG}}^2), \qquad (\xi^2)\downarrow:\ a^2 C_P \ge c\ \ (C_P \gtrsim \xi_{\mathrm{RG}}^2) \quad (14)$$

C_P is the supremum of (7), and $\xi_{\mathrm{RG}} = 1/a$ is a length fixed separately from the measure, so the two have opposite quantifiers over the test function f.

$$(\xi^2)\downarrow \iff \forall \beta \ge \beta_0\ \exists f:\ \mathrm{Var}(f) \ge c\,\xi_{\mathrm{RG}}^2\,\mathcal{E}(f), \qquad (\xi^2)\uparrow \iff \forall \beta \ge \beta_0\ \forall f:\ \mathrm{Var}(f) \le C\,\xi_{\mathrm{RG}}^2\,\mathcal{E}(f) \quad (15)$$

Proved here This just writes out the definition of the supremum. The lower-bound assumption needs only one test function to be shown; the upper-bound assumption is a genuine Poincaré inequality over all functions. "Easy from above, hard from below" for eigenvalues (1-10) becomes, for their reciprocal C_P, "easy from below, hard from above". This asymmetry determines the whole of the roads and walls of 23-02.

Example 5 (families where only one holds). In the family $C_P = \xi_{\mathrm{RG}}^2 \ln \xi_{\mathrm{RG}}$, for $\xi_{\mathrm{RG}} \ge e$ we have $a^2 C_P \ge 1$, so the lower-bound assumption holds with $c = 1$, and since $a^2 C_P = \ln \xi_{\mathrm{RG}} \to \infty$, the upper-bound assumption breaks (the power statement holds, as in Example 4). Conversely, in a family where C_P is bounded independently of β (the form of the theorems on the strong-coupling side, Table 7 in § 06), the upper-bound assumption holds and the lower-bound assumption breaks Proved here . The band statement is the sentence that neither of these two ways of breaking happens.

Note — "the relaxation-time assumption" and "the four double-well conditions"

In this part "the relaxation-time assumption" refers only to the power statement (13). The upper-bound assumption and the lower-bound assumption are the halves of the band statement, with

names separate from the relaxation-time assumption. The four conditions into which the upper side of the double-well power statement is split on the first step are written "the four double-well conditions", always with the word "conditions" (23-03 § 05, 23-05). The in-phase local Poincaré condition is not "the first half of the relaxation-time assumption" but a different statement, "local Poincaré within a phase" for the model of the first step. The letters in Lean theorem names (H1 and so on) are not changed.

Note — topological sectors, and the order of making the volume infinite

The supremum of (7) runs over every f, so the (smoothed) topological charge Q, which can no longer move between sectors in the continuum limit, is also among the test functions. On four-dimensional lattices with periodic boundaries, the autocorrelation time of Q is reported to grow clearly faster than ξ^2 Reading (Del Debbio–Panagopoulos–Vicari 2002 with local heat bath and overrelaxation, Schaefer–Sommer–Virotta 2011 with HMC-type algorithms, Bonanno–Bonati–D'Elia 2021 with local algorithms; as a power the exponent is about 5, or else exponential in $1/a$, and all three write that power and exponential cannot be distinguished by the data). The groups of the three original sources are all $SU(3)$ or larger, and whether the exponent exceeds 2 for $SU(2)$, where this book's relaxation-time assumption is stated, is not settled in the primary sources found. There is one primary source found that measures the dependence of the autocorrelation of the topological charge on the lattice spacing for $SU(2)$ (Abe–Morikawa–Suzuki 2025; HMC, periodic boundaries, small boxes with the physical side held fixed, three lattice spacings). There the integrated autocorrelation time is reported to grow close to a^{-2} Reading . So the following reading is a reading on the original sources for $SU(3)$ and larger. For reversible dynamics, the integrated autocorrelation time of any observable does not exceed C_P ($\tau_{\mathrm{int}} \le C_P$ Cited , 23-02 § 05), so under the conjecture that HMC and Langevin are in the same universality class Assumption , the upper-bound assumption can be read as false in a periodic box. Open boundaries remove this obstacle only inside a finite box with the physical side held fixed (in Lüscher–Schaefer 2011, the autocorrelation time of Q^2 with open boundaries grows roughly in proportion to the length in the time direction Reading). In this book's order, which makes the volume infinite first, this is expected not to help Assumption . If the relaxation-time assumption is to be kept, candidate directions are to rewrite it as a statement sector by sector, or as a local statement with support limited to a few correlation lengths; that study is dealt with in Part 24 (24-03, 24-04).

06

What the diffusive-relaxation-time assumption gives and what it does not — the one-sided bridge, a counterexample, analogous cases

The remaining three of the six stages: (4) what the relaxation-time assumption gives, (5) what the relaxation-time assumption does not give, (6) analogous cases. (4) and (5) start from the fact that the quantity of the problem statement (the gap in Euclidean time) and the quantity of the relaxation-time assumption (the Langevin relaxation time) are different quantities, and fix precisely the relation between the relaxation-time assumption and the mass gap through the one-sided bridge joining the two and an example in which the converse of the bridge fails.

(4) What the relaxation-time assumption gives — rereading as a mass, and the one-sided bridge

The version with equality. If the relaxation chain is put as the equality $C_P = 1/m_{\mathrm{lat}}^2$, the two halves of (14) are reread as statements about the mass in physical units $m_{\mathrm{phys}} = m_{\mathrm{lat}}\,\xi_{\mathrm{RG}}$.

$$(\xi^2)\uparrow \implies m_{\mathrm{phys}} \;\geq\; C^{-1/2}, \qquad (\xi^2)\downarrow \implies m_{\mathrm{phys}} \;\leq\; c^{-1/2} \quad (16)$$

Proved here Proof: multiply both sides of $1/m_{\mathrm{lat}}^2 \leq C\xi_{\mathrm{RG}}^2$ in the upper-bound assumption by m_{lat}^2/C to get $1/C \leq (m_{\mathrm{lat}}\xi_{\mathrm{RG}})^2$. For the lower-bound assumption, the same with the inequality reversed. ∎ The level of proof is algebra, and two Lean theorems check this algebra.

```
theorem hup_is_gap_positivity {CP xi mlat K : ℝ}
    (hmlat : 0 < mlat) (hCP : CP = 1 / mlat ^ 2) (h : CP ≤ K * xi ^ 2) :
    1 ≤ K * (mlat * xi) ^ 2

theorem hdown_is_mass_finiteness {CP xi mlat c : ℝ}
    (hmlat : 0 < mlat) (hCP : CP = 1 / mlat ^ 2) (h : c * xi ^ 2 ≤ CP) :
    c * (mlat * xi) ^ 2 ≤ 1
```

Lean `LatticeGauge.hup_is_gap_positivity` (assumptions: $m_{\mathrm{lat}} > 0$, $C_P = 1/m_{\mathrm{lat}}^2$, $C_P \leq K\xi^2$. Conclusion: $1 \leq K(m_{\mathrm{lat}}\xi)^2$) and `LatticeGauge.hdown_is_mass_finiteness` (assumptions: $m_{\mathrm{lat}} > 0$, $C_P = 1/m_{\mathrm{lat}}^2$, $c\,\xi^2 \leq C_P$. Conclusion: $c\,(m_{\mathrm{lat}}\xi)^2 \leq 1$). Inside Lean all four letters are named real numbers; that it is the Poincaré constant of the Wilson measure, and that C_P is a supremum (running over every f), are outside Lean (23-13). The upper-bound assumption is "the mass does not collapse to 0", that is, a lower bound on the side of the mass gap; the lower-bound assumption is the side "the mass does not escape to infinity".

The equality $C_P = 1/m_{\mathrm{lat}}^2$ is the value for the free field, and is too strong an assumption to put down for a theory with interaction. However, the proof that derives a lower bound on the mass from the upper-bound assumption uses only one side of the equality, $C_P \geq \kappa/m_{\mathrm{lat}}^2$. And on a lattice with continuous time, this one side can be shown as a proposition with its assumptions named.

The one-sided bridge (continuous time, finite spatial lattice, $T = \infty$)

Take the space to be a finite lattice, the space of configurations at a single time to be Q ($\mathbb{R}^n$, or a compact connected manifold), the metric of the kinetic term M, $H = -\frac{\hbar^2}{2}\Delta_M + V$, $A = (H - E_0)/\hbar$. Assume the following. (A1) The ground-state assumption: the spectrum of H is discrete, the ground state ψ_0 is non-degenerate, smooth and positive, and $\Delta = E_1 - E_0 > 0$. (A2) The stationary path-measure assumption: the path measure is the stationary measure at $T = \infty$ (the distribution at a single time is ψ_0^2, the transition is $e^{-\tau A}$). (A3) The metric comparison assumption: the metric of the Langevin Dirichlet form $\mathcal{E}_G(f) = \hbar \int \mathbb{E}\langle d_{q(\tau)}f, G\, d_{q(\tau)}f\rangle d\tau$ satisfies $G \leq \lambda_G M^{-1}$, and $\kappa := 1/\lambda_G$. Then, for $\xi = \hbar/\Delta$, $F = \psi 1/\psi 0$ and $f_T = \int_0^T F(q(\tau))\,d\tau$, for every $T > 0$

$$\frac{\mathrm{Var}(f_T)}{\mathcal{E}_G(f_T)} \;\geq\; \kappa\xi^2\Big[1 - \frac{\xi}{T}\big(1 - e^{-T/\xi}\big)\Big], \qquad \text{hence} \qquad C_P \;\geq\; \kappa\xi^2 = \frac{\kappa\hbar^2}{\Delta^2} \quad (17)$$

holds. With the canonical choice $G = M^{-1}$ ($\kappa = 1$), the supremum as $T \to \infty$ over the family of test functions local in time is exactly ξ^2.

Proved here Proof [Y3]. Set $m = \Delta/\hbar = 1/\xi$ and $\varphi = (F - \langle F\rangle)\psi_0$. Since $\langle F\rangle = \int \psi_0\psi_1 = 0$, $\varphi = \psi_1$ and $A\varphi = m\varphi$.

(i) The variance. Under the stationary path-measure assumption (A2), the correlations of the measure are $\mathrm{Cov}(F(q(s)), F(q(t))) = \langle \varphi, e^{-|s-t|A}\varphi\rangle = \|\varphi\|^2 e^{-m|s-t|}$ Cited (the formula writing correlations with the transfer operator, of the type of (12) in 2-07 § 08 and 23-04 § 04). Integrating over the square $[0,T]^2$ gives $\mathrm{Var}(f_T) = \|\varphi\|^2\big(2T/m - 2(1-e^{-mT})/m^2\big)$ (close $\iint e^{-m|s-t|} = 2\int_0^T (T-u)e^{-mu}du$ with one integration by parts).

(ii) The Dirichlet form. Differentiating f_T with respect to the path $q(\tau)$ gives $dF(q(\tau))$ for $\tau \in [0,T]$ and 0 otherwise. From stationarity and the metric comparison assumption (A3), $\mathcal{E}_G(f_T) = \hbar T \int \psi_0^2 \langle dF, G\, dF\rangle \le \hbar T \lambda_G \int \psi_0^2 |dF|_M^2 - 1$.

(iii) The ground-state transformation identity. For a smooth real function F,

$$\big\langle F\psi_0, (H - E_0)F\psi_0\big\rangle = \frac{\hbar^2}{2}\int \psi_0^2\, |dF|_M^2 - 1 \quad (18)$$

Proved here. Using $(V - E_0)\psi_0 = \frac{\hbar^2}{2}\Delta_M\psi_0$ gives $(H-E_0)(F\psi_0) = -\frac{\hbar^2}{2}\big(\psi_0\Delta_M F + 2\langle dF, d\psi_0\rangle_M - 1\big) = -\frac{\hbar^2}{2\psi_0}\,\mathrm{div}_M(\psi_0^2\,\nabla_M F)$, and multiplying by $F\psi_0$ and integrating by parts once gives the right-hand side (boundary terms vanish because Q is compact without boundary, or the functions decay at infinity). ∎ It has the same form as the one-dimensional calculation of 1-10 § 08 and 2-05 § 08. Since $F\psi_0 = \psi_1$, the left-hand side is $\Delta\|\varphi\|^2$, and $\int \psi_0^2 |dF|_M^2 - 1 = (2m/\hbar)\|\varphi\|^2$; hence $\mathcal{E}_G(f_T) \le 2\lambda_G m T \|\varphi\|^2$.

(iv) The ratio. Dividing (i) by (ii)(iii) gives $\mathrm{Var}/\mathcal{E}_G \ge \kappa\big(1/m^2 - (1-e^{-mT})/(Tm^3)\big)$, which is the left of (17). C_P is a supremum, so it is at least the right-hand side, and as $T\to\infty$, $C_P \ge \kappa\xi^2$. For the supremum in the canonical case, any f local in time gives $\mathrm{Var}/T \to 2\langle\varphi, A^{-1}\varphi\rangle$ and $\mathcal{E}/T = 2\langle\varphi, A\varphi\rangle$, and using $1/a \le a/m^2$ for the eigenvalues $a \ge m$ of A it is at most ξ^2, with equality when φ lies in the eigenspace of eigenvalue m (the same as (13) of 23-04 § 04). ∎

Lean `LatticeGauge.HupBridge.cont_ratio_closed` (assumptions: $0 < m$, $0 < T$. Conclusion: the ratio of (i) divided by (ii)(iii) equals $1/m^2 - (1-e^{-mT})/(Tm^3)$) and `one_sided_bridge` (assumptions: a lower bound on the variance, an upper bound on the Dirichlet form, $\mathrm{Var}/\mathcal{E} \le C_P$, positive numbers. Conclusion: $\kappa/m^2 \le C_P$) check only the algebra of numbers in (i)–(iv). The path measure, the formula for correlations, (18), and that C_P is a supremum are outside Lean.

Table 6 The assumptions of the one-sided bridge, and where they are used

Symbol	Assumption	Where it is used
The ground-state assumption (A1)	Discrete spectrum, $\Delta > 0$, $\psi_0 > 0$ smooth and non-degenerate, ψ_1 exists	$F = \psi_1/\psi_0$ can be defined and is smooth
The stationary path-measure assumption (A2)	The stationary path measure at $T = \infty$ (the distribution at a single time is ψ_0^2, the transition is $e^{-\tau A}$)	The formula for correlations in (i)
The metric comparison assumption (A3)	$G \le \lambda_G M^{-1}$ ($\kappa = 1/\lambda_G$)	The comparison in (ii)
Continuous time	The kinetic term of the paths has the form $\frac{1}{2}\lvert\dot q\rvert_M^2$	(18) is used with the same metric as the $\mathcal{E}$ of the path measure
Finite spatial lattice	Q is finite-dimensional	The ground-state assumption and the integration by parts in (18)

κ does not depend on the length of time T. T enters only the factor $1-(\xi/T)(1-e^{-T/\xi})\in(0,1)$ of (17), which approaches 1 as $T/\xi\to\infty$. Setting $G=M^{-1}=1$ for a one-dimensional well gives the One-Dimensional One-Sided Bridge Proposition (23-04 § 04), and the one-sided bridge is its multidimensional version with a metric. In the language of the chains, the one-sided bridge shows one side of the relaxation chain, $\lambda_1\le m_{\mathrm{lat}}^2/\kappa$ (the half on the side of the lower-bound assumption), on a lattice with continuous time. Whether a claim of the same form exists in the literature has not been checked (it may be known).

Why the power is two. The variance is the time integral of correlations, $T\cdot(2/m)\|\varphi\|^2$, that is, it grows to first order in $1/\Delta$. The Dirichlet form, for the function $F=\psi_1/\psi_0$ of the slowest excitation, whose gradient is small, is $T\cdot 2m\|\varphi\|^2$ by (18), that is, it becomes small to first order in Δ. The ratio is $1/\Delta^2$. If one overlooks the smallness of the gradient and estimates the Dirichlet form as a quantity independent of Δ, one drops to a lower bound of first order, c/Δ, and the next (19) does not follow.

Note (two meanings of the symbol Δ). In this chapter Δ is used with two meanings. The $\Delta(\beta)=m_{\mathrm{lat}}/a$ of (1) is the mass in physical units. The $\Delta=E_1-E_0$ of the one-sided bridge and the examples of this section is the gap of the Hamiltonian with space made a finite lattice, tied to the correlation length in lattice units by $\xi=\hbar/\Delta$ (with $\hbar=1$ it corresponds to m_{lat}, and the $\Delta(\beta)$ of (1) is that divided by the lattice spacing a). In Part 24, Δ is restricted to the meaning of the one-sided bridge, E_1-E_0, and the mass in physical units is written m_{phys} (24-09 § 02).

Example 6 (checking the bridge by hand on a two-site lattice). Take the same two sites as in Example 2 as the spatial lattice, with continuous time ($\hbar=1$, $M=G=1$, $V=\frac12 x^{\mathsf T}Kx$, where K is the Hessian of Example 2). The normal modes are $u=(x_1+x_2)/\sqrt2$ (angular frequency m_0) and $v=(x_1-x_2)/\sqrt2$ (angular frequency $\sqrt{m_0^2+2}$); the first excitation raises the oscillation of u by one, so $\Delta=m_0$, $\xi=1/m_0$ and $F=\psi_1/\psi_0\propto u$. On the paths, $u(\tau)$ is a stationary Gaussian process with $\mathbb{E}[u(s)u(t)]=e^{-m_0|s-t|}/(2m_0)$. For $f_T=\int_0^T u\,d\tau$, $\mathrm{Var}(f_T)=\frac{1}{2m_0}\big(\frac{2T}{m_0}-\frac{2(1-e^{-m_0T})}{m_0^2}\big)$; since $|\nabla u|^2=\frac12+\frac12=1$, $\mathcal{E}(f_T)=T$, and the ratio is $1/m_0^2-(1-e^{-m_0T})/(Tm_0^3)$, exactly the right-hand side of (17). In numbers, with $m_0=\frac12$ ($\xi=2$) and $T=20$ the ratio is $4-0.99995/2.5\approx 3.600$, and with $T=200$ it is $4-1/25=3.96$, approaching $\xi^2=4$ from below. (18) can also be checked: the left-hand side is $\Delta\,\mathbb{E}[u^2]=m_0\cdot\frac{1}{2m_0}=\frac12$ and the right-hand side is $\frac12\,\mathbb{E}|\nabla u|^2=\frac12$ Proved here . In this example the path measure is Gaussian and the largest eigenvalue of the covariance $(-\partial_\tau^2+K)^{-1}$ is $1/m_0^2$, so $C_P=\xi^2$, and the bridge holds with equality.

Combining the upper-bound assumption with the bridge. Setting the $C_P\le C\xi_{\mathrm{RG}}^2$ of the upper-bound assumption beside the $C_P\ge\kappa/m_{\mathrm{lat}}^2$ of the one-sided bridge gives

$$\frac{\kappa}{m_{\mathrm{lat}}^2}\ \le\ C_P\ \le\ C\,\xi_{\mathrm{RG}}^2\qquad\Longrightarrow\qquad m_{\mathrm{phys}}^2=(m_{\mathrm{lat}}\,\xi_{\mathrm{RG}})^2\ \ge\ \frac{\kappa}{C}\ \text{(19)}$$

Proved here . For example, with $\kappa=1$ and $C=4$, the gap in physical units stays at least $\frac12$ for every $\beta\ge\beta_0$. It is the form with the equality assumption of (16) weakened to one side, and in Lean

```
theorem hup_is_gap_positivity_of_lower {CP xi mlat K κ : ℝ}
    (hmlat : 0 < mlat) (hCP : κ / mlat ^ 2 ≤ CP) (h : CP ≤ K * xi ^ 2) :
    κ ≤ K * (mlat * xi) ^ 2
```

Lean `LatticeGauge.HupBridge.hup_is_gap_positivity_of_lower` (assumptions: $0 < m_{\mathrm{lat}}$, $\kappa/m_{\mathrm{lat}}^2 \le C_P$, $C_P \le K\xi^2$. Conclusion: $\kappa \le K(m_{\mathrm{lat}}\xi)^2$). Setting $\kappa = 1$ recovers the theorem on the left of (16) (`hup_is_gap_positivity_recovered`). The right of (16), on the side of the lower-bound assumption, uses $C_P \le 1/m_{\mathrm{lat}}^2$ (the hard side), so it cannot be weakened with the one-sided bridge.

We list the conditions for (19) to become a sentence on the side of the mass gap. First, κ must be uniform in β. In the field graduation $\mathcal{E}_A$, κ is a number independent of the coupling (its value depends on the convention for normalising the metric of the group), and the condition is met. In the link-angle graduation $\mathcal{E}_\vartheta$, $\kappa \propto g^2 \to 0$, and (19) gives $m_{\mathrm{phys}}^2 \gtrsim g^2/C$, that is, it loses by a logarithm (the path C_P measured in a graduation, Table 3). Second, the treatment of time. The one-sided bridge is a sentence on a lattice with continuous time (a Hamiltonian lattice with only space made a lattice); for the Wilson measure, which also discretises time, there is no counterpart of the ground-state transformation identity (18). On a time lattice of step 1, with $q = e^{-\Delta}$ the second eigenvalue of the transfer operator $\hat{T}$ (divided by its largest eigenvalue), putting down an assumption comparing the increment between neighbouring times with the gradient,

$$(\mathrm{D}): \quad \mathbb{E}_{\psi_0^2}|dF|_G^2 \le c_D \,\langle \varphi, (1-\hat{T})\varphi\rangle \qquad \Longrightarrow \qquad C_P \;\ge\; \frac{1+q}{c_D(1-q)^2} \;\ge\; \frac{2}{c_D\,\Delta^2} \tag{20}$$

gives a lower bound of the same type (the Discrete-Time One-Sided Bridge Proposition) Proved here (on top of (D). The variance over a window of N sites is $\|\varphi\|^2 \sum_{s,t\le N} q^{|s-t|}$, the Dirichlet form is at most $N\,c_D(1-q)\|\varphi\|^2$, and the ratio as $N \to \infty$ is the middle expression. The right inequality, with $y = \Delta/2$, is the same as $\sinh^2 y \le y^2 \cosh y\, e^y$, which follows from $\tanh y \le y$ and $\cosh y \le e^y$) Lean `pairSum_closed` (closed form of the window sum), `disc_limit_ge` (a weak version with coefficient 1; assumptions: $0 < \Delta$, $0 < c_D$). When $\hat{T} = e^{-(H-E_0)}$ holds exactly, (18) gives $c_D = 2\Delta/(1-e^{-\Delta}) \to 2$, returning to the one-sided bridge with continuous time. The transfer operator of the Wilson measure is not of this form, so (D) remains an assumption, together with a c_D uniform in β Assumption. Third, the volume. The one-sided bridge is a sentence about a finite spatial box, and the stage connecting the C_P of the infinite-volume measure with the limit of the gaps of the boxes has not been examined Assumption.

Why the question becomes one-sided on the first step. Using the correlation length fixed by the gap, $\xi = 1/m_{\mathrm{lat}}$ ($\hbar = 1$), the bridge $\kappa\xi^2 \le C_P$ gives the lower half of the power statement automatically.

$$\frac{\ln C_P}{\ln \xi} \;\ge\; 2 + \frac{\ln \kappa}{\ln \xi} \qquad (\xi > 1), \qquad \text{so} \quad \liminf \frac{\ln C_P}{\ln \xi} \ge 2 \tag{21}$$

Proved here (take ln and divide by $\ln \xi > 0$; if κ is uniform the second term goes to 0) Lean `power_lower_half_of_bridge` (assumptions: $0 < \kappa$, $1 < \xi$, $\kappa\xi^2 \le C_P$. Conclusion: the left of (21)). Under the assumption of the bridge, the content of the relaxation-time assumption is only the upper half $\limsup \ln C_P/\ln \xi \le 2$. For the double well, the One-Dimensional One-Sided Bridge Proposition is exactly this bridge ($\kappa = 1$, one-dimensional), so the power statement on the first step becomes the one-sided question "can the upper side be shown", and its target is the Double-Well Relaxation-Time Upper-Bound Proposition of 23-05, $C_P \le K\xi^2 S_0/\hbar$.

Algebra on the side of the chains. Assuming the six band inequalities of the three chains puts $a^2 C_P = a^2/\lambda_1$ in a positive band.

$$c_1 m^2 \le \lambda_1 \le C_1 m^2, \;\; c_2\sigma \le m^2 \le C_2\sigma, \;\; c_3 a^2 \le \sigma \le C_3 a^2 \;\Longrightarrow\; c_1c_2c_3\,a^2 \le \lambda_1 \le C_1C_2C_3\,a^2 \tag{22}$$

Proved here Lean `chain_band`, `sq_times_poincare_band` (assumptions: the six band inequalities and positivity of the coefficients. Conclusion: (22), and that a^2/λ_1 lies in $[1/C, 1/c]$). The chains themselves are assumptions, and the converse (chains from the band statement) does not follow. The one-sided bridge gives the right inequality of the relaxation chain, $\lambda_1 \le C_1 m^2$ ($C_1 = 1/\kappa$), on a lattice with continuous time.

(5) What the relaxation-time assumption does not give — a different quantity, the converse, the limit

That it is a different quantity. C_P is the Poincaré constant of the path measure, that is, the reciprocal of the gap of Langevin dynamics running in an artificial time, while the mass of the problem statement is the gap of the transfer matrix (the Hamiltonian) (the path C_P and the vacuum C_P of Table 3). They are different quantities, and the bridge of (4) only puts a one-directional inequality between them. Assuming the relaxation-time assumption does not make the two the same.

The converse does not hold in general. (19) was "the upper-bound assumption ⇒ the gap in physical units is positive". Its converse, "the gap in physical units is positive ⇒ the upper-bound assumption", fails in the following example.

> The Free-Particle-on-a-Circle Counterexample
>
> Let $Q = S^1$ (a circle of circumference 2π), $M = 1$, $V = 0$, $H = -\frac{\hbar^2}{2}\frac{d^2}{dx^2}$. The gap is $\Delta = \hbar^2/2 > 0$ and $\xi = \hbar/\Delta = 2/\hbar$, but the canonical C_P of the path measure at $T = \infty$ is $+\infty$.

Proved here Proof [Y3]. The eigenfunctions are e^{ikx} with eigenvalues $\hbar^2 k^2/2$, so $\Delta = \hbar^2/2$. The continuous lift $\tilde{x}(\tau)$ of a path $x(\tau)$ to the real line is determined up to a constant $2\pi k$. Take w with support $[0, L]$ vanishing at the ends, and set

$$f = \int w(\tau)\, d\tilde{x}(\tau) = -\int w'(\tau)\, \tilde{x}(\tau)\, d\tau, \qquad \mathrm{Var}(f) = \hbar \int w^2\, d\tau, \qquad \mathcal{E}(f) = \hbar \int w'^2\, d\tau \quad (23)$$

Since $\int w' = 0$, the indeterminacy of the constant of the lift disappears, and f is a function of the path. The variance follows from $\tilde{x}$ being a Brownian motion of strength $\hbar$ and the Itô isometry Cited, and the Dirichlet form from $\delta f/\delta x(\tau) = -w'(\tau)$. Stretching as $w(\tau) = w_0(\tau/L)$, the ratio is $L^2 \int w_0^2 / \int w_0'^2$, which grows without bound as $L \to \infty$. ∎ Lean `rotor_ratio_unbounded`, `rotor_gap_pos` (assumptions: $0 < r$ / $0 < \hbar$. Conclusions: for every B there is $L > 0$ with $B < L^2 r$ / $0 < \hbar^2/2$. Only the arithmetic of the skeleton of the Free-Particle-on-a-Circle Counterexample).

Example 7 (the random walk of the winding number). For $w_0(\tau) = \sin(\pi\tau)$ ($0 \le \tau \le 1$), $\int w_0^2 = \frac{1}{2}$ and $\int w_0'^2 = \pi^2/2$, so the ratio is L^2/π^2. It is the same number as the $C_P \approx L^2/\pi^2$ of the single road of Example 1, and not by chance. The winding number counts how many times the particle on the circle has gone round, and it performs a random walk on an endless single road. With $\hbar = 0.1$, $\xi = 20$ and $\xi^2 = 400$, but at $L = 100$ the ratio is about 1013, and at $L = 1000$ about 1.01×10^5, exceeding ξ^2 without limit. In the family $\hbar \to 0$, setting $a := 1/\xi$, $m_{\mathrm{phys}} = m\,\xi = 1$ is positive for every $\hbar$, yet since $C_P = \infty$, the upper-bound assumption breaks for every $\hbar$.

To name the type: relaxation becomes slower than the gap when a quantity not local in time and not reflected in the gap (a winding number, a topological charge, a number of kinks) is carried by diffusion. It is the same mechanism by which conserving dynamics has $C_P = \infty$ (the detour of 2-10); in gauge theory the freezing of the topological charge in a periodic box is a candidate of this type (23-02 § 05). Note the scope. For the four-dimensional Wilson measure on a finite periodic box the configuration

space is a compact connected finite-dimensional space, so $C_P < \infty$, and the Free-Particle-on-a-Circle Counterexample is not a counterexample in that class. What the Free-Particle-on-a-Circle Counterexample shows is a logical gap (a positive gap does not even imply finiteness of C_P); whether the converse is false within the class of Wilson measures is not settled.

In summary, under the assumption of the bridge, the upper-bound assumption implies a lower bound on the gap of the lattice in physical units, and the converse does not hold in general. **Under the assumption of the bridge, the upper-bound assumption is a stronger sentence than the lattice mass gap in physical units.** The road of the relaxation-time assumption is a road that restates a stronger sentence in a language where the tools of (2) can be used.

The relaxation-time assumption is not non-triviality

For a free massive field, as in Table 4, $a^2 C_P = 1$, and in the field graduation the relaxation-time assumption, the band statement and the lower-bound assumption all hold with equality Proved here . So the lower-bound assumption is a condition separate from the "non-trivial" of the problem statement (that there is interaction, 0-03), and the relaxation-time assumption as a whole does not include non-triviality either. What the relaxation-time assumption says is only the form "for a family of measures heading to a limit with a mass gap, how the time of fluctuations grows".

The strong-coupling side is the opposite side

Many theorems of lattice gauge theory are on the side of small β (strong coupling), and what they show is a lattice gap uniform in the volume, or Poincaré and logarithmic Sobolev inequalities, that is, the form $C_P = O(1)$. Shen–Zhu–Zhu (2023) show both inequalities with Langevin dynamics, and write 'the infinite volume measure has a strictly positive mass gap' Cited . Converting the condition to Wilson's β gives $\beta < N^2/(16(d-1)) = 1/12$ $(N = 2, d = 4)$.

Table 7 The β where theorems exist and the β on the side of the limit ($SU(2)$, $d = 4$. ξ is a rough guide from the leading term of the strong-coupling expansion $m_0 = -4 \ln u$, $u = I_2(\beta)/I_1(\beta)$)

Region	β	ξ	What is said
Condition of Shen–Zhu–Zhu	< 0.0833	0.065	Cited Uniqueness, both inequalities, exponential decay
Curvature after one-link integration	< 0.2722	0.093	The lower bound on curvature $-27\beta^2$ is Lean `StaplePerturbation.hess_gauge` (assumptions: the period L is even with $L \geq 3$, links are unit quaternions, perturbations are pure imaginary). The criterion is Cited (Bakry–Émery). The stage proceeding to the gap is Assumption (5-11)
Numerical window (Table 2)	2.25–2.60	0.72–1.95	Reading $\Delta/\sqrt{\sigma} \approx 3.3$ to 3.8
Two-loop extrapolation	3.24, 4.14, 5.02	10, 100, 1000	Reading A rough guide assuming asymptotic scaling

The ξ column of Table 7 is Reading (a rough guide from the leading term). The strong-coupling theorems are important results giving the infinite-volume uniqueness statement at small β, but if the range of β is bounded, improving the constants does not bring the physical-unit gap statement or the relaxation-time band at the bookkeeping length any closer. If they extended as they are uniformly in β, the upper-bound assumption would be satisfied and the lower-bound assumption broken, falling into the trivial limit $m_{\text{phys}} \to \infty$ (the direction is the same as (5); the second half of Example 5).

The limit and lifting. Even if the relaxation-time assumption closed on the four-dimensional lattice and the assumptions of the bridge were in place, what would be obtained goes only as far as a lower bound

on the lattice gap in physical units at each $\beta \geq \beta_0$. That $\Delta(\beta)$ has a limit (the rest of the physical-unit gap statement), the existence of the limiting measure (the infinite-volume uniqueness statement, the Wilson-loop limit statement), the recovery of rotations with the OS axioms and reconstruction (the rotation-recovery statement, the OS reconstruction statement), and the non-triviality statement lie outside the relaxation-time assumption. And even if the relaxation-time assumption closed on the first step (the double well), there is no theorem of implication to the relaxation-time assumption on the four-dimensional lattice; what has a prospect of lifting is only the form of the sentence and the form of the tools (23-03 § 06).

(6) Analogous cases — models where a question of the same type became a theorem

"Does the slowness of relaxation of a dynamics grow in the same form as a power of the correlation length" is the subject of theorems outside gauge theory.

Example 8 (the theorem of Bauerschmidt–Bodineau in one sentence). For the hierarchical version of the four-dimensional n-component $|\varphi|^4$ model (a model in which the lattice is replaced by nested boxes so that one step of renormalisation can be written down), in the family approaching the critical point from the high-temperature side, the spectral gap of Glauber-type dynamics goes to 0 with the same power as the gap of the free-field dynamics (with logarithmic corrections for $|\varphi|^4$) Cited (abstract and § 1– § 2 of Bauerschmidt–Bodineau, arXiv:1809.02075, checked). The gap of the free-field dynamics is the square of the mass, that is, it vanishes as a power of ξ^{-2}, so this is a sentence of the same type as the diffusive-relaxation-time assumption: "CP grows as a power of ξ^2, up to logarithmic factors" (the correspondence between mass and correlation length depends on definitions inside the model, so here we keep to a comparison of types).

Three things can be read from this example. First, the question of the type of the relaxation-time assumption stands as mathematics, and there is an example where it was answered for a four-dimensional model with interaction. Second, the answer comes with logarithmic corrections, and holds in the form of a power statement, not a band statement. This is the same situation as the reason for placing the relaxation-time assumption at the power level (the detour of § 07). Third, the method is an induction of Brascamp–Lieb type over discrete scales: the covariance is split scale by scale, and the spectral gap of the measure at each scale is handed on from the spectral gap at the next scale. The conclusion is in the form of a spectral gap (a Poincaré inequality); it uses as an assumption that the potential is uniformly close to convex at each scale, and takes results of equilibrium renormalisation as input. It is a result for scalar fields taking values in a flat space, not for gauge fields. How to transfer it to fields taking values in a group is dealt with, as a question outside this part, in 24-06 § 05 of Part 24.

Classification of the rows of the diffusive-relaxation-time assumption, and the dependency graph

We put the statements of (3)–(6) into one table in the format of the five grades (23-00 § 01). The numbers of the rows are the numbers of the nodes of the dependency graph below. The scope column says what the row is about (the range of β, the volume of space, the treatment of time).

Table 8 The relaxation-time assumption and the rows around it ("—" is an assumption row not shown in any range)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
[01]	Upper-bound assumption: $a^2 C_P \leq C$	Assumption	(14)(15)	—	—
[02]	Lower-bound assumption: $a^2 C_P \geq c$	Assumption	(14)(15)	—	—

[16]	(19) $m_{\mathrm{phys}}^2 \geq \kappa / C$ from the upper-bound assumption and the bridge	Proved here	(19)	$\beta \geq \beta_0$	`hup_is_gap_positivity_of_lower` (assumptions: $0 < m_{\mathrm{lat}}$, $\kappa / m_{\mathrm{lat}}^2 \leq C_P$, $C_P \leq K \xi^2$)
[17]	(21) The lower half of the power statement is automatic	Proved here	(21)	$\xi > 1$	`power_lower_half_of_bridge` (assumptions: $0 < \kappa$, $1 < \xi$, $\kappa \xi^2 \leq C_P$)
[18]	(22) Algebra of the bands of the chains	Proved here	(22)	$\beta \geq \beta_0$	`chain_band`, `sq_times_poincare_band` (assumptions: the six band inequalities and positivity of the coefficients)
—	The gap of the dynamics of hierarchical $\lvert\varphi\rvert_4^4$ has the same power as the free field (with logarithms)	Cited	Example 8 (an analogous case; not used in the rows of the relaxation-time assumption)	Hierarchical model, criticality and its vicinity	—

The "Proved here" rows are all either algebra taking assumption rows as input, or propositions with their assumptions named. The one-sided bridge is a proposition whose proof is given in this section, but it is not a theorem that applies as it is to the four-dimensional Wilson measure (for discretised time the time-step comparison assumption remains, for infinite volume the stage from the bridge in a box to the bridge in infinite volume, and for the graduation the uniformity of κ).

How to check. In every row with "⟸", check by eye that the numbers on the right are smaller than the number on the left ([11] from [06], [12] from [06][07][11], [13] from [06][07][09], [15] from [01][02][05], [16] from [01][08][10][12] (or [13]), [17] from [08][12] (or [13]), [18] from [04]). Every row keeps the rule, so there are no cycles. The ASM leaves are the nine [01]–[06] and [08]–[10]; the CIT leaf is [07]. The relaxation-time assumption [03] is a premise of no row. With the bridge, the lower half of the relaxation-time assumption follows automatically by [17], and the content of [03] is only the upper half: that is the content of (4). The Free-Particle-on-a-Circle Counterexample [14] is a counterexample with no premises, and shows that the converse of [16] does not hold in general.

Precisely, this graph is the dependency of the assembly of the relation between the relaxation-time assumption and the mass; it does not include the rows supporting the relaxation-time assumption itself (for the first step, the graph of 23-05 § 07). The one that joins everything together is the integrated graph of 23-12.

07

Detour: the number of rescalings and four clocks — logarithms that do not show in the power

A section you may skip. We look, through formulas for the three metaphors of 23-00 § 05 (the number of rescalings, the graduation of the clock, the clock that runs slow), at why the relaxation-time assumption is placed as a power statement rather than a band statement.

The number of rescalings — the bookkeeping length ξ_{RG}

In four-dimensional lattice Yang–Mills there is no way to obtain ξ by formula as a function of β. So we coarsen the scale of the map one step at a time, and make separately a length that counts how many times it takes to reach a picture of fixed coarseness. In one step that coarsens the lattice by a factor b (one step of the renormalisation group, 7-05), we count the coupling as decreasing as follows.

$$\beta \longmapsto \beta - \kappa\,\big(\ln b - \delta(b)\big), \qquad \kappa = \frac{11}{3\pi^2} \approx 0.3715 \tag{24}$$

κ is the one-loop coefficient (asymptotic freedom, 4-06) rewritten in the lattice β Cited , and $\delta(b)$ is what one step of bookkeeping misses (23-02 § 02). With $k(\beta)$ the number of steps it takes to come down to a fixed value β_*, set

$$\xi_{\mathrm{RG}} = b^{\,k(\beta)}, \qquad a := \frac{1}{\xi_{\mathrm{RG}}}, \qquad \xi_{\mathrm{RG}} = e^{(\beta-\beta_*)/\kappa} \quad (\delta = 0) \tag{25}$$

If $\delta = 0$, the number of steps is $(\beta - \beta_*)/(\kappa \ln b)$, and the bookkeeping length does not depend on b. It has the same form as the one-loop formula of dimensional transmutation (4-07).

Proved here Table 9 The number of rescalings (one loop, $\delta = 0$, $b = 2$, with $\beta_* = 2.0$ as an example. Values of the closed formula (25))

β	Number of steps k (number of halvings)	$\log_{10} \xi_{\mathrm{RG}}$
2.5	1.94	0.58
4	7.77	2.34
6	15.53	4.68
10	31.07	9.35
20	69.90	21.04

Each increase of β by 1 adds about 3.9 halvings. The choice of β_* affects only a constant factor. The bookkeeping length is not a length fixed directly by the measure but a length fixed by the convention of bookkeeping, and that it agrees with ξ up to a constant factor is the assumption of the one-scale chain and the bookkeeping-length chain Assumption . If the bookkeeping is truncated at one loop, the difference from the two-loop running (for pure $SU(N)$, $b_1/(2b_0^2) = 51/121$) remains as a factor $\beta^{51/121}$ Cited (at the level of perturbation theory, 4-06).

The graduation of the clock and the clock that runs slow

Writing an $SU(2)$ link as $U = e^{i\vartheta\cdot\sigma}$, the relation to the field of the continuum theory is $A = \sqrt{\beta}\,\vartheta$. $\mathcal{E}$ is a square of derivatives, so

$$\mathcal{E}_A = \frac{\mathcal{E}_\vartheta}{\beta}, \qquad C_P^{(A)} = \beta\, C_P^{(\vartheta)}, \qquad \text{in the free approximation } C_P^{(A)} = \xi^2,\ C_P^{(\vartheta)} = \frac{g^2}{4}\,\xi^2 \tag{26}$$

Proved here . Further, Langevin time itself stretches and shrinks with scale. When stochastic quantisation (7-09) is renormalised in perturbation theory, besides the field and the coupling, the graduation of stochastic time is also renormalised multiplicatively Cited (at the level of perturbation theory). Transferring its one-loop coefficient into the language of graduations, it can be read as

$$C_P^{(A)} \;\propto\; \xi^2\,\beta^{13/22}, \qquad C_P^{(\vartheta)} \;\propto\; \xi^2\,\beta^{-9/22} \tag{27}$$

can be read Assumption (a reading that presupposes that it is the leading one-loop logarithm, that the leading logarithm of the lattice agrees with that of dimensional regularisation, the multiplicative renormalisability of the five-dimensional theory, and the relaxation-time assumption itself). The power $\beta^{-9/22}$ in the angle graduation is the same power as the factor $g_0^{9/11}$ that Lüscher–Schaefer (2011) write for the autocorrelation time. It comes from the same one-loop coefficient, so it is not an independent check.

Table 10 lines up C_P/ξ^2 for four clocks: two graduations, with and without the slowing. ξ is replaced by the bookkeeping length ξ_{RG} of (25) ($\beta_* = 0$), and the constants are set to 1 at $\beta = 2.5$. The power is $d\ln C_P/d\ln\xi = 2 + \varepsilon\kappa/\beta$.

Proved here Table 10 Four clocks (schematic. Values of the closed formulas $\xi = e^{\beta/\kappa}$ and (26)(27))

β	$\log_{10}\xi$	Field A ($\varepsilon = 0$)	Angle ϑ ($\varepsilon = -1$)	Field A, slowed ($\varepsilon = 13/22$)	Angle ϑ, slowed ($\varepsilon = -9/22$)
2.5	2.92	1	1	1	1
4	4.68	1	0.625	1.32	0.8251
10	11.69	1	0.25	2.269	0.5672
100	116.90	1	0.025	8.844	0.2211
1000	1168.99	1	0.0025	34.48	0.0862
Power ($\beta = 2.5$)	–	2.0000	1.8514	2.0878	1.9392
Power ($\beta = 100$)	–	2.0000	1.9963	2.0022	1.9985

For every clock the power approaches 2, and the constant factor does not settle. Precisely, Table 10 is a schematic representing the interaction only through one-loop logarithmic factors; it is not a computation of the C_P of four-dimensional lattice Yang–Mills. The three logarithms of graduation, order of bookkeeping and stochastic time move the band statement, and do not move the power statement (13).

08

What of the line is in hand — on to 23-02 and 23-03

We line up the statements of this chapter as a single arrow, in the order of the line.

$$\underbrace{\text{one step of bookkeeping}}_{\text{23-02}} \xrightarrow{(\xi^{\prime})\wedge\sum\delta<\infty} \text{(S5)} \xrightarrow{(\xi^{\prime})\text{band}} \text{(S4)} \xrightarrow{\text{(S3)(S6)(S7)(S8)}} \text{the demand of the}$$

The first arrow is the sentence at the power level with the finiteness of the sum of the shortfalls of bookkeeping $\sum\delta$ added (23-02 § 02); the next arrow needs the band statement. Of (28), what is in hand is only part of the first box (the algebra of one step of bookkeeping), and none of the arrows is proved. The ultraviolet side has been crossed by a different road (a construction stacking steps of renormalisation) in the construction published on 2026-11-10. That a theory satisfying the Wightman axioms can be built as a limit of four-dimensional Wilson lattice gauge theory is proved in Lean, according to the committee's assessment (Part 6). Even so, a uniform mass gap is not shown (6-04). Where the setters name the need for new ideas is also the infrared: 'New ideas are needed to prove the existence of a mass gap that is uniform in the volume of space-time.' (Jaffe–Witten § 6.5)Cited .

What follows if the relaxation-time assumption closes. As in § 06, if the upper-bound assumption closes on the four-dimensional lattice and the assumptions of the one-sided bridge are in place (a lattice with continuous time, or, on a lattice with discretised time, the time-step comparison assumption ((D) in the paper "one-sided bridge"); κ uniform in β; the stage from the box to infinite volume), it follows that at each $\beta \geq \beta_0$ the lattice gap in physical units stays at least $(\kappa/C)^{1/2}$ ((19)). From the relaxation-time assumption alone (a power statement, not the band statement), no gap in physical units follows. C_P is the reciprocal of the gap of Langevin dynamics running in an artificial time, a different quantity from the gap of the Hamiltonian of the transfer matrix (the mass) (the vacuum C_P and the path C_P of Table 3). The bridge is a one-directional inequality between them, and the converse does not hold in general (the Free-Particle-on-a-Circle Counterexample). Even with the relaxation-time assumption and the bridge in place, it does not follow that $\Delta(\beta)$ has a limit, nor the existence of the limit (the infinite-volume uniqueness statement, the Wilson-loop limit statement), the OS axioms and reconstruction (the

rotation-recovery statement, the OS reconstruction statement), or the non-triviality statement. And even if the relaxation-time assumption closed on the first step (the double well), there is no theorem of implication to the relaxation-time assumption on the four-dimensional lattice; what has a prospect of lifting is only the form of the sentence and the form of the tools (23-03 § 06).

The roads that pushed the arrows of (28) on the four-dimensional lattice as it is, and where each stopped, are gathered in 23-02. As seen there, on the side of the lower-bound assumption (some f) there are several roads that reach, and on the side of the upper-bound assumption (every f) no tool that reaches has been found. The relaxation-time assumption is a sentence independent of dimension, so the first step of the staircase is to move the same sentence to the smallest model where the relaxation-time assumption is expected to hold, and build the assembly of the upper side there first (23-03).

What this chapter can say

Said	Not said
Cited The split into eight statements and their current status in four dimensions (Table 1), the footnote of the problem statement and § 6.5, the direction of the lattice correlation-length problem, the strong-coupling theorems (Table 7), the relation of the vacuum C_P among the three C_P to the gap, the convexity and perturbation criteria of (9), the gap of the dynamics of hierarchical $\lvert\varphi\rvert^4_4$ (Example 8, as an analogous case)	The infinite-volume uniqueness statement at large β; the Wilson-loop limit statement, the physical-unit gap statement, the rotation-recovery statement and the non-triviality statement (along the line of this chapter; for the relation to the published construction, see the note in § 02). This chapter shows nothing about them
Proved here That a uniform lattice gap means a divergent physical mass ((5)), that the physical-unit gap statement and the relaxation-time band at the bookkeeping length say the same thing for the free field ((8), Table 4), the relation between band and power ((11), Example 4), the asymmetry of quantifiers ((15)), the hand calculations of Examples 1–7, the conversion of graduations (26), the values of the closed formulas in Tables 9 and 10	Joining the physical-unit gap statement and the relaxation-time band at the bookkeeping length in a theory with interaction (the relaxation-time assumption, the band statement)
Proved here The one-sided bridge ($C_P \geq \kappa\xi^2$; conditions: (A1)–(A3), continuous time, finite spatial lattice, $T = \infty$) and the Discrete-Time One-Sided Bridge Proposition (condition: (D)), the ground-state transformation identity (18), the Free-Particle-on-a-Circle Counterexample (on the circle $\Delta > 0$ and $C_P = \infty$)	Applying the bridge to the four-dimensional Wilson measure ((D) for discretised time, uniformity of κ, the stage to infinite volume). Whether "positive gap ⇒ the upper-bound assumption" is false within the class of Wilson measures
Proved here The algebra rereading the upper-bound assumption and the lower-bound assumption as lower and upper bounds on the mass ((16)) Lean `hup_is_gap_positivity`, `hdown_is_mass_finiteness` (assumptions: $m_{\mathrm{lat}} > 0$, $C_P = 1/m^2_{\mathrm{lat}}$, one side of (14)). The version weakened to one side, (19), `hup_is_gap_positivity_of_lower` (assumptions: $0 < m_{\mathrm{lat}}$, $\kappa/m^2_{\mathrm{lat}} \leq C_P$, $C_P \leq K\xi^2$). The lower half of the power statement, (21), `power_lower_half_of_bridge` (assumptions: $0 < \kappa$, $1 < \xi$, $\kappa\xi^2 \leq C_P$). The algebra of the bands of the chains, (22), `chain_band` (assumptions: the six band inequalities)	The relaxation-time assumption, the upper-bound assumption, the lower-bound assumption and the three chains themselves. That $C_P = 1/m^2_{\mathrm{lat}}$ holds in a theory with interaction
Reading That $\Delta/\sqrt{\sigma}$ is roughly constant in the Monte Carlo values of the original source (Table 2); the rough guide to ξ in Table 7	That the extrapolated value is the value of the constructed theory
Assumption The exponents of stochastic time $13/22$ and $-9/22$ (a one-loop reading with premises), that the bookkeeping length and ξ agree up to a constant factor, the assumption rows of Table 8	That those exponents apply to the C_P of four-dimensional lattice Yang–Mills. About the mass gap and the continuum limit, this chapter shows nothing

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time seventeen roads, twenty-one walls (five types) · Kiichi, Shiori and Rin

Roads tried on the four-dimensional lattice, and walls — they reach from below, and not from above

> This chapter is this book's own investigation. § 01 is guide material; § 03, § 06 and § 08 are a map of open questions.

What this chapter shows — We put on one sheet the seventeen roads tried on the four-dimensional lattice towards the diffusive-relaxation-time assumption and the arrows of the line of construction, and the twenty-one places where they stopped (the walls). The roads through test functions, gauge fixing and spectroscopy all end in lower bounds on C_P or upper bounds on the mass; tools that reach the upper side (inequalities for every f) existed only on the strong-coupling side, where curvature works, and in a form moved into a single assumption. What was closed in Lean is the algebra from assumptions to conclusions. At the end of this chapter we say, through the correspondence between tools and walls, why we step down to the first step (the double well in 0+1 dimensions).

Prerequisite chapters — 23-01 (the eight statements, the diffusive-relaxation-time assumption, the relaxation-time upper-bound assumption and the relaxation-time lower-bound assumption, the three chains), 1-10 (the variational principle, the Poincaré constant), 4-11 (the gap and finite windows), 5-02 (the strong-coupling expansion), 7-05 (steps of the renormalisation group). Notation as in 23-01 ($SU(2)$, $d = 4$, $\beta = 4/g^2$, lattice units).

Said first — This chapter does not solve the problem. "Stopped" for a road means "we checked that this tool, in this family, does not reach this arrow"; it does not say that the proposition not reached is false. The seventeen roads and twenty-one walls of this chapter are the series on the side of the four-dimensional lattice, separate from the series of the first step (the four double-well conditions, routes, strands, detour plans). Many of the numbers are readings inside models, not computations for four-dimensional $SU(2)$.

The order of this chapter

1. How to read the map — the formula of arrows, and the names of the roads and walls
2. One step of bookkeeping — complete families, one-link integration, the deficit of bookkeeping, the shortfall and the form of the answer (Table 1)
3. The seventeen roads tried — one row each (Table 2)
4. Reaching from below — test functions, gauge fixing and spectroscopy end in upper bounds

5. Not reaching from above — curvature, tubes, one-dimensional chains of scales, boundaries
6. Twenty-one walls — five types (Table 3)
7. What remained — algebra closed in Lean, and numerical readings (Table 4)
8. Why we step down to the first step — which tool stopped at which wall (Table 5)

01

How to read the map — the formula of arrows, and the names of the roads and walls

The roads and walls of this chapter are attempts to push one of the arrows of the line of construction in 23-01 § 08. Rewritten with the band statement split into its upper and lower halves, it has the following form.

$$\underbrace{\text{one step of bookkeeping}}_{\S 02} \xrightarrow{\sum_k \delta(bk)<\infty} \text{(S5)} \xrightarrow{(\xi^{\angle})\downarrow \wedge (\xi^{\angle})\uparrow} \text{(S4)} \xrightarrow{\text{properties of the limit}} \text{t}$$

$\delta(b)$ is the shortfall of one step (§ 02); in the formula, (S5) (the relaxation-time band at the bookkeeping length) is $a^2 C_P \asymp 1$, (S4) (the physical-unit gap statement) is that the gap in physical units stays positive, and the properties of the limit are the infinite-volume uniqueness statement, the reflection-positivity preservation statement, the Wilson-loop limit statement, the rotation-recovery statement, the OS reconstruction statement and the non-triviality statement (23-01 Table 1). The lower-bound assumption is $C_P \gtrsim \xi_{\mathrm{RG}}^2$ (one test function suffices), and the upper-bound assumption is $C_P \lesssim \xi_{\mathrm{RG}}^2$ (an inequality over all test functions). None of the arrows of (1) is proved.

A road is the pair of one question and one set of tools applied to it, and is named after the content of the question. The road of comparison with the defect of a submission and the road of a one-dimensional chain of scales take up the original question again. A wall is a one-sentence statement of why a certain road, with certain tools, stopped short of a certain arrow; the walls are divided into five types (principle, structure, tools, assumptions, measurement and literature) (§ 06).

Example: the road of lower-bound test functions (test functions giving the lower-bound assumption) pushed the lower-bound assumption of (1), and stopped short of the upper-bound assumption at the one-sided test-function wall (test functions bound C_P only from below). The road of strong-coupling curvature is not on (1); it sits outside to the left. Uniform estimates at strong coupling are $C_P = O(1)$, the opposite side of the relaxation-time band at the bookkeeping length (23-01 § 06).

02

One step of bookkeeping — from complete families to the sum of shortfalls

One step is the map that coarsens the lattice spacing from a to ba, integrates out some of the fine variables, and makes the action of the coarse lattice (7-05). The bookkeeping here takes three moves: (i) choose links that can be integrated in closed form, (ii) write the remaining action with characters, (iii) read the coefficient of the fundamental representation of the coarse plaquette as β'. It is of the "decimation" type, keeping some of the original links (Migdal–Kadanoff is an approximation of the same type). The area law, dimension counting and the one-loop coefficient are known rewritings, not counted as results.

Complete families. If the links to be integrated never lie on the same plaquette, then with the rest held fixed the weight of each link separates independently and can be integrated. A family that removes exactly one link from every plaquette is called a complete family.

$$F \subset E \text{ is complete} \iff \text{for every plaquette } P,\ |P \cap F| = 1; \qquad f_x \le 2,\ \frac{1}{|V|}\sum_x f_x = \frac{d}{2} \implies d \le 4$$

Proved here An edge lies on $2(d-1)$ plaquettes, so counting the pairs $(P, \ell \in P \cap F)$ in two ways gives the density of the family $|F|/|E| = 1/4$. Two perpendicular edges at the same vertex are two adjacent edges of one plaquette, so the number f_x of edges of the family at a vertex x is at most the two along one axis, and comparing with the average $d/2$ gives $d \le 4$. The classification including existence is Table 1; the statements are Lean `PerfectFamily.perfectK_one_iff` (assumption: $2 \le d$. Conclusion: the box $(\mathbb{Z}/L)^d$ of period L has a complete family of edges $\iff$ $d \le 4$ and L is even) and `no_perfectZ_of_five` (assumption: $d \ge 5$. There is none on $\mathbb{Z}^d$). No prior record was found in what we searched, but it may be known. This 4 is a combinatorial number of the lattice; its agreement with the four dimensions of spacetime is a coincidence with no relation.

Proved here Table 1 Existence of complete families of edges on $(\mathbb{Z}/L)^d$ (the statement of `perfectK_one_iff` written out. In brackets, the number of edges in one family = 1/4 of the number of edges)

Period	$d=2$	$d=3$	$d=4$	$d=5$
$L=2$	Yes (2)	Yes (6)	Yes (16)	No
$L=3$	No	No	No	No
$L=4$	Yes (8)	Yes (48)	Yes (256)	No

One-link integration. The 6 plaquettes on which an edge ℓ of the family lies contain no other edges of the family, so U_ℓ pairs only with the sum M of staples (the products of the three edges of a plaquette other than ℓ), and the integral is determined by $|M|$ alone.

$$\int_{SU(2)} e^{\frac{\beta}{2}\operatorname{tr}(UM)}\,dU = \frac{2I_1(\beta|M|)}{\beta|M|} =: F(\beta|M|), \qquad \frac{\beta^2 t}{8} - \frac{\beta^4 t^2}{64} \le \ln F(\beta\sqrt{t}) \le \frac{\beta^2 t}{8} \quad (3)$$

The left is the standard formula of the $SU(2)$ heat-bath method Cited (5-07); the two-sided estimate on the right is Lean `log_F0_le`, `log_F0_ge` (assumption: only that the argument is non-negative). The conditional density of the remaining edges is a product of six sources and

does not close into the one-link type, so this trick works only once Assumption (there is a paper argument, but this book gives no proof).

The deficit of bookkeeping. After integrating a complete family, not a single "intact" plaquette with all 4 edges remaining is left, and the coupling can only be reborn from broken plaquettes. For the fraction e of remaining edges and the fraction q of intact plaquettes, counting pairs gives

$$e - q = \frac{1}{4|\mathcal{P}|} \sum_{P \text{ broken}} |P \cap E_K| \;\geq 0 \quad (4)$$

Proved here (double counting) Lean `Incidence.intact_frac_le` (assumption: the incidence is regular. Conclusion: $q \leq e$). Stacking steps does not reach it: in a sequence of complete steps the remaining edges are $(2^k+1)/2^{k+1} > 1/2$, `no_blocking` (assumption: a sequence of complete steps), and in any sequence removing at most $1/4$ at each step, reducing the edges to $1/16$ leaves at most $1/65536$ of the 4-loops, `blocking_shortfall` (assumption: fraction $\leq 1/4$). The reading of this subsection is that the wall of bookkeeping was neither curvature nor packing, but the way of bookkeeping that counts only intact plaquettes.

Discs and a weak-coupling step. Integrating the interior of a disc-shaped set of A plaquettes raises the coefficients of every channel of the character expansion to the power A: $u(\beta') = u(\beta)^A$, and for a 2×2 disc, $\beta' = \beta^4/64 + O(\beta^6)$ Cited (a rewriting of the strong-coupling area law and two-dimensional decimation, 5-02, 7-02). It is a semigroup in the area, with $\beta' < \beta$ everywhere Lean `discStep_semigroup`, `step_lowers_coupling` (assumption: surfaces of disc shape). In the Gaussian approximation at weak coupling, the b^2 plaquettes of a disc act in series and the b^{d-2} transverse layers in parallel, giving

$$\beta'_{\text{disc}} = \frac{\beta}{b^2}, \qquad \beta'_{\text{tree}} = \beta\, b^{d-4}, \qquad \kappa_{\text{disj}}(b) = \frac{1}{b^2} + \frac{2}{b^2+4b} < 1 \quad (5)$$

βb^{d-4} is the dimension count of the coupling, marginal at $d = 4$ Cited (4-04). The contribution of surfaces sharing no edges does not reach 1 Lean `kappaDisj_lt_one` (assumption: $b \geq 2$), and the bookkeeping of surfaces has the multiplicative form $\beta' = \kappa(b)\beta$, not the subtractive form of one loop $\beta' = \beta - \kappa \ln b$.

The one-loop slope and the shortfall. On top of the tree-level $\beta' = \beta$ sits the one-loop correction from the fast modes (momenta between $\pi/(ba)$ and π/a). Measured by the integral over a lattice window, it takes the form

$$\beta' = \beta - \kappa L_{\text{eff}}(b), \qquad L_{\text{eff}}(b) = \ln b + C - \delta(b), \qquad \delta(b) = \frac{c_2}{b^2} + O(b^{-4}) \quad (6)$$

$\kappa = 4Nb_0 = 11/(3\pi^2) = 0.3715110$ is the known one-loop coefficient Cited (4-06). The slope read from the difference of windows is 1.000028 at $b = 32 \to 64$; multiplied by κ it is 0.371521, agreeing with $11/(3\pi^2)$ to a relative 2.8×10^{-5} Reading (an agreement inside the model of the one-loop kernel; not a non-perturbative check). The coefficients of the shortfall are $c_2 = 0.0197(5)$ (weight w) and $0.4200(5)$ (weight w^2), and at $b = 2$, $\delta(2) = 0.1335$ and 0.2284 Reading

(fits in the same model). On the other side, the effective slope $\Delta\beta/\ln(a_1/a_2)$ read from the actual lattice $a\sqrt{\sigma}$ (Table 2 of 23-01) is 0.304 over $\beta = 2.25 \to 2.60$, reaching neither the one-loop 0.3715 nor the two-loop 0.397 Reading . Assuming the step-by-step form $\xi(\beta - \kappa \ln b) = \xi(\beta)/b$ for every $b \geq 1$ gives $\xi(\beta) = \xi(0)e^{\beta/\kappa}$ Proved here Lean `xi_eq_exp` (assumption: that functional equation; neither continuity nor monotonicity is assumed). The physical content lies on the side of the assumed functional equation (the one-loop running put down as an equation).

The form of the answer. Stacking steps with b fixed, the shortfall accumulates by the same amount each step, and if $\delta(b) \neq 0$ the sum diverges. For a sequence with growing step scales $b_k = k + 2$, $\sum_k c_2/(k+2)^2 < \infty$ and it stays bounded Proved here Lean `fixed_step_bounded_iff` (assumption: a constant error $\varepsilon_j = d \geq 0$. Conclusion: the partial sums are bounded $\iff d = 0$). For example, with the provisional value $c_2 = 1$, fixing $b = 2$ gives a total of 250 after 1000 steps, while with $b_j = j + 2$ the total stays within $\pi^2/6 - 1 = 0.645$ (values of closed formulas). What ties this shortfall to the first arrow of (1) is the algebra of two powers.

$$C_P \asymp \xi^{\,2-\eta}, \qquad a\,\xi \propto a^{\theta} \quad\Longrightarrow\quad a^2 C_P \propto a^{p}, \qquad p = \eta + (2-\eta)\,\theta \;(7)$$

θ is the exponent of accumulation of the shortfall (with b fixed, $\delta(b)/\ln b$), and η is the dynamical power η_{dyn}. If $0 \leq \eta \leq 2$ and $\theta \geq 0$, then $p = 0 \iff \eta = 0 \wedge \theta = 0$ Proved here Lean `drain_exponent`, `drainExp_eq_zero_iff` (assumptions: the power form of (7) and the signs). In words, "under the relaxation-time assumption ($\eta = 0$), the physical-unit gap statement $\Longleftrightarrow \sum_k \delta(b_k) < \infty$", and this is "the form of the answer". Besides the relaxation-time assumption, this statement stands on the power form of (7), a model in which the errors of the steps are additive and bounded, and δ being the value of the model of the one-loop kernel Assumption . The algebra that if the partial sums of the errors of the steps are bounded then $a_k^2 C_P^{(k)}$ stays in a positive band is also closed Lean `S4_two_sided` (assumptions: partial sums $|\sum_{j<k} \varepsilon_j| \leq M$, positivity of coefficients. Reading this as $a_k^2 C_P^{(k)}$ is on the side of the text).

A road that changes the kernel to make $\delta(2) = 0$ exists in the one-parameter family $c_1(q) = \alpha + (1-\alpha)\cos q$ at $\alpha_0 = 1.4400$, but the neighbouring weight is negative Reading . For kernels with positive weights, $c_2 > 0$ Lean `c2_ge_of_nonneg_weights` (assumption: c_2 is an increasing affine function $A + \kappa S$ of the kernel quantity $S \geq 0$, with $A, \kappa > 0$, a measured dependence. Not an unconditional claim). Negative weights can collide with reflection positivity, so within the families examined, removing the shortfall and the condition for returning to a quantum theory are not compatible. Outside the families it is undecided.

03

The seventeen roads tried — one row each

Table 2 lines up the seventeen roads one row each. The names in the "Where it stopped" column are the walls of § 06, and the "What remained" column is algebra closed in Lean (assumptions in brackets) or labelled statements.

Table 2 The seventeen roads tried on the four-dimensional lattice

Road	What (arrow pushed)	With which tools	Where it stopped	What remained
Road of strong-coupling curvature	Widen the β where the curvature method works (outside (1), strong-coupling side)	Lower bound on the Hessian form after one-link integration of a complete family, and the Bakry–Émery criterion	Up to $\beta < \sqrt{2/27} = 0.2722$. The correlation length is about 1/10 of a lattice spacing, on the opposite side from the limit (upper-bound tool wall)	Lean `hess_gauge` (assumptions: the period L is even with $L \geq 3$, unit quaternions, pure imaginary perturbations. Conclusion: $\partial_\tau^2 \Phi \geq -27\beta^2 \sum \lvert X_e \rvert^2$). The stage proceeding to the gap is Assumption
Road of one-step bookkeeping	Bookkeep the continuum limit as a sequence of steps (one-step bookkeeping)	Complete families, character expansion, disc steps, one-loop windows	One-link integration works only once (single-step integral wall). The bookkeeping of surfaces is multiplicative and does not produce the one-loop slope	`discStep_semigroup`, `step_lowers_coupling`, `kappaDisj_lt_one`, `intact_frac_le`, `no_blocking`, `blocking_shortfall`
Road of the sum of shortfalls	Is the sum of the shortfalls $\delta(b)$ finite (the summability-of-shortfalls assumption)	Window integrals of the model of the one-loop kernel	With b fixed the sum diverges. The kernel with $\delta(2) = 0$ has a negative neighbouring weight (positive-weight kernel wall). The difference of c_2 with the choice of gauge went only as far as reading it positive in two gauges (gauge dependence of the shortfall wall)	`fixed_step_bounded_iff`, `c2_ge_of_nonneg_weights` (assumption: the measured dependence). Reading c_2

Road	What (arrow pushed)	With which tools	Where it stopped	What remained
Road of the strong-coupling series	Can the dynamical power η be read from the strong-coupling series (the η of the relaxation-time assumption)	High-order strong-coupling expansion, Dlog-Padé	Near the pole the series takes the renewal form $G = A/(1 - K(p))$, which forces $\eta = 0$. At an essential singularity under asymptotic freedom the exponent cannot be read (renewal-series wall)	Lean `renewal_chi_mul_massSq`, `renewal_residue_pos` (assumption: coefficients of the renewal form $A, c_0 > 0$. Conclusion: $\chi m_0^2 = A/c_0 > 0$). That it takes the renewal form is Assumption
Road of the dimension of complete families	In which dimensions do complete families of edges and faces exist (one-step bookkeeping)	Double counting, exhaustive search for exact covers	For edges, only for $d \le 4$ with an even period. For k-cells there is an upper limit $d \le 3k + 1$, and $d = 9$ for $k = 3$ is undecided	`perfectK_one_iff`, `no_perfectZ_of_five`, `no_perfect_k4_d9`, `no_perfect_k5_d8` (assumption: period 2 only)
Road of the dimensional threshold	Why four dimensions is the borderline (the summability-of-shortfalls assumption)	The recursion for the drift of the steps $x_{k+1} = b^{d-4} x_k + \varepsilon_k$	Contracts for $d < 4$, accumulates for $d = 4$. The same as the standard dimension count; not a reproduction of the constructions in lower dimensions	Lean `dev_le_of_contracting` (assumptions: $0 \le \lambda < 1$, $\lvert\varepsilon_j\rvert \le E$. Conclusion: drift $\le E/(1 - \lambda)$), `dev_eq_of_marginal` (with $\lambda = 1$ and constant E, drift $= nE$)
Road of reflection positivity	Use reflection positivity for an estimate from below (the reflection-positivity preservation statement, the OS reconstruction statement)	Representation by the transfer matrix	For the overlap $\tilde{Z}$ with the lightest state, an upper bound $\tilde{Z} \le \chi m$ came out where a lower bound was wanted. The question moved to the road of lower-bound test functions	Lean `overlap_le_susc_mul_gap` (assumptions: $m > 0$, $\tilde{Z} \ge 0$, $\tilde{Z} \coth(m/2) \le \chi$)

Road	What (arrow pushed)	With which tools	Where it stopped	What remained
Road of an area law in the bookkeeping	Does the form of the area law appear inside the bookkeeping (the Wilson-loop limit statement)	Coefficient $4(\beta/4)^{A}$	A rewriting of the strong-coupling area law, which holds even for abelian groups. Not counted as evidence of confinement. The content went to the road of the lower half at one scale	Cited (Wilson 1974, Osterwalder–Seiler 1978)
Road of multi-link integrals	Is the closed form of k-link integration analytic even in the continuum limit (one-step bookkeeping)	Closed form of a single sum	The two-link correction is of size β^{3} and not an obstacle. Analyticity has not been shown	Assumption (a calculation inside the strong-coupling expansion)
Road of comparison with the defect of a submission	Is the "small defect" of a submission that claims a construction the same quantity as δ (the summability-of-shortfalls assumption)	Comparison of types	The sum of defects is a quantity of the contracting sector; δ is the shortfall of the coefficient of the marginal sector. The words sit in the same place, but the quantities differ	We do not judge whether the submission is right or wrong (the policy of 16-01)
Road of multiscale curvature	Stack the curvature method scale by scale to make a tool for the upper-bound assumption (the upper-bound assumption)	Multiscale Bakry–Émery, curvature on the Gribov region, one step of gradient flow	Cannot be written beyond the cross terms of two scales (upper-bound tool wall). Details in § 05	Lean `comp_class_eq_of_equivariant_bijection` (assumption: the flow is a bijection commuting with the gauge action), `autocov_sum_le_on_invariant` (assumption: Poincaré on an invariant subspace)

Road	What (arrow pushed)	With which tools	Where it stopped	What remained
Road of volume and boundary	Is the estimate of C_P uniform in volume and boundary condition (the infinite-volume uniqueness statement)	Bare link angles, comparison of boundary conditions	With bare link angles the ratio is 1 and the worry about zero modes disappeared. Instead the boundary condition matters, and the upper-bound assumption can break in a periodic box (periodic-boundary conjecture wall)	Assumption (a reading under the conjecture that HMC and Langevin are in the same universality class)
Road of lower-bound test functions	Is there a test function giving the lower-bound assumption (the lower-bound assumption)	Three families: plaquettes, bare link angles, gauge-fixed long-wavelength modes	Local operators have dimension 4, so $\eta \geq 2$ (local-operator dimension wall); link angles give ratio 1; gauge fixing runs into single-valuedness (gauge-fixing single-valuedness wall)	`profileQuotient_isGreatest`, `fisherEta_eq_zero_iff_canonical`, `eta_ge_two_of_bounded_susc` (assumption: susceptibility uniformly bounded), `prop_at_gap_scale` (assumption: pure-power propagator), `jump_energy_ge`
Road of gauge-fixed long wavelengths	Can gauge-fixed long-wavelength modes be made single-valued (the lower-bound assumption)	Weighted averages over orbits (the schemes of Parrinello–Jona-Lasinio and Zwanziger)	Sharp means multivalued, blunt means the long wavelengths vanish (gauge-fixing single-valuedness wall). The numbers are tests on compact $U(1)$	`orbitAvg_gauge_invariant`, `orbitAvg_continuous` (assumptions: orbits of a finite group, positive continuous weights)

Road	What (arrow pushed)	With which tools	Where it stopped	What remained
Road of spectroscopy	Bound the gap with smoothed operators and spectroscopy (the lower-bound assumption and upper bounds)	Wilson flow, APE, variational method, effective mass	Ends in upper bounds (spectroscopic upper-bound wall). A lower bound needs a lower bound on the overlap. The cost of measuring the numerator is $\geq cL^{d+2}$ (measurement-cost wall)	`meff_antitone`, `meff_ge_of_corr`, `gap_ge_of_overlap` (assumption: a lower bound q on the overlap), `light_admixture_invisible`, `cost_ge`, `sqQuotient_between`
Road of the lower half at one scale	Build the lower half at one scale, $m^2 \gtrsim \sigma$ (the one-scale chain)	Entropy of tubes, deficit $D = m - 4\sigma$, pillar model, Wulff shape	Moved into the tube transfer-operator inequality (the tube inequality), but there is no type of proof for it (tube-inequality wall)	`mass_sq_ge_of_tube` (assumption: a norm estimate that is a consequence of the tube inequality), `mass_bound_localized`, `linear_regime_breaks_onescale`, `casimir_only_no_bound`, `linear_deficit_breaks_inv`
Road of a one-dimensional chain of scales	Sandwich the upper-bound assumption with a one-dimensional chain of scales (the upper-bound assumption)	The radial type of holography, two-weight Hardy inequality, sandwiching autocorrelations	Sandwiched only under the assumption of projection onto a one-dimensional chain of scales. The projection assumption is not weaker than the relaxation-time assumption, and in a periodic box it breaks through the topological charge (projection-assumption wall)	`conditional_scale_bound` (assumptions: the projection assumption, shortfalls non-negative with bounded partial sums, geometric-series weights), `const_defect_scale_unbounded`, `tau_int_le`, `rayleigh_le_tau`

Seen arrow by arrow, there is a bias. Stopped roads gather at the lower-bound assumption and outside (1). Only two roads aimed at the upper-bound assumption, the road of multiscale curvature and the road of a one-dimensional chain of scales; the road of multiscale curvature stopped at the cross terms, and the road of a one-dimensional chain of scales sandwiched only under the projection assumption. No road of this chapter reached the rotation-recovery statement or the non-triviality statement (on the side of the published construction, the committee's assessment is that the recovery of rotations is shown for the theory phase by

phase; 6-03). The Wilson-loop limit statement and the rotation-recovery statement are claims of a kind that do not come out however many times the map of one step is composed (limit-property wall).

04

Reaching from below — test functions, gauge fixing and spectroscopy end in upper bounds

The road of reflection positivity, the road of lower-bound test functions, the road of gauge-fixed long wavelengths and the road of spectroscopy all aimed at estimates from below, and stopped at a place of the same form. C_P is a supremum over test functions, and the gap is an infimum over states, so what one test function or one operator gives is in either case only one side.

$$C_P = \sup_f \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} \;\geq\; \frac{\mathrm{Var}(f_0)}{\mathcal{E}(f_0)}, \qquad E_{\mathrm{low}} = \inf_{\psi \perp \Omega} \frac{\langle \psi, H\psi\rangle}{\langle \psi,\psi\rangle} \;\leq\; m_{\mathrm{eff}}(k) \quad (8)$$

Cited The variational principle (1-10). Ω is the vacuum, H the Hamiltonian of the transfer matrix, and $m_{\mathrm{eff}}(k) = \ln(C(k)/C(k+1))$ the effective mass at time k. The lower-bound assumption is a statement about "some f", the side test functions can reach; the upper-bound assumption is about "every f", the side they cannot.

Local operators (the road of lower-bound test functions). In the family made by translating one operator O_x and summing with weights, the freedom of the weights collapses to a single best momentum Lean `profileQuotient_isGreatest` (assumptions: finitely many momenta, the Fourier transform of the denominator is positive). The numerator is a susceptibility, and estimating it by the integral up to radius ξ,

$$\frac{\mathrm{Var}(f_O)}{\mathcal{E}(f_O)} \asymp \xi^{\,2-\eta_s}, \qquad \eta_s = \min\bigl(2\Delta_O - (d-2),\, 2\bigr), \qquad \Delta_O \geq 4 \Rightarrow \eta_s = 2 \quad (9)$$

(assuming a power form of the correlations). η_s is the static power of each operator, a different quantity from the dynamical η_{dyn} (18-05). The lowest dimension of gauge-invariant local operators is the 4 of $\mathrm{tr}\, F^2$ Cited , so the ratio does not grow with ξ Lean `eta_ge_two_of_bounded_susc` (assumption: the susceptibility is uniformly bounded; the boundedness comes from the physical assumptions of the form of correlations and $\Delta = 4$). For bare link angles, under the measure without gauge fixing each link angle is uniform and independent, and the ratio is 1 independently of β and the volume Proved here (a direct calculation from the invariance of the Haar measure; the same mechanism as Elitzur's theorem).

Gauge fixing (the road of gauge-fixed long wavelengths). Gauge-fixed long-wavelength modes are non-local and avoid the wall of dimension, but the choice of representative must be single-valued. Taking a weighted average at temperature T over the orbit makes it single-valued and continuous Lean `orbitAvg_gauge_invariant`, `orbitAvg_continuous`. In the smallest example, the $U(1)$ ring (L edges), the amplitude of the averaged mode vanishes exponentially

with L as $(I_1/I_0)^{L-1}$ for blunt fixing, and jumps at the total angle $\Phi = \pi$ for sharp fixing Proved here (closed formulas from Fourier series). The same functional serves both as "a tool for choosing among copies" and "a tool for evening out long wavelengths", so the two demands sit at the two ends of a single knob. The numbers measured for four-dimensional compact $U(1)$ (the scatter between copies being 3.25 standard deviations, and so on) are Reading ; they were not measured for $SU(2)$.

Spectroscopy (the road of reflection positivity, the road of spectroscopy). Smoothing in the three spatial directions only stays on one time slice, and correlations keep the form $C(k) = \sum_n w_n e^{-E_n k}$ $(w_n \geq 0)$ Cited (5-03). With this form the effective mass decreases monotonically Lean `meff_antitone` (assumption: a representation with non-negative weights), and at every k it is an upper bound on the lowest energy `meff_ge_of_corr`. A lower bound needs a different input.

$$E_{\text{low}} \;\geq\; \frac{1}{k}\Big[\ln q + \ln \frac{C(0)}{C(k)}\Big] \qquad (w_{\text{low}} \geq q\, C(0) \text{ assumed}) \quad (10)$$

Proved here Lean `gap_ge_of_overlap` (assumptions: a representation with non-negative weights and a lower bound q on the overlap). The price of the lower bound is exactly one lower bound on the overlap; without q, a light state of weight ε changes the correlation by only ε at every k `light_admixture_invisible` (a concrete two-level example). That no lower bound on the gap follows from finitely many measurements is a restatement of the known framework of the equivalence of a gap and exponential clustering Cited (4-11). On the numerical side, the effective mass of a smoothed operator at $\beta = 2.6$, 12^4 was $\leq 0.501 \pm 0.071$, touching the $am(0^{++}) = 0.514(8)$ of the original source from below Reading (Monte Carlo, reading of an upper bound). A four-dimensional flow that also smooths in the time direction does not stay on one slice, and breaks the upper-bound property with an effective mass that increases monotonically Proved here (closed formulas for the free field). The cost of measuring is $\geq cL^{d+2}$, from the relaxation time $\propto L^2$ of the softest mode in a box of side L `cost_ge` (assumptions: a lower bound on the relaxation time, and the number of sweeps needed for relative precision).

The three roads reached the same wall. Each needs "the overlap of gauge-invariant operators with the lightest fluctuation is bounded from below", which includes "no other light state is hidden", a statement about all states. It has the same form as the upper-bound assumption.

05

Not reaching from above — curvature, tubes, one-dimensional chains of scales, boundaries

The upper-bound assumption is an upper bound on CP. The types of tools that give upper bounds are limited; there are two representative ones.

$$\nabla^2 U \geq K > 0 \implies CP \leq \frac{1}{K} \quad \text{(Bakry–Émery)}, \qquad B \leq CP \leq 4B \quad \text{(one dimension, Muckenhoupt}$$

Cited The left comes from a lower bound on the curvature of the measure e^{-U} (1-10); the right sandwiches C_P within a factor of 4 by the maximum B of "the mass before a point $\times$ the resistance beyond it", which can be computed only in one dimension.

Curvature scale by scale (the road of strong-coupling curvature, the road of multiscale curvature). The known places where inequalities of the type of the upper-bound assumption stand as theorems are only curvature, diameter, convexity, strong coupling, and the multiscale Bakry–Émery uniform in the lattice regularisation for the high-temperature phase of continuum scalar fields in two and three dimensions Cited (Theorem 1.1 of Bauerschmidt–Dagallier; the criterion is Theorem 2.5 of Bauerschmidt–Bodineau). For four-dimensional gauge fields, the curvature after one-link integration is positive only at strong coupling (the road of strong-coupling curvature). Examining the curvature on the Gribov region in a finite-dimensional model, it was positive only on the strong-coupling side, and the non-convexity came from the zero-momentum mode Reading (on samples with $L = 2, 3, 4$). The ultraviolet fluctuations remaining after removing the zero modes cannot be overcome by one step of gradient flow: the flow is a bijection commuting with the gauge action, so it does not shrink the space of functions Lean `comp_class_eq_of_equivariant_bijection`; the only gain is in changing the metric, and the curvature of the pushed-forward measure became more deeply negative with flow time Reading (within the range measured: open box $\ell = 3$, typical points at $\beta = 2.3, 4$, $t \le 0.5$).

The deficit of tubes (the road of the lower half at one scale). We moved the lower half of the one-scale chain, $m^2 \gtrsim \sigma$, into an inequality between the transfer operator $\mathcal{T}$ of closed tubes and the perimeter operator $\hat{\ell}$.

$$T(c,1): \quad \mathcal{T} \;\le\; \exp\Big(-\big(\sigma\hat{\ell} + c/\hat{\ell}\big)\Big) \qquad \Longrightarrow \qquad m \;\ge\; \min_{\ell>0}\Big(\sigma\ell + \frac{c}{\ell}\Big) = 2\sqrt{c\sigma} \quad (12)$$

Proved here (the right is the AM–GM inequality) Lean `mass_sq_ge_of_tube` (assumption: the norm of the transfer operator is at most $e^{-2\sqrt{c\sigma}}$. Conclusion: $m^2 \ge 4c\sigma$). The power of $1/\ell$ is the only power that makes the coefficient c dimensionless. The content is on the side of the tube inequality, which itself has no type of proof. In the region where the strong-coupling surface expansion converges, the lower half at one scale is itself false `linear_regime_breaks_onescale` (assumption: a sandwich in the region of convergence); in counting with the pillar model the deficit can have either sign, the Wulff shape is a rhombus, and the tube inequality stands only after the anisotropy is subtracted `linear_deficit_breaks_inv` (negative control). The final form is three assumptions, "localised T on short loops, a Casimir floor on large loops, and a seam between them" `mass_bound_localized`; the floor alone gives no lower bound `casimir_only_no_bound`.

A one-dimensional chain of scales (the road of a one-dimensional chain of scales). In holographic models the gap is an eigenvalue problem in a single radial variable, and on that variable the band statement $C_P \asymp \xi^2$ becomes an identity needing no proof Proved here (ground-state transformation $H = P^\dagger P$ and the variational principle). To bring this onto the lattice, we put a one-dimensional chain on the scale $s = \ln \ell$ and sandwiched C_P with the discrete version of the right of (11).

$$(\mathrm{P}) \ \wedge \ \sum_k \delta(b_k) \le S_\delta \quad \Longrightarrow \quad e^{-2T} C_P \text{ is bounded independently of } T = \ln(1/a) \tag{13}$$

Lean `conditional_scale_bound` (assumptions: the projection assumption, shortfalls non-negative with bounded partial sums, geometric-series weights; the Hardy sandwich for finite chains is a reproof of a known result). As a negative control, with a constant shortfall the boundedness breaks `const_defect_scale_unbounded`. The content is on the side of the projection assumption, and the projection assumption splits into four, "the variance can be split scale by scale", "the conditional Poincaré constants of each stage are uniform", "the conductance across stages is bounded", "the state space is a single line of scales", of which the last three have not been shown Assumption . The projection assumption is not weaker than the relaxation-time assumption. The one-dimensional chain did not show the upper-bound assumption; it restated the upper-bound assumption as the projection assumption.

Boundaries and the topological charge (the road of volume and boundary, the road of a one-dimensional chain of scales). In a periodic box the state space splits into sheets by topological charge Q, connected only at the ultraviolet end. For reversible dynamics, for every observable

$$R(f) = \frac{\operatorname{Var} f}{\mathcal{E}(f)} \ \le \ \tau_{\mathrm{int}}(f) \ \le \ C_P \tag{14}$$

holds Cited Lean `tau_int_le`, `rayleigh_le_tau` (finite reversible chains; a reproof of known facts), and every measured τ_{int} is a lower bound on C_P. The original source reports for HMC-type dynamics an effective dynamical exponent of the square of the topological charge of "about 5" Reading (Schaefer–Sommer–Virotta 2011); combining this with the conjecture that HMC and Langevin are in the same universality class Assumption and (14), in a periodic box $C_P \gtrsim a^{-5}$ and the upper-bound assumption breaks. It is a conditional reading on top of a conjecture. "About 5" is a value for $SU(3)$; the same measurement for $SU(2)$ was found in one source (HMC, periodic boundaries, small boxes, three points), reported to be close to a^{-2} Reading (Abe–Morikawa–Suzuki 2025; the note in 23-01 § 05). Open boundaries remove this barrier only inside a finite box with the physical side held fixed (a count using the charge of a subregion as test function Assumption ; in the original source too, the autocorrelation time of Q^2 with open boundaries grows roughly in proportion to the length in the time direction Reading). In this book's order, which makes the volume infinite first, this is expected not to help, and the candidate direction is to rewrite the statement of the relaxation-time assumption itself as a sentence sector by sector of topology, or as a local sentence with support limited to a few correlation lengths (the note in 23-01 § 05; how to rewrite it is dealt with in Part 24).

Thus every road on the upper side stopped by naming the place to which the difficulty had moved.

$$m^2 \gtrsim \sigma \ \Longleftarrow \ T_{\mathrm{loc}}(c) \wedge \text{floor} \wedge \text{seam}, \qquad C_P \lesssim \xi^2 \ \Longleftarrow \ (\mathrm{P}) \wedge \textstyle\sum \delta < \infty \tag{15}$$

The arrows go only one way, from right to left, and every right-hand side is an assumption.

06

Twenty-one walls — five types

A wall is a one-sentence statement of why a certain road, with certain tools, stopped short of a certain arrow of (1). There are five types: walls of principle come from the direction of an inequality and do not depend on the details of the tool; walls of structure are where demands are not compatible within the chosen family, bookkeeping or series (outside the family it is undecided); walls of tools are where the type of inequality needed is known but there is no tool to show it; walls of assumptions are the footing of conditional statements; walls of measurement and literature are what was not settled by numbers, boxes or primary sources. No wall is a proof that it "cannot be crossed".

Table 3 Twenty-one walls ("To move" is what follows from the definition)

No.	Wall	One line	To move	Arrow
1	One-sided test-function wall	Test functions bound C_P only from below Cited	An inequality of a type other than test functions	Upper-bound assumption
2	Spectroscopic upper-bound wall	Spectroscopy ends in upper bounds on the gap. A light state with small weight is invisible in a finite window Cited	A lower bound on the overlap with the lightest state	Physical-unit gap statement
3	Local-operator dimension wall	Local gauge-invariant operators have dimension 4 or more, so $\eta_S = 2$ (algebra under the assumption that the susceptibility is bounded)	Smooth out up to radius ξ ($\to$ measurement-cost wall)	Lower-bound assumption
4	Gauge-fixing single-valuedness wall	Gauge fixing: sharp means multivalued, blunt means the long wavelengths vanish Reading ($U(1)$)	A construction separating selection from smoothing (no proposal)	Lower-bound assumption
5	Measurement-cost wall	The numerator of smoothed operators is the zero-momentum susceptibility, and the cost of measuring it is $\geq cL^{d+2}$	Bound the numerator by estimates rather than measurement	Lower-bound assumption
6	Positive-weight kernel wall	The kernel with $\delta(2) = 0$ has a negative neighbouring weight. For kernels with positive weights $c_2 > 0$ (under the measured dependence)	Kernels outside the family	Summability of shortfalls
7	Renewal-series wall	The strong-coupling series has the renewal form, forces $\eta = 0$, and does not let the exponent be read	Information from outside the series	The η of the relaxation-time assumption
8	Single-step integral wall	One-link integration of a complete family works for one step only	A different bookkeeping that stacks steps	One-step bookkeeping
9	Limit-property wall	The Wilson-loop limit statement and the rotation-recovery statement do not come out of compositions of the map of one step	Another tool to show the properties of the limit	Limit
10	Upper-bound tool wall	There is no tool of the type of the upper-bound assumption. The proposal of stacking curvature scale by scale stops at the cross terms	Estimates of the cross terms	Upper-bound assumption

No.	Wall	One line	To move	Arrow
11	Tube-inequality wall	$m^2 \gtrsim \sigma$ moved to the tube inequality, but the tube inequality has no type of proof	A gauge-invariant definition of the transfer operator on loop space	One-scale chain
12	Projection-assumption wall	The projection assumption is not weaker than the relaxation-time assumption. The lower-bound assumption does not drop to one dimension	Derive the projection assumption from a weaker statement	Upper-bound assumption
13	Checking-tool wall	The Riemannian geometry of the one-link argument, and the generalised eigenvalue problem of the matrix variation of CP, lack tools for machine checking	Building up the library	One-step bookkeeping
14	Wall of the assumption itself	The relaxation-time assumption and the three chains (the relaxation chain, the one-scale chain, the bookkeeping-length chain) are not proved Assumption	The upper-bound assumption itself, the projection assumption, or one of the lower bounds of the three chains	The η of the relaxation-time assumption, chains
15	Equivalence-scaffold wall	The scaffold of the equivalence for the physical-unit gap statement: the power form, $\eta \geq 0$, additive errors of the steps, the δ of the one-loop kernel Assumption	Remove each assumption	Summability of shortfalls
16	Periodic-boundary conjecture wall	The breaking of the upper-bound assumption with periodic boundaries depends on the conjecture that HMC and Langevin are in the same universality class Assumption	Dynamical exponent of local dynamics for $SU(2)$	Upper-bound assumption
17	Fitting wall	That the breaking of $m/\sqrt{\sigma}$ is $O(a^2)$ is a fit to tables of numbers Reading	Estimates of the distortion of the steps	One-scale chain
18	Box-size wall	The boxes are small (8^4 is in the small-box phase for $\beta \gtrsim 2.45$, and 12^3 has $L\sqrt{\sigma} < 3$)	Large boxes with matched physical volume	Lower-bound assumption
19	Gauge dependence of the shortfall wall	The difference of c_2 with the choice of gauge went only as far as reading it positive in both of two gauges inside the model of the one-loop kernel Reading	A gauge-independent definition of δ	Summability of shortfalls
20	Tube-model sign wall	In the tube model, the sign of the $1/P$ coefficient at finite u is undecided	An effective model of the zero modes of shape	One-scale chain
21	Primary-source wall	Gaps in primary sources (the dynamical exponent of local dynamics for $SU(2)$; the texts of Bałaban, Magnen–Rivasseau–Sénéor and Osterwalder–Seiler)	Obtain them	Physical-unit gap statement

Walls of principle. The one-sided test-function wall and the spectroscopic upper-bound wall are the two one-sided halves of (8), and they do not move however many measurements are stacked. For example, for the standard normal distribution ($C_P = 1$, with equality at $f = x$), the maximum ratio over a family of odd polynomials not containing x approaches 1 as the family is enlarged, but the numbers inside the family alone do not tell whether 1 is the final value Reading (lower bound over a family). One knows it is 1 because of an input from outside the family ($C_P \le 1$ from the convexity $V'' = 1$), and an input of this kind is what the upper-bound assumption needs.

Walls of structure. Incompatibilities inside the chosen family; they say nothing about outside it. The local-operator dimension wall, the gauge-fixing single-valuedness wall and the measurement-cost wall are the ways the three roads of § 04 stopped; the positive-weight kernel wall is the tension between reflection positivity and removing the shortfall, the same tension, in the opposite direction, as what the problem statement says about continuum regularisations, "once reflection positivity is lost there are few ways to recover it". The renewal-series wall, the single-step integral wall and the limit-property wall are limits of the form of bookkeeping and series.

Walls of tools. They gather in the column of the upper-bound assumption. The upper-bound tool wall, the tube-inequality wall and the projection-assumption wall are the three places of § 05 to which the difficulty moved; the checking-tool wall alone is not a mathematical obstacle but a lack of tools for checking. The $\beta < 0.2722$ where the curvature theorem exists and the $\beta = 2.60$ used by spectroscopy (correlation length 1.95 lattice spacings) are about 9.6 times apart, and an estimate crossing that interval uniformly is the content of the upper-bound tool wall.

Walls of assumptions. The band statement $a^2 C_P \asymp 1$ splits into the product of three ratios $(a^2/\sigma)(\sigma/m^2)(m^2/\lambda_1)$, and the central equivalence also stands on footing other than the relaxation-time assumption. Each assumption corresponds to a concept of Parts 1–5 and Parts 7, 17 and 18: the relaxation-time assumption, the one-scale chain and the bookkeeping-length chain are candidates for restating "a single scale" (4-07) in terms of the Poincaré constant; the relaxation chain is the dynamical exponent $z = 2$ (18-03); the one-scale chain is a single scale (17-12); the bookkeeping-length chain is the specialisation of asymptotic scaling (5-05) to the bookkeeping length. These are analogies, not mathematical equivalences.

Walls of measurement and literature. They move by computation or by obtaining sources, but even if they move, the logic of (1) does not change. The representative is the size of the box: $12 \times 0.15896 = 1.91$ ($\beta = 2.55$) and $12 \times 0.13395 = 1.61$ ($\beta = 2.60$), both small boxes that do not contain 3 physical lengths $1/\sqrt{\sigma}$ Reading .

The walls in the column of the upper-bound assumption are the one-sided test-function wall, the upper-bound tool wall, the projection-assumption wall and the periodic-boundary conjecture wall, with no wall of measurement and literature. That is, short of the upper-bound assumption there is no wall that moves by measuring. Where the setters wrote that "new ideas are needed" is also the side of the gap uniform in the volume (Jaffe–Witten § 6.5) Cited , the same place where the walls that measurement does not move gather.

07

What remained — algebra closed in Lean, and numerical readings

Most of what remained from the seventeen roads is finite inequalities and algebra with the assumptions made explicit as arguments. Table 4 lines up the theorems cited in the text by what their statements are about. Inside Lean every theorem is a sentence about real numbers, sequences, or sums over finite sets; that they are quantities of the Wilson measure is a reading attached by the text. There are no theorems about expectation values, correlations or gaps of the Wilson measure (23-13).

Table 4 The main theorems closed in Lean on the side of the four-dimensional lattice (character: reproof = a known fact proved again / arrangement = algebra of definitions and assumptions / conditional = only the arrow from unproved assumptions to conclusions / negative control = an example that breaks when an assumption is removed / lattice theorem = a theorem about families of edges or effective actions, assuming only the shape of the lattice)

Theorem	Assumptions	Statement	Character
`log_F0_le`, `log_F0_ge`	Argument non-negative	Two-sided estimate (3) of the logarithm of one-link integration	Reproof
`Incidence.intact_frac_le`	Incidence regular	Fraction of intact faces $\leq$ fraction of remaining edges (4)	Arrangement
`no_blocking`, `blocking_shortfall`	Sequence of complete steps / fraction removed at each step $\leq 1/4$	Stacking steps does not bring intact faces back	Arrangement
`discStep_semigroup`, `step_lowers_coupling`	Surfaces of disc shape	Disc steps form a semigroup in the area, with $\beta' < \beta$	Reproof
`kappaDisj_lt_one`	$b \geq 2$	The contribution of surfaces sharing no edges is less than 1 (5)	Arrangement
`xi_eq_exp`	$\xi(\beta - t) = \xi(\beta)e^{-t/\kappa}$ for all steps	$\xi(\beta) = \xi(0)e^{\beta/\kappa}$	Arrangement
`fixed_step_bounded_iff`, `S4_two_sided`	Constant error / partial sums bounded	Partial sums bounded $\iff d = 0$ / stays in a positive band	Arrangement, conditional
`drain_exponent`, `drainExp_eq_zero_iff`	Power form of (7), $0 \leq \eta \leq 2, \theta \geq 0$	$p = 0 \iff \eta = \theta = 0$	Arrangement
`c2_ge_of_nonneg_weights`	$c2 = A + \kappa S$ (measured dependence)	$c2 > 0$	Conditional
`PerfectFamily.perfectK_one_iff`, `no_perfectZ_of_five`	$2 \leq d$ / $d \geq 5$	Classification of complete families of edges (Table 1)	Lattice theorem

Theorem	Assumptions	Statement	Character
`StaplePerturbation.hess_gauge`	Period even and ≥ 3, unit quaternions, pure imaginary perturbations	Hessian form of the effective action $\geq -27\beta^2$	Lattice theorem
`renewal_chi_mul_massSq`	Coefficients of the renewal form positive	$\chi m_0^2 = A/c_0$	Arrangement
`dev_le_of_contracting`, `dev_eq_of_marginal`	$0 \leq \lambda < 1$ / $\lambda = 1$	Drift bounded / proportional to the number of steps	Arrangement
`overlap_le_susc_mul_gap`	$m > 0$, $\tilde{Z} \coth(m/2) \leq \chi$	$\tilde{Z} \leq \chi m$	Arrangement
`profileQuotient_isGreatest`	Finitely many momenta, denominator positive	The supremum of the ratio over a rank-one family is the maximum of the componentwise ratios	Reproof
`eta_ge_two_of_bounded_susc`	Susceptibility uniformly bounded	$\eta_s \geq 2$	Conditional
`orbitAvg_gauge_invariant`	Action of a finite group	Weighted averages over orbits are gauge-invariant	Reproof
`meff_antitone`, `meff_ge_of_corr`	Representation with non-negative weights	The effective mass decreases monotonically and is an upper bound on the lowest energy	Reproof
`gap_ge_of_overlap`, `light_admixture_invisible`	Lower bound q on the overlap / two-level example	(10) / a light state is invisible in the window	Conditional, negative control
`cost_ge`	Lower bound on the relaxation time, number of sweeps	Cost $\geq cL^{d+2}$	Conditional
`mass_sq_ge_of_tube`, `mass_bound_localized`	Consequence of the tube inequality / localised T, floor, seam	$m^2 \geq 4c\sigma$ (12)	Conditional
`linear_regime_breaks_onescale`, `casimir_only_no_bound`, `linear_deficit_breaks_inv`	Region of convergence / floor only / raw perimeter	Under each assumption the lower half of a single scale is false	Negative control
`conditional_scale_bound`, `const_defect_scale_unbounded`	The projection assumption, bounded shortfall / constant shortfall	(13) / boundedness breaks	Conditional, negative control
`tau_int_le`, `rayleigh_le_tau`	Finite reversible chains	(14)	Reproof

Theorem	Assumptions	Statement	Character
`comp_class_eq_of_equivariant_bijection`	Bijection, commuting with the action	The class of functions of the flowed field is the same as the class of invariant functions	Arrangement

The content of the conditional rows lies on the side of the assumptions, and the theorems do not take a single step towards showing those assumptions. Only the two rows of lattice theorems (the classification of complete families and the lower bound on the Hessian form of the effective action) are theorems on the lattice that assume only the shape of the lattice. The former is a combinatorial fact about the lattice; the latter is an estimate that works on the strong-coupling side, where the correlation length is about 1/10 of a lattice spacing. Both concern places far from the continuum limit.

What remained on the numerical side is readings Reading : the agreement of the slope in the model of the one-loop kernel with the known coefficient (relative 2.8×10^{-5}, inside the model), the values of c_2 (two weights and two gauges), the effective slope 0.304 read from the lattice $a\sqrt{\sigma}$ of the original source, the upper bound 0.501 ± 0.071 on the effective mass of smoothed operators ($\beta = 2.6$, 12^4), the scatter of gauge-fixed copies for compact $U(1)$, the strong-coupling range where the curvature of the Gribov region is positive (samples of a finite-dimensional model), and the curvature of the pushed-forward measure of the gradient flow (at the typical points measured). None of them is used in a proof of an upper or lower bound.

08

Why we step down to the first step — which tool stopped at which wall

Summing up § 04– § 06: there is no tool to attack the upper side of the relaxation-time assumption (the upper-bound assumption, every f) while staying on the four-dimensional lattice. The tools of the lower side (test functions, spectroscopy) stopped at walls of principle, and the tools of the upper side (curvature, tubes, one-dimensional chains) all stopped where they had moved the difficulty into a single assumption. Where each stopped is as in the following table, tool by tool. The right column is the prospect of what changes when the same tool is brought to the model of the first step (the path measure of the double well in 0+1 dimensions, 23-04).

Table 5 Correspondence of tools and walls, and what changes on the first step (the right column is a prospect; the content on the first step is in each chapter)

Tool	Wall where it stopped on the four-dimensional lattice	What changes on the first step
Test functions, spectroscopy (lower side)	One-sided test-function wall, spectroscopic upper-bound wall, local-operator dimension wall, gauge-fixing single-valuedness wall, measurement-cost wall	On the lower side, a family of test functions local in time reaches equality in $C_P \geq \xi^2$ (the One-Dimensional One-Sided Bridge Proposition, 23-04 § 04). That the upper side needs different tools does not change on the first step either

Tool	Wall where it stopped on the four-dimensional lattice	What changes on the first step
Curvature (Bakry–Émery)	Upper-bound tool wall (positive only at strong coupling; cross terms)	The measure as a whole has two valleys and is not convex, but inside one phase without kinks local Poincaré can be asked through an assembly of sectors (the in-phase local Poincaré condition, 23-06)
One-dimensional chain of scales (the projection assumption)	Projection-assumption wall (the projection assumption is not weaker than the relaxation-time assumption)	The slow degree of freedom is the position of the kinks, and the form of the projection to one dimension is visible from the model. The projection assumption splits into, and is named as, transport along the family of saddles (the saddle-tube condition) and reduction to the box dynamics (the box-reduction condition) (23-07, 23-11)
Transfer operator of tubes (the tube inequality)	Tube-inequality wall (there is no type of proof for the lower bound on the mass)	The side of the mass is not needed: the correlation length $\xi = \hbar/\Delta$ is obtained accurately and independently from the tunnelling splitting, and what it is compared with is clear (23-04)
One-step bookkeeping (the summability-of-shortfalls assumption)	Positive-weight kernel wall, single-step integral wall, equivalence-scaffold wall	No need to make a bookkeeping length: the correlation length grows in $\hbar$ at the rate $e^{S_0/\hbar}$, and the length to compare with is fixed directly by the measure
Boundaries and the topological charge	Periodic-boundary conjecture wall (the breaking in a periodic box rests on a conjecture)	Stated in a regime where the length of the paths T is made infinite first, so the question is set up in a form where the topological sheets of a periodic box do not appear
Boxes and primary sources	Walls of measurement and literature (box size, gauge dependence of the shortfall, tube-model sign, primary sources)	With numerics of the transfer operator, semiclassical formulas and interval arithmetic, many of the quantities compared are obtained to high precision or as inequalities (23-08)

Some things do not change. That the upper-bound assumption is an inequality over "every f", and that tools of the lower side cannot reach it in principle (the one-sided test-function wall), are the same on the first step. So what the first step does is to build the assembly of the upper side first, in the form of propositions with their assumption rows named. The relaxation-time assumption is a sentence independent of dimension (23-01 § 05), so we build the same sentence in the smallest model where the ruler grows exponentially in the parameter, the slow motion is the motion of "changing phase", and the quantities compared are known exactly.

Even if the first step is closed, there is no guarantee that it lifts to the four-dimensional lattice. What has a prospect of lifting is the form of the sentence and the form of the tools; constants and ranges of parameters do not lift (23-03 § 06). The table of walls in this chapter is kept as a table for reading which walls the tools of the first step might hit again on the second step.

The relaxation-time assumption is one restatement chosen as a handle, and the roads and walls of this chapter too are within the scope of a study with the relaxation-time assumption at its axis. Viewpoints other than the relaxation-time assumption are dealt with in Part 24.

What this chapter can say

Said	Not said
The arrangement of seventeen roads and twenty-one walls (Tables 2 and 3), the correspondence of tools and walls (Table 5)	None of the arrows of (1) is proved. "Stopped" does not mean that anything was shown about the mass gap or the continuum limit, nor that the propositions not reached are false
Cited The variational principle and finite windows, the lowest dimension of local operators, reflection positivity, the strong-coupling area law, the one-loop coefficient, dimension counting, the Bakry–Émery and Muckenhoupt inequalities, $R \le \tau_{\mathrm{int}} \le C_P$	Counting these as results
Proved here The count (2) giving $d \le 4$ for complete families, the identity (4) of the deficit of bookkeeping, the algebra of powers in (7), the algebra of (10) and (12), the ratio 1 for bare link angles, the closed formulas for gauge fixing on a ring. Lean The theorems of Table 4 (assumptions on the same row)	Proofs of the relaxation-time assumption, the three chains, the tube inequality, the projection assumption, boundedness of the susceptibility, lower bounds on the overlap, the measured dependence of c_2, the model of errors of the steps
Reading The agreement of κ in the model of the one-loop kernel and c_2, the effective slope of the lattice, upper bounds from spectroscopy, gauge fixing for $U(1)$, the curvature of the Gribov region and of the gradient flow, the effective exponent of the topological charge	That the numbers of the models are non-perturbative quantities of four-dimensional $SU(2)$. Using readings as proofs of upper or lower bounds
Assumption That one-link integration works only once, the renewal form, the breaking of the upper-bound assumption in a periodic box (on top of a conjecture), what changes on the first step (the prospects in the right column of Table 5)	That results of the first step lift to the second step and beyond. About the mass gap and the continuum limit, this chapter shows nothing

Words used in this chapter — one-step bookkeeping, complete family, one-link integration, shortfall $\delta(b)$, the form of the answer, the seventeen roads tried on the four-dimensional lattice, the twenty-one walls (five types), renewal form, lower bound on the overlap, the tube inequality, the projection assumption, topological charge, negative control. Their meanings are in A-02 Glossary.

To the next chapter — 23-03 The four steps of the staircase — why we start from 0+1 dimensions: divides the relaxation-time assumption into four steps, and fixes the conditions for choosing the double well for the first step and the form of the statement of the first step

(the double-well relaxation-time power statement and the Double-Well Relaxation-Time Upper-Bound Proposition).

Next chapter to read: 23-03 The four steps of the staircase — why we start from 0+1 dimensions.

The four steps of the staircase — why we start from 0+1 dimensions

> This chapter is this book's own investigation. § 03 and § 06 are a map of open questions; § 07 is guide material.

What this chapter shows — the diffusive-relaxation-time assumption is a sentence of a dimension-independent form: "the relaxation time of a path measure grows as a power of the square of the correlation length of that measure". So we divide the diffusive-relaxation-time assumption into four steps (the double well in 0+1 dimensions / the four-dimensional lattice, non-abelian / the continuum limit and the OS axioms / the mass gap in the limit), and give the reasons for choosing the double well for the first step. The statement of the first step is "the double-well relaxation-time power statement" (below, the double-well power statement), $\ln C_P / \ln \xi \to 2$, and putting its upper side in the form $C_P \le K \xi^2 S_0/\hbar$ (the First-Step Upper-Bound Proposition) is the centre of the assembly of the first step. The First-Step Upper-Bound Proposition is a conditional proposition on top of four conditions, and is not proved. We give both the prospects of lifting from the first step to the second and beyond, and the reasons it does not lift.

Prerequisite chapters — 23-00 (the entrance, the five labels), 2-07 (the path integral and imaginary time), 2-05 § 07 (the tunnelling splitting of the double well). Definitions on the side of the four-dimensional lattice are in 23-01.

Said first — The relaxation-time assumption is an assumption both on the four-dimensional lattice and for the double well. The First-Step Upper-Bound Proposition is algebra on top of the four double-well conditions, and every one of the four conditions leaves assumption rows. This chapter fixes the form of the statement and proves nothing new.

The order of this chapter

1. The relaxation-time assumption is a sentence of a dimension-independent form — a family of measures, the correlation length, the relaxation time
2. Definition of the four steps — the form in which each step can be called "closed" (Table 1)

3. Why we do not attack it on the four-dimensional lattice as it is — there are no tools for the upper side
4. Conditions on the model chosen for the first step — a ruler that grows exponentially, two phases, quantities that can be compared (Table 2)
5. The power statement and the form of the First-Step Upper-Bound Proposition — the lower bound ξ^2 and the target for the upper bound
6. What lifts and what does not (Table 3)
7. A map inside the first step — a guide to 23-04 to 23-11

01

The diffusive-relaxation-time assumption is a sentence of a dimension-independent form — a family of measures, the correlation length, the relaxation time

Three things appear in the relaxation-time assumption: a family of probability measures μ_s lined up by one parameter, the correlation length $\xi(s)$ of each μ_s, and the Poincaré constant $C_P(s)$ of each μ_s (the relaxation time of the Langevin dynamics having that measure as equilibrium). When moving the parameter gives $\xi(s) \to \infty$, the relaxation-time assumption is the one sentence

$$(\xi^2): \quad \lim \frac{\ln C_P(s)}{\ln \xi(s)} = 2 \quad (1)$$

This sentence does not say on what space the measure lives. On the four-dimensional lattice μ_s is the Wilson measure with $s = \beta \to \infty$ (23-01); for the double well in 0+1 dimensions μ_s is the measure on paths in imaginary time $e^{-S/\hbar}$ with $s = 1/\hbar \to \infty$ (23-04). Sentences of the same form can be lined up with the object changed.

Example: for the free field (a Gaussian chain of mass m_0), $C_P = 1/m_0^2$ and $\xi \approx 1/m_0$, and (1) holds as $m_0 \to 0$ (23-00 § 04) Proved here . With interaction, new mechanisms that slow relaxation enter (crossing barriers, moving between configurations in different phases), and (1) is no longer trivial.

Precisely, "the relaxation-time assumption" in this part refers only to the sentence (1) at the power level. A sentence stated within the width of a constant factor (a band statement) is called by another name, not the relaxation-time assumption (23-01). Also, the four conditions of the first step are written "the four double-well conditions", always with the word "conditions" so as not to be confused with the relaxation-time assumption. The letters in Lean theorem names (H1 and so on) are not changed.

02

Definition of the four steps — the form in which each step can be called "closed"

We place four steps, from easy places to hard ones.

- **The first step**: the path measure of the double well in 0+1 dimensions. Parameter $\hbar \to 0$.
- **The second step**: non-abelian gauge theory on the four-dimensional lattice (the Wilson measure of SU(2) or SU(3)). Parameter $\beta \to \infty$.
- **The third step**: the continuum limit as the lattice spacing $a \to 0$. That the limiting measure exists and satisfies the Osterwalder–Schrader axioms (4-10).
- **The fourth step**: the mass gap of the limiting theory (4-11).

Table 1 Object, target, tools and state in this book, step by step

Step	Object	Form in which it can be called "closed"	Main tools	State in this book
First step	The path measure of the double well	State the upper side of the double-well power statement with a table of finitely many named assumption rows, and fill each row with a proof, an original source, or computer assistance	Splitting of the variance, local Poincaré, reduction to the box, interval arithmetic	Up to the First-Step Upper-Bound Proposition (algebra on top of the four double-well conditions). Every one of the four conditions leaves Assumption rows (23-05, 23-12)
Second step	The Wilson measure on the four-dimensional lattice	The sentence (1) of the same form, as $\beta \to \infty$	Prospect of transferring the types made on the first step (§ 06)	The relaxation-time assumption is Assumption. Only estimates from below have been reached (23-02)

Step	Object	Form in which it can be called "closed"	Main tools	State in this book
Third step	The measure of the continuum limit	Existence of the limit and the OS axioms	The sequence of renormalisation group steps, constructive field theory (Part 7)	Not dealt with. That a theory satisfying the Wightman axioms can be made as the limit of four-dimensional Wilson lattice gauge theory is, in the committee's assessment, proved in Lean by the construction published on 2026-11-10 (Part 6). The uniqueness of the infinite-volume limit and the continuum probability measure have not been shown (6-04)
Fourth step	The reconstructed quantum field theory	The gap of the Hamiltonian is positive	The OS reconstruction (4-10)	Not dealt with. The published construction does not show it either (6-04)

"Closed" for the first step means putting the proposition of the upper side into a form where "which rows are proofs and which are assumptions" can be read on one table. Only when every row is filled with a proof, an original source or computer assistance, and the stage of the First-Step Upper-Bound Proposition goes through as a single proof, does the first step become a theorem. At present it is not so (23-12).

To go up from the second step, one more bridge is needed between each pair of steps. Even if the sentence (1) of the second step holds, that alone does not give the existence of the continuum limit (the third step), and the gap in the limit (the fourth step) is a form that can be reread only after adding to the upper side of (1) the assumptions joining the correlation length to physical length (the chains of 23-01). This part has no theorem of implication for any bridge between steps.

03
```

Why we do not attack it on the four-dimensional lattice as it is — there are no tools for the upper side

In the record for the four-dimensional lattice (23-02), every road through test functions, gauge fixing and spectroscopy ended in lower bounds on C_P or upper bounds on the mass, and no tool reaching the upper side (C_P not too large, over every f) has been found. There are estimates on the strong-coupling side (C_P bounded) and the Bakry–Émery type that works for convex measures, but neither reaches the regime $\xi \to \infty$. In an example applying a known volume-uniform criterion to the path lattice of the double well, the upper bound obtained is of the type $e^{c\xi}$ (doubly exponential in $\hbar$), read as far from a power statement Cited (criterion: Theorem 2.1 of Bauerschmidt–Dagallier) Reading ($c \approx 1.4$ to 1.8; numbers for $\varepsilon = 0.25$, $\hbar \in [0.1, 0.4]$). So we first make an "assembly from above" on the smallest test bed where the relaxation-time assumption is expected to hold. The detailed roads and walls are in 23-02.

04

Conditions on the model chosen for the first step — a ruler that grows exponentially, two phases, quantities that can be compared

There are three conditions we ask of the model of the first step.

1. **The ruler grows exponentially in the parameter.** The correlation length of the four-dimensional lattice grows exponentially in β in the one-loop count (4-07). To make a test bed that does not confuse powers with exponentials, a ruler growing at the same rate is needed.
2. **The slow motion is the motion of "changing phase".** What slows relaxation is a rare event of moving between two (or more) phases. There are two scales: fluctuations inside the two phases are fast, and only the motion of changing phase is slow.
3. **The quantities compared are known exactly.** The correlation length can be found to high precision by an independent method. If what it is compared with is blurred, the growth of C_P/ξ^2 will be misread.

The path measure of the double well in 0+1 dimensions, $V(x) = (x^2-1)^2/8$, satisfies all three. The ruler grows exponentially as $\xi = \hbar/\Delta \propto \hbar^{1/2} e^{S_0/\hbar}$ (Δ is the tunnelling splitting, $S_0 = 2/3$ the action of the path moving from valley to valley); the two phases are "the intervals where the path is in the right valley" and "those where it is in the left valley", and the event of changing phase is a kink (a short transition with action S_0). Δ is found by two routes, the semiclassical formula ((10) of 2-05 § 07) and numerics of the transfer operator (23-04).

The action S_0 of one kink, and the correlation length $\xi \propto e^{S_0/\hbar}$. This pair has, in the smallest dimension, the structure in which "the action of an instanton" and "a correlation length growing exponentially" sit side by side on the four-dimensional lattice. This is an analogy, however, not a theorem of correspondence.

Table 2 How the double well and the four-dimensional lattice line up (the right column is an analogy, not a theorem of correspondence)

Item	Double well (first step)	Four-dimensional lattice (second step)
Measure	The path measure $e^{-S/\hbar}$ (the line of imaginary time)	The Wilson measure (four-dimensional lattice)
Parameter and limit	$\hbar \to 0$	$\beta \to \infty$
Ruler	$\xi \propto \hbar^{1/2} e^{S_0/\hbar}$ Cited (leading semiclassical term)	$\propto e^{3\pi^2 \beta/11}$ from one-loop bookkeeping (SU(2); that it agrees with ξ is Assumption)
Slow degrees of freedom	The positions of kinks (action $S_0 = 2/3$)	The positions, sizes and orientations of instantons, the density of topological charge (analogy)
Lower side	$CP \geq \xi^2$ (One-Dimensional One-Sided Bridge Proposition, 23-04 § 04)	Lower bounds from test functions (23-02)
Upper side	Conditional on four conditions (the First-Step Upper-Bound Proposition)	None

The first step is an easy model, but not too easy. No known theorem giving the upper side of the double-well power statement was found in what we searched. There are theorems of Eyring–Kramers type that hold the length of the interval fixed and take $\hbar \to 0$, but the regime that makes the length of the paths T infinite first ($T \gg \xi$) is outside the scope of those theorems Cited (Brooks–Di Gesù 2026 state explicitly in the text that the regime of infinite length and the family of translations are outside their scope).

05

The power statement and the form of the First-Step Upper-Bound Proposition — the lower bound ξ² and the target for the upper bound

The statement of the first step, for the path measure of the double well (taking $T \to \infty$ first), is

$$\text{power form of Assumption } (\xi^2): \quad \lim_{\hbar \to 0} \frac{\ln C_P(\hbar)}{\ln \xi(\hbar)} = 2 \quad (2)$$

Setting $R := CP/\xi^2$, $\ln CP / \ln \xi = 2 + \ln R / \ln \xi$, so (2) is the same as "$\ln R$ is small compared with $\ln \xi$".

The label "power assumption (ξ^2)" on the left of (2) is what the text calls the double-well power statement (the double-well relaxation-time power statement).

The lower side. $R \geq 1$, that is $C_P \geq \xi^2$, holds for every well in 0+1 dimensions (the One-Dimensional One-Sided Bridge Proposition; the proof is in 23-04 § 04).

The target for the upper side. The position of a kink moves with diffusion coefficient $D = \hbar / S_0$, and the time to cross a length ξ by diffusion is $\xi^2 / D = \xi^2 S_0 / \hbar$ (23-04 § 03). So we set the target for the upper side as

$$C_P \;\leq\; K\,\xi^2\,\frac{S_0}{\hbar} \qquad (K \text{ does not depend on } \hbar\,) \quad (3)$$

In the count at the level of physics (counting kinks as a dilute gas) it is read as $C_P \approx \xi^2 S_0/\hbar$, and (3) is that with a margin of a constant factor Assumption (the count is heuristic, not a proof).

From (3) to (2). From (3) and $R \geq 1$, $1 \leq R \leq K S_0/\hbar$. When $\hbar$ is small, $\ln \xi \geq s/\hbar$ (for some $s > 0$), so

$$0 \;\leq\; \frac{\ln R}{\ln \xi} \;\leq\; \frac{\hbar\,\big(\ln(K S_0) + \ln(1/\hbar)\big)}{s} \;\longrightarrow\; 0 \qquad (\hbar \to 0) \quad (4)$$

and (2) follows Proved here Lean `power_H_of_kink_ratio` (assumptions: $0 < K$, $0 < s$, $0 < \delta$, and for $0 < \hbar < \delta$, $1 \leq R \leq K/\hbar$ and $s/\hbar \leq \ln \xi$. The K of Lean is the $K S_0$ of the text). $\ln \xi \geq s/\hbar$ is a row coming from the leading semiclassical term $\ln \xi \approx S_0/\hbar$, and in the lattice model it is Reading. The values are in 23-04 § 07.

The form of the First-Step Upper-Bound Proposition

(3) is not proved. The assembly of the first step splits (3) into the following four conditions, and puts it in the form of a conditional proposition: on top of them, (3) follows.

The First-Step Upper-Bound Proposition (conditional; statement only)

For the path measure of the double well in 0+1 dimensions, assuming the four double-well conditions, taking $T \to \infty$ first, as $\hbar \to 0$, $C_P \leq K \xi^2 S_0/\hbar$ (K depends only on the constants of the conditions). Hence the double-well power statement (2) follows.

- The in-phase local Poincaré condition (local Poincaré within a phase without kinks)
- The saddle-tube condition (transport along the family of flat saddles)
- The box-reduction condition (reduction to the box dynamics)

- The gap-inside-the-box condition

The content of the four conditions, the algebra of the splitting of the variance for the First-Step Upper-Bound Proposition, and how what has been shown is separated from the assumption rows are in 23-05. The current status of each condition is in 23-06 to 23-11, and the table putting all rows on one sheet is 23-12.

Precisely, every one of the four conditions leaves assumption rows at present. And there is not yet a single $\hbar$ at which all rows of all conditions hold at once (23-12). The First-Step Upper-Bound Proposition is a proposition naming "what must be shown for the first step to close", not a proposition saying that the first step has closed.

06

What lifts and what does not

Even if (3) closes on the first step, the sentence of the second step (the four-dimensional lattice) does not follow. This section states, with reasons, what has a prospect of lifting and what does not. Both are descriptions of prospects, not theorems of implication.

Table 3 From the first step to the second (prospects)

	Prospect of lifting	Reason it does not lift
Form	The sentences (1) and (2) do not depend on dimension. The two-scale split "fast inside a phase / slow when changing phase" can also be written in the same form for any measure with slow degrees of freedom	The slow degrees of freedom of the four-dimensional lattice (collective coordinates of instantons, the density of topological charge) increase in number in proportion to the volume. Even on the first step, when the path is much longer than ξ, a split taking only one slow variable cannot be used (the band of 23-04 § 05). In four dimensions this situation is expected to be stronger still
Tools	The splitting of the variance, the lemma of two projections, the Efron–Stein inequality and the stage of sums over sectors are algebraic stages that do not use the dimension of the space of the measure, and can be written as they are	Many stages of the first step depend on properties peculiar to one-dimensional nearest-neighbour measures (the transfer operator, the boundary between phases being a point, kinks being countable as a dilute gas). Gauge symmetry and the geometry of the orbit space (3-04) are absent from the first step
Constants	—	The constants of the first step were fixed by computer assistance and numerical readings at particular nodes and windows of $\hbar$, and give no information about the β of the four-dimensional lattice. The correspondence between $\hbar$ and β is also an analogy

We still start from the first step because the procedure itself of assembling the proposition of the upper side in a form where "which rows are assumptions" is visible is also needed on the second step. The procedure of naming the assumption rows, checking the direction of dependence (23-12), and separating what machine checking guarantees (23-13) does not depend on the model. Taking the procedure through on the first step means that when a proposition of the same form is set up on the second step, we can name which rows are newly needed.

Precisely, setting up "a sentence of the same form" on the second step is not evidence that the sentence of the second step holds. Even if the relaxation-time assumption is read as holding for the model of the first step (counts at the level of physics and readings of lower bounds), whether it holds on the second step is a separate question (23-15).

Words used in this chapter — staircase (four steps), the double-well power statement, the four double-well conditions, the First-Step Upper-Bound Proposition, kink, tunnelling splitting, phase (phase without kinks), local Poincaré, box dynamics (box reduction). Their meanings are in A-02 Glossary.

Next chapter to read: 23-04 The path measure of the double well, and kinks — defines the setting of the first step, and derives the lower bound $C_P \geq \xi^2$ and the form of the target for the upper bound.

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time double well, kinks, lower bound · Kiichi, Shiori and Rin

The path measure of the double well, and kinks

In this chapter, § 01– § 03 are established knowledge and § 04 onward are this book's own investigation.

What this chapter shows — The setting of the first step is the measure $e^{-S/\hbar}$ on paths in imaginary time for the double well $V(x) = (x^2-1)^2/8$. The correlation length $\xi = \hbar/\Delta$ (Δ is the tunnelling splitting) grows at the rate $\hbar^{1/2}e^{S_0/\hbar}$, where $S_0 = 2/3$ is the action of the path moving from valley to valley (the kink). The Poincaré constant C_P of whole paths is at least ξ^2 (the One-Dimensional One-Sided Bridge Proposition), and the target for the upper side is a constant times the diffusion time of kinks, $\xi^2 S_0/\hbar$. At three values of $\hbar$, $\ln \xi$ is 218 / 661 / 2213 (readings).

Prerequisite chapters — 2-07 (the path integral, imaginary time, the transfer matrix), 2-05 § 07 (the double well), 1-10 § 07– § 09 (Poincaré inequalities), 23-03 (the staircase and the double-well relaxation-time power statement).

Said first — § 01– § 03 and § 07 are written at [Y2], § 04– § 06 at [Y3]. No upper bound on C_P is shown here. The One-Dimensional One-Sided Bridge Proposition is a lower bound, and the target for the upper side (15) is the conclusion of the conditional Double-Well Relaxation-Time Upper-Bound Proposition (23-05). All the numbers in this chapter are numbers of a 0+1-dimensional model, not of four-dimensional gauge theory.

The order of this chapter

1. Setting — the action, the path measure, the lattice ε=½, the Dirichlet form, C_P
2. Two times — the correlation length ξ=ħ/Δ and the Langevin gap 1/C_P
3. Kinks — action S_0=2/3, the position degree of freedom, diffusion coefficient D=ħ/S_0, how ξ grows
4. The lower bound C_P ≥ ξ² — the One-Dimensional One-Sided Bridge Proposition, and readings beyond it
5. The target for the upper side, and the band of long paths — why the naive reduction cannot be used
6. The plateau at the top — the curvature falls ¼ short of convexity

7. Numerical examples — $\ln \xi$ at three values of $\hbar$ (Table 2). Detour: the tunnelling splitting by Herring's formula

---

01

Setting — the action, the path measure, the lattice, the Dirichlet form

A particle of mass 1 sits in a potential with two valleys.

$$V(x) = \frac{(x^2-1)^2}{8}, \qquad V'(x) = \frac{x(x^2-1)}{2}, \qquad V''(x) = \frac{3x^2-1}{2} \quad (1)$$

The valleys are at $x = \pm 1$, the curvature at the bottom of a valley is $V''(\pm 1) = 1$ (the angular frequency of oscillation inside a valley is 1), and the top of the hill is at $x = 0$ with $V''(0) = -\frac{1}{2}$. This is (9) of 2-05 § 07 with $a = 1$.

To a path $x(\tau)$ in imaginary time τ ($0 \le \tau \le T$) we attach the Euclidean action

$$S[x] = \int_0^T \left[\frac{1}{2}\dot{x}(\tau)^2 + V\big(x(\tau)\big) \right] d\tau \quad (2)$$

and make a probability measure on paths with weight $e^{-S[x]/\hbar}$. This is the measure of (7) of 2-07 § 05 (mass $m = 1$); closing the path into a loop gives the partition function of (9) of 2-07 § 06, that is, a classical chain in which the length T of the loop plays the role of inverse temperature. In this part we take $T \to \infty$ (temperature 0, the side of the ground state) **first**, and then $\hbar \to 0$. The quantity with the order reversed (holding T fixed and taking $\hbar \to 0$) is a different quantity. For short paths ($T < 2\pi\sqrt{2}$), from the known theorem that the mean time to move between valleys grows at the rate $e^{T/(8\hbar)}$ Cited (Theorem 2.6 of Berglund–Gentz, of Eyring–Kramers type with the interval held fixed), C_P/ξ^2 is read as falling exponentially to 0 Reading (the rereading from mean times to eigenvalues is by reduction to two states).

The lattice. The numbers in the later chapters of this part are numbers on a lattice that discretises imaginary time with step $\varepsilon = \frac{1}{2}$. With x_i the value at site $i \in \mathbb{Z}$,

$$S_{\mathrm{lat}} = \sum_i \frac{(x_{i+1} - x_i)^2}{2\varepsilon} + \varepsilon \sum_i V(x_i), \qquad \varepsilon = \frac{1}{2} \quad (3)$$

and the measure at $T = \infty$ is a one-dimensional nearest-neighbour Gibbs measure. The integral kernel of the transfer operator ((13) of 2-07 § 08) is positive, so the measure is expected to be uniquely determined Assumption (using the integral-operator version of the Perron–Frobenius theorem of 2-07 § 08 on $\mathbb{R}$. A statement of this form in

an original source has not been checked in this part, so it is put as an assumption row). Some chapters also cite numbers with step $\varepsilon = 0.25$, and say so each time.

The Dirichlet form and C_P. For a function f of the path, we set the "size of the change when it is moved" to be

$$\mathcal{E}(f) = \hbar \int \mathbb{E}\Big|\frac{\delta f}{\delta x(\tau)}\Big|^2 d\tau, \qquad \text{on the lattice} \quad \mathcal{E}(f) = \frac{\hbar}{\varepsilon}\sum_i \mathbb{E}\,|\partial_i f|^2 \tag{4}$$

(the canonical Dirichlet form), and set the Poincaré constant as $C_P = \sup_f \mathrm{Var}(f)/\mathcal{E}(f)$ ((2) of 23-00 § 04). The $\hbar$ attached to $\mathcal{E}$ is a normalisation matching the form differentiated with respect to the canonical field $x/\sqrt{\hbar}$ rather than the position x (the scale of the clock in 23-00 § 05). The Langevin dynamics with this $\mathcal{E}$ is, on the lattice,

$$dx_i = -\frac{1}{\varepsilon}\frac{\partial S_{\mathrm{lat}}}{\partial x_i}\,dt + \sqrt{\frac{2\hbar}{\varepsilon}}\,dW_i \tag{5}$$

(W_i are independent Brownian motions); it has $e^{-S_{\mathrm{lat}}/\hbar}$ as equilibrium, and its gap is $1/C_P$ Cited (1-10 § 07). Along an artificial time t the whole path sways, and the slowest fluctuation decreases by a factor $1/e$ every time C_P.

Example (free field). With $V = \frac{1}{2}x^2$ the measure is Gaussian, $C_P = 1$, the correlation length is also $\xi = 1$, and the ratio C_P/ξ^2 is exactly 1 Proved here Lean `ratioR_free_eq_one` (assumptions: $C_P = 1/m^2$, $m \neq 0$). On the lattice it is the same in the zero-momentum direction.

Precisely, the measures of (2)–(5) are path measures of a 0+1-dimensional quantum-mechanical model, and no gauge field enters anywhere. The relation to four-dimensional gauge theory is only the analogy of 23-03 § 04.

02

Two times — the correlation length ξ=ħ/Δ and the Langevin gap 1/C_P

This model has two "times" of different character.

The first is a length in imaginary time, the correlation length ξ. With $\Delta = E_1 - E_0$ (the tunnelling splitting) the difference between the lowest two levels of the quantum-mechanical Hamiltonian $H = -\frac{\hbar^2}{2}\frac{d^2}{dx^2} + V$, the correlation of two points on the path decreases as

$$\langle x(0)\,x(\tau)\rangle - \langle x\rangle^2 \;\approx\; C\,e^{-\tau\Delta/\hbar}, \qquad m := \frac{\Delta}{\hbar}, \qquad \xi := \frac{1}{m} = \frac{\hbar}{\Delta} \tag{6}$$

(the ratio of eigenvalues of the transfer operator; the same line of argument as 2-07 § 07) Cited . ξ is a length in the imaginary-time direction; counted in lattice sites it is $\xi/\varepsilon = 2\xi$.

The second is an artificial time, the smearing time C_P. It is the time for the whole path to approach equilibrium under the dynamics (5), a time in a direction different from imaginary time.

The quantity comparing the two is

$$R := \frac{C_P}{\xi^2} = C_P\, m^2 \tag{7}$$

For the free field $R = 1$, and the double-well relaxation-time power statement (the power statement) is the same as "$\ln R$ is small compared with $\ln \xi$" (23-03 § 05).

Precisely, the ξ of (6) is the definition for the model with continuous time; for the lattice model it is fixed by $\xi = \varepsilon/\ln(\lambda_0/\lambda_1)$ from the top two eigenvalues $\lambda_0 > \lambda_1$ of the transfer operator. As $\hbar \to 0$ the difference between the lattice value and the continuum value enters the exponent as the difference of actions $S_0^{\text{lat}} \neq S_0$, so lattice values are used when writing numbers (§ 03, § 07).

03

Kinks — action S₀=2/3, the position degree of freedom, diffusion coefficient D=ħ/S₀

When $\hbar$ is small, the weight $e^{-S/\hbar}$ concentrates on paths with small action. What makes the action 0 is the path staying in the right valley all along, $x \equiv 1$, and the path staying in the left valley all along, $x \equiv -1$. The path with the next-smallest action, "moving from valley to valley", is the **kink**.

The stationarity equation of (2) is $\ddot{x} = V'(x)$ (motion in the potential $-V$, 2-07 § 05), and solutions that settle into valleys as $\tau \to \pm\infty$ satisfy conservation of energy $\frac{1}{2}\dot{x}^2 = V(x)$. From (1), $\dot{x} = \sqrt{2V(x)} = (1 - x^2)/2$, and solving this gives

$$x_{\text{cl}}(\tau) = \tanh\frac{\tau - \tau_0}{2}, \qquad S_0 = \int \dot{x}_{\text{cl}}^2\, d\tau = \int_{-1}^{1} \sqrt{2V(x)}\, dx = \int_{-1}^{1} \frac{1 - x^2}{2}\, dx = \frac{2}{3} \tag{8}$$

Proved here (putting $\frac{1}{2}\dot{x}^2 = V$ into (2) makes the integrand $\dot{x}^2$, and $dx = \dot{x}\, d\tau$ turns it into an integral over x). The width of the kink is about 2 in τ, and its action is the number $2/3$, independent of $\hbar$. This is the $S_0 = 2a^2/3$ ($a = 1$) of 2-05 § 07, in the language of physics the action of an instanton (3-05).

The position degree of freedom. The τ_0 of (8) is arbitrary, and shifting the kink in the imaginary-time direction does not change the action. The second derivative of the action (the fluctuation operator) $-\partial_\tau^2 + V''(x_{\mathrm{cl}})$ has $\dot{x}_{\mathrm{cl}}$ as an eigenfunction with eigenvalue 0 Proved here (differentiating the stationarity equation $\ddot{x}_{\mathrm{cl}} = V'(x_{\mathrm{cl}})$ with respect to τ gives $\dddot{x}_{\mathrm{cl}} = V''(x_{\mathrm{cl}})\dot{x}_{\mathrm{cl}}$). This flat direction (the zero mode) is one slow degree of freedom, the position of the kink. The next eigenvalue is $3/4$, and above it is the continuous part $[1, \infty)$, as is known Assumption (an operator of Pöschl–Teller type; the statement in the original source has not been checked in this part).

The diffusion coefficient. Projecting the noise of (5) onto the direction of the position of the kink, the position X diffuses. The direction that shifts the position by one is $\dot{x}_{\mathrm{cl}}$, and the square of its length is $\int \dot{x}_{\mathrm{cl}}^2 d\tau = S_0$, so the noise strength $\hbar$ is divided by S_0, giving

$$\mathbb{E}\big[(X_t - X_0)^2\big] \approx 2Dt, \qquad D = \frac{\hbar}{S_0} \quad (9)$$

follows. Cited The same projection count reproduces the coefficient of the theorem that a single interface in the stochastic Allen–Cahn equation on an interval converges to Brownian motion with diffusion coefficient $3/4$ (the Single-Interface Diffusion Theorem (Theorem 2.1 of Bertini–Brassesco–Buttà)). That is, at the level of "the motion of a single kink", (9) is a restatement of a known theorem. Reading In Langevin numerics following one kink on a ring with step $\varepsilon = 0.25$, $D/(\hbar/S_0)$ was 1.00 ± 0.03 ($\hbar = 0.02$), 1.04 (0.07) and 1.14 ± 0.05 (0.1).

Precisely, (9) is a sentence about the process of the position of one kink, not about the gap $1/C_P$ of whole paths. Whether, on a long path with many kinks, the gap is determined by the diffusion of kinks is exactly the question of the upper side (the First-Step Upper-Bound Proposition).

How the ruler grows

The tunnelling splitting Δ is determined, in terms of paths in imaginary time, by "the weight of inserting one kink", $e^{-S_0/\hbar}$. The leading semiclassical term is ((10) of 2-05 § 07 written with $\hbar$)

$$\frac{1}{\xi} = \frac{\Delta}{\hbar} \approx \frac{4}{\sqrt{\pi\hbar}}\, e^{-S_0/\hbar}, \qquad \xi^2 \approx \frac{\pi\hbar}{16}\, e^{2S_0/\hbar}, \qquad \ln \xi = \frac{S_0}{\hbar} + \frac{1}{2}\ln\hbar + O(1) \quad (10)$$

Cited (the formula of the leading term is a copy from the source of 2-05. When Δ is found by two independent numerical methods, the ratio to the leading term approaches 1, from 0.47 at $\hbar = 0.5$ to 0.92 at $\hbar = 0.05$ Reading), and the correlation length grows exponentially as $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$. In the lattice model, instead of S_0 the

action of the lattice kink $S_0^{\mathrm{lat}} = 0.665266$ ($\varepsilon = \frac{1}{2}$; it differs from $2/3$ by 0.2%) enters the exponent Reading . At $\hbar = 10^{-3}$ this difference moves $\ln \xi$ by 1.4, so lattice values are used when writing numbers.

04

The lower bound C_P ≥ ξ² — the one-dimensional one-sided bridge, and readings beyond it

C_P is a supremum, so one test function bounds it from below (23-00 § 06). The plainest test function is a function $h(x)$ of a single time, summed over time,

$$f = \int_0^T h\big(x(\tau)\big)\, d\tau \quad (11)$$

(a test function local in time). In this family the lower bound reaches exactly the square of the ruler.

The One-Dimensional One-Sided Bridge Proposition (continuous time, $T \to \infty$, any one-dimensional well)

The supremum of the limit as $T \to \infty$ of the Rayleigh quotient $\mathrm{Var}(f)/\mathcal{E}(f)$ of f of the form (11) is exactly $\xi^2 = 1/m^2$, attained at $h = \psi_1/\psi_0$ (ψ_0, ψ_1 are the lowest two eigenfunctions of H). Hence $C_P \geq \xi^2$, that is, $R \geq 1$.

Proved here Proof [Y3]. Set $\varphi := (h - \langle h \rangle)\psi_0$ and $A := (H - E_0)/\hbar$. A is the generator of imaginary time, and $A \geq m$ on functions orthogonal to ψ_0. Writing the correlations with the transfer operator (2-07 § 08),

$$\frac{\mathrm{Var}(f)}{T} \longrightarrow \int_{-\infty}^{\infty} \langle \varphi, e^{-|\tau|A}\varphi \rangle\, d\tau = 2\,\langle \varphi, A^{-1}\varphi \rangle \quad (12)$$

On the other hand $\delta f/\delta x(\tau) = h'(x(\tau))$, so $\mathcal{E}(f)/T = \hbar \int \psi_0^2 h'^2\, dx$, and from the ground-state transformation identity $\langle \varphi, (H - E_0)\varphi \rangle = \frac{\hbar^2}{2} \int \psi_0^2 h'^2\, dx$ (2-05 § 08, 1-10 § 08), $\mathcal{E}(f)/T = 2\langle \varphi, A\varphi \rangle$. With the eigendecomposition of A, $\varphi = \sum_k c_k e_k$ (eigenvalues $a_k \geq m$), $1/a \leq a/m^2$ gives

$$\frac{\sum_k |c_k|^2/a_k}{\sum_k |c_k|^2 a_k} \;\leq\; \frac{1}{m^2} = \xi^2 \quad (13)$$

with equality when φ lies in the eigenspace of eigenvalue m, that is, when $h - \langle h \rangle \propto \psi_1/\psi_0$. ∎ The transfer-operator formula (12) and the ground-state transformation identity

are cited as known facts Cited . Lean `local_rayleigh_ratio_le_one` (assumptions: $0 < m$, $a_k \geq m$, $c_k \geq 0$, $\sum c_k a_k > 0$) checks only the skeleton of finite sums of (13); the eigendecomposition, (12) and the ground-state transformation are outside Lean.

The One-Dimensional One-Sided Bridge Proposition holds not only for the double well but for every one-dimensional well. Whether a claim of the same form exists in the literature has not been checked (it may be known).

Readings beyond it. The One-Dimensional One-Sided Bridge Proposition also says that "for test functions local in time, $R = 1$ is the ceiling". Seeing $R > 1$ needs test functions that span times (for example, blurring the path in time and then looking at the sign, or counting the collective position of kinks). Evaluating the Rayleigh quotients of such test functions with samples drawn directly from the transfer operator (not samples approached by running a Markov chain), the lower bound on R grew from 1.06 at $\hbar = 0.4$ to 6.5 at $\hbar = 0.07$ Reading (lower bound over a family, step $\varepsilon = 0.25$, a window of the measure at $T = \infty$, variation between seeds ± 10–15%). It also agreed, for $\hbar = 0.3$ to 0.15, with values from measuring the decay of the slowest observable in Langevin dynamics Reading (both are lower bounds, not upper bounds).

The type of growth, in the count at the level of physics that counts kinks (a dilute gas of kinks, the diffusion coefficient of (9)), is $R \approx S_0/\hbar \approx \ln \xi$, that is,

$$C_P \;\approx\; \xi^2 \,\frac{S_0}{\hbar} \;\approx\; \frac{\pi}{24}\, e^{4/(3\hbar)} \qquad (14)$$

Assumption (the count is heuristic, not a proof). The numbers in this range alone cannot distinguish whether R grows as $1/\hbar$ or as $e^{c/\hbar}$. In the former case the double-well power statement holds; in the latter it breaks. This is why, even for the double well, the sentence stated within the width of a constant factor, $C_P \leq K\xi^2$, is read as being on the side that breaks.

05

The target for the upper side, and the band of long paths

Matching the form of (14), we put the target for the upper side as

$$C_P \;\leq\; K\,\frac{\xi^2}{D} = K\,\xi^2\,\frac{S_0}{\hbar} \qquad (K \text{ does not depend on } \hbar\,) \qquad (15)$$

Together with the One-Dimensional One-Sided Bridge Proposition this gives $1 \leq R \leq K S_0/\hbar$, and the double-well power statement follows ((4) of 23-03 § 05). (15) is the conclusion of the First-Step Upper-Bound Proposition on top of the four double-well conditions, and is not proved (23-05).

The naive road to showing (15) is to choose one slow variable (for example the mean position of the path, the magnetisation) and show that "functions orthogonal to it relax fast". For short paths ($T \ll \xi$, at most one pair of kinks) this form gives the right count. For long paths ($T \gg \xi$), however, this road cannot be used.

The reason can be seen in the Glauber dynamics of the one-dimensional Ising chain. The space spanned by functions of a single spin is closed under the generator, and the Fourier component of wave number k, $S_k = \sum_j e^{ikj}\sigma_j$, is an eigenfunction with eigenvalue $\alpha(1-\gamma\cos k)$ (α is the rate, $\gamma = \tanh 2K$). The magnetisation is $k=0$, and its ratio to the slowest component orthogonal to the magnetisation, $k = 2\pi/N$, is

$$\frac{1-\gamma\cos(2\pi/N)}{1-\gamma} = 1 + \frac{\gamma\,(1-\cos(2\pi/N))}{1-\gamma} \;\approx\; 1 + \Big(\frac{2\pi\xi}{N}\Big)^2 \qquad (16)$$

which approaches 1 when the chain is much longer than the correlation length ($N/\xi \to \infty$) Proved here (rewriting the ratio) Lean `glauber_band_ratio` (assumption: $\gamma \neq 1$). For the formula of the eigenvalues itself, we saw to 8 digits that the two eigenvalues appear as they are in the diagonalisation of all states of chains with $N = 8, 10$ Reading (the statement in Glauber's original paper has not been checked in this part). The slowest fluctuation is not an isolated single mode but the lower edge of a continuous band. On long paths of the double well too, long-wave fluctuations of the density of kinks make the same band, and the Poincaré constant of the conditional measure with the magnetisation fixed stays of the same size as ξ^2/D.

So on long paths one has to take a number of slow variables proportional to the volume, or cut the problem into boxes of length $C\xi$. The latter is the box-reduction condition (reduction to the box dynamics) and the gap-inside-the-box condition (23-11).

06

The plateau at the top — the curvature falls ¼ short of convexity

If the measure $e^{-S/\hbar}$ had a convex action (a log-concave density), the Bakry–Émery criterion would bound C_P by the reciprocal of the curvature of the action, independently of length and of $\hbar$ Cited (1-10). The path measure of the double well is not convex. We look on the lattice (3) at where convexity breaks.

The second derivative of the action (3) (the Hessian) is a matrix with $2/\varepsilon + \varepsilon V''(x_i)$ on the diagonal and $-1/\varepsilon$ between neighbours. For $\varepsilon = \frac{1}{2}$ the diagonal is $4 + \frac{1}{2}V''(x_i)$ and the neighbours -2. For uniform convexity over a long interval it suffices that the diagonal be at least the size 4 of the sum of the two neighbours (diagonal dominance).

Inside a valley ($|x_i|$ close to 1), $V'' \approx 1$ and the diagonal is 4.5, which is enough, but at the top of the hill $x_i = 0$, $V''(0) = -\frac{1}{2}$, so

$$\underbrace{4 + \tfrac{1}{2} \cdot \left(-\tfrac{1}{2}\right)}_{\text{curvature at one site at the top}} = \frac{15}{4} = 4 - \frac{1}{4} \quad (17)$$

which falls short by $\frac{1}{4}$ Proved here . For the path with every site at the top, $x \equiv 0$, the smallest eigenvalue of the Hessian (in the uniform direction) is exactly $\varepsilon V''(0) = -\frac{1}{4}$.

Between a pair of kinks, the interval where the path stays near the top makes a flat direction (a plateau) along which the action hardly changes. Conversely, confining the path to the convex core deep in a valley, $\{x_i \geq a\}$ ($a > 1/\sqrt{3}$), Bakry–Émery gives $C_P \leq 2/(3a^2 - 1)$ uniformly in length and $\hbar$ Proved here (lower bound on curvature) Cited (of Bakry–Émery type) Lean `convex_core_curvature` (assumptions: $1/3 < a^2$, $0 \leq a \leq x$). But the action of an excursion that leaves the core and comes back, $2/3 - a + a^3/3$, is smaller than the action of a kink $2/3$ (0.1535 at $a = 1/\sqrt{3}$) Lean `excursion_action_lt_kink` (assumption: $0 < a < 1$), and an interval of length ξ contains exponentially many excursions. The convex core alone does not give local Poincaré within a phase (the in-phase local Poincaré condition).

This shortfall of $\frac{1}{4}$ comes back, in changed form, to the same place on every road that builds the upper side. In later chapters it is called the common wall (23-09).

07

Numerical examples — ln ξ at three values of ħ

The later chapters of this part use three values of $\hbar$ as representatives. The order is always from large to small, $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$. The reason for the choice is that $\ln \xi$ changes widely, from about 218 to about 2213, making them representatives of the regime where the correlation length grows exponentially in $\hbar$. Table 2 gives values on the lattice $\varepsilon = \frac{1}{2}$.

Reading Table 2 $\ln \xi$ and $\ln(\xi^2 S_0/\hbar)$ at three values of $\hbar$ (lattice $\varepsilon = \frac{1}{2}$, $T = \infty$. ξ is a length in imaginary time. Floating-point values)

Quantity	$\hbar = 3 \cdot 10^{-3}$	$\hbar = 10^{-3}$	$\hbar = 3 \cdot 10^{-4}$
$\ln \xi$	218.08	661.04	2212.72
$S_0^{\mathrm{lat}}/\hbar$	221.76	665.27	2217.55
$\ln \xi - S_0^{\mathrm{lat}}/\hbar - \frac{1}{2} \ln \hbar$	−0.774	−0.777	−0.778
$\ln(\xi^2 S_0/\hbar)$ (scale of the target for the upper side)	441.6	1328.6	4433.1

$\ln \xi$ is the value obtained for the difference of the top two eigenvalues of the transfer operator by Herring's formula, which involves no subtraction (the next detour). At intermediate $\hbar$ (0.2, 0.05, 0.04), the road of finding the eigenvalues of the matrix directly and the road of Herring's formula agreed to six digits Reading . That the remainder in the third row approaches a number independent of $\hbar$ is consistent with the form $\ln \xi = S_0/\hbar + \frac{1}{2}\ln \hbar + O(1)$ of (10), and the difference from the continuum semiclassical value $\frac{1}{2}\ln(\pi/16) \approx -0.814$ is read as a lattice correction.

The fourth row is the scale of the right-hand side of (15), and its difference from $2\ln \xi$ is $\ln(S_0/\hbar)$. The ratio of the two columns is close to 2, and approaches 2 as $\hbar$ is lowered. The "2" of the double-well power statement is a restatement of how small this difference is.

Precisely, Table 2 gives floating-point values, not values enclosed by interval arithmetic. ξ is of size e^{218} to e^{2213}, not a length that can be measured directly by Monte Carlo but a quantity read from the eigenvalues of the transfer operator. The three values of $\hbar$ are representative points, with a role different from the "nodes" and "windows" of later chapters (the distinction is in 23-12).

Detour: the tunnelling splitting by Herring's formula

A subsection you may skip. At $\hbar = 10^{-3}$, $\Delta/\hbar$ is of size e^{-661}, and if the two eigenvalues λ_0, λ_1 are found separately and subtracted, every digit of floating point is lost. So we use a formula that writes the difference directly.

The integral kernel $K(x,y)$ of the transfer operator is symmetric and unchanged under $x \to -x$, $y \to -y$. Making two kernels on the half-line $x, y > 0$, $A(x,y) = K(x,y)$ and $C(x,y) = K(x,-y)$, the even eigenfunctions are eigenfunctions of $A + C$ and the odd eigenfunctions of $A - C$ (eigenvalues λ_e and λ_o). Since A and C are both symmetric, for an even eigenfunction u and an odd eigenfunction v,

$$v \cdot (A+C)u - u \cdot (A-C)v = (\lambda_e - \lambda_o)\, u \cdot v \quad \Longrightarrow \quad \lambda_e - \lambda_o = \frac{2\, u \cdot Cv}{u \cdot v} \tag{18}$$

Proved here (on the left $v \cdot Au = u \cdot Av$ cancels, and two copies of $v \cdot Cu = u \cdot Cv$ remain). The right-hand side involves no subtraction. The kernel of $A - C$ is positive for $x, y > 0$ (since $(x+y)^2 > (x-y)^2$, $K(x,y) > K(x,-y)$), so the odd eigenfunction can also be taken positive on the half-line, and can be computed in the logarithmic domain keeping relative precision out to the tails. This is the transfer-operator version of Herring's formula of quantum mechanics (the formula writing the splitting through overlaps of wave functions).

Classification of the statements of this chapter

We put the statements of this chapter into one table in the format of the five grades of this part (Table 1 of 23-00 § 01). The columns are the same as in the tables of propositions in later chapters.

Table 3 The statements of this chapter (one grade per row; the machine-checking column is outside the grades)

Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
Shape of the kink $\tanh(\tau/2)$ and action $S_0 = 2/3$	Proved here	(8) of § 03	Independent of $\hbar$	—
The fluctuation operator has $\dot{x}_{\mathrm{cl}}$ with eigenvalue 0 (the position degree of freedom)	Proved here	§ 03	Independent of $\hbar$	—
Next eigenvalue of the fluctuation operator $3/4$, continuous part $[1, \infty)$	Assumption	§ 03 (Pöschl–Teller type; original source unchecked)	Independent of $\hbar$	—
Diffusion coefficient of the position of one kink $D = \hbar/S_0$ (at the level of the process)	Cited	(9) of § 03. A copy of the coefficient of the Single-Interface Diffusion Theorem of Bertini–Brassesco–Buttà	$\hbar \to 0$	—
$D/(\hbar/S_0) = 1.00$ to 1.14	Reading	§ 03 (Langevin point values, $\varepsilon = 0.25$)	$0.02, 0.07, 0.1$	—
Leading semiclassical term (10) of ξ	Cited	§ 03, 2-05 § 07	$\hbar \to 0$	—
Lattice $\ln \xi$ (Table 2) and $S_0^{\mathrm{lat}} = 0.665266$	Reading	§ 07 (transfer operator, Herring's formula, floating point)	Three points	—

Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
The One-Dimensional One-Sided Bridge Proposition: the ceiling of the family local in time is ξ^2, hence $C_P \geq \xi^2$	Proved here	Proof in § 04 ((12) and the ground-state transformation cited). Continuous time, $T \to \infty$	Every $\hbar$	`local_rayleigh_ratio_le_one` (assumptions: $0 < m$, $a_k \geq m$, $c_k \geq 0$, $\sum c_k a_k > 0$. Skeleton of finite sums only)
The lower bound on R grows from 1.06 to 6.5	Reading	§ 04 (lower bound over a family, $\varepsilon = 0.25$)	$[0.07, 0.4]$	—
$C_P \approx \xi^2 S_0/\hbar$ ((14))	Assumption	§ 04 (count with a dilute gas; heuristic)	$\hbar \to 0$	—
The ratio (16) to the component orthogonal to the magnetisation approaches 1 (the band)	Proved here	§ 05 (rewriting the ratio)	Independent of $\hbar$	`glauber_band_ratio` (assumption: $\gamma \neq 1$)
The Glauber eigenvalues $\alpha(1 - \gamma \cos k)$ appear in the spectrum of all states	Reading	§ 05 (diagonalisation for $N = 8, 10, 8$ digits)	—	—
Curvature at one site at the top $15/4 = 4 - \frac{1}{4}$	Proved here	(17) of § 06	Independent of $\hbar$	—
$C_P \leq 2/(3a^2 - 1)$ on the convex core $\{x_i \geq a\}$	Proved here	§ 06 (the lower bound on curvature is proved here; the Bakry–Émery type is cited)	Independent of $\hbar$	`convex_core_curvature` (assumptions: $1/3 < a^2$, $0 \leq a \leq x$)
Target for the upper side (15), $C_P \leq K\xi^2 S_0/\hbar$	Assumption	Conclusion of the First-Step Upper-Bound Proposition (on top of the four double-well conditions). 23-05	$\hbar \to 0$	From (15) to the double-well power statement by `power_H_of_kink_ratio` (assumptions in 23-03 § 05)

What this chapter can say

Said	Not said
Proved here The kink action $S_0 = 2/3$ and the zero mode, the shortfall $\frac{1}{4}$ of curvature at the top, the transfer-operator version (18) of Herring's formula	Checking the rest of the spectrum of the fluctuation operator (the next eigenvalue) in the original source
Proved here The One-Dimensional One-Sided Bridge Proposition: $C_P \geq \xi^2$ (continuous time, $T \to \infty$; (12) and the ground-state transformation cited)	An upper bound on C_P. Whether R grows as $1/\hbar$ or exponentially
Cited The diffusion coefficient of one kink $D = \hbar/S_0$ (at the level of the process), the leading semiclassical term of ξ	That the gap of whole paths is determined by the diffusion of kinks (the question of the upper side)
Reading The growth of the lower bound on R (1.06→6.5), $\ln \xi$ at three values of $\hbar$ (Table 2), the numbers for D	Enclosing the values of Table 2 by interval arithmetic. Conversion between readings at $\varepsilon = 0.25$ and readings at $\varepsilon = \frac{1}{2}$
Assumption The target for the upper side (15) was put in the form of the conclusion of the First-Step Upper-Bound Proposition	(15) itself. The double-well power statement. About four-dimensional gauge theory, this chapter shows nothing

Words used in this chapter — double well, path measure, Dirichlet form, kink, zero mode, diffusion coefficient of kinks, tunnelling splitting, correlation length (of the double well), Herring's formula, plateau, convex core, phase (phase without kinks). Their meanings are in A-02 Glossary.

Next chapter to read: 23-05 The statement of the first step — the four double-well conditions and the upper-bound proposition — splits the upper side into four conditions by the algebra of the splitting of the variance, and states the First-Step Upper-Bound Proposition divided into the parts shown and the assumption rows.

The statement of the first step — the four double-well conditions and the upper-bound proposition

> This chapter is this book's own investigation. § 05 is established knowledge.

What this chapter shows — We split the upper side $CP \le K\xi^2 S_0/\hbar$ for the path measure of the double well into the four double-well conditions (the in-phase local Poincaré condition, the saddle-tube condition, the box-reduction condition and the gap-inside-the-box condition). The box-reduction condition reduces infinitely long paths to boxes of length $C\xi$, the gap-inside-the-box condition controls the gap inside a box, and the in-phase local Poincaré condition and the saddle-tube condition enter the gap-inside-the-box condition as the fast part inside the box. On top of this we state, as one line of argument, how $R = CP/\xi^2$ is squeezed into $1 \le R \le K'/\hbar$ and the double-well relaxation-time power statement follows, adding for each step "what it uses and which grade it has". At the end of the chapter the steps of the First-Step Upper-Bound Proposition are collected in a table of the five grades and a dependency graph.

Prerequisite chapters — 23-03 § 05 (the double-well power statement and the form of the First-Step Upper-Bound Proposition), 23-04 (the path measure, kinks, the One-Dimensional One-Sided Bridge Proposition), 1-10 § 07– § 09 (Poincaré inequalities), 23-00 § 01 (the labels of the five grades).

Said first — The level is [Y3]. The First-Step Upper-Bound Proposition is algebra on top of four conditions, and every one of the four conditions leaves assumption rows. This chapter does not say that the first step is closed. It names what would have to be shown to close it. This part is a study that chose the diffusive-relaxation-time assumption as its foothold, and the split into the four conditions is one way of building within it. Other views are treated in Part 24.

The order of this chapter

1. The splitting of the variance — the algebra of splitting into two valleys, and why that alone is not enough for long paths
2. The parts shown — the algebra of the splitting, the convex core, the reduced plateau, the diffusion coefficient of kinks

3. The statements of the four conditions — for which measure, which constant, uniform in what
4. The First-Step Upper-Bound Proposition as one line — box reduction → inside the box → $C_P \le K\xi^2 S_0/\hbar \to R \le K'/\hbar$ → the double-well power statement
5. The distance from known theorems — where they reach and where they do not (Table 1)
6. The table of the five grades — the rows of the steps of the First-Step Upper-Bound Proposition (Table 2)
7. The dependency graph — checking by the numbers that there is no circle
8. A $\hbar$ that fits all, and where the four conditions stand — a guide to 23-06–23-12

01

The splitting of the variance — the algebra of splitting into two valleys

The setting is as in 23-04 § 01. The lattice is $\varepsilon = \frac{1}{2}$, the action S_{lat}, the measure $\mu \propto e^{-S_{\mathrm{lat}}/\hbar}$, the Dirichlet form $\mathcal{E}(f) = (\hbar/\varepsilon)\sum_i \mathbb{E}|\partial_i f|^2$, $C_P = \sup_f \mathrm{Var}(f)/\mathcal{E}(f)$, the diffusion coefficient of kinks $D = \hbar/S_0$, and $S_0 = 2/3$. We take $T \to \infty$ first and then $\hbar \to 0$.

The first tool for building the upper side is the algebra of splitting the measure into two parts. Split the space of configurations in two (for example by the sign of the smoothed value of the path) and write $\mu = Z_+\mu_+ + Z_-\mu_-$ ($Z_\pm \ge 0$, $Z_+ + Z_- = 1$, and $\mu_\pm$ the measures restricted to each part and normalised). Then for every f

$$\mathrm{Var}_\mu f = Z_+\,\mathrm{Var}_{\mu_+} f + Z_-\,\mathrm{Var}_{\mu_-} f + Z_+Z_-\big(\mathbb{E}_{\mu_+} f - \mathbb{E}_{\mu_-} f\big)^2 \quad (1)$$

holds Proved here (the identity for the variance of a mixture. Put $m_\pm = \mathbb{E}_{\mu_\pm} f$ and $m = Z_+m_+ + Z_-m_-$, split $\mathbb{E}_\mu(f-m)^2$ on each part into $f - m_\pm$ and $m_\pm - m$, and use $Z_+(m_+ - m)^2 + Z_-(m_- - m)^2 = Z_+Z_-(m_+ - m_-)^2$).

Suppose that each of the three terms on the right-hand side has the following inequality.

$$\mathrm{Var}_{\mu_\pm} f \le C_{\mathrm{loc}}\,\mathcal{E}_\pm(f), \qquad \big(\mathbb{E}_{\mu_+} f - \mathbb{E}_{\mu_-} f\big)^2 \le C_{\mathrm{md}}\,\mathcal{E}(f), \qquad Z_+\mathcal{E}_+(f) + Z_-\mathcal{E}_-(f) \le$$

The first is local Poincaré inside a valley, the second is the "transport of the mean difference", which controls the difference of the means of the two valleys by the Dirichlet form, and the third is the additivity of the form. Since $Z_+Z_- \le \frac{1}{4}$,

$$C_P \;\le\; C_{\mathrm{loc}} + \frac{C_{\mathrm{md}}}{4} \quad (3)$$

holds Proved here Lean `split_poincare_le` (assumptions: $Z_+ + Z_- = 1$, $Z_\pm \ge 0$, the splitting formula (1), the two local Poincaré inequalities, the mean difference, additivity of the form, non-negative constants). The splitting formula (1) has the same form as the Variance-Splitting Lemma (Lemma 2.4 of Menz–Schlichting) Cited (the skeleton of the Poincaré version of finite-dimensional Eyring–Kramers).

Of the two constants in (3), C_{loc} later becomes the in-phase local Poincaré condition and C_{md} becomes the saddle-tube condition. But (3) cannot be applied to long paths as it stands.

For long paths, one coarse variable is not enough. (1) is a split of the form "take one slow variable (which valley the path is in) and treat the rest as fast". When the path is much longer than the correlation length ($T \gg \xi$), long-wave fluctuations of the density of kinks form a continuous band, and the Poincaré constant of the conditional measure with one valley fixed stays of the same size as ξ^2/D (the Glauber band of 23-04 § 05). That is, C_{loc} does not become $O(1)$. So instead of taking a number of slow variables proportional to the volume, we cut the problem into boxes of length $C\xi$. This is the box-reduction condition and the gap-inside-the-box condition, and the in-phase local Poincaré condition and the saddle-tube condition are used inside the box (§ 04).

02

The parts shown — the algebra of the splitting, the convex core, the reduced plateau, the diffusion coefficient

First we list the parts of the construction of the upper side that can be said without assumption rows.

(a) The algebra of the splitting. (1)–(3) are as in § 01 Proved here .

(b) The convex core. For the measure restricted to the convex region deep in a valley, $\{x_i \ge a\ \forall i\}$ ($a > 1/\sqrt{3}$), the Hessian of the action is at least $\varepsilon\kappa_a$ ($\kappa_a = (3a^2-1)/2$), so Bakry–Émery on a convex region gives $C_P \le 2/(3a^2-1)$ uniformly in the length, $\hbar$ and the boundary Proved here (the lower bound on the curvature) Cited (Bakry–Émery on a convex region, Theorem 1.2 of Kolesnikov–Milman). The proof and the Lean statement are in 23-04 § 06. But excursions out of the core have smaller action than a kink, and exponentially many of them fit in an interval of length ξ, so the convex core alone does not give the in-phase local Poincaré condition.

(c) The two-state value of the reduced plateau. On a short ring ($T \ll \xi$) the path that moves between valleys is one pair of kinks, and the separation ℓ of the pair becomes

the one slow coordinate. In the one-dimensional model that keeps only ℓ (ℓ moves with diffusion coefficient $2D$, with an atom of a valley at each end and the plateau weight $\pi(\ell)$ in between), we control the mean difference by the Cauchy–Schwarz inequality, write the difference of the values at the two ends of ℓ as $\int f'(\ell)\,d\ell$, and

$$\big(f(\text{right valley}) - f(\text{left valley})\big)^2 \;\le\; \int \frac{d\ell}{\pi(\ell)} \cdot \int \pi(\ell)\, f'(\ell)^2\, d\ell \quad (4)$$

gives a value of the form $C_{\mathrm{md}}/4 = J/(4D)$, with equality nearly attained by the sign test function Proved here ((4) is the Cauchy–Schwarz inequality) Lean `reduced_two_state_value` (assumptions: $0 < T$, $0 < D$, $J = 4\xi^2 I/T$, with I the integral of the plateau weight). The reduced model itself (that everything other than ℓ may be thrown away) is an assumption of the model, and this value is "a value on the reduced model" Assumption .

(d) The diffusion coefficient of kinks. The position of a single kink moves with diffusion coefficient $D = \hbar/S_0$. At the level of the process of a single interface, this is a copy of the coefficient of a known theorem Cited ((9) of 23-04 § 03). It is not a statement about the gap of the whole path.

These four are all. The remaining parts, namely that local Poincaré inside a valley is uniform in the length and in $\hbar$, that transport along the family of flat saddles is uniform in the dimension, the reduction of long paths to boxes, and the gap inside a box, lie outside the assumptions of known theorems (§ 05). We name them as four conditions.

03

The statements of the four conditions — for which measure, which constant, uniform in what

We write the four conditions making three things explicit: the measure, the constant and the uniformity. All are statements about the 0+1-dimensional double well $V = (x^2 - 1)^2/8$, the lattice $\varepsilon = \frac{1}{2}$ and the Dirichlet form $\mathcal{E}$. "Uniform" means that for some $\hbar_0 > 0$ with $\hbar \in (0, \hbar_0]$, the constant does not depend on $\hbar$ (does not grow as $\hbar \to 0$).

The in-phase local Poincaré condition (local Poincaré within a phase)

Measure: the measure of the phase without kinks. The measure $\mu^{(+)} = \mu(\cdot \mid x_i \ge 0\ \forall i)$ restricted to configurations in which the path stays on the side of one valley, for example to configurations with $x_i \ge 0$ at every site (reflected at the wall $x_i = 0$).
Constant: the Poincaré constant C_{loc} of $\mu^{(+)}$, that is, $\mathrm{Var}_{\mu^{(+)}} f \le C_{\mathrm{loc}}\, \mathcal{E}(f)$.
Uniformity: $C_{\mathrm{loc}} = O(1)$ uniformly in $\hbar$ and in the length of the path. For use

inside the box, the version for segments with end values (length $\leq C\xi$) is needed (the segment local Poincaré assumption), and it must also be uniform in the end values.

The saddle-tube condition (transport along the family of flat saddles)

Measure: the conditional measure of configurations in the tube around the family of kink–antikink pairs (the family of saddles, parametrised by the centre X and separation ℓ of the pair, along which the action is almost flat). **Constant**: the constant of transport of the mean difference along that family from valley to valley (of the type of C_{md} in (2)), and the Poincaré constant inside the tube. **Uniformity**: uniform in the number of sites of the path (the dimension) and in $\hbar$. For use inside the box it becomes two rows: Poincaré in the tube uniform in tube length $\leq C\xi$ (the saddle-tube Poincaré assumption), and Poincaré of the core inside the tube (the interval that stays near the top) uniform in the core length k (the core Poincaré uniformity assumption).

The box-reduction condition (reduction to the box dynamics)

Measure: the measure μ on the lattice line $\mathbb{Z}$ with $T = \infty$, and the conditional measure $\mu_B^{a,b}$ with the values $(a, b) \in \mathbb{R}^2$ on both neighbours of a box B of length L sites ($L\varepsilon = C\xi$) fixed. **Constants**: $C_{\mathrm{box}}(L) := \sup_{a,b\in\mathbb{R}} C_P(\mu_B^{a,b})$ and the constant c_M of mixing between boxes. **Statement**: $C_P(\mu) \leq C_{\mathrm{box}}(L)/c_M$. **Uniformity**: c_M depends only on lengths in units of ξ (C and the fraction of overlap of the boxes), not on $\hbar$ or the boundary values.

The gap-inside-the-box condition

Measure: the conditional measure $\mu_B^{a,b}$ of a box of length $C\xi$. The number of kinks in the box is $O(1)$ on average (the density of kinks is $1/(2\xi)$, so the expectation is $C/2$). **Constant**: the gap $1/C_P(\mu_B^{a,b})$. **Statement**: $1/C_P(\mu_B^{a,b}) \geq c\,D/(C\xi)^2$, that is, $C_{\mathrm{box}} \leq K_4(C\xi)^2/D$ ($K_4 = 1/c$). **Uniformity**: c is uniform in $\hbar$ and in all boundary values (a, b) (it may depend on C).

The four are not conditions of the same weight. The box-reduction condition is the step that "moves the problem of long paths to a problem of boxes", the gap-inside-the-box condition is the step that "splits the inside of a box into slow variables (the arrangement of kinks) and fast variables", and the in-phase local Poincaré condition

and the saddle-tube condition are statements on the side of those fast variables. The next section puts into one line the place where the in-phase local Poincaré condition and the saddle-tube condition enter the gap-inside-the-box condition.

To be precise, the four double-well conditions are different from the relaxation-time assumption (the power statement, 23-01 § 05). The relaxation-time assumption is a statement on the side of the conclusion, and the four double-well conditions are conditions put in place to derive it in the first step (23-03 § 05).

04

The First-Step Upper-Bound Proposition as one line

The First-Step Upper-Bound Proposition (conditional)

For the path measure of the 0+1-dimensional double well (lattice $\varepsilon = \frac{1}{2}$, taking $T \to \infty$ first), assume the four double-well conditions and the premise rows of Step 0 below. Then as $\hbar \to 0$

$$C_P \;\le\; K\,\xi^2\,\frac{S_0}{\hbar} = K\,\frac{\xi^2}{D} \qquad (K \text{ depends only on the constants of the conditions, not on}$$

holds, hence $1 \le R = C_P/\xi^2 \le KS_0/\hbar$, and the double-well power statement $\ln C_P / \ln \xi \to 2$ follows.

(5) is the same formula as (15) of 23-04 § 05 and (3) of 23-03 § 05. Below, each step is given with "what it uses" and its grade.

Step 0 (the step aligning the assumptions) The premise rows

That the measure μ with $T = \infty$ is uniquely determined (simplicity of the principal eigenvalue, from the positivity of the integral kernel of the transfer operator) Assumption (the original source for the version with a positive kernel on $\mathbb{R}$ has not been checked; the same row as in 23-04 § 01). The relation between $C_P(T)$ of the finite ring and C_P of the measure with $T = \infty$ (the step of the limit), and the regularity of the functions used in the steps below (conditional measures, smoothness of the kink coordinates) Assumption . These three are premises placed outside the First-Step Upper-Bound Proposition, and they are counted as assumption rows in the integrated table (23-12) too.

Step 1 (the box-reduction step) Box reduction — the box-reduction condition in the form of the Box-Reduction Proposition

Cover the line $\mathbb{Z}$ by boxes of length L sites. Neighbouring boxes overlap in l sites ($l \le L/3$), and the boxes are divided alternately into an even family E and an odd family O. Let $\mathcal{G}_E$ be the σ-algebra generated by the values at the sites outside the even family, define $\mathcal{G}_O$ in the same way, and let the maximal correlation of the two σ-algebras be

$$c_{\mathrm{alt}} := \sup\{\operatorname{corr}_\mu(F,G) : \ F \in L^2(\mathcal{G}_E),\ G \in L^2(\mathcal{G}_O)\} \quad (6)$$

.

The Two-Projection Lemma. If $c = c(\mathcal{G}_1,\mathcal{G}_2) < 1$, then for all $f \in L^2(\mu)$, $\operatorname{Var} f \le (1-c)^{-1}\big(\mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_1) + \mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_2)\big)$.

Proved here Proof. Put $\tilde f = f - \mathbb{E}f$ and $a_i = \mathbb{E}[f \mid \mathcal{G}_i] - \mathbb{E}f$. Then $s := \|a_1\|^2 + \|a_2\|^2 = \langle \tilde f, a_1 + a_2\rangle \le \|\tilde f\|\,\|a_1+a_2\|$, while $\|a_1+a_2\|^2 \le s + 2c\|a_1\|\|a_2\| \le (1+c)s$. Hence $s \le (1+c)\|\tilde f\|^2$, and adding $\mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_i) = \|\tilde f\|^2 - \|a_i\|^2$ gives at least $(1-c)\|\tilde f\|^2$. ∎ Lean `two_proj_var` (assumption: $A + B \le (1+c)V$. The geometry of the projections is outside Lean).

The product over boxes. Even boxes are $L - 2l \ge 1$ sites apart, so by the Markov property of the nearest-neighbour interaction they are mutually independent under $\mathcal{G}_E$. The variance of a function of independent components is at most the sum of the conditional variances component by component (of the Efron–Stein type), so

$$\mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_E) \ \le \ C_{\mathrm{box}}(L) \sum_{B \in E} \mathcal{E}_B(f) \quad (7)$$

holds Proved here (the Markov property and the variance inequality for independent products; the proof is placed in 23-11). The same holds for the odd family. Each site lies in the even family at most once and in the odd family at most once, and only the overlaps lie in both.

Averaging over shifts. Shift the arrangement of boxes by l at a time, in $n = \lfloor (L-l)/l \rfloor$ ways. Every shift has the same c_{alt}, and the overlap sites are disjoint between shifts. Applying the Two-Projection Lemma and (7) to each shift and averaging gives

$$C_P(\mu) \ \le \ \Big(1 + \frac{1}{n}\Big)\frac{C_{\mathrm{box}}(L)}{1 - c_{\mathrm{alt}}} \quad (8)$$

Proved here Lean `box_two_family`, `box_shift_average` (assumptions: the two-family inequality for each shift, $C_{\mathrm{box}} \ge 0$, the sum of the forms on the overlaps at most $\mathcal{E}$). This is the Box-Reduction Proposition, and c_M of the box-reduction condition

corresponds to $(1 - c_{\mathrm{alt}})/(1 + 1/n)$. This step uses only Poincaré inequalities, not the logarithmic Sobolev inequality.

One assumption row remains in (8): that the alternating maximal correlation $c_{\mathrm{alt}} < 1$ is uniform in $\hbar$ (the alternating maximal-correlation assumption for boxes). Its value is read as $c_{\mathrm{alt}} \approx 0.73$ at $C = 2$ and overlap $\theta = l/L = \frac{1}{4}$ Reading (a family value copied from the closed formula for the two-state telegraph chain; not a proof of an upper bound). The type of the box reduction has the same form as the Box-Dynamics Proposition for Glauber dynamics of discrete spins (Propositions 3.4 and 3.5 of Martinelli's lectures) Cited (discrete spins, in the form of a total-variation coupling; here rewritten in one dimension, in L^2, in the form of maximal correlation).

Step 2 (the step inside the box) Inside the box — the gap-inside-the-box condition in the form of the Gap-Inside-the-Box Proposition, and where the in-phase local Poincaré condition and the saddle-tube condition enter

Fix a box B ($L\varepsilon = C\xi$) and boundary values (a, b). Let the slow variable inside the box be Y = the arrangement of kinks (the number of kinks, and the position of each kink defined by projection onto the manifold of kinks). Splitting the variance by Y gives

$$\operatorname{Var} f = \mathbb{E} \operatorname{Var}(f \mid Y) + \operatorname{Var}\big(\mathbb{E}[f \mid Y]\big) \quad (9)$$

Proved here (the identity for conditional expectations).

First term = the fast side. The in-phase local Poincaré condition and the saddle-tube condition enter here. By the nearest-neighbour Markov property, the conditional measure with Y fixed splits into a product of the following parts. (i) Segments of the phase without kinks between kinks (length $\le C\xi$, with values at both ends). (ii) The tube around each kink or kink pair, and the core inside it (the interval that stays near the top). The Poincaré constant of a product measure is the maximum of the constants of the components (the variance inequality for independent products), so

$$\mathbb{E} \operatorname{Var}(f \mid Y) \;\le\; C_{\mathrm{loc}}\, \mathcal{E}(f), \qquad C_{\mathrm{loc}} = \max\big(C_{(\mathrm{H1}^{\mathrm{seg}})},\, C_{(\mathrm{H2}^{\mathrm{tube}})},\, C_{(\mathrm{T0}'_{\mathrm{P}})}\big) \quad (10)$$

Proved here (the Poincaré constant of a product measure is the maximum of the constants of the components. That it splits into a product depends on how Y is defined, and its regularity is included in the row of Step 0). The constant of (i) is the segment version of the in-phase local Poincaré condition, and the constants of (ii) are the tube and core rows of the saddle-tube condition Assumption (all three are assumption rows).

Second term = the slow side. Longitudinal transport along the family of saddles enters here. $\mathbb{E}[f \mid Y]$ is a function of Y alone, and its fluctuations relax by the diffusion

of kink positions and by the creation and annihilation of kink pairs. The Dirichlet form $\mathcal{E}_Y$ on Y has mobility per kink of the form $D = \hbar/S_0$ (the kink diffusion-coefficient row: the projection formula, 23-04 § 03). Here we put two rows.

- The kink-gas gap assumption: the Poincaré constant of the box for the reduced kink gas, $C_{\mathrm{kg}} \le (C\xi)^2/\big(c_{\mathrm{kg}}(C)(1-\eta_{\mathrm{KG}})D\big)$, with $\eta_{\mathrm{KG}} < 1$ uniform in $\hbar$ and the boundary values Assumption (the assumption that the kink gas falls into the same type as the Glauber dynamics of the one-dimensional Ising model).
- The cross-term uniformity assumption: the cross term $\mathcal{E}_Y(\mathbb{E}[f \mid Y]) \le (1+\chi)\,\mathcal{E}(f)$, with χ uniform in $\hbar$ and the boundary values Assumption (of the type of the cross constant of a two-scale inequality; a statement of this form is not taken from a known theorem).

c_{kg} of the kink-gas gap assumption comes from reading in the continuum limit the closed formula for the gap of the Glauber box with fixed ends, $(1-\gamma)+\gamma(1-\cos(\pi/(L+1)))$,

$$\frac{D}{\xi^2} + \frac{\pi^2 D}{L_\tau^2} = \big(C^2+\pi^2\big)\frac{D}{(C\xi)^2} \qquad (L_\tau = C\xi) \quad (11)$$

which gives $c_{\mathrm{kg}} = C^2+\pi^2$ Proved here (the algebra of (11)) Lean `kg_constant` (assumption: $C\xi \neq 0$). The first term D/ξ^2 is the creation and annihilation of pairs, and the second is the diffusion of kink positions. When a boundary value is near the top, half a kink can sit at the end of the box (corresponding to a free end), and in the sup including that case $c_{\mathrm{kg}} = c_{\mathrm{ff}}(C)$, read as 7.17 at $C = 2$ Reading (a family value obtained from lattice values of the gap of the free-end box of the one-dimensional Ising model).

Combining (9)(10) with the kink-gas gap assumption and the cross-term uniformity assumption gives

$$C_{\mathrm{box}} \;\le\; C_{\mathrm{loc}} + (1+\chi)\,C_{\mathrm{kg}} \;\le\; K_4\,\frac{(C\xi)^2}{D}, \qquad K_4 = \frac{1+\chi}{c_{\mathrm{kg}}(1-\eta_{\mathrm{KG}})} + C_{\mathrm{loc}}\,\frac{D}{(C\xi)^2} \quad (12)$$

Proved here Lean `H4_two_scale` (assumptions: the inequality of decomposition (9), first term $\le C_{\mathrm{loc}}\mathcal{E}$, the kink-gas gap assumption $\le C_{\mathrm{kg}}\mathcal{E}_Y$, the cross-term uniformity assumption, $C_{\mathrm{kg}} \ge 0$), `H4_gap_form` (assumptions: $D>0$, $C\xi \neq 0$, $c_{\mathrm{kg}}>0$, $\eta_{\mathrm{KG}}<1$, $1+\chi \ge 0$, the two inequalities above). This is the Gap-Inside-the-Box Proposition.

The second term of K_4 is C_{loc} multiplied by $D/(C\xi)^2$, and $D/\xi^2 = \hbar/(S_0\xi^2)$ is of size $e^{-441.6}/e^{-1328.6}/e^{-4433.1}$ at the three values of $\hbar$ ($\hbar = 3\cdot10^{-3}/10^{-3}/3\cdot10^{-4}$) Reading (Table 2 of 23-04 § 07). Unless C_{loc} grows exponentially in $\hbar$, this term vanishes as $\hbar \to$

0. In this sense the demand of the in-phase local Poincaré condition for $C_{\mathrm{loc}} = O(1)$ is a demand with room to spare.

A note on where the saddle-tube condition goes. In the two-valley split of § 01, the saddle-tube condition was the mean-difference constant C_{md} itself. In the box split, the direction along the family of saddles (the kink positions) was taken as the slow variable Y, so transport in that direction is handled by the kink-gas gap assumption and the cross-term uniformity assumption in the second term, and what remains in the saddle-tube condition is the Poincaré of the tube and the core with Y fixed. In this book the tube and core rows are counted as rows of the saddle-tube condition, and the kink-gas gap assumption and the cross-term uniformity assumption as rows of the gap-inside-the-box condition (the same counting as the integrated table, 23-12).

Step 3 (the composition step) Composition — $C_P \le K\xi^2 S_0/\hbar$

Putting (12) into C_{box} of (8) and using $L\varepsilon = C\xi$ and $D = \hbar/S_0$ gives

$$C_P(\mu) \;\le\; K\,\xi^2\,\frac{S_0}{\hbar}, \qquad K = \Big(1+\frac{1}{n}\Big)\frac{C^2 K_4}{1-c_{\mathrm{alt}}} \tag{13}$$

Proved here Lean `H3_H4_compose` (assumptions: the conclusion (8) of the Box-Reduction Proposition, the conclusion $C_{\mathrm{box}} \le K_4(C\xi)^2/D$ of the Gap-Inside-the-Box Proposition, $D = \hbar/S_0$, $n > 0$, $\hbar > 0$, $S_0 > 0$, $c_{\mathrm{alt}} < 1$). That K does not depend on $\hbar$ is the uniformity of c_{alt}, χ, η_{KG}, c_{kg} and C_{loc}, that is, the very content of the assumption rows.

Putting in the values of the reduced model ($\chi = \eta_{\mathrm{KG}} = 0$, $n = 3$, $\theta = \frac{1}{4}$) gives $K \approx 2.76$ at $C = 2$ (the sup including boundary values at the top), 1.43 (ends on the well side only), and $K \approx 1.78$ at $C = 4$ Reading (family values, not upper bounds on K) Lean `K_ff_C2`, `K_ff_C4` (assumptions: the measured values of c_{ff} and c_{alt}; arithmetic only). The value is the same at the three values of $\hbar$ because $\hbar$ does not enter the reduced model.

Step 4 (the step bracketing the ratio) Bracketing the ratio R — $1 \le R \le K'/\hbar$

Dividing (13) by ξ^2 gives $R = C_P/\xi^2 \le KS_0/\hbar =: K'/\hbar$ Proved here (division). From below, the One-Dimensional One-Sided Bridge Proposition (23-04 § 04) gives $R \ge 1$ Proved here (continuous time, $T \to \infty$; the proof is placed in 23-04). Together,

$$1 \;\le\; R \;\le\; \frac{K'}{\hbar}, \qquad K' = KS_0 \tag{14}$$

The One-Dimensional One-Sided Bridge Proposition is a lower bound that uses no conditions, and the left inequality of (14) does not depend on the four double-well

conditions.

Step 5 (the step reading the power) The double-well power statement — $\ln C_P / \ln \xi \to 2$

$\ln C_P / \ln \xi = 2 + \ln R / \ln \xi$, and (14) gives $0 \le \ln R \le \ln K' + \ln(1/\hbar)$. The remaining input is how the ruler grows, $\ln \xi \ge s/\hbar$ (for some $s > 0$ and small $\hbar$), which comes from $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$. The semiclassical leading term of the continuum model is a copy of a known formula Cited , and for the lattice model it is a reading that $\ln \xi - S_0^{\mathrm{lat}}/\hbar - \frac{1}{2}\ln \hbar$ settles to a constant, $-0.774/-0.777/-0.778$, at the three values of $\hbar$ Reading (23-04 § 07). On this input

$$0 \;\le\; \frac{\ln R}{\ln \xi} \;\le\; \frac{\hbar\big(\ln K' + \ln(1/\hbar)\big)}{s} \;\longrightarrow\; 0 \qquad (\hbar \to 0) \quad (15)$$

and the double-well power statement follows Proved here Lean `power_H_of_kink_ratio` (assumptions: $0 < K$, $0 < s$, $0 < \delta$, and $1 \le R \le K/\hbar$ and $s/\hbar \le \ln \xi$ for $0 < \hbar < \delta$. K in Lean is K' in the text).

Checking the single line

Shrinking Steps 1–5 to one line gives

$$\underbrace{(\mathrm{H1}^{\mathrm{seg}}),\ (\mathrm{H2}^{\mathrm{tube}}),\ (\mathrm{T0}'_{\mathrm{P}})}_{C_{\mathrm{loc}}} \xrightarrow{(9)(10),\ (\mathrm{KG}),\ (\mathrm{X})} \underbrace{C_{\mathrm{box}} \le K_4 \frac{(C\xi)^2}{D}}_{\text{Proposition H4}} \xrightarrow{\text{Proposition H3, (M}}$$

Of the inputs written above the arrows, the assumption rows are the segment local Poincaré assumption, the saddle-tube Poincaré assumption, the core Poincaré uniformity assumption, the kink-gas gap assumption, the cross-term uniformity assumption, the alternating maximal-correlation assumption for boxes, and the premises of Step 0; the rest are elementary algebra, known theorems or readings.

Here we also check that the statements of the assumption rows do not contain the quantities of the conclusion. The quantities of the conclusion are $C_P(\mu)$ of the whole measure with $T = \infty$ and the ratio R. The segment local Poincaré assumption, the saddle-tube Poincaré assumption and the core Poincaré uniformity assumption are constants of the measures of segments, tubes and cores, the kink-gas gap assumption is a constant of the reduced gas, the cross-term uniformity assumption is a comparison of forms, and the alternating maximal-correlation assumption for boxes is a quantity of correlation. None of them contains $C_P(\mu)$ or R. A form that puts the conclusion among the premises (a circle of dependence) does not appear in the way these steps are built (for how to check this, see 23-13).

To be precise, the conclusion of the First-Step Upper-Bound Proposition is the first-step statement that "the relaxation time C_P of Langevin dynamics grows as a power of ξ^2". C_P is a different quantity from the gap of the transfer operator (the tunnelling splitting), and even if every row of the First-Step Upper-Bound Proposition were in place, the statements from the second step on would not follow (23-01 § 08, 23-03 § 06).

05

The distance from known theorems

Within the range searched, no known theorem gives the upper bound (5) of the First-Step Upper-Bound Proposition. Table 1 summarises how far nearby theorems reach and where they stop.

Table 1 Where known theorems reach and where they do not (the grade is the grade of the row that cites the theorem)

Known theorem	Where it reaches	Where it does not	Grade
The Poincaré version of Eyring–Kramers (Bovier–Gayrard–Klein; the Variance-Splitting Lemma of Menz–Schlichting, Theorems 2.9 and 2.12)	For a Morse function at fixed dimension, from the splitting of the variance, local Poincaré and transport of the mean difference up to the asymptotics of the gap and the prefactor	The constants are not uniform in the dimension. Degenerate families of saddles such as translation of a kink are outside the assumptions	Cited
Eyring–Kramers for the stochastic Allen–Cahn equation on a fixed interval (Di Gesù–Le Peutrec; Brooks–Di Gesù)	Asymptotics of the gap with the length of the interval fixed below the bifurcation threshold	The regime with infinite interval length and the translation family are stated by the authors themselves in the text to be out of scope	Cited
Transition times of short paths (Berglund–Gentz Theorem 2.6)	The mean time to move between valleys for $T < 2\pi\sqrt{2}$ (uniform saddle)	Long paths ($T \gg \xi$)	Cited
Diffusion of a single interface (Bertini–Brassesco–Buttà Theorem 2.1)	That the position of a single kink approaches Brownian motion with diffusion coefficient D (at the level of the process)	Not a statement about the spectral gap of the whole path	Cited
A criterion uniform in the volume (Bauerschmidt–Dagallier Theorem 2.1)	Applies directly to the lattice of paths and gives an upper bound uniform in the volume	The value is $C_P \le e^{c\xi}$ with $c \approx 1.4 \to 1.8$ ($\varepsilon = 0.25$, $\hbar = 0.4 \to 0.1$), doubly exponential in $\hbar$. It does not reach the double-well power statement	Cited (theorem) Reading (value)

Known theorem	Where it reaches	Where it does not	Grade
The Box-Dynamics Proposition (Propositions 3.4 and 3.5 of Martinelli's lectures)	For discrete spins, the type that controls the whole gap by the box dynamics and the gap inside the box	Unbounded spins, sup over boundary values. Step 1 borrows only the type, rewritten in one dimension in the L^2 form	Cited (type)

As the last three rows of Table 1 show, the known tools sit at the two ends, "a single kink" and "an upper bound uniform in the volume but coarse", and what lies between them (an upper bound on long paths sharp up to the diffusion time ξ^2/D of the kink gas) is the place of the First-Step Upper-Bound Proposition. The Bauerschmidt–Dagallier bound becoming $e^{c\xi}$ is read as follows: the criterion looks at a single quantity, the susceptibility, so it cannot distinguish slow but local relaxation from slow and global relaxation, and ξ enters the exponent Reading .

06

The table of the five grades — the rows of the steps of the First-Step Upper-Bound Proposition

We put the steps of § 04 into one table in the format of the five grades (23-00 § 01). Each row has one grade, and the column of machine checking is outside the grades. The row numbers are the numbers of the nodes of the dependency graph in § 07 (the labels in the formulas, (H1^{seg}), (H2^{tube}), (T0′$_{\mathrm{P}}$), (KG) and (X), are the assumptions [02]–[06] respectively).

Table 2 The rows of the steps of the First-Step Upper-Bound Proposition ("—" in the range of $\hbar$ marks an assumption row not shown at any $\hbar$)

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[01]	Uniqueness of the measure with $T = \infty$, the step of the limit, regularity	Assumption	§ 04 Step 0 (the original source for the principal eigenvalue of a positive kernel on $\mathbb{R}$ is unchecked)	—	—
[02]	The segment local Poincaré assumption: Poincaré of segments without kinks uniform in the length, the end values and $\hbar$	Assumption	§ 03, (10) of § 04 Step 2. The node propositions for the ring version are in 23-06	—	—

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[03]	The saddle-tube Poincaré assumption: Poincaré of the tube uniform in length $\leq C\xi$	Assumption	§ 03, (10)	—	—

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[04]	The core Poincaré uniformity assumption: Poincaré of the core uniform in the core length	Assumption	§ 03, (10). The proposition with an assumption at the lower end of the window is in 23-09 and 23-11. For the core on the sector side (both ends in the well), it is supported for every $\hbar \in (0,1]$ by the Dobrushin criterion of the coarse chain: conditional on a proof in the paper (the Coarse-Chain Dobrushin Theorem (Theorem CC of the paper)) + Computer-assisted ($\hbar \in [10^{-5},1]$, 239 intervals, interval arithmetic, $\rho_{\mathrm{col}} \leq 0.400$) + a paper proof and Computer-assisted (the Small-$\hbar$ Coarse-Chain Proposition (Proposition PIN of the paper): $\hbar \leq 10^{-5}$, $\rho_{\mathrm{col}} \leq 0.874$) + Cited (the Poincaré Version of Helffer's Criterion in Bobkov–	Sector side: $(0,1]$	—

The "Proved here" rows of Table 2 are all algebra that takes assumption rows as input. That "Proved here" rows line up does not mean that the conclusion of the First-Step Upper-Bound Proposition has been shown. The conclusion becomes unconditional only when every "Assumption" row and the "Reading" row (the row of the growth of the correlation length, [09]) have been replaced.

07

The dependency graph — checking by the numbers that there is no circle

We turn the rows of Table 2 into a list of numbered nodes. The format is common to this part (the integrated graph of 23-12 is the same), and **the numbers of the premises to the right of "⟸" are always placed smaller than the number of the conclusion on the left**. The leaves (assumptions, known results, readings) have small numbers, and the conclusion has the largest number.

```

How to check. In every row with "⟸", look to see that the numbers on the right are smaller than the number on the left. [11] and [12] use only [01], [14] uses [07][10][11], [15] uses [02]–[06][08][12][13], [16] uses [08][14][15], [17] uses [01], [18] uses [16][17], and [19] uses [09][18]. Every row keeps the rule. If the rule is kept, following the premises always lowers the number and eventually reaches a leaf, so there is no circle.

Among the leaves, "Assumption" covers the seven [01]–[07], "Cited" is [08], and "Reading" is [09]. The conclusion [16] of the First-Step Upper-Bound Proposition depends on all of [01]–[08] (on [01] also through [11][12]), and the double-well power statement [19] depends further on [09]. Only the One-Dimensional One-Sided Bridge Proposition [17] depends on nothing but [01] and does not use the four double-well conditions.

To be precise, this graph is the dependency of the construction of the steps of the First-Step Upper-Bound Proposition, and it does not include the content of each assumption

row (for example the Six-Node In-Phase Poincaré Proposition, which supports [02] at the nodes). Those are in the graphs of the chapters on each condition, and the graph that joins them all into one is the integrated graph of 23-12.

08

A $\hbar$ that fits all, and where the four conditions stand

There is no $\hbar$ at which all rows are in place. The node propositions of the in-phase local Poincaré condition are at six points with $\hbar \geq 0.005$, the conditional propositions that support the core row are at the lower end of the window, of order $\hbar \leq 10^{-3}$, and the two do not meet. The kink-gas gap assumption, the cross-term uniformity assumption and the saddle-tube Poincaré assumption are assumption rows at every $\hbar$. The band figure and the way of fitting them together are placed in 23-12.

We list where each of the four conditions stands, one line each. The details are in each chapter.

Where the four conditions stand

1. The in-phase local Poincaré condition — the Six-Node In-Phase Poincaré Proposition for the ring version: margin ≥ 0.067 at the six nodes $\hbar \in \{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$, with neighbours and ends in $[0, 2.5]$ (computer-assisted). What remains is between the nodes, $\hbar < 0.005$, ends > 2.5, and the segment version (23-06)
2. The saddle-tube condition — a map split into seven routes. The condition on the chain outside the window is computer-assisted on the whole window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$, five steps of the sector framework are propositions, and for the one remaining proposition three strands stop at the curvature shortfall $\frac{1}{4}$ at one site at the top (23-07–23-10)
3. The box-reduction condition — the Box-Reduction Proposition (§ 04 Step 1). The alternating maximal-correlation assumption for boxes and the $\sup$ over boundary values remain (23-11)
4. The gap-inside-the-box condition — the Gap-Inside-the-Box Proposition (§ 04 Step 2). The cross-term uniformity assumption, the kink-gas gap assumption, the segment local Poincaré assumption and the core row remain, and the core constant is controlled in three steps (23-11)

This part is a study that chose the relaxation-time assumption as its foothold, and the First-Step Upper-Bound Proposition is one way of splitting to build the upper side of

the first step. Other views are treated in Part 24.

What this chapter can say

What is said	What is not said
Proved here The algebra of the splitting of the variance (3), the Two-Projection Lemma, the Box-Reduction Proposition (8), the Gap-Inside-the-Box Proposition (12), the composition (13), the bracketing of the ratio (14), the algebra to the double-well power statement (15). All are algebra on named assumption rows Lean (the assumptions are the rows of Table 2)	None of the assumption rows [01]–[07]. Hence neither (5) itself nor the double-well power statement for the first step

Words used in this chapter — splitting of the variance, local Poincaré, transport of the mean difference, the four double-well conditions, the First-Step Upper-Bound Proposition, phase (phase without kinks), segment, tube, core, box dynamics (box reduction), maximal correlation, alternating maximal correlation, the Two-Projection Lemma, Efron–Stein inequality, reduced kink gas, cross term, dependency graph. Their meanings are in A-02 Glossary.

Next chapter to read: 23-06 The in-phase local Poincaré condition — turns the Poincaré constant of the measure of the phase without kinks into node propositions at six values of $\hbar$, by a two-scale construction of kept sites and bridges, and describes the method and cost of filling in between the nodes.

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time the in-phase local Poincaré condition, the Six-Node In-Phase Poincaré Proposition, six nodes · Kiichi, Shiori and Rin

The in-phase local Poincaré condition

This chapter is this book's own investigation. The established knowledge it builds on is in 2-05 and 2-07.

What this chapter shows — The in-phase local Poincaré condition is the statement that the Poincaré constant of the measure restricted to the phase without kinks (configurations in which the path stays on the side of one valley) is $O(1)$ uniformly in $\hbar$ and in the length of the path. In this chapter we turn the version on the ring into the Six-Node In-Phase Poincaré Proposition, by a two-scale construction that splits the path into kept sites and bridges of 11 sites between them. The Six-Node In-Phase Poincaré Proposition holds at six nodes of $\hbar$, $\{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$, and its key inequality (margin on the coarse side ≥ 0.067) is computer-assisted. At the end we list the method and cost of filling in the $\hbar$ between the nodes, and what remains that needs other methods, such as $\hbar < 0.005$ and large end values.

Prerequisite chapters — 23-05 (the four conditions and the Double-Well Relaxation-Time Upper-Bound Proposition, the format of the table of the five grades and the dependency graph), 23-04 § 06 (the plateau at the top and the convex core), 1-10 § 07– § 09 (Poincaré inequalities). For how to read computer-assisted results, see 23-08.

Said first — § 01 is a summary readable at [Y3], and § 02 onwards is at the research level [Res]. You can read only the summary and go on to 23-07. The Six-Node In-Phase Poincaré Proposition is not a proof of the in-phase local Poincaré condition. The $\hbar$ outside the six nodes, end values > 2.5, and the segment version used inside the box remain as assumption rows.

The order of this chapter

1. Summary [Y3] — statement, construction, the Six-Node In-Phase Poincaré Proposition, what remains
2. The statement and the measure of the phase — what is hard
3. The two-scale construction — kept sites, bridges, nesting, the criterion on the coarse side, the algebra of the rate
4. The Six-Node In-Phase Poincaré Proposition — the margins at the six nodes (Table 1) and the constant

5. The table of the five grades — the rows of the Six-Node In-Phase Poincaré Proposition (Table 2)
6. The $\hbar$ between the nodes — method and cost (Tables 3 and 4)
7. The remaining rows — what needs other methods (Table 5)
8. The dependency graph

01

Summary [Y3]

Statement. On the lattice of paths of the double well ($\varepsilon = \frac{1}{2}$), consider the measure $\mu^{(+)}$ restricted to $x_i \geq 0$ at every site. The in-phase local Poincaré condition says "$C_P(\mu^{(+)})$ is at most a constant independent of $\hbar$ and of the length". Bakry–Émery on the convex core works only deep in a valley ($x_i \geq a > 1/\sqrt{3}$), and exponentially many excursions within the valley fit in an interval of length ξ, so this measure is not convex (23-04 § 06).

Construction. Keep one site in every 12 (the coarse side), and treat the 11 sites between them as bridges with both ends fixed (the fine side). Split the variance into "the conditional variance with the kept sites fixed" and "the variance of its expectation". The fine side is controlled by splitting each bridge further into three small bridges and two sites, and the coarse side is judged on the chain of kept sites by the gap at one site and the strength of the coupling between neighbours. The key to the criterion on the coarse side is the margin inequality

$$\underbrace{\hbar\rho}_{\text{gap at one site}} - 2 \underbrace{\hbar\kappa}_{\text{coupling to neighbours}} > 0 \quad (1)$$

, and interval arithmetic is used to check it for every combination of end values.

The Six-Node In-Phase Poincaré Proposition. At each of the six nodes of $\hbar$, the margin ≥ 0.067 is checked computer-assisted for all neighbour and end values in $[0, 2.5]$, and on top of the remaining rows (assumptions and known theorems) $C_P(\mu^{(+)}) \leq C$ with $C \leq 1.6 \times 10^{10}$ (from paper and interval-arithmetic inputs only). With numerical readings as input, $C \leq 658$. Neither depends on the length of the ring.

What remains. For the $\hbar$ between the nodes, there is a scheme that fills in subinterval by subinterval by making $\beta = 1/\hbar$ a third direction of tilting, and its cost is estimated at tens of hours on one core. $\hbar < 0.005$ needs infinitely many subintervals and so needs another method (asymptotics as $\hbar \to 0$). End values > 2.5, the sharpness of the constant, the scrap version used inside the box, and checking the bibliography of the cited theorems also remain.

02

The statement and the measure of the phase — what is hard

The measure of the phase. From the lattice action on a ring of $N = 12n$ sites ($n \geq 3$),

$$S = \sum_i \frac{(x_{i+1} - x_i)^2}{2\varepsilon} + \varepsilon \sum_i V(x_i), \qquad V(x) = \frac{(x^2-1)^2}{8}, \qquad \varepsilon = \frac{1}{2} \quad (2)$$

we form the measure $\mu^{(+)} \propto e^{-S/\hbar} \mathbf{1}\{x_i \geq 0 \ \forall i\}$ restricted to configurations with $x_i \geq 0$ at every site. The orthant is convex, so this measure is the equilibrium of Langevin dynamics reflected at the wall $x_i = 0$ (Neumann condition). The Dirichlet form is $\mathcal{E}(f) = (\hbar/\varepsilon) \sum_i \mathbb{E}|\partial_i f|^2$. The path stays on the side of the valley $x = 1$ and has no kinks. This is "the phase without kinks".

The in-phase local Poincaré condition (ring version)

There exist $\hbar_0 > 0$ and $C < \infty$ such that $\mathrm{Var}_{\mu^{(+)}} f \leq C\, \mathcal{E}(f)$ for all $\hbar \in (0, \hbar_0]$ and all n.

The version used inside the box (the segment local Poincaré assumption used in the step inside the box, 23-05 § 04) uses, instead of the ring, segments of length $\leq C\xi$ with values at both ends, and asks for uniformity in the end values as well.

What is hard. Three naive roads all lose a factor exponential in $\hbar$.

- The convex core: restricting to $x_i \geq a > 1/\sqrt{3}$ gives $C_P \leq 2/(3a^2 - 1)$ by Bakry–Émery, but the action of an excursion out of the core (0.1535 at $a = 1/\sqrt{3}$) is smaller than the kink action $2/3$, and $e^{(S_0 - c_a)/\hbar}$ excursions fit in an interval of length ξ Proved here (23-04 § 06).
- Global perturbation (of the Holley–Stroock type): the oscillation of the difference from a convex action is proportional to the length of the path, and the constant is of the type $e^{T\delta/\hbar}$ Cited (the Holley–Stroock perturbation lemma; type checked in the restatement as Proposition 6.1 of Ledoux).
- Perturbation site by site: the non-convexity per site is $\varepsilon/(8\hbar)$, but the coupling between neighbours $(x_{i+1} - x_i)^2/(2\varepsilon)$ is strong, so sites cannot be detached and treated one at a time Reading .

The numbers do not contradict the in-phase local Poincaré condition. Measuring the integrated autocorrelation time of the magnetisation for Langevin dynamics on the ring with a wall gave $0.86/1.40/1.50/1.39$ at $\hbar = 0.3/0.15/0.1/0.07$, sizes that do not depend on $\hbar$ Reading (the autocorrelation of a single observable gives only a lower bound on the Poincaré constant, and is not evidence for an upper bound).

03

The two-scale construction

Kept sites and bridges. Keep the sites $y_j := x_{12j}$, and treat the 11 sites $x_{12j+1}, \dots, x_{12j+11}$ between y_j and y_{j+1} as a bridge with both ends fixed at y_j, y_{j+1}. Splitting the variance by the kept sites y gives

$$\mathrm{Var}_\mu(+)\ f = \mathbb{E}\big[\mathrm{Var}(f \mid y)\big] + \mathrm{Var}\big(\mathbb{E}[f \mid y]\big) \quad (3)$$

(the variance-decomposition row: the decomposition of the variance is elementary; the regularity and density of the functions used are assumptions). Because the interaction is nearest-neighbour, the bridges are independent once y is fixed, and the marginal measure of y is a nearest-neighbour chain of the kept sites (the nearest-neighbour chain row: the Markov property).

The fine side: nesting inside the bridge. A bridge of 11 sites is not convex (the smallest eigenvalue of the Hessian of the bridge is $(1/\varepsilon)\lambda_{\min}(L_{11}) - \varepsilon/2 = -0.11$). So we keep sites 4 and 8 of the bridge as one more level and split it into three small bridges (3 sites) and two sites (x_4, x_8).

- A small bridge of 3 sites is log-concave: Hessian $\geq (1/\varepsilon)\lambda_{\min}(L_3) - \varepsilon/2 = 2(2-\sqrt{2}) - \frac{1}{4} \approx 0.92$. Bakry–Émery gives the gap $\rho_f = 0.922$ Proved here (lower bound on the curvature) Cited (Bakry–Émery on a convex region).
- The cross term between the small bridges and the two sites is $\kappa_f = 1.98$ by the Brascamp–Lieb inequality Cited .
- The gap of the marginal measure of the two sites (x_4, x_8) is $\lambda_c \geq 1.3 \times 10^{-4}$ (end values $[0,4]^2$, $\hbar \in (0, 0.2]$) Computer-assisted (the two-site gap row).

Combining the three by the nested two-scale algebra, the gap of the bridge is at least the smaller root of $t^2 - (\rho_f + \lambda_c + \kappa_f^2/\rho_f)t + \rho_f \lambda_c = 0$, and $\lambda_S \geq 2.3 \times 10^{-5}$ Proved here (arithmetic of the root).

The coarse side: the gap at one site and the coupling. The one-dimensional conditional measure of y_j with the neighbour values c, d fixed is $\propto e^{-U(t)/\hbar}$, with

$$U'(t) = \varepsilon V'(t) + \frac{2t - e(c,t) - e(d,t)}{\varepsilon}, \qquad e(a,b) := \mathbb{E}_{a,b}\, x_{11} \quad (4)$$

($\mathbb{E}_{a,b}$ is the expectation over the bridge with ends a, b). Write $\hbar\rho(c,d)$ for its Poincaré gap multiplied by $\hbar$, and let the strength of the coupling between the two ends of the bridge be

$$\hbar\kappa(a,b) := \frac{\mathrm{Cov}_{a,b}(x_1, x_{11})}{\varepsilon^2 \hbar} = \frac{1}{\varepsilon}\,\partial_a e(a,b) \ \geq\ 0 \quad (5)$$

(the second equality is the identity obtained by differentiating $\partial_a \log Z(a,b)$ in b Proved here ; non-negativity follows from e being increasing in a Cited (the FKG correlation inequality)). Using the Poincaré Version of Helffer's Criterion in the Gershgorin form on the ring, the gap of the chain on the coarse side is at least the margin

$$\lambda := \min_{c,d} \hbar\rho(c,d) - 2 \max_{a,b} \hbar\kappa(a,b) \quad (6)$$

Cited (the Poincaré Version of Helffer's Criterion, Proposition 3.1 of Ledoux) Proved here (the Gershgorin form) Lean `ring_gershgorin` (the inequality for quadratic forms on the ring; assumption: $\kappa \geq 0$). (1) means $\lambda > 0$.

The cross term and the algebra of the rate. The strength of the cross term linking the fine side and the coarse side is $\kappa^2 = 2(v/\hbar)\lambda_S/\varepsilon^2$, with $v/\hbar \leq 2\big(644/1455 + (60/97)^2/\lambda_c\big) \leq 5888$ (the crossing row) Proved here (arithmetic) Lean `T4_paper_numeric` (assumption: $\lambda_c \geq 1.3 \times 10^{-4}$) Cited (Brascamp–Lieb). Both λ and λ_S are in units of the gap for the flat Dirichlet form $\int |\nabla f|^2$ multiplied by $\hbar$. Then if $0 \leq t < \lambda$ satisfies

$$t\,\kappa^2 \;\leq\; \lambda_S(\lambda_S - t)(\lambda - t) \quad (7)$$

, we have $C_P(\mu^{(+)}) \leq \varepsilon/t$ Proved here Lean `H1_assembly` (algebra with the assumptions named: decomposition (3) [`hT5`], the fine side [`hFine`; ρ in Lean is λ_S in the text], the conclusion of the criterion on the coarse side [`hLedoux`], the margin $\lambda \leq \hbar\rho - 2\hbar\kappa$ [`hT1`], $0 < \lambda$, the cross term [`hT4`], the rate condition (7)).

The whole construction, as a tree of decompositions of the variance, is as follows.

```
Var f = E[Var(f|y)] + Var(E[f|y])                                  (varia
 ├ fine side: bridges of 11 sites with y fixed
 │    └ nesting {4,8}: small bridges BE ρ_f=0.922, cross term BL κ_f=1.9
 ├ coarse side: ring of kept sites (nearest-neighbour chain row) ── Poin
 │    └ margin row: gap at one site ħρ (Muckenhoupt, FKG band, tail) − 1
 └ crossing: κ² = 2(v/ħ)λ_S/ε² (crossing row ← two-site gap row)
 → rate condition tκ² ≤ λ_S(λ_S−t)(λ−t) (H1_assembly) → C_P ≤ ε/t
```

04

The Six-Node In-Phase Poincaré Proposition — the margins and the constant

The Six-Node In-Phase Poincaré Proposition (0+1 dimensions, ring version, with a table of assumptions)

Let $V = (x^2-1)^2/8$, $\varepsilon = \frac{1}{2}$, the ring $N = 12n$ ($n \geq 3$), the measure of the phase $\mu^{(+)}$ with the wall $x_i \geq 0$, the kept sites $y_j = x_{12j}$, and the nested sites inside the bridge $\{4,$

8}. Under the "Assumption" and "Cited" rows of Table 2, at each point $\hbar \in \{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$,

$$\mathrm{Var}_{\mu}(+)\, f \;\le\; C\,\mathcal{E}(f), \qquad C \le 1.6 \times 10^{10} \quad (8)$$

holds independently of n. With numerical readings as input, $C \le 658$.

The key row is the margin (6), and the values of Table 1 are obtained at the six nodes for every combination of neighbour and end values in $[0, 2.5]$.

Computer-assisted Table 1 The margin on the coarse side at each node (neighbour and end values $[0, 2.5]^2$; $\hbar\rho$ is a lower bound and $\hbar\kappa$ an upper bound, values rounded outwards)

$\hbar$	$\hbar\rho \ge$	$\hbar\kappa \le$	**Margin** $\hbar\rho - 2\hbar\kappa \ge$
0.2	0.7755	0.0358	0.7039
0.1	0.7140	0.0664	0.5812
0.05	0.8121	0.1222	0.5677
0.02	0.8846	0.2636	0.3574
0.01	0.8670	0.39996	0.0670
0.005	0.92182	0.41868	0.0844

The interval arithmetic is implemented by adding outward widths to float64 operations (rounding of non-negative sums is widened outwards by a relative 10^{-10}, interval arithmetic operations by a relative 10^{-12}, weights below e^{-700} are replaced from above, and the region $\varepsilon V/\hbar > 690$ is covered by a tail upper bound). It is not rounding with a direction specified for each operation, but an added width that presupposes correct IEEE rounding. This premise is written in the same row, row [01] of Table 2. The arithmetic that gives the margin ≥ 0.067 from the six pairs of values is Lean `T1_margin_six_nodes` (no assumptions, numbers), and the step from the interval output to the margin at one node is `T1_node_margin` (assumptions: the two inequalities of the interval output and $0.067 \le r - 2k$).

Tools that extend the intervals to the continuum between nodes. Table 1 gives values "for every combination of neighbour and end values", and to pass from computations on finitely many boxes to the continuum we use three lemmas.

- The $\hbar\rho$ side: Muckenhoupt's estimate, which squeezes the Poincaré constant of a one-dimensional measure by a Hardy-type quantity B as $B \le C_P \le 4B$ Cited ; a lemma that builds a band from the values at the nodes to the continuum of neighbours by the monotonicity (FKG) of $e(c, t)$ in the neighbour value Cited (FKG); and a lemma for the tail on the side of large t (the continuous version of Holley's comparison and a tilted Gaussian bridge) Assumption (the theorem number of the continuous version has not been checked in the original source).

- The $\hbar\kappa$ side: the Tilted Second-Order Taylor Lemma, which tilts the measure at the centre of a box of end values and controls the whole box by the second-order Taylor expansion of the cumulant generating function and a Hölder remainder Proved here (the Taylor remainder and Hölder's inequality). This formula is exact whatever constant is chosen for the centring.
- The smaller of two upper bounds is also an upper bound, and the reflection symmetry $\hbar\kappa(a,b) = \hbar\kappa(b,a)$ covers half Proved here Lean `min_of_two_upper`, `symm_upper` (assumptions: two upper bounds / symmetry and a one-sided upper bound).

The moves that made the margin positive at $\hbar = 0.01$ and 0.005. When $\hbar$ is small the upper bound on $\hbar\kappa$ swells, and in a coarse computation the margin was negative at $\hbar = 0.01$, with 0.634. What limits it differs from place to place, and three moves bring it down. (i) At the corner of the ends $(0,0)$, the centring constant of the Tilted Second-Order Taylor Lemma is retaken for each subrectangle as the median of that range (the formula is exact for any centre, so only the upper bound goes down). (ii) The second-order term acts as the square of the box width δ, so δ is halved. (iii) At the large end $(2.5, 2.5)$, the bridge jumps far into the well in one step, so the quadrature error is the limit, and the quadrature step is halved. At $\hbar = 0.005$, refining the quadrature on the $\hbar\rho$ side raises the lower bound from 0.6945 to 0.92182. The last two rows of Table 1 are the results of these moves Computer-assisted .

The constant. $C \le 1.6 \times 10^{10}$ in (8) is the ε/t that follows from $t = 3.2 \times 10^{-11}$ satisfying the rate condition (7) with the paper and interval-arithmetic inputs ($\lambda \ge 0.067$, $\lambda_S \ge 2.3 \times 10^{-5}$, $v/\hbar \le 5888$) Proved here (arithmetic) Lean `H1_rate_paper_six_nodes` (no assumptions, numbers). Taking the gap of the two sites to be the numerical $\lambda_C = 0.57$ gives $\lambda_S \ge 0.093$, $v/\hbar \le 1.0015$, then $t = 7.6 \times 10^{-4}$ and $C \le 658$ Reading (the input is a floating-point reading) Lean `H1_rate_numeric_six_nodes` (no assumptions, numbers). Most of the difference between the two values comes from the weakness of the paper value of λ_C.

05

The table of the five grades — the rows of the Six-Node In-Phase Poincaré Proposition

We put the inputs of the Six-Node In-Phase Poincaré Proposition into one table in the format of the five grades. Items whose paper proof is placed in this book are "Proved here", those whose proof is not are "Assumption", interval arithmetic is "Computer-assisted" with the premises of its implementation written in the same row, and cited theorems are split into "Cited" or "Assumption" according to the level to which their bibliography has been checked. The numbers in the row column are the numbers of the nodes of the dependency graph in § 08, and "—" marks a row not in the graph.

Table 2 The rows of the Six-Node In-Phase Poincaré Proposition ("six nodes" in the range of $\hbar$ means $\{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$)

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[01]	Margin row: margin $\hbar\rho - 2\hbar\kappa \geq 0.067$ (neighbours and ends $[0, 2.5]^2$)	Computer-assisted	§ 04 Table 1. float64 + outward widths (relative 10^{-10}, 10^{-12}), presupposing correct IEEE rounding; tails covered by upper bounds	Six nodes	`T1_margin_six_nodes` (numbers), `T1_node_margin` (assumption: the interval output)
[02]	The Tilted Second-Order Taylor Lemma (second-order Taylor of the tilt and Hölder remainder, any centre)	Proved here	§ 04 (Taylor remainder, Hölder's inequality)	Independent of $\hbar$	—
[03]	Squeezing the one-dimensional Poincaré constant, $B \leq C_P \leq 4B$ (Muckenhoupt)	Cited	Statement checked in the restatement as Theorems 1 and 2 of Barthe–Roberto	Independent of $\hbar$	—
[04]	Monotonicity of $e(c, t)$ and $\hbar\kappa \geq 0$ (the MTP_2 correlation inequality)	Cited	Proposition 2.1 of Karlin–Rinott (checked in the restatement as Proposition 3.5 of Fallat et al.)	Independent of $\hbar$	—
[05]	The continuous version of Holley's comparison used for the tail lemma	Assumption	§ 04 (the theorem number in the original source is unchecked)	Six nodes	—
[06]	The Poincaré Version of Helffer's Criterion (gap of the chain on the coarse side $\geq \lambda$)	Cited	The Poincaré Version of Helffer's Criterion (Proposition 3.1 of Ledoux; checked in the original text)	Independent of $\hbar$	—
[14]	The Gershgorin form on the ring	Proved here	§ 03 (6)	Independent of $\hbar$	`ring_gershgorin` (assumption: $\kappa \geq 0$)

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[11]	Nearest-neighbour chain row: the marginal of the kept sites is a nearest-neighbour chain	Proved here	§ 03 (the Markov property)	Independent of $\hbar$	—
[07]	Two-site gap row: $\lambda_c \geq 1.3 \times 10^{-4}$ (ends $[0,4]^2$)	Computer-assisted	§ 03. Interval arithmetic (multiprecision intervals and float64 + outward widths)	$(0, 0.2]$	—
[08]	The Poincaré–Miranda theorem used to cover the boxes of the two-site gap row	Assumption	The statement in the original source is unchecked (bibliographic only)	$(0, 0.2]$	—
[15]	Nesting: small bridge $\rho_f = 0.922$ (Bakry–Émery)	Proved here	§ 03 (lower bound on the curvature; Bakry–Émery is Cited via Theorem 1.2 of Kolesnikov–Milman)	Independent of $\hbar$	—
[09]	Nesting: cross term $\kappa_f = 1.98$ (also used in the crossing row; Brascamp–Lieb)	Cited	Theorem 4.1 of Brascamp–Lieb (checked in a restatement); convex regions by Kolesnikov–Milman	Independent of $\hbar$	—
[16]	Crossing row: arithmetic of $v/\hbar \leq 5888$ and $\lambda_S \geq 2.3 \times 10^{-5}$	Proved here	§ 03	$(0, 0.2]$	`T4_paper_numeric` (assumption: $\lambda_c \geq 1.3 \times 10^{-4}$)
[12]	Variance-decomposition row: decomposition of the variance (3)	Proved here	§ 03	Independent of $\hbar$	—
[10]	Variance-decomposition row: regularity and density of the functions used	Assumption	§ 03 (not checked in the original source)	—	—

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[17]	The algebra of the rate (7) $\Longrightarrow C_P \leq \varepsilon/t$	Proved here	§ 03	Independent of $\hbar$	`H1_assembly` (the assumptions are the seven named ones of § 03)
[18]	$C \leq 1.6 \times 10^{10}$	Proved here	§ 04 (arithmetic from the values of [01], [07] and [16])	Six nodes	`H1_rate_paper_six_nodes` (numbers)
—	$C \leq 658$	Reading	§ 04 ($\lambda_c = 0.57$ is floating point)	Six nodes	`H1_rate_numeric_six_nodes` (numbers)
—	Margin row (large-end side): neighbours and ends > 2.5	Assumption	§ 07	—	—
—	Margin row (between nodes): the $\hbar$ between the nodes	Assumption	§ 06 (method and cost)	Outside the nodes of $(0.005, 0.2)$	—
—	Margin row (small ħ): $\hbar < 0.005$	Assumption	§ 07	—	—
—	Two-site gap row (large-end side): ends of the two sites > 4	Assumption	§ 07	—	—
—	The segment local Poincaré assumption: from the ring to segments (with end values)	Assumption	§ 07 (the transfer to the chain version of the criterion is a reading)	—	—

The "Computer-assisted" rows [01] and [07] of Table 2 are inequalities at the computed nodes and within the computed ranges. They say nothing about $\hbar$ or end values outside those ranges, and that is what the five "Assumption" rows at the end of Table 2 (with "—" in the number column) take on.

06

The $\hbar$ between the nodes — method and cost

The Six-Node In-Phase Poincaré Proposition is a statement at six points. The in-phase local Poincaré condition is a statement on the continuum of $\hbar$, so the gaps between the points must be filled. This section describes the method for that, the result of trying the method on one subinterval, and an estimate of the cost for the whole range.

(a) β as a third direction of tilting. $\beta = 1/\hbar$ enters the measure $e^{-\beta S}$ only as an exponent of the weight, so we regard an interval $[\hbar_1, \hbar_2]$ of $\hbar$ as an interval $[\beta_{\mathrm{lo}}, \beta_{\mathrm{hi}}]$ of β, and add a third direction (the observable $-S$) to the two directions of tilting in the end values in the Tilted Second-Order Taylor Lemma. β enters the margin (6) in six places (the weight, the width of the tilt, the prefactor, the quadrature step, the tail, the monotonicity band), and for each it is determined at which end of the interval the worst case lies Proved here . A guide for the ratio of one step, $r = \beta_{\mathrm{hi}}/\beta_{\mathrm{lo}}$, is $r \approx 1.17$, from the fluctuation of the action $\mathrm{Var}(\beta S)$ (about half the degrees of freedom of the bridge, near $11/2$ Reading), and $\hbar \in [0.005, 0.2]$ can be covered by 24 subintervals Proved here $(0.2/1.17^{24} \le 0.005)$ Lean `nodes_reach_117` (no assumptions, numbers).

(b) The chord form breaks. With the end values (a, b) fixed, $f(\beta) = \hbar\kappa(a, b; 1/\beta)$ is smooth in β, and a lower bound on the second derivative $f'' \ge -C$ gives the chord upper bound

$$f(\beta) \;\le\; \max\bigl(K2(\beta_{\mathrm{lo}}), K2(\beta_{\mathrm{hi}})\bigr) + \frac{(\beta_{\mathrm{hi}} - \beta_{\mathrm{lo}})^2}{8} \sup|f''| \quad (9)$$

Proved here Lean `chord_beta_upper` (assumptions: $f \in C^2$, $f'' \ge -C$, $0 \le C$, $\beta_{\mathrm{lo}} \le \beta_{\mathrm{hi}}$, upper bounds at the ends). But f'' is a connected cumulant, and controlling it by a product of absolute values (Hölder) gives 5×10^3–1.8×10^6 times the true value Reading , so at $r = 1.17$ the remainder is 0.25–0.64, far beyond what is allowed Lean `holder_r117_exceeds` (numbers).

(c) A step-by-step scheme (a scheme that carries $\hbar$ as an interval). Compute the unnormalised integral $J_X(\beta) = \int X e^{-\beta H}\,dx$ ($X \ge 0$ is the weight of the product of end observables) at three points of β, and interpolate by a quadratic. The interpolation error is $|\omega(\tau)|/6 \cdot \sup|J_X'''|$, with $\max|\omega| = 2\Delta^3/(3\sqrt{3})$ Proved here (ω is the cubic that vanishes at the three nodes. Choosing K so that $g(t) = J_X(t) - p_X(t) - K\omega(t)$ vanishes at the three interpolation points and at τ, four points in all, Rolle's theorem used three times gives a zero of g''', and $K = J_X'''(\eta)/6$). The third derivative is controlled by $|y|^3 \le c_3(\lambda_+)e^{\lambda+y} + c_3(\lambda_-)e^{-\lambda-y}$ and the log-convexity of J_X, through the maximum at the ends of the integrals at four shifted values of β Proved here . Splitting the interval of β further into small pieces, on each piece the expectation is a linear-fractional function, and its value lies between the values at the two ends of the piece, so it can be enclosed by the interval hull Proved here Lean `mobius_between` (assumption: the denominator is positive at both ends of the piece), `lebesgue_le` (assumption: $|u| \le 1$), `cube_le_exp_split` (assumption: $\lambda_\pm > 0$). This scheme never uses monotonicity. The remainder enters as a third-order quantity of raw integrals that needs no cancellation, and the Hölder loss of (b) does not appear.

(d) A trial on one subinterval. Table 3 is the result of running (c) in interval arithmetic on $\hbar \in [0.008547, 0.01]$ ($r = 1.17$) and the rectangle of end values $[0, 0.18]^2$ Computer-assisted (the same implementation premises as Table 1).

Computer-assisted Table 3 Trial on one subinterval ($\hbar \in [0.008547, 0.01]$, rectangle $[0, 0.18]^2$, values of the largest box)

Quantity	Value	How to read it
Upper bound at the point $\hbar = 0.01$ (cross-check)	0.18996	Agrees with the computation of Table 1 to five digits
Upper bound on the subinterval (including the remainder)	0.23638	Swelling from the point upper bound $+0.0464$
Share of the remainder	0.00968	Within the uniform allowance 0.0335
Breakdown of the swelling	–	Growth of the node upper bound with β 48%, interpolation and hull of the pieces 31%, remainder 21%

The allowance. What is needed on the subinterval at $\hbar = 0.01$ is "point upper bound + swelling $\leq \hbar\rho/2 = 0.4335$" in every box. If the same amount is allowed to every box, the uniform allowance set by the worst box (upper bound 0.39996) is $0.4335 - 0.39996 \approx 0.0335$, and the swelling 0.0464 of Table 3 exceeds it. On the other hand, the allowance for the boxes in the rectangle of Table 3 is $0.4335 - 0.19 \approx 0.24$, and the swelling falls within it.

What limits it. The limit is not the remainder but the growth of the node upper bound itself with β (the quadrature width widens with β). The upper bound 0.39996 of the worst box is mostly quadrature width, and the floating-point value for the same box is 0.0076 Reading . Recomputing the band containing this box with finer quadrature brings the upper bound of the box down to 0.0751 Computer-assisted , but the maximum over the whole range only comes down to 0.39971. This is because about 32,000 boxes with upper bounds above 0.19 remain at the coarse setting in a frame along the four sides of the square of end values.

Cost. Table 4 is the estimate for the whole range $\hbar \in [0.005, 0.2]$ (computation time on one core; all are estimates, none has been run yet). The cost of one subinterval is about 3.4 times that of a point computation (measured in the trial of Table 3), and the smaller $\hbar$ is, the larger the cost of one point.

Table 4 Estimated cost of filling in between the nodes (the $\hbar\kappa$ side; the $\hbar\rho$ side is needed separately)

Road	Premise	r	Subintervals	Computation time
After recomputing the frame with finer quadrature	That the point upper bounds in the frame come down to 0.318 or below (not yet computed)	1.17	24	About 23–39 hours (+ 30–50 minutes to recompute the frame)
Point upper bounds as they are (a model in which the swelling acts additively)	The swelling of Table 3 does not depend on the box	1.12	33	About 22 hours

Road	Premise	r	Subintervals	Computation time
Point upper bounds as they are (a model in which the swelling acts multiplicatively)	The ratio 1.363 of Table 3 does not depend on the box	1.04	94	About 63 hours

Which of the two models is right cannot be decided from a trial on one rectangle. The road that recomputes the frame first passes at $r = 1.17$ regardless of the model if the upper bound in the frame falls below 0.318, so it also narrows the range of the cost estimate. The $\hbar\rho$ side (a one-dimensional measure, 23 degrees of freedom) is read by the same guide as $r \approx 1.12$ and 33 subintervals Reading .

To be precise, Table 3 is the result for one rectangle of one subinterval, and does not close that subinterval. To close a subinterval, every rectangle in it must be computed by the scheme of (c).

07

The remaining rows — what needs other methods

Table 5 lists the rows that remain in going from the Six-Node In-Phase Poincaré Proposition to the in-phase local Poincaré condition, and to the segment local Poincaré assumption used inside the box. The cost column is filled only where there is an estimate.

Table 5 The remaining rows of the in-phase local Poincaré condition

Row	Content	Current state	What is needed
Remaining item between nodes	The $\hbar \in (0.005, 0.2)$ between the nodes	The scheme of the method of § 06 exists, and has been tried on one rectangle of one subinterval	Recomputing the frame, and computing all subintervals and all rectangles (Table 4). The $\hbar\rho$ side by the same scheme too
Small-ħ remaining item	$\hbar < 0.005$	The computer-assisted scheme cannot be used: with the ratio r fixed, the number of subintervals $\ln(0.005/\hbar)/\ln r$ grows without bound as $\hbar \to 0$, and the cost of each one grows too	An argument uniform in the asymptotics $\hbar \to 0$ (another method)
Large-end-value remaining item	Neighbour and end values > 2.5	The road of covering by monotonicity is closed: FKG gives an order of likelihood ratios, and the gap is not monotone (the Gap Non-Monotonicity Proposition). Also $e(c, t)$ is not bounded in c (it grows at the rate $c^{3^{-11}}$)	A paper argument that the one-dimensional U becomes uniformly convex for large neighbours. The finite range $[2.5, 4]$ is expected to be covered by the same computation if $\hbar \geq 0.05$

Row	Content	Current state	What is needed
Sharp-constant remaining item	Sharpness of the constant	1.6×10^{10} with paper inputs, 658 with numerical inputs. The difference is carried by the weakness of the paper value of the gap of the two sites λ_c	Rebuilding the two-site gap row. The statement of the in-phase local Poincaré condition does not need the size of the constant (only that it does not depend on $\hbar$)
Segment-version remaining item	The segment version (the segment local Poincaré assumption)	The Six-Node In-Phase Poincaré Proposition is a statement on the ring. Inside the box, segments with values at both ends are needed	Transfer to the chain version of the criterion (fewer neighbours than the ring). At present at the level of a reading
Bibliographic remaining item	Bibliography of the cited theorems	Muckenhoupt and FKG have their statements checked in restatements in secondary sources, Ledoux in the original. The theorem number of Holley's continuous version and the original source of the Poincaré–Miranda theorem are unchecked	Obtaining the original sources. If they cannot be obtained, the rows stay "Assumption" ([05] and [08] of Table 2)

The Gap Non-Monotonicity Proposition is a small proposition of a negative type. The variance $p(1-p)$ of the measure $(1-p, p)$ on two points $\{0, 1\}$ is not monotone when p is raised in the order of likelihood ratios $(3/16 < 1/4 > 3/16)$ Proved here Lean `tilt_variance_not_monotone` (no assumptions, numbers). The same holds for the family obtained by tilting the symmetric double well linearly, and FKG alone does not give "the gap is monotone in the neighbour".

08

The dependency graph — the Six-Node In-Phase Poincaré Proposition

We turn the rows of Table 2 into a list of nodes in the same format as 23-05 § 07. The numbers of the premises are always placed smaller than the number of the conclusion.

          Lean H1_rate_paper_six_nodes (numbers)
```

In every row with "⟸" the numbers on the right are smaller than the one on the left, so there is no circle. Among the leaves, "Assumption" covers [05][08][10] and "Computer-assisted" covers [01][07]. $C \leq 658$ from numerical inputs (the row of Table 2 with numerical inputs) puts reading values into the algebra of [17], and does not enter the conclusion [18] of this graph. The five rows at the end of Table 2 are not premises of the Six-Node In-Phase Poincaré Proposition but rows for going from the Six-Node In-Phase Poincaré Proposition to the in-phase local Poincaré condition and the segment local Poincaré assumption, and in the integrated graph (23-12) they come between [18] and the node of the in-phase local Poincaré condition.

The construction of this chapter is one way of handling one condition within the first step, with the diffusive-relaxation-time assumption as the foothold. Other views are treated in Part 24.

What this chapter can say

What is said	What is not said
Computer-assisted At the six nodes, margin ≥ 0.067 for all neighbours and ends in $[0, 2.5]^2$ (Table 1, with the premises of the implementation). Gap of the two sites $\lambda_c \geq 1.3 \times 10^{-4}$	The $\hbar$ between the nodes, $\hbar < 0.005$, $\hbar > 0.2$. Neighbours and ends > 2.5
Proved here The algebra of the two-scale construction and the rate condition (7), the constant 1.6×10^{10} of the Six-Node In-Phase Poincaré Proposition (on the assumption rows of Table 2) Lean (the assumptions are in Table 2)	The in-phase local Poincaré condition itself (a statement uniform on the continuum of $\hbar$). The segment version (the segment local Poincaré assumption)
Cited The Muckenhoupt squeeze, the MTP_2 correlation inequality, the Poincaré Version of Helffer's Criterion, Bakry–Émery, Brascamp–Lieb	Checking the continuous version of Holley's comparison and the Poincaré–Miranda theorem in the original sources ([05] and [08] of Table 2 are Assumption)

The list of statements is in 23-13.

Words used in this chapter — phase (phase without kinks), kept site, bridge, nesting, Helffer's criterion, margin, node, subinterval, allowance, swelling, frame, segment version (the segment local Poincaré assumption), computer-assisted, interval arithmetic. Their meanings are in A-02 Glossary.

Next chapter to read: 23-07 The map of the saddle-tube condition — seven routes and the seam of the ring — puts on one sheet the map that splits transport along the family of saddles (the saddle-tube condition) into seven routes, and the seam of the ring (the outer chain closes on the whole window, the inner chain has finite coefficients).

The map of the saddle-tube condition — seven routes and the seam of the ring

> This chapter is this book's own investigation. § 02 is a map of open questions; § 07 is guide material.

What this chapter shows — We put the saddle-tube condition (transport along the family of flat saddles) on one sheet, as a map split into seven routes. For each route we give, in one line, what it tries to show, its current grade (proved here, cited, computer-assisted, reading, assumption), what remains, and the chapter that treats it in detail. The second half deals with the place where a kink and an antikink meet on a periodic path (the seam of the ring). The seam is the plateau at the top itself. The outer chain becomes a computer-assisted inequality on the whole computed window of $\hbar$, and the inner chain remains with a finite coefficient above 1.

Prerequisite chapters — 23-05 § 03 (the statements of the four conditions), 23-05 § 04 The step inside the box (where the saddle-tube condition enters the box), 23-04 § 06 (the plateau), 23-00 § 01 (the labels of the five grades).

Said first — The level is [Y3]. This part places the diffusive-relaxation-time assumption (the time over which fluctuations are smoothed out grows as a power of the square of the correlation length, 23-01) at the axis of the study. The diffusive-relaxation-time assumption rephrases the quantities of the problem statement as quantities that can be computed on the lattice and pursued with machine checking, and the saddle-tube condition is one of the four pillars that support its first step. This chapter does not say that the saddle-tube condition is closed. It puts on one sheet which routes have come how far and what remains. Another view is treated in Part 24.

The order of this chapter

1. The statement of the saddle-tube condition and two places — the rows left in the saddle-tube condition by the box split, the tube of the bridge and the seam of the ring
2. The map of the seven routes — grade and what remains, one line each (Table 1)
3. The seam of the ring — the plateau at the top, the outer chain and the inner chain (Table 2)
4. The remaining numbers of the route of the window-constant numerics and their cost — estimates of the number of runs and the time
5. The table of the five grades — the rows of the saddle-tube condition (Table 4)
6. The dependency graph — checking by the numbers that there is no circle
7. A guide to 23-08–23-11

01

The statement of the saddle-tube condition and two places

The statement of the saddle-tube condition is as in 23-05 § 03. We copy it here.

The saddle-tube condition — transport along the family of flat saddles (copied from 23-05)

Measure: the conditional measure of configurations in the tube around the family of kink–antikink pairs (the family of saddles, parametrised by the centre X and separation ℓ of the pair, along which the action is almost flat). **Constant**: the constant of transport of the mean difference along that family from valley to valley, and the Poincaré constant inside the tube. **Uniformity**: uniform in the number of sites of the path (the dimension) and in $\hbar$. For use inside the box it becomes two rows: Poincaré in the tube uniform in tube length $\leq C\xi$ (the saddle-tube Poincaré assumption), and Poincaré of the core inside the tube (the interval that stays near the top) uniform in the core length k (the core Poincaré uniformity assumption).

What the box split leaves in the saddle-tube condition. In the box split of 23-05, the direction along the family of saddles (the kink positions) was taken as the slow variable, so longitudinal transport in that direction is handled by the rows of the gap-inside-the-box condition (the kink-gas gap assumption and the cross-term uniformity assumption) (the note in the step inside the box, 23-05 § 04). What remains in the saddle-tube condition are the **tube and core rows** after the arrangement of kinks is fixed, namely the saddle-tube Poincaré assumption and the core Poincaré uniformity assumption. The map of this chapter is a map of the tools that support these two rows.

Why it is hard. On the core $Q_k = (-x_c, 0)^k$ ($x_c = 0.89$; k sites of boxes, each running from the side of the valley -1 to just short of the top 0), the action is almost flat at the top and the curvature at one site is negative (the summit-curvature shortfall wall of Table 4 in § 05; for details see 23-09 § 06). Convexity tools (Bakry–Émery) do not apply to the whole core, and the core length k grows up to the correlation length, so that the constant is uniform in k must be shown by another means.

Two places — the tube of the bridge and the seam of the ring

The rows of the saddle-tube condition appear in two places where the shape of the path differs.

- **The tube of the bridge.** The tube around a kink, for configurations with one kink on an interval with both ends fixed in the two valleys (a bridge). The core is the interval inside the tube that stays near the top. The saddle-tube Poincaré assumption and the core Poincaré uniformity assumption inside the box have this shape.
- **The seam of the ring.** Configurations on a short periodic path (a ring, length $T \ll \xi$) with one kink–antikink pair, at the place where the separation ℓ of the pair shrinks and the two meet. The configuration just before the pair disappears is the plateau at the top itself (§ 03). The argument for the tube of the bridge uses the fact that the kinks are apart, so the seam needs a different treatment.

In both places, the tool that controls the core constant is of the same type. We attach a coarse mark "valley side or top side" to the sites in the core, and combine the logarithmic Sobolev constant AW of the marginal of the marks on a range of 17 sites around one site (the site window W) with the contraction ratio q of the chain extending outside the window. The contraction condition $q < 1$ of

this "chain outside the window" is the centre of the route of the chain outside the window and of the outer chain in the route of the seam of the ring, and the size of A_W is the centre of the route of the window-constant numerics, the route of the sector framework and the route of the window log-Sobolev inequality. The site window W is different from the range of $\hbar$ treated computer-assisted (the window of $\hbar$, $[3\cdot10^{-4},3\cdot10^{-3}]$). The window in "the chain outside the window" and "the stages inside the window" is the site window, while the window in "the whole window" and "the lower end of the window" is the window of $\hbar$. Where they could be confused we add "site".

02

The map of the seven routes

Seven routes were set up to close the core rows of the saddle-tube condition. The routes are called by the names of their content. The order of the rows of the table indicates neither order nor weight. "Grade" in Table 1 uses the symbols of the five grades of 23-00 § 01, and when two or more grades are mixed in one route they are listed from the main one.

Table 1 The seven routes (window = $\hbar\in[3\cdot10^{-4},3\cdot10^{-3}]$, three points = $\hbar=3\cdot10^{-3}/10^{-3}/3\cdot10^{-4}$)

Route	What it shows	Current grade	Range of $\hbar$	What remains	Chapter
The route of the chain outside the window (contraction of the chain outside the window)	In the core of the bridge, the Stein-kernel ratio $q_{\mathrm{free}}<1$ of the unmarked chain extending outside the site window	Computer-assisted $q_{\mathrm{free}}\le0.998854904$ (float64 + outward widths, presupposing correct IEEE rounding, $\hbar$ as an interval, 25 subintervals)	The whole window	Says nothing outside the window or as $\hbar\to0$	23-08
The route of the window-constant numerics (remaining numbers)	Constants of the site window: minimal weight π_*, rarity Λ, one-site Poincaré C_{LD}^{W}, gap of the mark dynamics gap_W, ratio of the inner chain of the window of the bridge	Reading (floating point at three points) Assumption (the paper reduction to a number of computations is not placed in the book)	Three points	The number of interval-arithmetic runs and the time (§ 04). Decided not to run them because of the floor of the product form	This chapter, § 04
The route of the sector framework	The five steps of the sector sum (sector sum, Gibbs decomposition, componentwise localisation, volume locality, sector composition) and the closing condition $b(A_W c_H+D_W+\ln2)<\kappa\ell_{\min}$	Proved here (the proof of the five steps is placed in 23-09). Inputs are Assumption , Reading	Steps independent of $\hbar$ / inputs at three points	Inputs (the marginal log-Sobolev input for the window, the bridge volume-locality input, E_m, the defect rows, regularity)	23-09 § 02

Route	What it shows	Current grade	Range of $\hbar$	What remains	Chapter
The route of the sector input (small assumptions)	The small assumptions of the sector input (eleven rows: the bridge volume-locality input, the core log-Sobolev uniformity assumption, the longitudinal term and regularity, plus seven rows whose content has not yet been written in one line)	Assumption (list only; not started)	—	Each row	This chapter, § 05
The route of the window log-Sobolev inequality (the one remaining proposition)	Window Log-Sobolev Threshold Proposition: the logarithmic Sobolev constant of the marginal on the site window lies within the needed value $A_{\max}(\hbar)$	Assumption . None of the three strands (componentwise, scalar, Feynman–Kac) is closed	Window (the Scalar-Strand Proposition is on $[3\cdot 10^{-4}, 10^{-3}]$)	The remaining step of each of the three strands	23-09 § 05
The route of the seam of the ring	The core on the ring: contraction of the outer chain and the coefficient of the inner chain	Outer: Computer-assisted (pin ≤ 0; the seam limit assumption and the random-end-value assumption are Assumption) / inner: Reading $q_{\text{in}} \approx 1.24$–$1.28$	Window	The seam limit assumption, the random-end-value assumption, the ratio conditioned on the plateau, the boundary stage, putting the inner chain into intervals	This chapter, § 03
The route of the range of $\hbar$	Outside the window and $\hbar \to 0$	Outside the scope of this part	—	Paper asymptotics	23-12, 23-15

Three notes on how to read Table 1.

(a) Only two rows are computer-assisted. They are the route of the chain outside the window and the outer chain in the route of the seam of the ring. Both are closed in the sense that "within the computed window of $\hbar$, the inequality holds given the table of outputs of interval arithmetic", and say nothing outside the window or as $\hbar \to 0$ (23-08).

(b) Even if the route of the chain outside the window closes, the saddle-tube condition does not close. The ratio q_{free} of the route of the chain outside the window enters only one factor $S_W = 1 + 2\big(16 + 1/(1-q_{\text{free}})\big)$ of the upper bound on the logarithmic Sobolev constant A_W of the site window ([12] of the dependency graph in § 06). In the current construction of the upper bound, the upper bound on A_W lies outside the needed value (by 4–5 orders of magnitude in the product form of the factors for the 17-site window, and by 29–74 times even in the form for the 3-site window with the needed side raised, 23-09 § 03), and the one remaining proposition (the route of the window log-Sobolev inequality) is being attacked by other strands.

(c) The route of the range of ħ was decided to be out of scope. The double-well relaxation-time power statement is a statement as $\hbar \to 0$, so in the end the four double-well conditions must be stated in the asymptotics $\hbar \to 0$, and computer assistance on a fixed window alone does not reach that. Outside the window, paper asymptotics are needed. In this part we first check the grades of the rows inside the window, and how to fit them together is described in 23-12 and 23-15.

03

The seam of the ring — the plateau at the top, the outer chain and the inner chain

A ring is a periodic path of length $T \ll \xi$ with one kink–antikink pair, and we write ℓ for the length of the arc on the negative side. The reduced plateau model of 23-05 § 02 (c) kept only this ℓ. The seam is where ℓ becomes small and the pair disappears.

The seam is the plateau at the top itself

The continuum minimal action $S(\ell)$ with the length of the negative arc fixed at ℓ tends, as $\ell \to 0^+$, not to 0 but to S_0 (the path touches the top and returns). For $\ell \le \pi\sqrt{2}$ the minimising configuration has no kinks: it is a plateau lying flat on the top 0, with action $S_0 + \ell/8$. For $\ell > \pi\sqrt{2}$ a dip appears and the action tends to $2S_0$ ($2S_0 - S \approx 8e^{-\ell}$) Assumption (a continuum variational argument and a cross-check with floating-point minima on the lattice; the proof is not placed in the book). On the lattice ($\varepsilon = \frac{1}{2}$) too, the minimum with m sites on the negative side lies on $S_{\mathrm{lat}}(1) + (m-1)/16$ for $m \le 9$ Reading (floating-point minima, difference $\le 5 \times 10^{-11}$). **The configuration at the seam is the core itself (the interval that stays near the top)**, and the same difficulty as for the core of the tube of the bridge appears here.

The ℓ direction is easy. One-dimensional transport in ℓ alone can be controlled, seam included. On each of the band, the collar and the plateau of the seam, the Muckenhoupt quantity, which squeezes the one-dimensional Poincaré constant within a factor 4, is at most $64S_0\hbar$, $L_0^2/(8D)$ and T^2/D, and the algebra passes machine checking Assumption (paper estimates on the one-dimensional model; the reduction to the model is itself an assumption). The hard part is the side of the coordinates: at the seam, the number of sign changes does not become a slow variable. So we fold by sectors that do not depend on the sign, namely runs of sites with $|z| < \theta$ ($\theta = \frac{1}{2}$) (**lumps**). With the rest fixed, the action of a lump of k sites is convex for $k \le 7$, from $V'' \ge -\frac{1}{2}$ Proved here (the smallest eigenvalue $8\sin^2\frac{\pi}{2(k+1)} - \frac{1}{4}$ of the tridiagonal matrix $\mathrm{tridiag}(-2, 4+w, -2)$, $w \ge -\frac{1}{4}$, is positive for $k \le 7$).

The outer chain and the inner chain

On a site window W of the ring (17 sites) we put marks: one lump (length $k \le 7$, possibly absent), the other sites of the window on the valley side, and outside the window the side of fixed sign. The construction of the logarithmic Sobolev constant of the window involves contraction ratios of two kinds of chain.

- **The outer chain**: the chain extending outside the site window. It moves in the region of fixed sign $[0, \infty)$, and mapped to $(-\infty, 0]$ by the reflection $x \mapsto -x$ it becomes a chain of the same type as the outer chain of the core of the bridge. The action is invariant under the reflection Proved here (V is even) Lean `chain_action_reflect` (no assumptions; the image of the measure and the reversal of the Stein kernel are outside Lean), but it is not the same chain as the chain of the bridge. The box of the bridge has a lower wall $-x_c$, and the outer chain of the ring has none.
- **The inner chain**: the stages inside the site window. From stage to stage the box alternates between "valley side" and "lump", and the lump box $(-\frac{1}{2}, \frac{1}{2})$ straddles 0.

The difference between the two chains can be read from the corner at the wall. The classical corner ratio at a wall at position b is $r(b) = \Delta/(\Delta - \varepsilon^2 V'(b))$. It is exactly 1 at a wall with $V'(b) = 0$ (the wall 0 of the outer chain), and exceeds 1 at a wall where the force pushes out of the box Proved here (the algebra of the sign of the ratio) Lean `corner_eq_one` (assumption: $\Delta \neq 0$), `corner_gt_one` (assumption: $0 < c < \Delta$). The formula for the ratio itself comes from a computation of the envelope, and its regularity is Assumption. At the upper wall $+\frac{1}{2}$ of the lump, $\varepsilon^2 V'(\frac{1}{2}) = -3/64$, so the force points towards the wall and the corner exceeds 1 (the classical value for an isolated wall is 1.2857).

Table 2 The outside and inside of the seam of the ring (triples in the order $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$)

Quantity	Value	Grade	Conditions
Outer chain (unconditioned form) q_{out}	≤ 0.998888530 at every $\hbar$ of the window (the maximum is at the lower end of the window; on the upper half $[10^{-3}, 3 \cdot 10^{-3}]$ it is ≤ 0.996606914)	Computer-assisted	All pins $p \le 0$, evaluation points $s \le 0$, end $z_0 = -1$. The seam limit assumption, the random-end-value assumption and regularity are Assumption. float64 + outward widths, presupposing correct IEEE rounding
Deep side of the outer chain (pin $p < -3$)	≤ 0.592898559	Computer-assisted	As above (uses the upper bound on the tail variance ≤ 0.357608022)
Boundary stage (pin $\in (0, \frac{1}{2})$)	≈ 1.004–1.045 (at the four points $\hbar = 3 \cdot 10^{-3}/10^{-3}/(3/9100)/3 \cdot 10^{-4}$: $1.0043/1.0282/1.0436/1.0446$)	Reading	A finite stage that appears only in configurations where the lump touches the end of the window. The outer-chain rows above do not cover this pin
Inner chain q_{in}	$1.2707/1.2765/1.2421$ (in the order of the triple; 1.2449 at the fourth point $\hbar = 3/9100 \approx 3.3 \cdot 10^{-4}$)	Reading	Floating-point transfer; it moves upwards as the grid is refined. The limit is set by the stage inside the lump with the pin at the edge of the far wall of the lump
Finite coefficient $\bar{q} = \max(q_{\text{in}}, 1)$	$\bar{q} \approx 1.3$, $\bar{q}^{16} \approx 27$–67 (applied to each of S_W and T_W; $\bar{q}^{32}$ for the product A_W)	Reading	$\bar{q} = 1$ does not hold
$S_W = 1 + 2\bar{q}^{16}(16 + 1/(1 - q_{\text{out}}))$	≤ 122745 (≤ 1833 if $\bar{q} = 1$)	Proved here (arithmetic)	Input $q_{\text{in}} \le 13/10$ is Reading, q_{out} is Computer-assisted. Lean `sw_inner_le` (assumptions: $q_{\text{in}} \le 13/10$, $q_{\text{out}} \le 0.998888530$)

In one line, Table 2 says: **the outside is closed (inside the window, conditional on pin ≤ 0), and the inside has a finite coefficient**. "Closed" here means that within the computed window of $\hbar$ the contraction of the outer chain became a computer-assisted inequality, not that the saddle-tube condition is closed on the ring. The result for the outer chain was first closed for the chain conditioned on the box (upper bound 0.998888525) and then extended to the unconditioned chain (the tail term put into the remainder of the interval arithmetic, deep pins covered by a closed-form upper bound). The extension removed the need for the four assumption rows that returned the conditioned chain to the original measure.

Why the inner chain exceeds 1, and the cost of putting it into intervals. What limits the inner chain is the stage with the pin at the edge of the far wall of the lump box, which is exactly the corner pushing outwards described above (close to the classical value 1.2857). The interval

machinery of the outer chain is built on the premises that the right wall is at 0 with $V'(0) = 0$, that there is one box, and that the pins and the grid coincide, so it cannot be used for the inner chain just by swapping the inputs. The estimated cost of putting the inner chain into interval arithmetic is 1–2 paper steps + 1–2 scripts + about 50 runs, about 42 hours (one core), and what it gives is only an upper bound on the finite coefficient $\bar{q} \approx 1.3$. This coefficient enters A_W as a factor $\bar{q}^{32} \approx 10^{3.6}$, so it is not a road to meeting the closing condition of the sector framework (23-09 § 02).

The rows that remain at the seam of the ring. The seam limit assumption (that the limit of stacking stages without end falls inside the enclosure of the fixed point at each $\hbar$), the random-end-value assumption (the case where the value at the end of the chain is given not by a point but by a distribution), the ratio conditioned on the plateau (the ratio conditioned on the length of the plateau), the boundary stage, and putting the inner chain into intervals. All remain Assumption or Reading .

04

The route of the window-constant numerics — the remaining numbers and their cost

In the current construction (the Product Bound for the Window Log-Sobolev Constant), the upper bound on the logarithmic Sobolev constant of the site window has the form of a product of factors $A = c_W \cdot C_{\mathrm{LD}}^{W} \cdot S_W \cdot T_W$. c_W is a constant of the marginal measure of the marks, built from the minimal weight π_* and the gap of the mark dynamics gap_W, and S_W and T_W are built from the contraction ratios of the chains. The route of the window-constant numerics is the paper reduction and estimate of the number of runs for moving the values of the factors from floating point at three points to interval arithmetic.

Table 3 The numbers of the route of the window-constant numerics, and the number of runs to move them to interval arithmetic (the numbers of runs and the times are estimates; not a single run has been made yet)

Quantity	Paper reduction (not placed in the book)	Estimated runs	Current value
Minimal weight π_*	The marginal measure of the marks is MTP_2, and the sequence giving the minimal weight is pushed to the extreme sequence (all on the valley side) (the preservation theorem of Karlin–Rinott Cited , statement checked in a restatement in a secondary source)	2–3 runs	Reading all on the valley side is the minimum at the three points
Rarity Λ	The sup over boundary values of a monotone function is attained by a single chain at the extreme (MTP_2 association)	1–2 runs	Reading
One-site Poincaré C_{LD}^{W}	The Muckenhoupt criterion quantity Cited (checked in a restatement in a secondary source), cell by cell of boundary values	About 20 runs	Reading of order ≤ 0.66
Gap gap_W	Since one mark screens the interaction of the interfaces, the congestion of the flow is controlled by the chain of the extreme sequence	4 runs	Reading 0.959–1.000
Ratio of the inner chain of the window of the bridge	The Stein-kernel ratio is not monotone in the sequence of marks (it fails for around 300 of the 665 pairs enumerated), so it is split by type of sequence and a band on the far side	About 13 runs	Reading < 1 at the three points

The estimate totals about 42 runs and about 21 hours (one core). **We decided not to run these 42.** The reason is the floor of the product form itself. From $S_W \geq 1 + 2/(1 - q_{\mathrm{free}})$, $T_W \geq |W|$ and c_W

$\geq \ln\bigl(1/\nu(\sigma_i = \text{valley side})\bigr) \approx E_U/\hbar$, even with the true values of the factors, $A \gtrsim 1.4 \times 10^4$–$1.4 \times 10^6$ Reading (estimate), which lies outside the needed value of the sector framework (23-09 § 03, tens to hundreds) by tens to tens of thousands of times. Even if the factors are confirmed in interval arithmetic, this form as it stands does not reach the closing condition. The paper reduction of the route of the window-constant numerics (screening, the extreme sequence) is kept as a tool that enters unchanged into upper bounds not of product form (the strands of the route of the window log-Sobolev inequality).

05

The table of the five grades — the rows of the saddle-tube condition

We put the rows of Tables 1–3 into one table in the format of the five grades. Each row has one grade, and the column of machine checking is outside the grades. The numbers of the rows are the numbers of the nodes of the dependency graph in § 06, and "—" marks a row not in the graph.

Table 4 The core rows of the saddle-tube condition ("—" in the range of $\hbar$ marks an assumption row not shown at any $\hbar$)

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[01]	Premises of interval arithmetic: correct rounding of IEEE 754 arithmetic, upper bounds on summation errors, upper bounds on the errors of our own exponential function	Assumption	23-08 § 03	—	—
[02]	The seam limit assumption, the random-end-value assumption, regularity	Assumption	§ 03	—	—
[03]	Window Log-Sobolev Threshold Proposition: $A_W < A_{\max}(\hbar)$	Assumption	The route of the window log-Sobolev inequality, 23-09 § 03	—	—
[04]	All the small assumptions of the route of the sector input	Assumption	Table 1	—	—
[05]	Product Bound for the Window Log-Sobolev Constant: $A_W \leq c_W C_{\mathrm{LD}}^{W} S_W \mathcal{T}_W$ (product form)	Assumption	§ 04 (the paper construction is not placed in the book)	—	—

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
[06]	The constants of the route of the window-constant numerics, π_*, Λ, C_{ID}^{W}, gap_W, and the ratio of the inner chain of the window of the bridge	Reading	Table 3 (floating point at three points)	Three points	—

The two "Computer-assisted" rows of Table 4 ([09] and [10]) are both computer-assisted on the premise, the row of interval-arithmetic premises, and what Lean checked is "the construction with the table of outputs of interval arithmetic placed as an assumption" (23-08 § 08). The "Proved here" core lower-bound row is algebra on the assumption, the window log-Sobolev threshold row, and does not mean that a lower bound on the gap of the core has been shown.

06

The dependency graph — checking by the numbers that there is no circle

We turn the rows of Table 4 into numbered nodes. **The numbers of the premises to the right of "⟸" are always placed smaller than the number of the conclusion on the left** (the format common to this part, 23-05 § 07).

How to check. [09] has only [01] on the right, [10] only [01][02], [11] only [02][04], [12] only [09], [13] only [07][08][10], [14] only [05][06][12], [15] only [03][11], and [16] only [02][15]. In every row the numbers on the right are smaller than the one on the left, so there is no circle.

What to read from this graph. (1) The road to the core row [16] passes through [15], and [15] depends on the assumption row [03] (the one remaining proposition of the route of the window log-Sobolev inequality). (2) The computer-assisted [09][10] enter only the product-form value [14] through [12][13], and [14] does not satisfy [03] (it lies outside the needed value). That is, **in the current graph the two computer-assisted rows are not on the road to [16]**. When an upper bound not of product form satisfies [03], [09][10] become part of the grounds of [03] if the ratio q enters that bound. (3) None of the reading rows [06][07][08] is used in the proof of an upper bound.

We also check that the statements of the assumption rows do not contain the quantities of the conclusion. The quantities of the conclusion are the gap of the measure of the core ([15]) and the constant of the core Poincaré uniformity assumption ([16]). [03] is the logarithmic Sobolev constant of the marginal of the marks on the site window, [04] constants of the sector input, [05] the construction of the product-form upper bound, and [02] limits and regularity. None of them contains the gap of the core itself.

Words used in this chapter — route, core, site window, window (of $\hbar$), chain outside the window, Stein-kernel ratio, ring, seam, lump, outer chain, inner chain, boundary stage, corner at the wall, computer-assisted, floor of the product form. Their meanings are in A-02 Glossary.

Next chapter to read: 23-08 What computer-assisted means — the conditions on the chain inside the window — explains the mechanism and premises by which interval arithmetic turns floating-point computations into proofs of inequalities, using the contraction condition of the chain outside the window as an example.

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time computer-assisted, interval arithmetic, window · Kiichi, Shiori and Rin

What computer-assisted means — the conditions on the chain inside the window

> This chapter is this book's own investigation. § 01 and § 03 are established knowledge.

What this chapter shows — We make it possible to read what results labelled "computer-assisted" (Computer-assisted) in this part guarantee and what they do not. The example is the contraction condition $q < 1$ for the chain extending outside the core. Instead of writing floating-point values as they are, we hold every number as an interval that contains the true value, make $\hbar$ itself an interval, and check that the inequality holds at every point of the computed window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$ of $\hbar$. We describe this mechanism and its premises (the rounding conventions). At the end we look at an example where computer assistance returns "no", and confirm that it says nothing about what lies outside the window.

Prerequisite chapters — 23-07 § 02 (the route of the chain outside the window and the route of the seam of the ring), 23-00 § 01 (the labels of the five grades), 23-04 § 01 (the path measure).

Said first — The level is [Y2]–[Y3]. § 01– § 03 are written to be readable at [Y2], and § 04 onwards lean towards [Y3]. The inequalities treated in this chapter are one input to the construction of the first step with the diffusive-relaxation-time assumption at its axis, and by themselves they do not close the saddle-tube condition (23-07 § 06).

The order of this chapter

1. Floating-point values, and inequalities written with intervals — a small example that can be checked by hand
2. What the chain condition $q < 1$ guarantees — the Stein-kernel ratio, and the geometric series of influence
3. The premises of interval arithmetic — the rounding conventions and our own exponential function
4. Making $\hbar$ an interval — why it breaks when done naively, and three lemmas
5. Example 1: the outer chain of the core of the bridge — 25 subintervals (Table 1)

6. Example 2: the outer chain of the ring — from the conditioned chain to the unconditioned chain
7. Cross-checks, controls, pre-registration — reproduction by another implementation, and positive and negative controls
8. What Lean checked — the construction with the table of outputs of interval arithmetic placed as an assumption
9. Examples where computer assistance returns "no" — the inner chain, and a subinterval with first-order tilting
10. What computer assistance does not say, and the cost — how to read the label (box)

01

Floating-point values, and inequalities written with intervals

This section and § 03 summarise existing knowledge (floating point and interval arithmetic in general). The line between theorem and observation is introduced in 5-07 § 09.

Real numbers on a computer are floating-point numbers, and the result of most operations is the true value rounded to the nearest representable number. For example, $0.1 + 0.2$ becomes 0.30000000000000004 in double precision. Each rounding is small, so in many computations it can be ignored. But when claiming an inequality "$q < 1$" about a value close to 1, such as $q \approx 0.9989$, one must show that accumulated rounding does not flip the direction of the inequality.

Interval arithmetic is computation in which every number is held as "an interval that is sure to contain the true value". Intervals are built from intervals: addition is $[a, b] + [c, d] = [a + c, b + d]$, multiplication takes the minimum and maximum of the four products of the ends, and so on. When the ends are computed, rounding is taken **outwards** (the lower end downwards, the upper end upwards). Then the final interval $[q^-, q^+]$ is sure to contain the true q, and if $q^+ < 1$, then $q < 1$ follows as an inequality. In this part, inequalities obtained in this way carry the label Computer-assisted . Floating-point values written as they are carry Reading .

An example that can be checked by hand. The true range of $g(x) = x - x^2$ on $x \in [0, 1]$ is $[0, \frac{1}{4}]$. A naive evaluation in interval arithmetic gives, from $x \in [0, 1]$ and $x^2 \in [0, 1]$, $x - x^2 \in [0 - 1,\ 1 - 0] = [-1, 1]$. This contains the true value, but the width has grown eightfold. The cause is that the intervals forget the **dependence** that x and x^2 come from the same x. There are two ways to fix this.

- **Split finely.** Splitting into $[0, \frac{1}{2}]$ and $[\frac{1}{2}, 1]$ gives $[0 - \frac{1}{4}, \frac{1}{2} - 0] = [-\frac{1}{4}, \frac{1}{2}]$ and $[\frac{1}{2} - 1, 1 - \frac{1}{4}] = [-\frac{1}{2}, \frac{3}{4}]$, together $[-\frac{1}{2}, \frac{3}{4}]$, and the width shrinks to 1.25.
- **Expand about the centre.** With $g(x) = g(c) + g'(\xi)(x - c)$, $c = \frac{1}{2}$ and $g'(\xi) = 1 - 2\xi \in [-1, 1]$, we get $\frac{1}{4} + [-1, 1] \cdot [-\frac{1}{2}, \frac{1}{2}] = [-\frac{1}{4}, \frac{3}{4}]$, and the width is 1. This takes the first-order part of the dependence outside the interval.

What we meet in § 04 when making $\hbar$ an interval is a large-scale version of these two fixes. We split the window of $\hbar$ into 25 subintervals (split finely), and within each subinterval expand the expectations in $\hbar$ to take the first- and second-order movement outside the interval (expand about the centre).

02

What the chain condition $q < 1$ guarantees

Seen from a site in the core, consider the chain $x_{i-1}, x_{i-2}, \dots$ extending to one side. The term of the action between neighbours is $(x_{i-1} - x_i)^2/(2\varepsilon)$, and the measure is $e^{-S/\hbar}$. Fixing $x_i = y$ and integrating out the far side, the conditional law of x_{i-1} takes the form

$$\rho_y(x) \;\propto\; \exp\Big(-\frac{1}{\hbar}\Big[\frac{(x-y)^2}{2\varepsilon} + U(x)\Big]\Big) \qquad (x \text{ in the box } [L, R]\ ) \quad (1)$$

(U is the effective potential with the far side integrated out, and does not depend on y). Let $m(y)$ be the mean of ρ_y, and let the Stein kernel be

$$\tau_y(x) = \frac{1}{\rho_y(x)} \int_L^x \big(m(y) - t\big)\rho_y(t)\,dt \quad \geq 0 \quad (2)$$

. Integration by parts gives $\mathrm{Cov}_y(\varphi(X), X) = \mathbb{E}_y[\varphi'(X)\tau_y(X)]$ (the boundary term vanishes since $\int_L^R (m - t)\rho_y\,dt = 0$). On the other hand, the logarithmic derivative of (1) in y is $(x - m(y))/(\varepsilon\hbar)$, so

$$\frac{d}{dy}\,\mathbb{E}_y[\varphi(X)] = \frac{\mathrm{Cov}_y(\varphi(X), X)}{\varepsilon\hbar} = \frac{\mathbb{E}_y[\varphi'(X)\tau_y(X)]}{\varepsilon\hbar}, \qquad \Big|\frac{d}{dy}\,\mathbb{E}_y[\varphi(X)]\Big| \;\leq\; q\,\sup|\varphi'|, \quad q :=$$

Proved here (differentiation under the integral sign and integration by parts; the box is bounded and the density is smooth). (3) reads: "each step back, the slope of a function (its Lipschitz constant) becomes at most q times as large". Going back d steps gives at most q^d times. **If $q < 1$, the influence of fluctuations at distant sites on nearby sites decreases as a geometric series.** This is the content of "the chain condition", and we call q the Stein-kernel ratio.

A check. If ρ_y is a normal distribution with variance σ^2, computing (2) gives $\tau_y \equiv \sigma^2$, and $q = \sigma^2/(\varepsilon\hbar)$. For the harmonic chain (U a quadratic), one can check by hand that this ratio converges stage by stage to a fixed value.

What it is used for. In the construction of the logarithmic Sobolev constant of the site window (the product form of 23-07 § 04), the quantity SW that adds up the influence of all stages outside the window enters as a factor. Adding the contribution of the stages inside the window and the contribution of the stages outside the window $\sum_{d\ge 0} q^d = 1/(1-q)$ on the two sides, left and right, gives

$$SW = 1 + 2\Big(16 + \frac{1}{1-q}\Big) \quad (4)$$

(the form with the ratio of the stages inside the window set to 1. The paper construction is not placed in the book, so the step that uses (4) sits on an Assumption row). If $q < 1$, then SW is finite, and if $q \le 0.998854904$, then $1/(1-q) \le 873.3$ and $SW \le 1779.6$ Proved here (arithmetic).

Why q is close to 1. The right wall of the box of the outer chain of the core is the top 0, and there $V'(0) = 0$. At the corner of this wall the classical ratio is exactly 1 (the corner at the wall in 23-07 § 03), and the departure from 1 is set by the width $\eta \approx 0.5\hbar$ of the thin layer near the wall, of size $1 - q \approx \eta \ln(1/\eta)$ Reading (an expansion of the classical map, cross-checked with transfer-matrix values). The smaller $\hbar$ is, the closer q comes to 1. **This also shows that checking $q < 1$ inside a fixed window of $\hbar$ leaves the behaviour as $\hbar \to 0$ as a separate question.**

03 The premises of interval arithmetic

The computer assistance of this part is interval arithmetic built on Python's double-precision floating point (float64). We collect the premises in one place.

- **Rounding conventions.** We assume that each arithmetic operation returns, as the IEEE 754 standard specifies, the floating-point number nearest the true value (correct rounding). The result of each operation is made into an interval by moving it outwards by one to the neighbouring floating-point number (the lower end one down, the upper end one up). The error of correct rounding is at most half a unit, so moving one unit outwards contains the true value. It is not a scheme that switches the rounding direction for each operation. Fused multiply–add (FMA) is not used.
- **Summation error.** Long sums are widened outwards by a known upper bound on summation error.

- **The exponential function.** The error of the standard mathematical functions is not guaranteed, so we use our own implementation of the exponential function and add an upper bound on its error to the interval. The arithmetic of the constants of the upper bound is checked in Lean.
- **Integrals.** For each grid cell we build upper and lower envelopes of the integrand (with a concavity correction) and squeeze the integral outwards. Truncation of the integral (cells with weight below e^{-40} of the maximum) enters the interval as an upper bound on the truncated mass.

In this part this premise row is Assumption (the row of interval-arithmetic premises in 23-07 § 05). That the computer and the language implementation keep correct IEEE 754 rounding is placed as a premise, not something we checked. When citing a computer-assisted result, we write this premise in the same row.

04

Making $\hbar$ an interval — why it breaks when done naively, and three lemmas

To get $q^{+} < 1$ at a point value of $\hbar$ (for example $\hbar = 3 \cdot 10^{-3}$), the interval arithmetic of § 03 is enough. To say it for **every** $\hbar$ in the window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$, $\hbar$ itself must be put into an interval. Even if a downward trend is seen at three points, that the upper bound is monotone in $\hbar$ cannot be derived on paper (the formula for the upper bound contains two terms that are largest at opposite ends of $\hbar$).

We fix notation. $\beta = 1/(\varepsilon\hbar) = 2/\hbar$; for a subinterval $\hbar \in [\hbar_1, \hbar_2]$, $\beta \in [\beta_2, \beta_1]$; midpoint $\beta_0 = (\beta_1 + \beta_2)/2$, half-width $\Delta = (\beta_1 - \beta_2)/2$, and $\tau = \beta - \beta_0 \in [-\Delta, \Delta]$. $\hbar$ enters only through β.

Naive intervals break. Multiplying the exponent of the density $\beta(sx - A(x))$ by the interval of β as it is allows the weight of each grid cell to move independently by factors $e^{\pm\Delta|sx - A|}$, and the width of the exponent is of order 10^2. It is the same loss of dependence as $x - x^2$ in § 01. Indeed, for the chain of the double well, at the second stage the interval of the mean spread over the whole box (width 0.89), and the map of the stages lost its meaning.

Linear-Fractional Lemma (making the expectation a linear-fractional function of τ). Putting $h = g - g^*$ (g^* a constant) and $\varphi_0 = \beta_0 h$, with $\beta = \beta_0 + \tau$,

$$\mathbb{E}_\beta[f] = \frac{\int f e^{\beta g}}{\int e^{\beta g}} = \frac{S_0 + \tau S_1 + R_S(\tau)}{Z_0 + \tau Z_1 + R_Z(\tau)}, \qquad 0 \le e^{\tau h} - 1 - \tau h \le \frac{(\Delta|h|)^2 e^{\Delta|h|}}{2} \quad (5)$$

($S_0 = \int f e^{\varphi_0}$, $S_1 = \int f h e^{\varphi_0}$, $Z_0 = \int e^{\varphi_0}$, $Z_1 = \int h e^{\varphi_0}$; R are the integrals of the remainders). With the values of the remainders fixed, $t \mapsto (S_0 + R_S + tS_1)/(Z_0 + R_Z$

$+ tZ_1$) is linear-fractional, and if the denominator is positive at $t = \pm\Delta$ it is monotone on $[-\Delta, \Delta]$. Hence for all $|\tau| \le \Delta$ the expectation lies between its two values at the ends $t = \pm\Delta$, and evaluating those two in intervals encloses it Proved here Lean `mobius_between` (assumptions: the denominator is positive at $t = \pm\Delta$, $-\Delta \le t \le \Delta$). The first-order term $\tau S_1/Z_0$ represents the real change with $\hbar$, and only Δ times the quadrature error and the remainder (of order Δ^2) are left in the width of the interval.

Tilted-Enclosure Lemma (first and second forms; holding the enclosure tilted in τ). The fixed points of the map of the stages (the conditional means m_k of each stage of the chain) really move with $\hbar$. When the width of a subinterval is 3%, that movement alone is 1.5×10^{-4}, and putting it into the width of the enclosure ruins the downstream estimates. So we hold the enclosure in the form "$m_k - \tau\mu_k - \tau^2\nu_k$ lies in an interval" (μ_k and ν_k are floating-point sequences). On the output side the identity

$$\frac{A + tB}{C + tD} = \frac{A}{C} + t\,\frac{B - (A/C)D}{C + tD} \tag{6}$$

extracts the first-order movement Proved here Lean `shear_identity` (assumptions: $C \neq 0$, $C + tD \neq 0$). Tilting to second order, the remaining width is of order Δ^3. This is the form "expand about the centre" of § 01.

Moving-Centre Lemma (moving the centre with τ). The upper bound on the variance has the form of a sum of two one-sided parts $\beta\,\mathbb{E}[(X - c)_+^2] + \beta\,\mathbb{E}[(c - X)_+^2]$, and when the mean moves by $\tau\mu$ one increases and the other decreases. Maximising the two separately at the ends of τ adds movements that in truth cancel. Moving the centre as $c_\tau = c + \tau\kappa$ and bounding by $(y - t)_+^2 \le y_+^2 - 2ty_+ + t^2$ brought this loss down from 3.6×10^{-3} to 2.2×10^{-4} Proved here Lean `dvtau_pos` (no assumptions).

Invariant sets. The chain is infinitely long, so we cannot run the map of the stages a finite number of times and stop. The map $\Phi_{[\hbar_1,\hbar_2]}$ on a subinterval is built to contain the results of the maps $\Phi_\hbar$ for all $\hbar \in [\hbar_1, \hbar_2]$, so if interval arithmetic confirms $\Phi_{[\hbar_1,\hbar_2]}(E^*) \subset E^*$ for some enclosure E^*, then $\Phi_\hbar(E^*) \subset E^*$ for every $\hbar$ Proved here (transitivity of inclusion). All later stages lie inside E^*, and it is enough to evaluate the upper bound on q once on E^*.

Table 1 The balance on one subinterval (outer chain of the core of the bridge; the upper bound at the point $\hbar = 3 \cdot 10^{-3}$ is 0.995611069)

Version	$\hbar \in [3/1030, 3/1000]$ **(width 3%)**	$\hbar \in [3/1100, 3/1000]$ **(width 10%)**
Naive intervals	Breaks at the second stage	Breaks at the second stage
Linear-Fractional Lemma only	Computer-assisted $q^+ =$ 0.998757877	—

Version	$\hbar \in [3/1030, 3/1000]$ **(width 3%)**	$\hbar \in [3/1100, 3/1000]$ **(width 10%)**
Linear-Fractional Lemma + first-order tilt + Moving-Centre Lemma	Computer-assisted $q^{+} = 0.996449644$	The upper bound is 1.00114, above 1, and no certificate is produced (§ 09)
Linear-Fractional Lemma + second-order tilt + Moving-Centre Lemma	—	Computer-assisted $q^{+} = 0.997808483$

Second-order tilting made subintervals of width 10% usable, and the window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$ was covered by 25 subintervals with ends $\hbar = 3/N$ ($N = 1000, 1100, 1210, \dots, 9100, 10000$, ratio between neighbours ≤ 1.1). The grid width is 2^{-11}, and the number of stages is 20 on the upper half and 25 on the lower half.

05

Example 1: the outer chain of the core of the bridge — $q_{\mathrm{free}} \le 0.998854904$ on the whole window

Write q_{free} for the ratio of the unmarked chain extending outside the site window of the core of the bridge (box $(-x_c, 0)$, $x_c = 0.89$) (the route of the chain outside the window in 23-07 § 02). On each of the 25 subintervals we built the enclosures of the map of the stages and an invariant set in interval arithmetic, and obtained an upper bound q_i^{+} on q for all chain lengths $n \ge 2$ and all pins of the box (the values at the end of the chain). The results are the left column of Table 2.

Result (computer-assisted)

For the path measure of the 0+1-dimensional double well ($V = (x^2 - 1)^2/8$, $\varepsilon = \frac{1}{2}$, $x_c = 0.89$, mark threshold $\theta = \frac{1}{2}$), under the premises of § 03, for every $\hbar$ in the window $\hbar \in [3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$

$$q_{\mathrm{free}}(\hbar) \;\le\; \max_i q_i^{+} \;=\; 0.998854904 \;<\; 1 \qquad (7)$$

On the upper half $\hbar \in [10^{-3}, 3 \cdot 10^{-3}]$, ≤ 0.998098180. The maximum is on the subinterval at the lower end of the window. Regularity and the inputs of the sector framework are Assumption .

The values in the table (rounded up at 9 digits) increase as $\hbar$ decreases, with a bulge only at the two at the upper end. The limiting place is the cell where the value at the end of the chain lies just below the wall 0. It is exactly the place in § 02 where "the corner at the wall is exactly 1".

Table 2 Upper bounds on the 25 subintervals (from the large-$\hbar$ side. Left = outer chain of the core of the bridge q_i^{+}, right = outer chain of the ring, unconditioned form Q_i^{unc}. Both rounded up at 9 digits; computer-assisted)

Example 2: the outer chain of the ring — from the conditioned chain to the unconditioned chain

The outer chain of the seam of the ring (23-07 § 03) is a chain moving in a region of fixed sign, and mapped to $(-\infty, 0]$ by reflection it becomes the same type as Example 1. But there is no lower wall $-x_c$ as in the box of the bridge, so the certificate of Example 1 cannot be used as it is. We swapped the grid of the same machinery and closed it in two stages.

1. **The chain conditioned on a box.** For a chain conditioned on a finite box for each subinterval ($[-7/5, 0]$ on the upper half, $[-6/5, 0]$ on the lower half), the upper bound on the whole window is 0.998888525 Computer-assisted . As it stands, four assumption rows are needed to pay separately for configurations that leave the box.
2. **The unconditioned chain.** Widen the box to $[-3, 0]$, and put the contribution of the tail $(-\infty, -3]$ into the remainder of the interval arithmetic by a tangent upper bound from the convexity of the tail. The upper bound on the tail variance, in a form that pushes the law onto a single row at the end of the tail, is ≤ 0.357608022 at every $\hbar$ (within < 5.25 needed for convexity and ≤ 1 needed for the correlation inequality). Pins deeper than -3 are covered by a closed-form upper bound, ≤ 0.592898559. The results are the right column of Table 2, with maximum 0.998888530 Computer-assisted (all pins $p \le 0$, evaluation points $s \le 0$, end value $z_0 = -1$; the seam limit assumption, the random-end-value assumption and regularity are Assumption).

Comparing the two columns, the upper bound for the bridge bulges at the two at the upper end, while that for the ring is smallest on the third subinterval and then increases monotonically. At the lower end the ring is slightly closer to 1 (difference 3.4×10^{-5}), and the order of the floating-point point values (the ring closer to 1) appears in the upper bounds as well. Each row of the unconditioned chain is higher than the corresponding row of the conditioned chain by only 2.4×10^{-9}–6.7×10^{-7}, with the same limiting place and shape.

The boundary stage is not covered. The claim of the right column is a claim for pins $p \le 0$. In configurations where the lump touches the end of the window, the pin of the first outer stage falls in $(0, \frac{1}{2})$, and there the floating-point reading is $q \approx 1.004$–1.045 Reading . It is a single finite stage, so it does not break the finiteness of the construction, but when citing the right column of Table 2 the condition "pin ≤ 0" cannot be dropped.

```
07
```

Cross-checks, controls, pre-registration

The correctness of the interval-arithmetic scripts themselves has not been formally verified. Instead they pass the following checks. All are checks to see "whether what we think we checked has drifted from what we wanted to check".

- **Cross-check with another implementation.** On every subinterval of Example 1, we ran the map of the stages by a floating-point recursion separate from the interval arithmetic, at three values of $\hbar$ (the two ends and the midpoint of the subinterval), and counted whether its values fell inside the interval enclosures at every stage and every grid point (75 runs, 0 misses). For the unconditioned chain of the ring, the same check at one $\hbar$ per subinterval (25 runs, 0 misses).
- **Cross-check with point values.** The floating-point point values obtained from the transfer matrix (26 ends) all lay below the upper bound of the subinterval containing that end (the smallest difference, at the lower end of the window, was 2.85×10^{-4}).
- **Positive control.** Whether the machinery reproduces the answer where it is known in closed form. For the pure Gaussian chain (variance per stage $v_k = (k-1)/k$, mean $m_k(s) = (k-1)s/k$, neither depending on $\hbar$), every point fell inside the enclosures with $\hbar$ kept as an interval. With the width of the interval of $\hbar$ set to 0, it gave the same values as the machinery at a point $\hbar$ to order 10^{-12}. The unconditioned machinery for the ring reproduced the limiting place and shape of the version conditioned on a box on the same subintervals, with values within an upward difference of order 10^{-8} (they are not the same chain, so this is a check of reproduction, not agreement).
- **Negative control.** Whether the machinery rejects claims that should not hold. We confirmed that lowering the target upper bound at the limiting cell by 10^{-7} makes the Lean check fail to close, that replacing one entry of the table by 1 makes < 1 on the whole window fail to close, and that setting the tail variance above the convexity line stops the tail stage.
- **Pre-registration.** Before running the computations, we wrote down the expected range of values, the limiting place, and the pass lines of the positive and negative controls, and recorded after the results whether they were right. In Example 1 we expected 60–120 subintervals and 25 sufficed (wrong), and the limiting place coming at the lower end of the window was right. That a prediction was wrong does not weaken the result, but it is a record that the pass lines were not moved after seeing the results.

```
08
```

What Lean checked — the construction with the table of outputs of interval arithmetic placed as an assumption

The Lean column attached to computer-assisted results splits into the following three layers.

1. **The algebraic core.** The monotonicity of the linear-fractional function in the Linear-Fractional Lemma (`mobius_between`), the tilting identity (`shear_identity`), the inequality of the Moving-Centre Lemma (`dvtau_pos`), and the algebra of passing from the cover to the whole window (`cover_le`, assumption: $f \le c$ on each subinterval).
2. **Recomputation of cells.** From the input values output by the interval arithmetic (exact values of the floating-point numbers) and the rational ends of the subintervals, for the limiting cells and randomly chosen cells (46 in Example 1, 23 in the conditioned version for the ring), the formula for the upper bound at the last stage was recomputed inside Lean, closing "at most the interval-arithmetic value + 2×10^{-9}". This is not verification of every cell (a few dozen out of more than several million cells in one subinterval).
3. **Assembly of the table.** `win_qfree_window_le_of_interval_table` (Example 1), `unc_window_lt_one_of_table` (Example 2) and `vt_window_of_table` (tail variance) place as an **assumption** "$q(\hbar) \le q_i^+$ for every $\hbar$ in each subinterval" (the table of outputs of interval arithmetic; q is an abstract function), and give as conclusion "$q \le \max_i q_i^+ < 1$ for every $\hbar$ in the window".

Outside Lean lie the map of the stages (the interval evaluation of the Linear-Fractional Lemma, the Tilted-Enclosure Lemma and the Moving-Centre Lemma), quadrature, the invariant sets, the layers of the formula for the upper bound on q, and the choice of evaluation points. So the machine-checking column guarantees "if the outputs of the interval arithmetic are correct, the conclusion on the whole window is correct as algebra", and "the outputs of the interval arithmetic are correct" rests on the premises of § 03 and the checks of § 07.

09

Examples where computer assistance returns "no"

When the upper bound from interval arithmetic exceeds 1, all one can say is "this construction produces no certificate", not "the true value exceeds 1". We distinguish two cases.

(a) An example where it fails on the side of the tool. On the subinterval of width 10% in Table 1, the version with first-order tilting only gave the upper bound 1.00114. On

the same subinterval the version with second-order tilting shows the true value is ≤ 0.997808483, so this "no" comes from the width of the tool (having put the curvature of the true m in $\hbar$ into the interval). It is the kind of "no" that disappears with finer subintervals or a higher order of expansion.

(b) An example where it fails on the side of the object — the inner chain of the ring. For the stages inside the site window of the ring (the inner chain), measuring q_{in} by floating-point transfer gave $1.2707/1.2765/1.2421$ at $\hbar = 3\cdot 10^{-3}/10^{-3}/3\cdot 10^{-4}$ Reading , moving upwards as the grid was refined. The limit is set by the stage with the pin at the edge of the far wall of the lump box, the corner where the wall force points out of the box (classical value 1.2857) (23-07 § 03). Here, even building interval machinery is not expected to give $q^{+} < 1$. What it would give is only a finite upper bound $\bar{q} = \max(q_{\mathrm{in}}, 1) \approx 1.3$. This "no" is of a kind that does not disappear however fine the tool is made, and it can only be absorbed on the side of the construction (making a form that does not need $q_{\mathrm{in}} < 1$, or paying a coefficient $\bar{q}^{16}$ on each of S_W and T_W, and $\bar{q}^{32}$ on A_W).

When reading a computer-assisted result and seeing a report that the upper bound exceeded 1, check whether (a) or (b) is what is written.

10

What computer assistance does not say, and the cost

Box: how to read the "Computer-assisted" label

An inequality carries Computer-assisted only when all of the following are in place. (1) It is the output of a computation that holds every number as an outward interval, not a floating-point value written as it is. (2) The premises (correct IEEE 754 rounding, upper bounds on summation error, upper bounds on the error of our own exponential function, regularity) are written in the same row. (3) The scope of the claim (the window of $\hbar$, the chain lengths, the range of pins) is written in the same row. It says nothing outside the window of $\hbar$, as $\hbar \to 0$, or for pins outside the range.

What it does not say. (i) $\hbar$ outside the window $[3\cdot 10^{-4}, 3\cdot 10^{-3}]$. As seen in § 02, q approaches 1 as $\hbar \to 0$, so the further the window is extended downwards, the finer the subintervals and grid must be, and no finite computation can cover the whole of $\hbar \to 0$. The double-well relaxation-time power statement is a statement as $\hbar \to 0$, so that is work for paper asymptotics. (ii) Anything outside the model on the lattice $\varepsilon = \frac{1}{2}$ (the difference from the continuum path measure). (iii) Regularity (smoothness of eigenfunctions and conditional expectations) and the inputs of the sector framework.

(iv) The boundary stage of Example 2 (pin $\in (0, \frac{1}{2})$). (v) The saddle-tube condition itself (23-07 § 06).

Table 3 Cost (one core; "estimate" means not run)

Computation	Runs	Time	Size of one run
Example 1, outer chain of the core of the bridge (whole window)	27 runs	About 4 hours 10 minutes	6–16 minutes, 107 MB or less
Example 2, outer chain of the ring, form conditioned on a box	25 runs	About 3 hours 19 minutes	5–12 minutes, 114 MB or less
Example 2, outer chain of the ring, unconditioned form	25 runs	About 6 hours 44 minutes	13–22 minutes, 123 MB or less
Putting the inner chain of the ring into intervals (estimate)	About 50 runs	About 42 hours	About 50 minutes
Remaining numbers of the route of the window-constant numerics (estimate; decided not to run)	About 42 runs	About 21 hours	Within 30 minutes

This part is a study with the diffusive-relaxation-time assumption at its axis, and within it computer assistance is used as a tool that raises individual inequalities inside the window from floating-point readings to inequalities. Another view is treated in Part 24.

The sector framework and the three strands of the window log-Sobolev route

> This chapter is this book's own investigation. The established knowledge it builds on is in 2-05 and 2-07.

What this chapter shows — We prove, split into five steps, the construction that controls the gap of the core uniformly in the core length k (the sector framework), and derive the condition under which it closes, $b(A_W c_H + D_W + \ln 2) < \kappa \ell_{\min}$, and the needed value $A_{\max}$ determined by it. We sort the constants of the condition into those that come from the structure and those that come from the choice of tools, and list the directions that raise the needed value and that lower the insufficient side. We put in one table how far the three strands (componentwise, scalar, Feynman–Kac) that attacked the one remaining proposition (that the logarithmic Sobolev constant of the site window lies within the needed value) got, and state in one line of diagonal dominance why all three stop at the same place: the curvature at one site at the top falls $\frac{1}{4}$ short of convexity.

Prerequisite chapters — 23-07 (the positions of the route of the sector framework and the route of the window log-Sobolev inequality), 23-08 § 02 (the chain condition), 23-05 § 03 (the saddle-tube condition and the core Poincaré uniformity assumption), 1-10 § 07– § 09 (Poincaré inequalities).

Said first — The level is [Res], and only § 01 is written to be readable at [Y3]. § 02 onwards are sections at the research level, and you can skip ahead to Table 4 in § 05 and the common wall in § 06 and still read the conclusions of this chapter. This part places the diffusive-relaxation-time assumption at the axis of the study (23-01), and this chapter says how far the core row of the saddle-tube condition of its first step could be built. The sector framework has been shown, but the one remaining proposition is not closed by any of the three strands.

The order of this chapter

1. Summary — a section readable at [Y3]
2. The five steps of the sector framework — sum over sectors, Gibbs in marginal form, componentwise localisation, locality of volume, composition

3. The closing condition and the needed value $A_{\max}$ — where the constants come from, and two directions (Tables 1 and 2)
4. The threshold mismatch — an example where the condition, taken literally, gave nothing
5. The three strands of the window log-Sobolev route — componentwise, scalar (the Scalar-Strand Proposition, Table 3), Feynman–Kac, and how far they got (Table 4)
6. The common wall — the curvature at one site at the top, $15/4$ against 4
7. The table of the five grades (Table 5)
8. The dependency graph

01

Summary

The core $Q_k = (-x_c, 0)^k$ is an interval of k sites where the path stays near the top, and here the Hessian of the action has negative directions. To control the gap of the measure of the core (the core Poincaré uniformity assumption) uniformly in k, one must pay using the fact that places with negative curvature are **rare**. The sector framework splits that payment into five steps.

1. **Sum over sectors.** Even when the space of configurations is split into a direct product of boxes, the Dirichlet form, the variance and the entropy split into sums over sectors, and the number of sectors does not enter the constants.
2. **Gibbs in marginal form.** The weight on a rare set B (measure at most $e^{-\ell}$) can be paid with the entropy and $\ln 2$: $\ell \int_B g^2 \le \mathrm{Ent} + \ln 2 \int g^2$.
3. **Componentwise localisation.** Applying the Gibbs step in marginal form to each component of the gradient with the logarithmic Sobolev constant A_W of the marginal of the marks on the 17 sites around that site (the site window), k does not enter the sum.
4. **Locality of volume.** The rarity exponent $\ell_{\min}$ does not depend on k.
5. **Composition.** Combining the above with the two inequalities of Barta and Bochner gives, for the gap of the core λ, $\lambda(1 + bA_W/\ell_{\min}) \ge \kappa - b(A_W c_H + D_W + \ln 2)/\ell_{\min}$. The condition for the right-hand side to be positive is the **closing condition** $b(A_W c_H + D_W + \ln 2) < \kappa \ell_{\min}$.

The closing condition rewritten for A_W is the needed value $A_{\max} = (\kappa \ell_{\min}/b - D_W - \ln 2)/c_H$. At the three values $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$, the original form on the road that defines defects by three sites is negative at $3 \cdot 10^{-3}$ (it closes for no A_W), 0.20 and 7.13, and correcting two choices of tools raises it to $25.1/90.3/312.3$ Reading (arithmetic on the measured rarity exponents). On the other hand, in the current construction the upper bound on A_W is of order $1857/2794/9106$ Reading (including estimates), 29–74 times short.

The one remaining proposition "$A_W < A_{\max}$" was attacked by three strands. The componentwise strand stopped at 1.4–5.5 times the needed value, the scalar strand became a proposition with a table of assumptions (the Scalar-Strand Proposition) for $\hbar \in [3 \cdot 10^{-4}, 10^{-3}]$, and the Feynman–Kac strand lies within 0.54 times the threshold by a Monte Carlo reading, but its upper bound is 10^3 times the threshold. All three stop at the same place: at the top, the diagonal at one site, $4 - \frac{1}{4} = 15/4$, does not reach the sum of the couplings to the neighbours, 4 (§ 06).

02

The five steps of the sector framework

Setting. Take the core $Q_k = (-x_c, 0)^k$ ($x_c = 0.89$), fix the end values $z_0, z_{k+1} \le -x_c$, and let $\mu \propto e^{-S/\hbar} \mathbf{1}_{Q_k}$ and $\mathcal{E}(f) = \hbar \int |\nabla f|^2 d\mu$ (Neumann on the faces of the box). Let λ be the first non-zero eigenvalue of $-L$, f the eigenfunction, $u = \nabla f$, and put

$$X = \int |u|^2 d\mu, \qquad Z = \hbar \int \|\nabla u\|^2 d\mu, \qquad Y = \sum_{j=1}^{k} \int_{N_j} u_j^2 \, d\mu \quad (1)$$

. N_j is the defect set of site j (configurations where j or one of its neighbours lies on the top side of the threshold $-\theta_B$, $\theta_B = 0.57$). Attach a mark $\sigma_j = \mathbf{1}[z_j > -\theta]$ to each site, and write σ_{W_j} for the set of marks on the window W_j around site j. A sector is a direct product of boxes for each type of marks, $\Omega_\sigma = \prod_j I_{\sigma_j}$.

Sector sum

For any partition $\mathcal{P}$ into direct products of boxes, (a) $\sum_P \mu(P) \mathcal{E}_P(f) = \mathcal{E}(f)$ (faces have measure 0, and $|\nabla f|^2$ is the same function on each sector), (b) $\mathrm{Var}_\mu f = \sum_P \mu(P) \mathrm{Var}_{\mu_P} f + \mathrm{Var}_\nu(\mathbb{E}[f \mid \mathcal{P}])$ (the law of total variance; the entropy has a chain rule of the same form), (c) if $\mathrm{Var}_{\mu_P} f \le C_P \mathcal{E}_P(f)$ on each sector, the first term is at most $(\sup_P C_P)\, \mathcal{E}(f)$ Proved here . The number of sectors appears only in the weights $\mu(P)$, which

sum to 1. Lean `var_split_cells` (no assumptions), `cell_sum_sup` (assumptions: $w_i \geq 0$, $E_i \geq 0$, $C_i \leq C_{\max}$).

Gibbs decomposition — the Gibbs step in marginal form

The Gibbs variational inequality. For a probability measure ν, $G \geq 0$ and a function F,

$$\int FG\,d\nu \;\leq\; \mathrm{Ent}_\nu(G) + \Big(\int G\,d\nu\Big)\ln \int e^F\,d\nu \tag{2}$$

Proved here Proof. Put $\tilde{G} = G/\int G$. Jensen's inequality gives $\ln \int e^F\,d\nu \geq \ln \int_{\tilde{G}>0} e^{F-\ln\tilde{G}}\tilde{G}\,d\nu \geq \int (F-\ln\tilde{G})\tilde{G}\,d\nu$. Multiplying both sides by $\int G$ gives (2). ∎

Taking $F = t\mathbf{1}_B$ and $p = \nu(B) \leq e^{-\ell}$ in (2) gives $\ln \int e^F = \ln(1-p+pe^t)$, and with $t = \ell$ this is $\leq \ln 2$ Lean `gibbs_ln2_cell` (assumptions: $p \geq 0$, $\ell \geq 0$, $pe^\ell \leq 1$). If B is a set determined by a coarse variable $\mathcal{F}$, taking $G = \mathbb{E}[g^2 \mid \mathcal{F}]$ gives

$$\ell \int_B g^2\,d\mu \;\leq\; \mathrm{Ent}_\nu\big(\mathbb{E}[g^2 \mid \mathcal{F}]\big) + \ln 2 \int g^2\,d\mu \tag{3}$$

. This is the form that pays for the weight on a rare set with the entropy of the marginal of the coarse variable.

Componentwise localisation

As input we assume, for all j and g, the logarithmic Sobolev inequality of the marginal on the window

$$(\mathrm{LS}_W) \qquad \mathrm{Ent}_{\nu W_j}\big(\mathbb{E}[g^2 \mid \sigma W_j]\big) \;\leq\; A_W\,\mathcal{E}(g) + D_W \int g^2 \tag{4}$$

Assumption , and let $N_j \subset B_j$ (B_j a set determined by σW_j, $\ell_{\min} = \min_j \ln(1/\mu(B_j))$). Applying (3) to $g = u_j$ and summing over j, from $\sum_j \mathcal{E}(u_j) = Z$ and $\sum_j \int u_j^2 = X$,

$$\ell_{\min}\,Y \;\leq\; A_W\,Z + (D_W + \ln 2)\,X \tag{5}$$

holds Proved here Lean `comp_sum_le` (assumptions: $0 < \ell \leq \ell_j$, the inequality for each component). k **does not enter.** For contrast, if (3) is applied to a single union $\bigcup_j B_j$ with a scalar g, without splitting the gradient into components, just putting in the constant function $g \equiv 1$ makes the defect term at least $\sum_j \mu(B_j)$, and it is not uniform in k Proved here Lean `scalar_not_uniform` (assumption: $p > 0$; the conclusion is "there is no d with $kp \leq d$ for all k"). **Uniformity in k and having A_W enter the condition are a trade-off.**

Volume locality

$\ell_{\min}$ is the rarity exponent of the defect set, and does not depend on k. On the road that defines defects by three sites, the measured values $\hbar \ln \mu(N_j)$ give $\ell_{\min} = 38.3/121.9/406.8$ ($\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$) Reading (floating-point transfer matrix; $3 \cdot 10^{-4}$ is an extrapolation, and the remeasured value is 420.0). On the road that defines defects by lumps of length 8 or more, $\ell_{\min} \geq E_8/\hbar - \ln V_{\mathrm{loc}}$ ($E_8 = 0.402$, $\ln V_{\mathrm{loc}} = 2.3$) Reading . To say the same on the bridge, one needs that the remainder of the transfer operator of a scrap is small uniformly in the end values (the bridge volume-locality input) Assumption .

Sector composition

We combine the following three inequalities.

- **Barta**: $\lambda X \geq \kappa X - bY$. It comes from the row inequality $(\mathcal{M}\psi)_j \geq (\kappa - b\mathbf{1}_{N_j})\psi_j$ obtained by applying a weight ψ to the componentwise operator $\mathcal{M} = -L + \operatorname{Hess} S$ ($u = \nabla f$ satisfies $\mathcal{M}u = \lambda u$). $\kappa = 3/1000$ is the lower bound on the rows outside the defects, and $b = 493/1000$ is the depth of the defects, determined by the worst row over the whole box Assumption (the paper estimate of the rows is not placed in the book).
- **(5)**: componentwise localisation itself.
- **Bochner**: $Z = \lambda X - \int u \cdot \operatorname{Hess} S\, u\, d\mu \leq (\lambda + c_H)X$, $\operatorname{Hess} S \geq -c_H$, $c_H = \frac{1}{4}$. The identity is the integrated form of Bochner's formula Cited (Proposition 1.3 of Ledoux's lectures, checked in the original text), and the vanishing of the boundary terms on the flat faces of the box and the smoothness of the eigenfunction up to the corners are Assumption .

Putting Bochner into (5), and that into Barta, gives

$$\lambda\Big(1 + \frac{bA_W}{\ell_{\min}}\Big) \;\geq\; \kappa - \frac{b\,(A_W c_H + D_W + \ln 2)}{\ell_{\min}} \quad (6)$$

Proved here Lean `comp_close` (assumptions: $X > 0$, $b, A \geq 0$, $\ell > 0$, and the three inequalities Barta, (5), Bochner). If the right-hand side is positive, that is, if

$$b\,(A_W c_H + D_W + \ln 2) \;<\; \kappa \ell_{\min} \quad (7)$$

, the gap of the core λ is bounded below by a positive number that does not depend on k. (7) is the **closing condition**. Of the five steps, the constructions of the sector sum, the Gibbs decomposition, componentwise localisation and sector composition have elementary proofs placed in the text, and what remains as assumptions is the marginal log-Sobolev input for the window, the bridge volume-locality input, the Barta rows, the

regularity for Bochner, and whether A_W is small enough to satisfy (7). **What remains as an assumption is not structure but the size of a constant.**

03

The closing condition and the needed value $A_{\max}$

Solving (7) for A_W gives the needed value

$$A_W \;<\; A_{\max}(\hbar) := \frac{\kappa \ell_{\min}/b - D_W - \ln 2}{c_H} \tag{8}$$

follows Proved here (rearranging (7)). That A_W is smaller than this is the one remaining proposition (the Window Log-Sobolev Threshold Proposition), the route of the window log-Sobolev inequality in 23-07 § 02.

Where the constants come from. We sort the six constants of (7) into those that come from the structure and those that come from the choice of tools.

Table 1 Where the constants of the closing condition (7) come from

Constant	Value	Origin	Side
κ	$3/1000$	Lower bound on the Barta rows outside the defects (small because the threshold $\theta_B = 0.57$ is placed just above the one-site threshold 0.5653)	Structure
b	$493/1000$	The worst value of the same rows over the whole box (-0.49 on the top side)	Structure
$\ell_{\min}$	Table 2	The rarity exponent of the defect set (not a length)	Structure
c_H	$\frac{1}{4}$	In the Bochner step, the minimum $w(0) = -\frac{1}{4}$ of the negative curvature $w = \varepsilon V''$ paid **uniformly over the whole** core	Choice of tools
$\ln 2$	0.693	The value with the tilt t in the Gibbs step fixed at $t = \ell$	Choice of tools
D_W	0	A construction that puts no defect term in the marginal log-Sobolev input for the window	—

The reason A_W enters the condition multiplied by c_H is this: when $A_W Z$ on the right of (5) is replaced by $(\lambda + c_H)X$ using Bochner, the λ part can be moved to the left side, but $c_H X$ remains without a factor λ and can only be paid by κ. The amplification $b/\kappa \approx 164$ multiplies $A_W c_H$ here.

Two directions — raising the needed side, lowering the insufficient side

Raising the needed side (correcting the choice of tools).

- **Localising Bochner.** The negative curvature $-w(z) = (1 - 3z^2)/4$ exists only for $z > -1/\sqrt{3}$, and that region is already inside the defect set N_j. From the one-line interval bound $-w(z) \le \delta + \gamma\,\mathbf{1}[z > -\theta_R]$ ($\delta = \max(0, (1 - 3\theta_R^2)/4)$, $\gamma = c_H - \delta$) Proved here Lean `negw_le_localized` (assumptions: $\theta \ge 0$, $z \le 0$, $(1 - 3\theta^2)/4 \le \delta \le \frac{1}{4}$), and using that the kinetic term $2T_k$ is positive semi-definite, we get

$$Z \;\le\; (\lambda + \delta)X + \gamma Y \quad (9)$$

  Proved here Lean `bochner_localized` (assumptions: the identity $Z = \lambda X - H$, $-H \le \delta X + \gamma Y$). Y is a term already paid by (5), so the coefficient of A_W goes down from $bc_H = 0.123$ to $b\delta + \kappa\gamma = 0.0038$ ($\theta_R = 0.57$; about 1/32).
- **Optimising the Gibbs tilt.** t in (2) may also satisfy $t < \ell$, and at $t^* = \ell - \ln((b - \kappa)/\kappa)$ $= \ell - 5.10$, which maximises $\kappa t - b\ln(1 + e^{t-\ell})$, the cost $b \ln 2 = 0.342$ is replaced by 0.0183 Proved here (maximum of a concave function of one variable). Lean's `tilt_cost_le` (assumptions: $b \ge 0$, $L \le 1/178$) shows only an upper bound of 0.0184 on the cost at t = ℓ − 5.2, not at the optimal point Lean (the optimisation itself is not in Lean).

The closing condition with both combined is $b(A_W\delta + D_W + L(t^*)) < \kappa(t^* - A_W\gamma)$, and the needed value is $A_{\max} = (\kappa\ell_{\min} - 0.0183 - bD_W)/(b\delta + \kappa\gamma)$. Raising the threshold θ further to near $1/\sqrt{3}$ gives $\delta \le 0$, and the condition becomes in effect $A_W \lesssim 4\ell_{\min}$.

Table 2 The needed value $A_{\max}$ ($D_W = 0$; triples are $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$; values are arithmetic on the measured $\ell_{\min}$, Reading)

Form	$A_{\max}$	Remarks
Original form (road defining defects by lumps of length 8 or more)	0.43/6.96/29.8	$\ell_{\min} \ge E_8/\hbar - \ln V_{\text{loc}}$
Original form (road defining defects by three sites)	Negative / 0.20 / 7.13	At $3 \cdot 10^{-3}$ it does not close even with $A_W = 0$
Gibbs tilt only	0.78/2.82/9.75	Three-site road
Localised Bochner only	Negative / 6.23 / 228	As above

Form	$A_{\max}$	Remarks
Both combined	25.1/90.3/312.3	As above. The value is Reading . What Lean's `judge_i_inside` shows goes only as far as this: for the two values of ħ on the small side (the cases where the lower bound on ℓ is 406 and 121), the condition for closing holds if $0 \le A \le 22$ (that is, the needed value, namely the upper limit of the A for which it closes, is 22 or more) Lean . The third ħ, and the values themselves, are not in Lean (assumptions: $\ell \ge 406$, $\ell \ge 121$, $0 \le A \le 22$, $0 \le L \le 1/178$)
Raising the threshold to $1/\sqrt{3}$	128/452/1604	$\kappa(\theta)$ and $\ell(\theta)$ are floating-point lattice values

Lowering the insufficient side (rebuilding the upper bound on A_W). The upper bound on A_W for the three-site window $|W| = 3$ is 1857/2794/9106 in the current construction Reading (including estimates), which is **74 / 31 / 29 times** outside the needed value with both combined, and 14.5 / 6.2 / 5.7 times outside the needed value with the threshold raised (the latter is an estimate that assumes the same upper-bound technique gives the same value when the threshold is raised). On the other hand, the lower bound on A_W measured by test functions is 1.71/1.74/2.59 and does not exclude the needed value. **That the true A_W lies within the needed value is not excluded; what falls short is the way the upper bound is built.** This is the starting point of the three strands of the route of the window log-Sobolev inequality.

04

The threshold mismatch — an example where the condition, taken literally, gave nothing

Componentwise localisation uses $N_j \subset B_j$, with B_j a set determined only by the marks of the window σ_{W_j}. In Table 1, κ, b and $\ell_{\min}$ were values measured with the defect threshold $\theta_B = 0.57$, while A_W was measured with the mark threshold $\theta_\sigma = \frac{1}{2}$. If $\theta_\sigma < \theta_B$, the atom of marks "all marks in the window on the valley side" contains points with $z_i \in (-\theta_B, -\theta_\sigma]$, that is, points of N_j. The only set determined by the marks that contains N_j is the whole space, so $\mu(B_j) = 1$ and $\ell = 0$ Proved here (one line of measurability). **With the two thresholds mismatched, (7), taken literally, gives nothing.** The fix is not to lower θ_B to $\frac{1}{2}$ (at $\theta = \frac{1}{2}$ the lower bound κ on the Barta rows becomes negative), but to measure A_W with marks at $\theta_\sigma = \theta_B$, which is an order to the insufficient side. It is an example showing that, when numerical constructions are stacked, a step is needed that checks literally whether each of the conditions being composed holds on the same definitions.

05

The three strands of the window log-Sobolev inequality

The one remaining proposition was attacked in three forms that differ in the functional form of the condition. None of the strands has shown sector composition, the core Poincaré uniformity assumption or the saddle-tube condition. All numbers are values on the 0+1-dimensional double well on the lattice $\varepsilon = \frac{1}{2}$. The full list of detour plans and the types of breakage are sent to 23-10.

The componentwise strand — the componentwise form

On top of the localised Bochner and the Gibbs tilt, adding a form that pays the negative curvature at each point by the rarity of that point (paying the curvature with a function of height $h = (-w(z_j))_+$) raises the needed value to $537/1754/6052$ Reading . The upper bound is built in the product form of "a coarse step" and "a propagation step".

- **The coarse step is exhausted.** With a mark chain that is multi-valued only in the middle, the logarithmic Sobolev constant of the coarse step is $\leq 3.584/3.544/3.613$, a ratio of $1.016/1.005/1.003$ to the lower bound from the indicator of a single point Reading (a rational decomposition on double-precision data). Nothing more can be gained from this step.
- **The propagation step has no upper bound.** Moving the rest into a weighted conditional Poincaré constant C_w, the needed value is $C_w \leq 39.3/138.2/476.3$, and the lower bound from a family of test functions is 15.4–15.6 (almost independent of $\hbar$) Reading . With the Lyapunov-function criterion (of the Bakry–Barthe–Cattiaux–Guillin type Cited , checked in a restatement in a secondary source), the family of Lyapunov functions that do not depend on the far end was $16.6/14.7/14.7$ times outside the needed value on the top face $x \equiv 0$. Measuring by duality the best of a split family extended to the far end goes beyond this leading term, but on the finest grid it stops at $215/355/654 = 5.5/2.6/1.4$ times the needed value Reading (grid values; the lower $\hbar$ goes, the more sensitive to the grid). The floor that holds for all Lyapunov functions is 31 (uniform in $\hbar$) Reading Lean `tilt_g1` (assumption: $\hat{\theta}\,\mathrm{Var} \leq \hbar b$), and the form of the criterion itself can get below the needed value.

The remaining step: a Lyapunov function with a coupling term between neighbours that lowers the finite-$\hbar$ correction. Grades: Reading and Assumption .

The scalar strand — the scalar form, and the Scalar-Strand Proposition

This form does not split the gradient into components: it applies Bakry–Émery to the convex bottom (the box on the valley side) and pays for the band at the top by the Gibbs step at each site. The condition is only $\ln k < \ell_{\mathrm{band}}$, and A_W, κ, b and c_H are not

needed, but k enters as $\ln k$, so it works only over a finite range of core lengths. The Poincaré constant of the core becomes the sum of $C_P^{(1)} \approx 50$–64 and a remainder (Rem_2), and, restricted to the first eigenfunction, the remainder only needs to be small, $R_2(f)/\int g^2 < \frac{1}{4}$. The Scalar-Strand Proposition turns this into a proposition with a table of assumptions.

Scalar-Strand Proposition (with a table of assumptions)

0+1-dimensional double well, $\varepsilon = \frac{1}{2}$, $x_c = 0.89$, core length $k = 20$, central lump $\{9, 10\}$, f the first non-zero eigenfunction. Under the rows of Table 3, at each node $\{3, 4, \ldots, 10\} \cdot 10^{-4}$ of $\hbar \in [3 \cdot 10^{-4}, 10^{-3}]$, the remainder quantity R satisfies $R \le 2A$, with $A = 2kP_v e^{-Ev} \int f^2$ and $2kP_v e^{-Ev} \le \frac{1}{4} e^{-3}$.

Lean `path5_conditional` (assumptions, named: the remainder inequality, the proxy ratio, the rarity, the arithmetic margin $c_0 + q_g + l_\mu \le -0.7$), `p5_assembly` (assumptions: the proxy ratio, the rarity, the threshold, arithmetic, monotonicity).

Table 3 The rows of the Scalar-Strand Proposition (five grades)

Row	Statement (one line)	Grade	Notes
Spectral regularity	Discrete spectrum, existence and regularity of eigenfunctions, simplicity of λ_1	Assumption	Regularity of the Neumann problem on a box with corners does not follow from standard theorems
Logarithmic Sobolev at one site of the band	Logarithmic Sobolev with a defect at one site of the band	Assumption	Not yet
Convex bottom and propagation in the band	Convex bottom and propagation in the band ($C_P^{(1)} \approx 50$–64)	Assumption	The paper argument is not placed in the book
Upper bound on λ_1	Upper bound on λ_1 uniform in k (Rayleigh quotient)	Reading	Interval-arithmetic scheme (1 run per node), not yet run
Localisation in the direction of exit	Estimate of localisation in the direction of exit	Assumption	A paper estimate. Interval-arithmetic scheme with 1 closed formula per node, not yet run. The IMS localisation formula is Cited (checked in a secondary source)
Rarity of the target	Rarity of the target $\mu(\mathrm{Rem}_v) \le e^{l_\mu(\hbar)}$, $l_\mu \le -4.97$	Reading	Floating-point transfer. Interval-arithmetic scheme with 7 runs per node, not yet run

Row	Statement (one line)	Grade	Notes
Rarity on non-convex fibres	Rarity on a non-convex fibre (the proportion of f^2 is at most e^{-7})	Assumption	Markov's inequality and transfer. Interval-arithmetic scheme with 2 runs per node, not yet run. The lower bound on the action difference ΔS_{nc} is not in interval-arithmetic form
Lifting the proxy ratio	Proxy ratio $c_1 \le c_*(\hbar)$ ($c_* \ge 5.39$, $\hbar \le 10^{-3}$)	Assumption	**The only assumption that lifts beyond the measured range**: a linear lift from the measured values for two-site lumps, 0.002–0.033, by +0.048 per step (tolerance ≥ 0.67)
Comparison of level sets	Comparison of level sets $\ln \Phi \le -4.209$	Reading	Interval-arithmetic scheme with 3 runs per node, not yet run
Arithmetic of the margin	Arithmetic of the margin $c_1 + \ln \Phi \le -3.7$	Proved here	Arithmetic
Enclosure between the nodes	Enclosure of $\hbar$ between the nodes	Assumption	Not yet. The range $[3 \cdot 10^{-4}, 10^{-3}]$ is point values at 8 nodes

The number of runs to move to interval arithmetic is 14 per node — upper bound on λ_1 1, localisation in the direction of exit 1, rarity of the target 7, rarity on non-convex fibres 2, comparison of level sets 3 — making 112 over the 8 nodes, plus the enclosures between the nodes, and not a single one has been run yet. Slightly beyond 10^{-3} the two conditions no longer hold together on the same window (they do not hold together at $1.35 \cdot 10^{-3}$ Reading), and it does not extend towards $\hbar \to 0$ either, because the estimate in the direction of exit is not uniform, by $\hbar^{-1/2}$. **The Scalar-Strand Proposition is a proposition with a table of assumptions on a finite range at the lower end of the window.**

The Feynman–Kac strand — the Feynman–Kac form

In the form that keeps the Feynman–Kac weight on the diagonal of the comparison, what is needed is that the logarithmic Sobolev constant of the whole core is $A_{\mathrm{core}} \lesssim a/\hbar$ with $a < 1.29/1.47/1.55$ (the question extends to the coefficient of $1/\hbar$). The lower bound from a family of test functions is $\hbar A_{\mathrm{core}} \approx 0.78$–$0.83$ Reading , a margin of 1.6–1.9 times. Splitting into radial chains, the chain constant is 0.54–0.56 times the needed value (on the model chain) Reading , and what remains is the quantity $K^2 = \sup |\nabla \psi|^2$ in the Helffer–Sjöstrand representation Cited (bibliographic only; the statement is unchecked, so this book treats it as Assumption), with threshold $1 + K^2 \le W$, that is, $K^2 \le W - 1 = 0.83$–0.86 (W is the ratio of the needed value to the chain constant).

- **Monte Carlo reading**: values from below after searching for starting points, $L = 0.4333 \pm 0.0067$ (10^{-3}) and 0.4163 ± 0.0079 ($3 \cdot 10^{-4}$); adding 3σ gives 0.453 = **0.54 times** the threshold 0.835 Reading (the maximum over starting points, not an upper

bound over the whole fibre = the assumption that the maximum over searched starting points suffices).

- **Paper upper bound**: a pathwise Grönwall-type upper bound counted at the same points along the same paths gives $U^2 = 798$ = about 10^3 times the threshold Reading . Most of the width comes from the step where the scalar Grönwall discards the direction of the gradient and reduces every direction at the softest rate. The version that controls the contraction by the smallest eigenvalue of the time-averaged matrix is false Lean `mbar_bound_false` (a two-dimensional counterexample, no assumptions).

The remaining step: an upper bound that keeps the direction (a matrix Lyapunov function along the path, or an estimate split into soft and hard subspaces).

The three side by side

Table 4 How far the three strands got (triples are $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$)

Strand	How far it got	Grade	Range of $\hbar$	The remaining step
2 Scalar	The Scalar-Strand Proposition (with a table of assumptions, one lifting assumption, 112 interval-arithmetic runs not yet made)	Assumption + Reading	8 nodes of $[3 \cdot 10^{-4}, 10^{-3}]$	Interval arithmetic at each node, enclosures between the nodes, making the lifting assumption explicit
3 Feynman–Kac	0.54 times the threshold by the Monte Carlo reading. The paper upper bound is 10^3 times the threshold	Reading	$10^{-3}, 3 \cdot 10^{-4}$	An upper bound that keeps the direction
1 Componentwise	Went beyond the leading term of the Lyapunov criterion, but 5.5 / 2.6 / 1.4 times the needed value. The floor for all Lyapunov functions is 31	Reading	Three points	A Lyapunov function with coupling terms

Table 4 is not a ranking of which strand is "close". The scalar strand has a form only at the lower end of the window, and only the componentwise strand and the Feynman–Kac strand have forms that cover the whole window. Read progress by the grade of each row.

06

The common wall — the curvature at one site at the top, $15/4$ against 4

The Hessian of the action of the core is, on the lattice $\varepsilon = \frac{1}{2}$, the tridiagonal matrix

$$\operatorname{Hess} S = \begin{pmatrix} 4+w_1 & -2 & & \\ -2 & 4+w_2 & -2 & \\ & \ddots & \ddots & \ddots \\ & & -2 & 4+w_k \end{pmatrix}, \qquad w_j = \varepsilon V''(z_j) = \frac{3z_j^2 - 1}{4} \quad (10)$$

(the neighbour term $(z_{j+1} - z_j)^2/(2\varepsilon)$ gives 4 on the diagonal and -2 next to it). Looking at one row, the diagonal is $4 + w_j$, and the sum of the absolute values of the couplings to the neighbours is $2 + 2 = 4$. At the top $z_j = 0$, $w_j = -\frac{1}{4}$, so

$$\text{diagonal} \;=\; 4 - \tfrac{1}{4} \;=\; \tfrac{15}{4} \;<\; 4 \;=\; \text{sum of couplings} \quad (11)$$

, and **diagonal dominance fails by $\frac{1}{4}$** Proved here . Row-by-row estimates (Gershgorin discs) only go as far as "smallest eigenvalue $\geq \min_j w_j = -\frac{1}{4}$", and in fact on the face $x \equiv 0$ where every site is at the top, the smallest eigenvalue of a lump of k sites with both ends fixed is $8\sin^2\frac{\pi}{2(k+1)} - \frac{1}{4}$, negative for $k \geq 8$ Proved here (the closed formula for the eigenvalues of $\operatorname{tridiag}(-2, 4, -2)$). To check by hand: at $k = 7$, $8\sin^2(\pi/16) \approx 0.304 > \frac{1}{4}$; at $k = 8$, $8\sin^2(\pi/18) \approx 0.241 < \frac{1}{4}$.

The three strands came back to this one-line shortfall in changed forms.

- However the Barta weight is chosen, the floor of the row of the one-site weight at the top is $F(0,0) = w(0) = -\frac{1}{4}$.
- The criterion of the uniform road of the componentwise strand was $A - 2B = -\frac{1}{4}$ with diagonal $A = 4 - \frac{1}{4}$ and coupling $B = 2$.
- The top face where the Lyapunov criterion of the componentwise strand stopped is exactly the face $x \equiv 0$ where the gradient of the action vanishes.
- In the Feynman–Kac strand, the coefficient of $1/\hbar$ lived in the radius from the corner at the top (the non-convex direction of the plateau).

Why the wall is universal (one line). Tools whose entrance is convexity (a positive lower bound on the Hessian) — Bakry–Émery, Brascamp–Lieb, the Barta rows, diagonal dominance — must, since the Hessian really has a negative direction on the plateau at the top, pay this $\frac{1}{4}$ somewhere with the rarity (entropy) of the plateau, and $\hbar$ enters that payment. A detailed study of this view, and other viewpoints that do not rely on convexity, are treated in Part 24 (24-06).

07

The table of the five grades — the rows of the sector framework and the route of the window log-Sobolev inequality

Table 5 The rows of this chapter ("—" in the range of $\hbar$ marks an assumption row not shown at any $\hbar$; the numbers in the row column are the numbers of the dependency graph in § 08)

How to check. The rows with ⟸ are [12] ([01][10][11]), [14] ([02][08]), [15] ([04][07]), [17] ([03][04][07][12][14]), [18] ([17]), [19] ([08][15][16][18]), [21] ([05]), [22] ([19]) and [25] ([06] [17]). In each the numbers on the right are smaller than the one on the left, so there is no circle.

What to read. The conclusion [25] depends, through [17], on the structural steps ([10]–[14]) and the input assumptions ([01]–[04]), and further on the assumption row [06] (the one remaining proposition). The candidates to support [06] are the three strands [21] [22][23], and none of them shows [06] ([21] is a proposition with a table of assumptions at the lower end of the window, [22][23] are readings). [20] is a checking row: unless [01] and [03] are measured at the same threshold, [12] is empty. [24] explains where the three strands stopped, and is a premise of no conclusion.

We also check that the statements of the assumption rows do not contain the quantity of the conclusion. The quantity of the conclusion is the gap λ of the measure of the core. [01] and [06] are logarithmic Sobolev constants of the marginal of the marks on the window, [02] the remainder of the transfer operator of a scrap, [03] the lower bound on the weighted rows, [04] the boundary terms and regularity, [05] the remainder quantity and the proxy ratio. None of them contains λ.

09

To the next chapters

The full list of detour plans tried in the route of the window log-Sobolev inequality (twenty-two, plus two born along the way, and their derivatives) and the types of breakage that appeared repeatedly are treated in 23-10. The construction that controls the core constant in three steps from the side of the box is 23-11. This part places the diffusive-relaxation-time assumption at the axis of the study, and this chapter has said how far the core row of the saddle-tube condition of its first step could be built. A viewpoint that handles the negative curvature at the top without relying on convexity is treated in Part 24 (24-06).

What this chapter can say

What is said	What is not said
Proved here The constructions of the sector sum, the Gibbs decomposition, componentwise localisation and sector composition in the sector framework, the closing condition (7), the needed value (8), the localised Bochner and the Gibbs tilt, the consequence of the threshold mismatch, the failure of diagonal dominance at the top Lean (algebra)	The inputs (the marginal log-Sobolev input for the window, the bridge volume-locality input, the Barta rows, regularity)
Reading The needed value $25.1/90.3/312.3$, the gap of 29–74 times to the upper bound on A_W, how far the three strands got	The one remaining proposition (the Window Log-Sobolev Threshold Proposition). Hence the core row (the core Poincaré uniformity assumption) and the saddle-tube condition

What is said	What is not said
Assumption The Scalar-Strand Proposition (8 nodes of $\hbar \in [3 \cdot 10^{-4}, 10^{-3}]$, with a table of assumptions)	Interval arithmetic for the Scalar-Strand Proposition, between the nodes, the upper half of the window and $\hbar \to 0$

The scalar strand: floating-point transfer, `path5_conditional`, `p5_assembly`. The Feynman–Kac strand: Monte Carlo of the adjoint estimator (32 paths, search for starting points), `mbar_bound_false`.

Words used in this chapter — sector framework, sector, mark, site window, defect set, rarity exponent, Gibbs variational inequality, componentwise localisation, closing condition, needed value, choice of tools and structure, threshold mismatch, the three strands, Scalar-Strand Proposition, lifting assumption, the common wall, diagonal dominance. Their meanings are in A-02 Glossary.

Next chapter to read: 23-10 The list of detour plans — types of breakage — puts the detour plans into one table with "the line that killed it", and reads the three sides (the needed side, the form, the floor) and the types of breakage that appeared repeatedly.

The list of detour plans — types of breakage

This chapter is a map of open questions. § 04 is this book's own investigation; § 07 is guide material.

What this chapter shows — We put into one table the twenty-four detour plans tried (the list of detour plans), arranged by which factor of the closing condition of the route of the window log-Sobolev inequality, $b(A_W c_H + D_W + \ln 2) < \kappa \ell_{\min}$, they move. Each row gives "the line that killed it" (for a dead plan) or "the remaining assumption" (for a live plan), and whether the factor moved comes from the structure or from the choice of tools. From the table we extract seven types of breakage that appeared repeatedly, and for each type give the plans it caught and a question with which readers can test their own plans.

Prerequisite chapters — 23-09 § 03 (the closing condition, the needed value, Table 1 of where the constants come from), 23-09 § 06 (the common wall), 23-07 § 02 (the position of the route of the window log-Sobolev inequality).

Said first — The level is [Y3]–[Res], and § 01, § 02 and the names of the types and the questions in § 04 can be read at [Y3]. This part places the diffusive-relaxation-time assumption at the axis of the study (23-01), and this chapter tidies up after the plans tried towards the core row of the saddle-tube condition of its first step. None of the plans has shown the saddle-tube condition. All numbers are values on the 0+1-dimensional double well on the lattice $\varepsilon = \frac{1}{2}$, and triples are in the order $\hbar = 3 \cdot 10^{-3} / 10^{-3} / 3 \cdot 10^{-4}$.

The order of this chapter

1. Summary — a section readable at [Y3]
2. The starting point — the closing condition, and three sides
3. The list of detour plans (Table 1, the count)
4. Types of breakage — seven types, and questions to test your own plan (Table 2)
5. Where the survivors went — into the three strands (Table 3)
6. The table of the five grades — the main lemmas for each type (Table 4)

01

Summary

The one remaining proposition of the route of the window log-Sobolev inequality was that the logarithmic Sobolev constant A_W of the site window lies within the needed value $A_{\max}$ (23-09 § 03). A detour plan moves one side of this inequality, or the form of the inequality itself.

- **The results of the twenty-four.** The twenty-two listed first split into 13 dead, 2 on hold, 3 conditional and 4 alive. Of the 4 alive, 2 (detour plan "localising negative curvature" and detour plan "optimising the Gibbs tilt") enter every later form as parts, and the other 2 (detour plan "scalar payment" and detour plan "replacing the functional inequality"), together with detour plan "paying with a height function", which was born along the way, became the three strands of 23-09.
- **The side of tools and the side of structure.** What moved the needed value a lot were the plans that corrected the choice of tools (localising negative curvature and optimising the Gibbs tilt: $0.20 \to 90.3$ at 10^{-3}, about 460 times), while the plans that moved factors coming from the structure (the depth of defects b, the rarity of the defect set ℓ) all stopped under a ceiling of 1.15 times.
- **Seven types of breakage.** One source (the curvature at one site at the top); a ceiling for structural factors that enter as ratios; paying for the same place twice; mixing up currencies; the address of $1/\hbar$; a mismatch between the direction of fluctuation and the soft direction; transfer. Of the 13 dead plans, 12 fall under one of these.

02

The starting point — the closing condition, and three sides

Copied from 23-09. The sector framework, which controls the gap λ of the core Q_k uniformly in the core length k, combines the three inequalities of Barta, componentwise localisation and Bochner, and closes under the following condition (23-09 (7)).

$$b\,(AW\,cH + DW + \ln 2) \;<\; \kappa\,\ell_{\min}, \qquad AW \;<\; A_{\max} = \frac{\kappa\ell_{\min}/b - DW - \ln 2}{cH} \quad (1)$$

Of the six constants, $\kappa = 3/1000$, $b = 493/1000$ and $\ell_{\min}$ are quantities of the **structure**, determined by the model and by how the defect set is defined, while $cH = \frac{1}{4}$ (the negative curvature paid uniformly over the whole core) and $\ln 2$ (the Gibbs tilt fixed at $t = \ell$) are quantities of the **choice of tools** (23-09 Table 1). In the original form the needed value was negative / 0.20 / 7.13, while the upper bound on AW was $1857/2794/9106$ Reading (including estimates) and the lower bound $1.71/1.74/2.59$ Reading (values from a family of test functions).

What a detour plan is. To close (1), one raises the needed value, lowers the upper bound, or changes the form of the condition. In this chapter we split the plans into three sides by that direction.

Figure 1 The three sides (three columns of text)

The needed side	Form	The insufficient side (floor)
Make $A_{\max}$ larger. Make κ and $\ell_{\min}$ on the right of (1) larger, and b, cH and $\ln 2$ on the left smaller	Change the functional form of (1). A construction in which AW does not enter the condition; a construction with Poincaré instead of logarithmic Sobolev	Lower the upper bound on AW. Reduce the structural loss (floor) of the construction of the upper bound
Localising negative curvature, optimising the Gibbs tilt, raising the threshold, layering defects by depth, narrowing the defect set, defects as long clusters, non-linear Barta weight, extension to the classical limit, Hölder and hypercontractive steps, paying with a height function	Scalar payment, detour plan "Agmon-type payment", detour plan "re-examining downstream needs", replacing the functional inequality	Paying for the summit band, coarse and propagation steps at once, log-Sobolev with clusters fixed, perturbing only the summit band, known uniform log-Sobolev, finite-volume criteria, Glauber log-Sobolev, two-step cluster expansion, one- or two-site windows, localising at the cluster core

The other axis is the character of the factor moved. Factors of the **structure** are quantities determined by the model, and moving them requires changing the definitions of the defect set or the weights. Factors of the **tools** are choices of steps in the proof, and can be changed with the same sets. The "Structure / tools" column of Table 1 is this axis, and "tools → structural floor" marks plans that changed tools but stopped on hitting a structural floor.

03

The list of detour plans

The words of the verdicts in Table 1 mean the following. **Alive** = in that form it came within the needed value (still not a proof of (1); remaining assumptions exist). **Conditional** = the remaining assumptions can be named. **On hold** = not decided on paper. **Dead** = the killing test put it outside the needed value, or no form came out. The line that killed it shrinks to one line the fact that stopped the plan, and all numbers are readings from floating-point grids or transfer matrices Reading (lower bounds are values within a family of test functions).

Table 1 List of detour plans (triples are $\hbar = 3\cdot 10^{-3}/10^{-3}/3\cdot 10^{-4}$; "Type" is the type of breakage in § 04)

Detour plan	Plan (one line)	What it moves	Structure / tools	Result	The line that killed it (dead) / remaining assumption	Type, chapter
Localising negative curvature	Localise the negative curvature of Bochner to the defect set	cH (needed side)	Tools	Alive (absorbed as a part)	Together with optimising the Gibbs tilt, needed value $25.1/90.3/312.3$. Remaining: regularity of the Bochner step; measuring AW with marks at the same threshold as the defects	Double-payment type, 23-09 § 03
Optimising the Gibbs tilt	Set the Gibbs tilt to $t^* = \ell - 5.10$	$\ln 2$ (needed side)	Tools	Alive (absorbed)	Cost $b\ln 2 = 0.342 \to 0.0183$. No remaining assumption (a one-line inequality)	Double-payment type, 23-09 § 03
Raising the threshold	Raise the threshold to $1/\sqrt{3}$, and the remainder of localisation δ to 0	δ, κ (needed side)	Tools	Conditional	The needed value is in effect $AW \lesssim 4\ell$: $128/452/1604$ against the upper bound $1629/2444/8153$ (12.8 / 5.41 / 5.08 times outside). Remaining: the tail outside the window	Type of the ceiling on structural factors
Layering defects by depth	Split the depth of defects b into layers	b (needed side)	Structure	Dead	Factor $1.05/1.01/1.004$. Plans that move only b and κ without changing the set have $A_{\max} < 4\ell$ (ceiling $1.15/1.04/1.01$ times the current value)	Type of the ceiling on structural factors
Narrowing the defect set	Narrow the defect set to the set where the rows fall below κ	$\ell_{\min}$ (needed side)	Structure	Dead	The set became 1.40 times rarer, but the rarity on the Barta side acts only multiplied by $\kappa/(\beta_0 - \kappa) \approx 1/47$ (factor $1.11/1.05/1.02$)	Type of the ceiling on structural factors

Detour plan	Plan (one line)	What it moves	Structure / tools	Result	The line that killed it (dead) / remaining assumption	Type, chapter
Defects as long clusters	Move to the road that defines defects by lumps of length 8 or more	$\ell_{\min}$ (needed side)	Structure	Dead	For short lumps of length ≥ 2, the best lower bound on the Barta rows is negative (-0.0096 at length 2)	Summit-curvature type
Paying for the summit band	Pay for the band at the top as a defect	Floor	Structure	Dead	The rarity of the band and the tail through the band are both $\propto 1/\hbar$ and cancel, and the tail of paths that touch the band and leave equals the whole tail	Type of the address of $1/\hbar$
Scalar payment	Pay for the defects of the sectors in scalar form	Form	Tools	Alive (conditional)	The condition is only $\ln k < \ell_{\text{band}}$; AW, κ, b and c_H are not needed. Remaining: the rows of the table of the Scalar-Strand Proposition	23-09 the scalar strand
Non-linear Barta weight	Make the Barta weight non-linear	b (needed side)	Tools → structural floor	Dead	The worst row rises $-0.4865 \to -0.25$, but the floor at the top $F(0,0) = w(0) = -\frac{1}{4}$ is there for every one-site weight (factor $1.02/1.006/1.002$)	Summit-curvature type
Agmon-type payment	Pay the weight of the defects with the gradient of the true eigenfunction alone (Agmon type)	Form	Tools → structural floor	Dead	Agmon's gain is only where the curvature has a positive margin, and the defect set is the one place where the curvature is negative = the most permissive side	Summit-curvature type
Re-examining downstream needs	Re-examine what is needed downstream	Form	Tools	On hold → absorbed into scalar payment	Downstream, "uniform in k, polynomial in $\hbar$" suffices, but the only tools that give the input uniformly in k were of logarithmic Sobolev type	23-09 the scalar strand
Coarse and propagation steps at once	Do the coarse step and the propagation step at once rather than as a product	Floor	Tools	Conditional	The coarse step is exhausted, with ratio $1.016/1.005/1.003$ to the lower bound. Remaining: the weighted conditional Poincaré constant C_w of the propagation step	23-09 the componentwise strand
Replacing the functional inequality	Poincaré instead of logarithmic Sobolev / modified LSI / Φ-entropy	Form	Tools	Poincaré alive (conditional), the other two dead	Modified LSI only moves $\ln(1/\pi_*)$ to the energy side, and Φ-entropy cannot beat the Poincaré endpoint	Transfer type, the scalar strand
Log-Sobolev with clusters fixed	Logarithmic Sobolev for the conditional measure with the state of the lumps fixed	Floor	Tools	Dead	After conditioning, the measure of the defect set is 0 or 1, and $\ell = 0$	Currency-mix-up type
Perturbing only the summit band	Bakry–Émery outside the window, Holley–Stroock perturbation only for the band at the top	Floor	Tools	Dead	The one-site oscillation $\mathrm{osc}/\hbar = 3.7/11/37$ enters the exponent and is multiplied by the length along the chain; paid in the defect term it is 2000–4900 times the allowance	Type of the address of $1/\hbar$
Known uniform log-Sobolev	Known theorems on uniform logarithmic Sobolev in one dimension	Floor	Tools	Dead	The uniform constant is a finite-volume constant for a box covering the correlation length (length $\gtrsim 230$–810), and is not below the window constant	Transfer type
Finite-volume criteria	Finite-volume criteria (of the Martinelli–Olivieri and Lu–Yau types)	Floor	Tools	Dead	Same as detour plan "known uniform log-Sobolev": the box of the criterion must cover the correlation length	Transfer type
Glauber log-Sobolev	Known logarithmic Sobolev for Glauber dynamics	Floor	Tools	Dead	The coarse step is not the limit, and the Glauber constant ≥ 39–400 is if anything worse	—
Two-step cluster expansion	Two-level cluster expansion, block spins	Floor	Tools	Dead	The pin of the largest path stays at the top, and the tail gain ≤ 1.8 (10^{-3}), ≤ 3 ($3 \cdot 10^{-3}$) falls short of the needed 5–13 times	Transfer type

Detour plan	Plan (one line)	What it moves	Structure / tools	Result	The line that killed it (dead) / remaining assumption	Type, chapter
Extension to the classical limit	Take $\hbar$ below the window (the classical limit)	Needed side (range)	Structure	On hold	Removing the band, the contraction of the boundary map is $0.976/0.952/0.929 < 1$ (band width $0.1/0.2/0.3$), and the tail is bounded independently of $\hbar$. Remaining: the self-loop lemma for the boundary and the band lemma (detour plan "paying for the summit band" is dead)	—
One- or two-site windows	Make the window one or two sites (half rows)	Floor	Tools	Conditional (small gain)	The effect is about 2/3, a factor gap of $8.45/3.59/3.38$. The propagation tail remains	Transfer type
Localising at the cluster core	Localise at the core of the lump instead of the window	Floor	Tools	Dead	Even in the limit with the window tail set to 1, $4.2/1.8/1.7$ times outside (the origin of the floor does not depend on how the window is chosen)	Transfer type
Hölder and hypercontractive steps	Replace the Gibbs step by Hölder and hypercontractivity	The needed side	Tools	On its own, dominated by detour plan "raising the threshold"	$\sqrt{k}$ does not appear, but A enters $\ln C^2$ linearly and the ceiling is the same, $\approx 4\ell$ (needed value 0.80–0.91 times that of raising the threshold). Its merit is that measurability of the set of marks is not needed	Type of the ceiling on structural factors
Paying with a height function	Pay the negative curvature by a function of height $h = (-w(z_j))_+$ (the curvature at each point by the rarity of that point)	The needed side	Tools	Conditional	Needed value $537/1754/6052$ (3.8–4.2 times that of raising the threshold). Dead if Rothaus's lemma is used as it is. Remaining: the propagation tail	The componentwise strand; together with detour plan "Hölder and hypercontractive steps", the Feynman–Kac strand

Counting. The first twenty-two (from localising negative curvature to localising at the cluster core in Table 1) are 4 alive (localising negative curvature and optimising the Gibbs tilt absorbed as parts; scalar payment and the Poincaré form of replacing the functional inequality conditional), 3 conditional (raising the threshold, detour plan "coarse and propagation steps at once", detour plan "one- or two-site windows"), 2 on hold (re-examining downstream needs, absorbed into scalar payment; detour plan "extension to the classical limit") and 13 dead. The 13 dead split into 8 on the side of the floor (paying for the summit band, log-Sobolev with clusters fixed, perturbing only the summit band, known uniform log-Sobolev, finite-volume criteria, Glauber log-Sobolev, two-step cluster expansion, localising at the cluster core), 4 on the needed side (detour plan "layering defects by depth", detour plan "narrowing the defect set", detour plan "defects as long clusters", detour plan "non-linear Barta weight") and 1 on form (Agmon-type payment). Of the two born along the way, Hölder and hypercontractive steps is, on its own, dominated by raising the threshold, and paying with a height function is conditional and entered the componentwise strand; the form combining it with Hölder and hypercontractive steps became the Feynman–Kac strand.

Contrasting the side of tools with the side of structure. Putting the "Structure / tools" column of Table 1 next to the results column, every row that moved the needed value a lot is "tools". Localising negative curvature and optimising the Gibbs tilt kept the same defect set and only corrected how the negative curvature is paid and how the Gibbs tilt is chosen, and moved the needed value from negative / 0.20 / 7.13 to $25.1/90.3/312.3$ (about 460 times at 10^{-3}, about 44 times at $3 \cdot 10^{-4}$, from negative to positive at $3 \cdot 10^{-3}$) Reading . The "structure" rows (layering defects by depth, narrowing the defect set, defects as long clusters, paying for the summit band) and the rows that hit a structural floor (non-linear Barta weight, Agmon-type payment), on the other hand, did not exceed a factor 1.15, or no form came out. Most of the loss on the needed side lay not in the structure of the model but in the choice of tools. Conversely, the gap that remains after the tools have been fully corrected (5–13 times in the form of raising the threshold) goes back to the structural floor of the summit-curvature type in § 04.

▶ List of derivatives (forms tried within the strands, collapsed)

04

Types of breakage

Lining up the lines that killed the plans in Table 1 and Table 1′, the same reasons appear again and again in changed forms. We group them into seven types. For each type we give the plans it caught, a paragraph on why plans break in that way, and a question to test your own plan. The types are not mutually exclusive, and one plan can fall under two types.

The summit-curvature type — one source (the curvature at one site at the top)

Plans caught: defects as long clusters, non-linear Barta weight, Agmon-type payment, and the uniform road and the Lyapunov criterion without sectors in Table 1′.

In one row of the Hessian of the action of the core, at the top the diagonal $4 - \frac{1}{4} = \frac{15}{4}$ falls $\frac{1}{4}$ short of the sum of the couplings to the neighbours 4 (23-09 (11)). This shortfall appears with the same value in the Barta weight rows, in the contraction criterion for chains and in the Lyapunov-function criterion, on the top face $x \equiv 0$ (every site at the top). For example, the Barta row of a one-site weight $\psi_j = \phi(z_j)$ has the form $F(z, n) = w(z) + (\text{log-derivative of the weight}) \times (\text{drift})$, and at the top $z = 0$ with neighbours $n = 0$ the drift $\varepsilon V'(0) + 8(0 - 0)$ is 0, so however the weight is chosen Proved here

$$F(0, 0) = w(0) = -\tfrac{1}{4} \ (2)$$

(a one-line computation on the same assumption row as the Barta rows of 23-09) Lean `floor_top` (assumption: weight value $/= 0$). The Agmon type in Agmon-type payment is a tool that gains where the curvature has a positive margin, and the defect set is exactly where the curvature is negative, so the coefficient of gain there is ≤ 0 Lean `agmon_no_gain_on_negative_curvature` (assumptions: curvature $w \leq 0$, $\lambda \geq 0$ and others; the framework of Agmon estimates is not placed in the book). In defects as long clusters, defining defects by long clusters made the rows of short clusters of length 2 or more negative, and the same shortfall came out on the side of short clusters.

Question to test: what does your plan pay on the top face $x \equiv 0$? If the quantity paid there is a constant independent of $\hbar$, the shortfall of $\frac{1}{4}$ remains as it is. Only the rarity (entropy) of the plateau at the top can pay for this shortfall, and $\hbar$ enters that payment.

The type of the ceiling on structural factors — structural factors that enter as ratios have a ceiling

Plans caught: layering defects by depth, narrowing the defect set, Hölder and hypercontractive steps, and the ceiling of raising the threshold.

Raising the threshold, with remainder of localisation $\delta \geq 0$, remaining coefficient γ, Gibbs tilt t and $L(t) = \ln(1 + e^{t-\ell})$, the closing condition is $b(A\delta + D_W + L(t)) < \kappa(t - A\gamma)$ (the form of localising negative curvature, optimising the Gibbs tilt and raising the threshold).

Ceiling lemma. If $0 < \kappa < b$ and $\delta, D_W \geq 0$, any $A \geq 0$ satisfying this condition satisfies $A\gamma < \ell$.

Proved here Proof. The left-hand side is at least $bL(t) > 0$, so $t - A\gamma > 0$. From $b > \kappa$, $b(t - A\gamma) > \kappa(t - A\gamma) > bL(t) \geq b(t - \ell)$ ($\ln(1 + e^x) \geq x$). Dividing by b gives $A\gamma < \ell$. ∎ Lean `ceiling_same_set` (assumptions: $0 < \kappa < b$, $t - A\gamma > 0$, $t - \ell \leq L$, the closing condition)

Plans that move only b and κ without changing the defect set (hence ℓ) cannot push the needed value above ℓ/γ (4ℓ in the form of raising the threshold). The needed value in the form of raising the threshold is already at $1/1.15/1/1.04/1/1.01$ of the ceiling Reading , and the $1.05/1.01/1.004$ times of layering defects by depth lies within it. In narrowing the defect set, which changes the set, the rarity on the Barta side (ℓ_B of the set where the rows fall below κ) enters the condition only multiplied by $\kappa/(\beta_0 - \kappa) \approx 1/47$ Assumption (the paper argument is not placed in the book) Lean `ceiling_split`, and making the set 1.40 times rarer stopped at a factor of 1.11. Hölder and hypercontractive steps changed the tool of the Gibbs step, but A enters in the same form, so the ceiling is the same.

Question to test: does your plan change the defect set? If not, the needed value does not exceed ℓ/γ. If it does, first write down which coefficient of the condition the rarity of the new set is multiplied by when it enters.

The double-payment type — the same place was paid for twice

Plans caught (on the side that fixed it): localising negative curvature, optimising the Gibbs tilt, and the construction of the window in Table 1′.

The Bochner step of the original construction paid the negative curvature $-\frac{1}{4}$ over the whole core X. But negative curvature exists only for $z > -1/\sqrt{3}$, and that region is inside the defect set already paid by the Gibbs step as Y. Paying the same place again on the X side made the coefficient of A_W equal to $bc_H = 0.123$, through the amplification $b/\kappa \approx 164$. Localisation (localising negative curvature) brings the coefficient down to 0.0038 (23-09 (9)). Fixing the Gibbs tilt at $t = \ell$ (optimising the Gibbs tilt), and the $(1 + \sqrt{C_w})^2$ in the construction of the propagation step (counting the same quantity twice), are of the same type. This is a type that has a large effect when fixed.

Question to test: is the quantity paid in that step on a set already paid for by an earlier step? Drawing the places where the two steps pay in the same figure makes it visible.

The currency-mix-up type — speed of exit and rarity

Plans caught: detour plan "log-Sobolev with clusters fixed", the form that pays on the band by rarity and the double threshold in Table 1′, and the naive decomposition of the variance in 23-11 § 04.

What a Poincaré inequality measures is the speed of exit (the ratio of the variance to the Dirichlet form), and what can pay for rarity $\mu(B) \le e^{-\ell}$ is the currency of entropy (23-09 (3): $\ell \int_B g^2 \le \mathrm{Ent} + \ln 2 \int g^2$). The ratio of the variance to the Dirichlet form does not change when the function is multiplied by a constant, so putting in a function supported on a rare set makes the rarity cancel between numerator and denominator. "The fluctuations are small because the path sticks to the band" is an intuition about the variance, and what the step that pays for rarity needs is an estimate of entropy. Log-Sobolev with clusters fixed is more direct: if the defect set is determined by the σ-algebra of the conditioning, the measure of that set under the conditional measure is 0 or 1 Proved here (the definition of conditional probability), and no rarity ℓ is left to pay with.

Question to test: does the step that pays for the rarity $\mu(B)$ pass through entropy (or an inequality of the same type)? If it uses only the variance and the Dirichlet form, rarity has no effect. Also check whether rarity is still left after conditioning.

The type of the address of 1/ħ — the address of $1/\hbar$

Plans caught: paying for the summit band, detour plan "perturbing only the summit band", and in Table 1′ the linear collective coordinate, the sector-split chain, the multi-stage cut at the wall, the chain of wall marks, and the chain with the mean height added.

What the Feynman–Kac strand needs is the coefficient of $1/\hbar$ in the logarithmic Sobolev constant of the core. If one mistakes which quantity that $1/\hbar$ lives in, the plan only moves $1/\hbar$ to another place. Three facts came up again and again.

- **$1/\hbar$ lives not in $\sum z$ but in the radius.** On the plateau at the top, the action changes not in the direction of the linear collective coordinate $\sum_j z_j/\sqrt{k}$ but along the radius from the corner at the top (the direction of $\sum_j z_j^2$), and its length is the crossing length $\ell_\times \approx 0.34/\hbar$ Reading . In the two-scale split into the collective coordinate and the transverse directions, the smallest curvature in the directions orthogonal to the collective coordinate on the top face, $4 - 4\cos(2\pi/(k+1)) - \frac{1}{4}$, becomes negative at $k = 17$ Proved here (the closed formula for tridiagonal eigenvalues) Lean `transverse_fails_k17` (no assumptions), so convexity holds only for $k \le 16$.
- **Cutting into sectors only allocates $1/\hbar$.** The chain rule of entropy $\mathrm{Ent} = \mathrm{Ent}(\text{marginal of the marks}) + \mathbb{E}\,\mathrm{Ent}(\text{inside the sector})$ is an identity Proved here Lean `chain_rule_cells` (assumptions: the chain rule, upper bounds on the two terms), and cutting the plateau at the position of the wall allocates $\approx 0.8/\hbar$ between the side of the marks and the side of the sectors Reading . The sum does not decrease.
- **A mark represents only the one step that crosses the face.** In the chain of wall marks the constant of the chain itself becomes small, but a mark does not distinguish positions on the plateau and represents only the step across the face, so $1/\hbar$ moved into the constant $\ge 13/26/66$ that compares the mark chain with the original measure Reading . Whether a variable added to the chain is good or bad is decided by whether its rate function is flat at the extremum (if flat, the cost of adding it is $O(1)$) Lean `S_ext_01_iff` (algebra); the mean height is not flat and pays $\propto 1/\hbar$, while the radius passed.

Paying for the summit band (the rarity of the band and the tail through the band are both $\propto 1/\hbar$ and cancel) and perturbing only the summit band (the cost of the Holley–Stroock perturbation $e^{\mathrm{osc}/\hbar}$) are also examples that only moved the place where $1/\hbar$ is paid.

Question to test: in your plan, which quantity is $1/\hbar$ attached to? If it has only moved to a sector, a mark, a comparison constant or the cost of a perturbation, it has not disappeared. Draw the rate function of the variable you add near its extremum.

The type of the misaligned fluctuation direction — mismatch between the direction of fluctuation and the soft direction

Plans caught: in Table 1′, radius and angles on the sphere, the three steps, the variance version of two-scale, and the interior radius; and the paper upper bound of the Feynman–Kac strand.

In a two-scale composition, taking the gradient outside the fibre with $\sup$ (the direction of fluctuation) and paying for it with the constant of the softest direction of the fibre (of the type $\kappa \times A_{\mathrm{fib}}$) makes the upper bound too large by orders of magnitude wherever the two directions are not aligned. Even in the version replaced by the variance, the lower bound on the loss, 0.66–1.8, was outside the needed 0.18–0.50 Reading . What must be paid is the gradient of the solution of the Poisson equation on the fibre ($|M^{-1}\nabla_\perp G|$ in the Helffer–Sjöstrand representation), and it must be estimated while keeping the direction. The gap in the Feynman–Kac strand, where the Monte Carlo reading is 0.54 times the threshold and the paper upper bound 10^3 times the threshold, also came from the step where the scalar Grönwall discards the direction of the gradient and reduces every direction at the softest rate (23-09 the Feynman–Kac strand).

Question to test: somewhere in your upper bound, have you crushed a vector quantity into a scalar? If there is such a step, it pays at the rate of the softest direction there. Draw the direction of large fluctuation and the soft direction in the same figure.

The transfer type — the weight only moves to another column

Plans caught: the modified LSI of replacing the functional inequality, known uniform log-Sobolev, detour plan "finite-volume criteria", detour plan "two-step cluster expansion", one- or two-site windows, detour plan "localising at the cluster core", and the proxy series in Table 1′.

Known uniformity theorems (known uniform log-Sobolev, finite-volume criteria) do not make the constant; they move the problem to the finite-volume constant of a box covering the correlation length (length $\gtrsim$ **230–810**). The window is finite, so existence was trivial from the start, and the reason they do not help is size. Plans that change how the window is taken (one- or two-site windows, localising at the cluster core) reduced the loss of the window, but the floor of the propagation step remained. In the cluster expansion (two-step cluster expansion) the pin of the largest path stayed at the top, and in the modified LSI (replacing the functional inequality) $\ln(1/\pi_*)$ moved to the energy side. In the proxy series of the Scalar-Strand Proposition, when the assumption column became lighter by changing proxy or direction, the computed column became heavier by the same amount (an identity in which the sum of the two columns does not depend on the direction) Assumption (the definitions are not placed in the book) Lean `threshold_gap_invariant` (assumption: the identity of the two sums).

Question to test: in your plan, has another column (the size of a box, the propagation step, a computed quantity) become heavier by as much as one column became lighter? If the sum is invariant, the margin has not moved.

Table 2 Types of breakage (one line each)

Type	One line	Plans caught	Question to test
Summit-curvature type	At one site at the top, the diagonal $15/4$ falls $\frac{1}{4}$ short of the coupling 4	Defects as long clusters, non-linear Barta weight, Agmon-type payment, the uniform road, Lyapunov without sectors	What is paid on the top face $x \equiv 0$
Type of the ceiling on structural factors	Moving b and κ without changing the set still gives $A\gamma < \ell$	Raising the threshold, layering defects by depth, narrowing the defect set, Hölder and hypercontractive steps	Does it change the defect set
Double-payment type	A later step pays again for a place an earlier step paid for	Localising negative curvature, optimising the Gibbs tilt (on the side that fixed it), the construction of the window	Have you drawn the places paid in the same figure
Currency-mix-up type	Poincaré is the speed of exit; rarity is the currency of entropy	Log-Sobolev with clusters fixed, the band by rarity, the double threshold, the naive decomposition of the variance	Does the step that pays for rarity pass through entropy
Type of the address of 1/ħ (the address of $1/\hbar$)	$1/\hbar$ lives in the radius, and sectors and marks only allocate it	Paying for the summit band, perturbing only the summit band, collective coordinate, sector-split chain, multi-stage, mark chain, mean height	Which quantity is $1/\hbar$ attached to
Type of the misaligned fluctuation direction	Paying a $\sup$ gradient in the softest direction is too large by orders of magnitude	Angles and radius, three steps, variance version, interior radius, Grönwall	Have you crushed a vector into a scalar
Transfer type	Another column becomes heavier by as much as one becomes lighter	Replacing the functional inequality, known uniform log-Sobolev, finite-volume criteria, two-step cluster expansion, one- or two-site windows, localising at the cluster core, the proxy series	Is the sum an invariant

Among the dead and on-hold plans, those whose type column in Table 1 is "—" are detour plan "Glauber log-Sobolev", which fixed a step that was not the limit, and extension to the classical limit, which is on hold (for the alive and conditional plans that column gives the chapter they went to). This table format, which keeps the line that killed each dead plan, can be used as it is to tidy up after sorting out detour plans for other problems too.

05

Where the survivors went — into the three strands

The alive and conditional plans were gathered into the table of needed values and the three strands. How far the three strands got and their remaining steps are in 23-09 Table 4, and here we list only the correspondence from the plans.

Table 3 Where the surviving plans went

Plan	Destination	What remains there
Localising negative curvature, optimising the Gibbs tilt (, raising the threshold)	The table of needed values (23-09 Table 2). Parts of every later form	Regularity of the Bochner step; measuring A_W with marks at the same threshold as the defects (23-09 § 04)
Paying with a height function, coarse and propagation steps at once (and the derivatives of the componentwise strand in Table 1′)	The componentwise strand — the componentwise form	An upper bound on C_w of the propagation step (a Lyapunov function with coupling terms)
Scalar payment, the Poincaré form of replacing the functional inequality, re-examining downstream needs	The scalar strand — the scalar form (the Scalar-Strand Proposition)	The interval-arithmetic rows, between the nodes, the one lifting assumption

Plan	Destination	What remains there
The form combining Hölder and hypercontractive steps with paying with a height function	The Feynman–Kac strand — the Feynman–Kac form	An upper bound that keeps the direction (the type of the misaligned fluctuation direction)

The place where all three strands stopped is the source of the summit-curvature type, the same as the common wall of 23-09 § 06. Another construction that controls the core constant from the side of the box rather than by the sector framework is treated in 23-11.

06

The table of the five grades — the main lemmas for each type

This chapter is a list, so its rows are limited to the lemmas supporting the types and the values of Table 1. None of the rows is a premise of the conclusion of the route of the window log-Sobolev inequality, and the dependence of the conclusion is in the graph of 23-09 § 08. So this chapter has no dependency graph.

Table 4 The rows of this chapter

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
Floor at the top	The floor of the Barta row of a one-site weight $F(0,0) = w(0) = -\frac{1}{4}$	Proved here	§ 04 (2) (the form of the row is on the Assumption row of 23-09 (the assumption of the Barta row))	Independent of $\hbar$	`floor_top` (assumption: weight value $/= 0$)
Agmon's gain	Where the curvature is negative, the coefficient of Agmon's gain is ≤ 0	Assumption	§ 04 summit-curvature type (the framework of Agmon estimates is not placed in the book)	—	`agmon_no_gain_on_negative_curvature` (algebra)
Ceiling lemma	The ceiling for plans that do not change the set, $A\gamma < \ell$	Proved here	Proof of the type of the ceiling on structural factors in § 04	Independent of $\hbar$	`ceiling_same_set` (assumptions: $0 < \kappa < b$, $t - A\gamma > 0$, $t - \ell \leq L$, the closing condition)
Rarity on the Barta side	The rarity on the Barta side enters only multiplied by $\kappa/(\beta_0 - \kappa)$	Assumption	§ 04 type of the ceiling on structural factors (the paper argument is not placed in the book)	—	`ceiling_split` (algebra)
Fixing the double payment	Localised Bochner and the Gibbs tilt (fixing the double payment)	Proved here	23-09 § 03	Independent of $\hbar$	`bochner_localized`, `tilt_cost_le` (the assumptions and scope are in 23-09)
Rarity after conditioning	Under the conditional measure, a set determined by the σ-algebra of the conditioning has measure 0 or 1	Proved here	§ 04 currency-mix-up type	Independent of $\hbar$	—
Transverse convexity	On the top face, the smallest curvature orthogonal to the collective coordinate is negative at $k = 17$	Proved here	§ 04 type of the address of $1/\hbar$ (closed formula)	Independent of $\hbar$	`transverse_fails_k17` (no assumptions)
Chain rule of entropy	The chain rule of entropy (cutting into sectors does not decrease the sum)	Proved here	§ 04 type of the address of $1/\hbar$ (identity)	Independent of $\hbar$	`chain_rule_cells` (assumptions: the chain rule, upper bounds on the two terms)
Values of the address of $1/\hbar$	The address of $1/\hbar$ (crossing length $0.34/\hbar$, allocation $\approx 0.8/\hbar$, comparison constant $\geq 13/26/66$)	Reading	§ 04 type of the address of $1/\hbar$	Three points	—
Loss from the mismatch of directions	The loss from the mismatch of directions (lower bound 0.66–1.8 against needed 0.18–0.50)	Reading	§ 04 type of the misaligned fluctuation direction	Three points	—
Invariance of the proxy series	Invariance of the sum of the two columns of the proxy series	Assumption	§ 04 transfer type (the definitions are not placed in the book)	—	`threshold_gap_invariant` (assumption: the identity of the two sums)
Reading of known uniformity	Known theorems on uniform logarithmic Sobolev in one dimension give the constant of a box	Assumption	§ 04 transfer type (the statements in the original sources have not been checked)	—	—

Row	Statement (one line)	Grade	Grounds	Range of $\hbar$	Machine checking
Values of Table 1	Factors, ceilings and needed values of Tables 1 and 1′	Reading	§ 03 (floating-point grids and transfer matrices; lower bounds within families)	Three points	—

The "Proved here" rows are general facts that identify the types, and do not mean that any detour plan succeeded. None of the rows of Table 4 shows the closing condition (1).

07

To the next chapter

The construction that controls the core constant in three steps from the side of the box-reduction condition and the gap-inside-the-box condition rather than the sector framework, and the drawing of the boundary of the end sets, are in 23-11. This part places the diffusive-relaxation-time assumption at the axis of the study, and this chapter tidied up after the plans aimed at the core row of the saddle-tube condition of its first step. Another viewpoint that handles the negative curvature at the top without relying on convexity is treated in Part 24 (24-06).

What this chapter can say

What is said	What is not said
Proved here The floor at the top (2), the ceiling for plans that do not change the set, the disappearance of rarity after conditioning, the threshold of transverse convexity, the chain rule of entropy Lean (algebra)	The closing condition (1). Hence the one remaining proposition of the route of the window log-Sobolev inequality and the saddle-tube condition
Reading The factors and needed values of Table 1; that plans on the side of tools moved the needed value by 44–460 times while plans on the side of structure stopped under a ceiling of 1.15 times	That the types exhaust all plans. There are plans that fit no type (Glauber log-Sobolev, extension to the classical limit)
Assumption Agmon's gain, how the rarity on the Barta side enters, the invariance in the proxy series, the reading of known uniformity theorems	That the propositions of the dead plans are false (death is a property of the tool, not the truth of the proposition)

Lemmas of the types	Proved here, Lean	§ 04 of the text. `floor_top`, `ceiling_same_set`, `ceiling_split`, `agmon_no_gain_on_negative_curvature`, `transverse_fails_k17`, `chain_rule_cells`, `S_ext_01_iff`, `threshold_gap_invariant`.
Numbers of Tables 1 and 1′	Reading	Floating-point grids, transfer matrices (midpoint rule), lower bounds from families of test functions, rational decompositions. Interval arithmetic is not used.

Words used in this chapter — detour plan, the line that killed it, needed side, form, insufficient side (floor), structure and choice of tools, ceiling, types of breakage, paying twice, currency (speed of exit and entropy), the address of $1/\hbar$, crossing length, direction of fluctuation and soft direction, transfer. Their meanings are in A-02 Glossary.

Next chapter to read: 23-11 Box reduction and the gap inside the box — the constant of the core — turns box reduction and the gap inside the box into propositions, and controls the core constant in three steps.

Box reduction and the gap inside the box — the constant of the core

> This chapter is this book's own investigation. The established knowledge it builds on is in 2-05 and 2-07.

What this chapter shows — We state Step 1 (box reduction) and Step 2 (inside the box) of the Double-Well Relaxation-Time Upper-Bound Proposition of the first step (23-05 § 04) as the Box-Reduction Proposition (box reduction, using only the Poincaré inequality) and the Gap-Inside-the-Box Proposition (the gap inside the box, with a table of assumptions), and we give the proof of the product inequality for boxes, which 23-05 graded "Proved here". Next, we bound the constant of the core that enters the fast side of the Gap-Inside-the-Box Proposition in three stages by the length of the core (convexity, two blocks, and the reduction to the box applied to the core). Finally, we state how far the set of values at the ends of the core is covered, and how the bistability that appears at ends beyond the top is paid for by the margin of the action barrier.

Prerequisite chapters — 23-05 § 03, § 04 (the statements of the box-reduction condition and the gap-inside-the-box condition, and the single line of argument), 23-04 (the path measure, the correlation length ξ, kinks), 23-09 § 06 (the curvature of one site at the top).

Said first — The level is [Res], and only § 01 is written so that it can be read at [Y3]. § 02 onwards are sections at the research level; you can skip them and go to the table of remaining rows in § 07 and still read the conclusion of this chapter. This part places the diffusive-relaxation-time assumption at the axis of the study (23-01), and this chapter states how far the box-reduction condition and the gap-inside-the-box condition of its first step could be put in the form of propositions. The Box-Reduction Proposition and the Gap-Inside-the-Box Proposition are propositions that leave assumption rows in place; they do not show the box-reduction condition or the gap-inside-the-box condition. All numbers are values on the 0+1-dimensional double well $V = (x^2-1)^2/8$ on the lattice $\varepsilon = \frac{1}{2}$, and triples are in the order $\hbar = 3\cdot 10^{-3}/10^{-3}/3\cdot 10^{-4}$.

The order of this chapter

1. Summary — a section readable at [Y3]
2. Box-Reduction Proposition — box reduction (Figure 1, Table 1)
3. Proof of the product inequality for boxes — the Markov property and Efron–Stein
4. Gap-Inside-the-Box Proposition — the gap inside the box (Table 2)
5. Three stages for the constant of the core — the Three-Range Core-Constant Proposition (Tables 3 and 4)
6. The set of ends — what is covered, and how to pay for bistability
7. The list of remaining rows (Table 5)
8. The table of the five grades (Table 6)
9. The dependency graph

01

Summary

The box-reduction condition bounds the Poincaré constant of a long path by the Poincaré constant of a box of length $C\xi$, and the gap-inside-the-box condition bounds the gap inside that box at the order of $D/(C\xi)^2$.

1. **Box-Reduction Proposition.** Cover the line with overlapping boxes and split them into even boxes and odd boxes; then $C_P \le (1+1/n)\,C_{\mathrm{box}}/(1-c_{\mathrm{alt}})$. It uses only the Two-Projection Lemma, the product inequality for boxes and averaging over shifts, and does not use the logarithmic Sobolev inequality. The remaining assumption rows are that the maximal correlation between even and odd, $c_{\mathrm{alt}} < 1$, is uniform, and the sup over the boundary values. The correlation length is read as $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$, and a box does not cut the plateau at the top.
2. **Gap-Inside-the-Box Proposition.** Splitting the inside of the box by the configuration of kinks Y gives $C_{\mathrm{box}} \le C_{\mathrm{loc}} + (1+\chi) C_{\mathrm{kg}}$. If the reduced kink gas is put in the same type as the Glauber dynamics of the one-dimensional Ising model, the gap is the sum of "creation and annihilation of pairs" and "diffusion of kinks", $(C^2+\pi^2)D/(C\xi)^2$. The remaining rows are the cross term (the cross-term uniformity assumption), the type of the gas (the kink-gas gap assumption), the version for segments (the segment local Poincaré assumption), and the constant of the core.
3. **Three stages for the constant of the core.** Core length $k \le 7$ is bounded by convexity, ≤ 9.18 (independent of $\hbar$ and of the end values); $8 \le k \le 14$ by the lemma

of two blocks; and $k \geq 15$ by applying the reduction to the box to the core. Taking the end values as samples in $[0, x_c]$ gives $\sup_k C_P(\text{core}) \leq 22.1/30.5/66.4$ Reading .

4. **The set of ends.** In the core of the sector framework, the ends are only on the side of the well, and there is no hole. In the core on the box side, the ends can lie beyond the top, and there the wall of conditioning creates bistability; but its barrier $\Delta S_* \approx 10^{-2}$ is about 95 times smaller than $2S_0$, and the local term of the Gap-Inside-the-Box Proposition vanishes as $\hbar \to 0$ (on the reading at $\hbar = 0$).

02

Box-Reduction Proposition

Setting. Take the action $S = \sum_i (x_{i+1} - x_i)^2/(2\varepsilon) + \varepsilon \sum_i V(x_i)$ on the lattice line $\mathbb{Z}$ (spacing $\varepsilon = \frac{1}{2}$) at $T = \infty$, the infinite-volume measure μ of $e^{-S/\hbar}$, and the Dirichlet form $\mathcal{E}(f) = (\hbar/\varepsilon) \sum_i \mathbb{E}_\mu |\partial_i f|^2$ (the uniqueness of μ and the nearest-neighbour Markov property are in the row of common premises (Step 0 in 23-05 § 04)). A box B is an interval of L sites, the boundary values (a, b) are the values at the neighbouring sites to the left and right of B, $\mu_B^{a,b}$ is the conditional measure with these fixed, and $\mathcal{E}_B$ is the sum over the sites of B only. We put

$$C_{\text{box}}(L) := \sup_{a,b \in \mathbb{R}} C_P\left(\mu_B^{a,b}; \mathcal{E}_B\right)$$

The maximal correlation of two σ-algebras is $c(\mathcal{G}_1, \mathcal{G}_2) := \sup\{\text{corr}_\mu(F, G) : F \in L^2(\mathcal{G}_1), G \in L^2(\mathcal{G}_2)\}$.

Two-Projection Lemma. If $c = c(\mathcal{G}_1, \mathcal{G}_2) < 1$, then for every $f \in L^2(\mu)$

$$\operatorname{Var} f \;\leq\; \frac{1}{1-c}\Big(\mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_1) + \mathbb{E}\operatorname{Var}(f \mid \mathcal{G}_2)\Big) \quad (1)$$

Proved here (proof in Step 1 in 23-05 § 04) Lean `two_proj_sum_le` (assumptions: Cauchy–Schwarz and the inequality of maximal correlation), `two_proj_var` (assumption: $A + B \leq (1 + c)V$).

The family of boxes. Line up boxes B_m of L sites so that neighbours overlap in l sites ($l \leq L/3$), and let E be the family of even-numbered boxes and O the family of odd-numbered ones. $\mathcal{G}_E$ is the σ-algebra generated by the values at the sites outside E, $\mathcal{G}_O$ likewise, and $c_{\text{alt}}(L, l) := c(\mathcal{G}_E, \mathcal{G}_O)$ (independent of translation).

```
Figure 1  Even and odd boxes, and the shift (example with L = 8, l =
sites       ....|....|....|....|....|....|....|....
even E      [ B0   ]       [ B2   ]       [ B4   ]
odd O            [ B1   ]       [ B3   ]
overlap          ^^     ^^      ^^     ^^          ← l sites each
shift s=1   move the whole row of boxes l sites right (the overlaps m
with n = ⌊(L−l)/l⌋ shifts, the overlap sites are mutually disjoint
```

The product over boxes. Even boxes are $L - 2l \geq 1$ sites apart from each other, and the following inequality holds (proof in § 03).

$$\mathbb{E}\,\mathrm{Var}(f \mid \mathcal{G}_E) \;\leq\; C_{\mathrm{box}}(L) \sum_{B \in E} \mathcal{E}_B(f) \quad (2)$$

Box-Reduction Proposition. $n := \lfloor (L-l)/l \rfloor$. If $c_{\mathrm{alt}}(L,l) < 1$, then

$$C_P(\mu) \;\leq\; \Big(1 + \frac{1}{n}\Big) \frac{C_{\mathrm{box}}(L)}{1 - c_{\mathrm{alt}}(L,l)} \quad (3)$$

Proved here Proof. Fix one shift s and let its even and odd families be E^s, O^s. From (1) and (2) for the two families, $(1 - c_{\mathrm{alt}})\,\mathrm{Var}\, f \leq C_{\mathrm{box}} \big(\sum_{B \in E^s} \mathcal{E}_B + \sum_{B \in O^s} \mathcal{E}_B \big)$. The boxes cover the line, each site lies in the even family at most once and in the odd family at most once, and only the overlap sites lie in both, so the bracket is $\mathcal{E}(f) + \mathcal{E}_{\mathrm{ov}^s}(f)$ (the sum over the overlap sites only). Averaging over the shifts $s = 0, \ldots, n-1$, the overlap sites are mutually disjoint across shifts, so $\sum_s \mathcal{E}_{\mathrm{ov}^s} \leq \mathcal{E}$, hence $(1 - c_{\mathrm{alt}})\,\mathrm{Var}\, f \leq C_{\mathrm{box}}(1 + 1/n)\mathcal{E}(f)$. ∎ Lean `box_two_family` (assumptions: the Two-Projection Lemma, (2) for each family, $\mathcal{E}_E + \mathcal{E}_O \leq \mathcal{E} + \mathcal{E}_{\mathrm{ov}}$, $C_{\mathrm{box}} \geq 0$), `box_shift_average` (assumptions: the two-family inequality for each shift, the sum over overlaps is at most $\mathcal{E}$).

(3) is built only from Poincaré inequalities and does not use the logarithmic Sobolev inequality. The in-phase local Poincaré condition and the saddle-tube condition enter only through C_{box} (§ 04). Putting in $C_{\mathrm{box}} \leq K_4 (C\xi)^2 / D$ of the gap-inside-the-box condition together with $L\varepsilon = C\xi$ and $D = \hbar / S_0$ gives $C_P \leq (1 + 1/n) K_4 C^2 / (1 - c_{\mathrm{alt}}) \cdot \xi^2 S_0 / \hbar$, the form of the First-Step Upper-Bound Proposition Lean `H3_with_H4`, `H3_H4_compose` (assumptions: (3), the gap-inside-the-box condition, $D = \hbar / S_0$, $n > 0$, $c_{\mathrm{alt}} < 1$). It is the same type as the box dynamics of the Glauber dynamics of discrete spins (Propositions 3.4 and 3.5 of Martinelli's lectures) Cited ; here we rewrite it in one dimension, in L^2, and in the form of maximal correlation.

The remaining assumption rows, and the numbers

- **Alternating maximal-correlation assumption for boxes: $c_{\mathrm{alt}} < 1$ uniformly in $\hbar$.** There is no paper proof Assumption . As values, on the reading that the slow part is a two-state chain of the sign (the telegraph chain), boxes with $\theta = l/L = \frac{1}{4}$ give $c_{\mathrm{alt}} = 0.731/0.410/0.138$ for $C = 2/4/8$ Reading (values of a family that copies the values of the closed formula of the two-state chain). These values agree with $\varphi(s,t)$ of the Closed Formula for the Alternating Maximal Correlation in § 05 with $s = e^{-C\theta}$ and $t = e^{-C(1-2\theta)}$ (at $C = 2$, $\varphi = 0.7308$).
- **The sup over boundary values.** C_{box} takes the sup over all real boundary values. We see in § 04 that boundary values near the top are the worst.
- **The size of ξ.** Computing the difference of the even and odd eigenvalues of the transfer operator in the logarithmic domain gives $\ln \xi = 218.08/661.04/2212.72$ and $\ln \xi - S_0^{\mathrm{lat}}/\hbar - \frac{1}{2}\ln\hbar \to -0.778$ Reading (two independent computational routes agree to six digits at intermediate $\hbar$). That is, $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$, and its ratio to the length of the plateau at the top (the crossing length $\ell_\times \approx 0.34/\hbar$, 23-10 type of the address of $1/\hbar$) is $\xi/\ell_\times \geq e^{213}$ Lean `xi_over_ellx` (assumption: the measured $\ln\xi - \ln\ell_\times \geq 213$). **A box of length $C\xi$ does not cut the plateau; it contains it whole.** In exchange, the constant of the core inside the box has to be uniform in the length of the core (§ 05).

Table 1 Positive controls for the inequality of the Box-Reduction Proposition (models in which both sides are known from a closed formula or by diagonalisation)

Model	What was compared	Result
Pure Gaussian ($V = x^2/2$)	The right-hand side $(1 + 1/n)C_{\mathrm{box}}/(1 - c_{\mathrm{alt}})$ against $CP = 1$	Right-hand side 1.10–1.33 ≥ 1 ($L = 4$–128) Reading . Approaches 1 as $l/L \to 0$, $l \to \infty$ Lean `gauss_box_le_one`
Heat-bath Glauber for the one-dimensional Ising model (rings of 12 and 16 sites, couplings $K = 0.3, 0.6, 1.0$)	Both sides of (3)	Holds in all 9 cases, with a loss of 1.17–1.35 times Reading (even at $c_{\mathrm{alt}} = 0.87$) Lean `ising_K1_holds` (assumption: measured values)
Negative control	$\mathcal{G}_1 = \mathcal{G}_2$ ($c = 1$)	The reduction says nothing Lean `no_bound_when_c_one`, `blowup_as_c_to_one`

In the Glauber dynamics examples, even when the gap of the ring (the lower edge of the band) was only about a sixth of the gap of the box, $1 - c_{\mathrm{alt}}$ carried exactly that difference. The band structure of the kink gas does not break the form of the box.

Proof of the product inequality for boxes

We give the proof of (7) of 23-05 ((2) of this chapter). The box-product inequality row was graded "Proved here" in the table of the five grades in 23-05 because of the proof in this section.

Proposition (product over boxes)

When the boxes of the even family E are $L - 2l \geq 1$ sites apart from each other, (2) holds for smooth functions f that depend on finitely many sites only.

Step (a) Conditional independence. The action S is the sum of terms between neighbours $(x_{i+1} - x_i)^2/(2\varepsilon)$ and one-site terms $\varepsilon V(x_i)$. If all values outside a box B are fixed, the conditional density of x_B is determined only by the terms of $e^{-S/\hbar}$ that contain x_B, which are the terms inside B and the two terms joining the two ends of B to the two neighbours a_B, b_B. So the conditional law is $\mu_B^{a_B, b_B}$, and it depends on the values outside B only through the two neighbours (the nearest-neighbour Markov property). Between even boxes there is at least one site fixed by $\mathcal{G}_E$, so given $\mathcal{G}_E$, the conditional density of the even boxes splits into a product of factors, one per box,

$$\prod_{B \in E} \frac{1}{Z_B} \exp\Big(- \frac{S_B(x_B; a_B, b_B)}{\hbar} \Big)$$

and the values of the even boxes $(x_B)_{B \in E}$ are mutually independent with the product law $\bigotimes_{B \in E} \mu_B^{a_B, b_B}$ Proved here (one line on the density splitting into a product in finite volume; that the measure at $T = \infty$ has the same conditional law is in the row of common premises).

Step (b) The Efron–Stein inequality for product measures. Let $\nu = \nu_1 \otimes \cdots \otimes \nu_m$ be a product measure on $X_1 \times \cdots \times X_m$, $F \in L^2(\nu)$, and $\mathrm{Var}_j F$ the variance obtained by moving only the j-th coordinate (the other coordinates fixed). Then

$$\mathrm{Var}_\nu F \;\leq\; \sum_{j=1}^{m} \mathbb{E}_\nu \big[\mathrm{Var}_j F \big] \qquad (4)$$

Proved here Proof. Put $F_j := \mathbb{E}[F \mid X_1, \ldots, X_j]$ ($F_0 = \mathbb{E}F$, $F_m = F$) and $\Delta_j := F_j - F_{j-1}$. The Δ_j are mutually orthogonal, so $\mathrm{Var}\, F = \sum_j \mathbb{E}\Delta_j^2$. Since the coordinates are independent, F_{j-1} is F_j integrated over the j-th coordinate with ν_j, and $\mathbb{E}\Delta_j^2 = \mathbb{E}[\mathrm{Var}_j F_j]$. Moreover F_j is F averaged over the later coordinates $X_{j+1}, \ldots, X_m$, and $G \mapsto \mathrm{Var}_j G = \| G - \int G \, d\nu_j \|^2_{L^2(\nu_j)}$ is convex (the square of a seminorm), so Jensen's

inequality gives $\mathrm{Var}_j F_j \le \int \mathrm{Var}_j F \, d\nu_{j+1} \cdots d\nu_m$. Taking expectations, $\mathbb{E}\Delta_j^2 \le \mathbb{E}\,\mathrm{Var}_j F$, and summing over j gives (4). ∎

Step (c) Poincaré for the box. Apply (4) to the conditional product of Step (a) (with the coordinate X_j the value x_B of the box B). The variance obtained by moving only the coordinates of a box B is the variance of the measure $\mu_B^{a_B,b_B}$, so

$$\mathrm{Var}_B f \;\le\; C_P(\mu_B^{a_B,b_B})\,\frac{\hbar}{\varepsilon}\sum_{i\in B}\int |\partial_i f|^2\, d\mu_B^{a_B,b_B} \;\le\; C_{\mathrm{box}}(L)\,\frac{\hbar}{\varepsilon}\sum_{i\in B}\int |\partial_i f|^2\, d\mu_B^{a_B,b_B}$$

by the sup in the definition of C_{box}.

Step (d) Putting it together. From (4) and Step (c), $\mathrm{Var}(f \mid \mathcal{G}_E) \le C_{\mathrm{box}} \sum_{B\in E} \mathbb{E}\big[(\hbar/\varepsilon) \sum_{i\in B} |\partial_i f|^2 \mid \mathcal{G}_E\big]$. Taking expectations, by the tower property of conditional expectation each term on the right becomes $\mathcal{E}_B(f)$, which is (2). Since f depends on finitely many sites only, finitely many boxes are involved, and the terms of boxes that do not touch the support of f are 0. ∎

The extension to general f in the domain of $\mathcal{E}$ (approximation by functions depending on finitely many sites) is included in the row of common premises. The odd family is the same. (4) of Step (b) is the Efron–Stein inequality (Efron–Stein 1981); since we give the proof here, the grade is "Proved here".

04

Gap-Inside-the-Box Proposition

Fix a box B ($L\varepsilon = C\xi$) and boundary values $(a,b) \in \mathbb{R}^2$, and let $\mu = \mu_B^{a,b}$ and $D = \hbar/S_0$. The expected number of kinks in the box is $C/2$ from the kink density $1/(2\xi)$, which is $O(1)$ Proved here Lean `pair_fugacity` (assumption: $\xi \;/= 0$).

The naive split goes round in a circle. Splitting by a rare set E (for example, configurations with a long core), with $p = \mu(E)$, gives $\mathrm{Var}\, f = p\,\mathrm{Var}_E f + (1-p)\,\mathrm{Var}_{E^c} f + p(1-p)(m_E - m_{E^c})^2$ Proved here (an identity). The second term can be paid with a constant on E^c, but the first term is as large as $\mathrm{Var}\, f$ if f is concentrated on E, and the smallness of p does not come out. What can be paid is up to $p\cdot \mathrm{osc}(f)^2/4$, which is not a gap but a weak form of the Poincaré inequality Lean `naive_split_weak` (algebra). It is an example of 23-10 currency-mix-up type: rarity cannot be paid with variance. So we take the split not by a rare set but by a slow variable.

Splitting by the slow variable. Let Y be the configuration of kinks in the box (the number of kinks, and the position of each kink defined by projection onto the manifold of kinks), and take the identity for conditional expectation Proved here

$$\operatorname{Var} f = \mathbb{E}\operatorname{Var}(f \mid Y) + \operatorname{Var}\big(\mathbb{E}[f \mid Y]\big)$$

as the starting point.

- **The first term (the fast side).** By the nearest-neighbour Markov property, the conditional measure with Y fixed splits into a product of scraps of the phase without kinks (length $\le C\xi$, with values at both ends), the tubes around the kinks, and the cores inside them. The Poincaré constant of a product measure is at most the maximum of the constants of the components ((4) and Poincaré for each component), so $\mathbb{E}\operatorname{Var}(f \mid Y) \le C_{\mathrm{loc}}\,\mathcal{E}(f)$ with $C_{\mathrm{loc}} = \max(C_{(\mathrm{H1}^{\mathrm{seg}})}, C_{(\mathrm{H2}^{\mathrm{tube}})}, C_{(\mathrm{T0}'_{\mathrm{P}})})$ Proved here (the algebra of products). The three constants are assumption rows Assumption, and the constant $C_{(\mathrm{T0}'_{\mathrm{P}})}$ of the core is bounded in § 05 and § 06.
- **The second term (the slow side).** $\mathbb{E}[f \mid Y]$ is a function of Y alone and relaxes by diffusion of the kink positions (mobility D, the kink diffusion-coefficient row Cited) and by the creation and annihilation of kink pairs. The kink-gas gap assumption: the Poincaré constant of the box of the reduced kink gas, $C_{\mathrm{kg}} \le (C\xi)^2/(c_{\mathrm{kg}}(1-\eta_{\mathrm{KG}})D)$ Assumption. The cross-term uniformity assumption: the cross term $\mathcal{E}_Y(\mathbb{E}[f \mid Y]) \le (1+\chi)\mathcal{E}(f)$ Assumption (of the type of the cross constant of a two-scale inequality; a statement of this form has not been drawn from a known theorem).

Gap-Inside-the-Box Proposition. Under the rows above, for every (a, b)

$$C_{\mathrm{box}} \;\le\; C_{\mathrm{loc}} + (1+\chi)\,C_{\mathrm{kg}} \;\le\; K_4\,\frac{(C\xi)^2}{D}, \qquad K_4 = \frac{1+\chi}{c_{\mathrm{kg}}(1-\eta_{\mathrm{KG}})} + C_{\mathrm{loc}}\,\frac{D}{(C\xi)^2} \quad (5)$$

Proved here (the sum of the two terms above) Lean `H4_two_scale` (assumptions: the decomposition inequality, first term $\le C_{\mathrm{loc}}\mathcal{E}$, the kink-gas gap assumption, the cross-term uniformity assumption, $C_{\mathrm{kg}} \ge 0$), `H4_gap_form` (assumptions: $D > 0$, $C\xi \neq 0$, $c_{\mathrm{kg}} > 0$, $\eta_{\mathrm{KG}} < 1$, $1+\chi \ge 0$). (5) is the same formula as (12) of 23-05.

Comparison with the Glauber dynamics of the one-dimensional Ising model

The constant c_{kg} of the kink-gas gap assumption is fixed by the assumption that puts the reduced kink gas in the same type as the heat-bath Glauber dynamics of the one-dimensional Ising model. The gap of a box of L sites with the spins at both ends fixed has the closed formula

$$\mathrm{gap}_{\mathrm{box}} = 1 - \gamma\cos\frac{\pi}{L+1} = (1-\gamma) + \gamma\Big(1-\cos\frac{\pi}{L+1}\Big), \qquad \gamma = \tanh 2K \quad (6)$$

Assumption (the original source is bibliographic only; diagonalisation on the lattice agrees to the 6 digits shown, and it is the same whether the boundary values are $(+,+)$

or $(+,-)$ Reading) Lean `glauber_split` (the right-hand equality, no assumptions). In the limit of long correlation length, the first term $1-\gamma \approx 1/(2\xi^2)$ is the infinite-volume gap = **creation and annihilation of pairs**, and the second term $\approx \pi^2/(2L^2)$ is the **diffusion of kinks** in an interval of length L. Written in the Glauber unit $D=\frac{1}{2}$, it is $D/\xi^2+\pi^2 D/L^2=(C^2+\pi^2)D/(C\xi)^2$, that is, $c_{\mathrm{kg}}=C^2+\pi^2$ Proved here (algebra) Lean `kg_constant` (assumption: $C\xi \;/=0$). The pair term is not a small perturbation; it enters additively as one of the main terms of the gap. The local term of the part without kinks does not appear at the lower edge of the gap.

When the boundary values are near the top, a half kink can sit at the end of the box. This corresponds to a free end of the Ising model, and there is no closed formula. Read by diagonalisation on the lattice, the gap does not fall below $1-\gamma$ for any type of boundary (ratio ≥ 1.17), but a free end is slower than a fixed end.

Table 2 The box constant of the reduced gas $c_{\mathrm{kg}}=\mathrm{gap}\cdot(C\xi)^2/D$ and the coefficient K of the First-Step Upper-Bound Proposition ($\chi=\eta\mathrm{KG}=0$, $n=3$, $\theta=\frac{1}{4}$; all are values of models independent of $\hbar$ Reading)

C	1	2	3	4	6
Fixed ends $C^2+\pi^2$	10.87	13.87	18.87	25.87	45.87
Free ends c_{ff} (lattice values)	2.86	7.17	12.94	20.32	39.07
c_{alt} (two-state chain)	0.915	0.731	0.550	0.410	0.234
K (fixed ends only)	1.44	1.43	1.41	1.40	1.37
K (the sup including boundary values at the top)	5.46	2.76	2.06	1.78	1.60

$K=(1+1/n)C^2/(c_{\mathrm{kg}}(1-c_{\mathrm{alt}}))$ Lean `K_fixed_C2`, `K_ff_C2`, `K_ff_C4` (assumptions: the measured c_{ff} and c_{alt}; arithmetic only). Since K_4 decreases with C, with fixed ends only K hardly depends on C, and including boundary values at the top, the larger C is taken, the better.

The rows remaining in the gap-inside-the-box condition. The cross-term uniformity assumption, the kink-gas gap assumption (the Glauber type and free ends), the segment local Poincaré assumption (the Six-Node In-Phase Poincaré Proposition of 23-06 is a statement on the ring, and there is no version for segments with end values), the saddle-tube Poincaré assumption, and the row of the core. The second term C_{loc} $D/(C\xi)^2$ of K_4 vanishes if C_{loc} is sufficiently smaller than $e^{2S0/\hbar}$, because D/ξ^2 is of size $e^{-441.6}/e^{-1328.6}/e^{-4433.1}$ Reading . We use this margin for the core in § 06.

05

The three-stage proposition for the constant of the core

Setting. A core is a maximal interval of sites at which the path stays between the top and the well, $(0, x_c)$ ($x_c = 0.89$). In this chapter we reverse the direction by symmetry and write the core as $(0, x_c)^k$ (the mirror image of $Q_k = (-x_c, 0)^k$ in 23-09). The measure of the core $\mu_k^{\alpha,\beta}$ is $e^{-S/\hbar}$ with the outside values at both ends α, β fixed, restricted to $(0, x_c)^k$ with Neumann boundary, and the Dirichlet form is $\mathcal{E} = (\hbar/\varepsilon) \sum_i \mathbb{E}|\partial_i f|^2$ (converted from the convention $\hbar \int |\nabla g|^2$ of 23-09 by $C^{(23\text{-}09)} = C/\varepsilon = 2C$). What the fast side of the gap-inside-the-box condition needs is that $C_P(\mu_k^{\alpha,\beta})$ is bounded uniformly in the length of the core k and in the end values (the row of the core Poincaré uniformity assumption).

The short-core step $k \le 7$: convexity (the Short-Core Convexity Lemma)

The Hessian of the action of the core is

$$\operatorname{Hess} S = \frac{1}{\varepsilon} T_k + \varepsilon \operatorname{diag} V''(x_i), \qquad T_k = \operatorname{tridiag}(-1, 2, -1)$$

, and the end values α, β enter S only in first-order terms, so they do not appear in the Hessian. From $\lambda_{\min}(T_k) = 4 \sin^2 \frac{\pi}{2(k+1)}$ Proved here (the closed formula for the eigenvalues of a tridiagonal matrix) and $\inf V'' = V''(0) = -\frac{1}{2}$, at $\varepsilon = \frac{1}{2}$

$$\operatorname{Hess} S \;\ge\; \kappa(k) := 8 \sin^2 \frac{\pi}{2(k+1)} - \frac{1}{4} \quad (7)$$

. This is the same formula that appeared in 23-09 § 06 as the smallest eigenvalue on the surface of the top; it is positive for $k \le 7$ and negative at $k = 8$ ($8 \sin^2(\pi/16) \approx 0.304 > \frac{1}{4}$, $8 \sin^2(\pi/18) \approx 0.241 < \frac{1}{4}$) Lean `kappa7_pos`, `kappa8_neg` (no assumptions).

Short-Core Convexity Lemma. If $\kappa(k) > 0$, then for all end values $\alpha, \beta \in \mathbb{R}$ and all $\hbar > 0$, $C_P(\mu_k^{\alpha,\beta}) \le \varepsilon/\kappa(k)$.

Proved here Proof. By (7), $S/\hbar$ is uniformly convex with $\kappa/\hbar$. A uniformly log-concave measure restricted with Neumann boundary to a convex domain (the box $(0, x_c)^k$) satisfies $\operatorname{Var} f \le (\hbar/\kappa) \int |\nabla f|^2$ Cited (Bakry–Émery on convex domains, checked in Theorem 1.2 (1) of Kolesnikov–Milman), and rewritten in $\mathcal{E} = (\hbar/\varepsilon) \int |\nabla f|^2$ this is $\le (\varepsilon/\kappa)\mathcal{E}$. ∎ Lean `lemma_BV` (assumptions: the lower bound of the Hessian is $\ge \kappa > 0$ independently of the end values, and the pointwise Bakry–Émery inequality).

The values are $\varepsilon/\kappa(k) = 0.133/0.286/0.543/0.973/1.749/3.42/9.18$ ($k = 1, \dots, 7$), independent of both $\hbar$ and the end values. The sup measured at $k = 1, 2$ (0.128 and 0.26)

lie within these Reading . **If the blocks are cut to 7 sites or fewer, the difficulty of the sup over end values disappears by convexity.** The price moves to the side of the correlation at the seams of the cut blocks.

The medium-core step $8 \le k \le 14$: two blocks (the Two-Block Lemma)

End-Reduction Lemma. If the chain $x_1, \dots, x_k$ is Markov, then for $a < b$, $c\big(\sigma(x_1, \dots, x_a), \sigma(x_b, \dots, x_k)\big) = c\big(\sigma(x_a), \sigma(x_b)\big)$.

Proved here Proof. Right-hand side $\le$ left-hand side follows from the inclusion of σ-algebras. Conversely, let F be a centred function of the front piece and G one of the back piece. By the Markov property $\mathbb{E}[G \mid x_1, \dots, x_a] = \mathbb{E}[G \mid x_a] = \mathbb{E}\big[\mathbb{E}[G \mid x_b] \mid x_a\big]$, so putting $\hat F = \mathbb{E}[F \mid x_a]$ and $\hat G = \mathbb{E}[G \mid x_b]$ gives $\mathbb{E}[FG] = \mathbb{E}[\hat F\, \mathbb{E}[\hat G \mid x_a]] = \mathbb{E}[\hat F \hat G] \le c(\sigma(x_a), \sigma(x_b))\|\hat F\|\|\hat G\| \le c(\sigma(x_a), \sigma(x_b))\|F\|\|G\|$. ∎

Two-Block Lemma. Let $1 \le a < b \le k$, $k - a \le 7$, $b - 1 \le 7$. Then

$$C_P(\mu_k^{\alpha,\beta}) \;\le\; \frac{M(a,b)}{1 - c(x_a, x_b)}, \qquad M(a,b) = \begin{cases} \varepsilon/\kappa(k-a) + \varepsilon/\kappa(b-1) & (b \ge a+2) \\ \max\big(\varepsilon/\kappa(k-a),\, \varepsilon/\kappa(b-1)\big) & (b = a+1) \end{cases} \tag{8}$$

Proved here Proof. Apply the Two-Projection Lemma to $\mathcal{G}_1 = \sigma(x_1, \dots, x_a)$ and $\mathcal{G}_2 = \sigma(x_b, \dots, x_k)$. By the End-Reduction Lemma, $c(\mathcal{G}_1, \mathcal{G}_2) = c(x_a, x_b)$. The conditional law given $\mathcal{G}_1$ is the chain $x_{a+1}, \dots, x_k$ of length $k - a \le 7$ (with ends x_a and β) restricted to the box, and the Short-Core Convexity Lemma gives $\mathrm{Var}(f \mid \mathcal{G}_1) \le (\varepsilon/\kappa(k-a))(\hbar/\varepsilon) \sum_{i>a} \mathbb{E}[|\partial_i f|^2 \mid \mathcal{G}_1]$. $\mathcal{G}_2$ likewise gives $\sum_{i<b}$ and $\varepsilon/\kappa(b-1)$. Taking expectations and putting them into (1), the coefficient of site i is $[i > a]\varepsilon/\kappa(k-a) + [i < b]\varepsilon/\kappa(b-1)$; both are switched on only when $a < i < b$, which happens only when $b \ge a + 2$. ∎ Lean `tb_far`, `tb_adjacent` (assumptions: the conclusion of the Two-Projection Lemma, the Short-Core Convexity Lemma for each block, $\mathcal{E}_i \le \mathcal{E}$, $c < 1$).

From the conditions $k - a \le 7$, $b - 1 \le 7$, $a < b$ we get $k \le 14$, and at $k = 15$ there is no (a, b) Lean `tb_range`, `tb_none_at_15` (arithmetic of natural numbers). The input is a single **two-point** maximal correlation $c(x_a, x_b)$, which is the second singular value of the normalised matrix of the joint distribution of two sites Cited (the singular-value representation of Witsenhausen and Rényi, checked in a restatement). For the measure on the lattice, this value can be computed from products of transfer matrices.

Values. Taking the ends as samples in $[0, x_c]$, the sup over $8 \le k \le 14$ of the upper bound (the Two-Block Lemma) is $22.1/30.5/66.4$; at 10^{-3} and $3 \cdot 10^{-4}$ it is attained at $k = 8$ with both ends 0, and at $3 \cdot 10^{-3}$ at $k = 13$ (at $3 \cdot 10^{-3}$, the value for $k = 8$ with both ends 0 is 15.5). The lower bound by polynomial test functions (Rayleigh–Ritz) is

$8.39/17.3/38.5$ Reading . $k = 8$ lies just outside the threshold of convexity; on the reading at $\hbar = 0$, the smallest eigenvalue of the Hessian at the constrained minimiser is 0.0175, heading towards $C_P \to \varepsilon/\lambda_{\min} = 28.55$. There is a peak at $\hbar \approx 10^{-4}$ (lower bound 57, upper bound 99) Reading , and it is not monotone in $\hbar$.

Why the form of the long-core step is not used here. In a core with $k = 8$ and both ends at the top, the alternating maximal correlation of subboxes of length 5 rises to $0.879/0.938/0.971$, and the coefficient of the long-core step becomes 76 or more Reading Lean `coeff_k8` (assumption: the measured $\bar{c} \geq 0.9713$). This is because the soft direction ($\lambda_{\min} = 0.0175$) pushes the correlation at the seams towards 1; the form of two blocks avoids the alternating correlation and can be paid with the two-point correlation alone.

The long-core step $k \geq 15$: applying box reduction to the core (the Box-Reduction Inequality for Long Cores)

The measure of the core is also one-dimensional and nearest-neighbour Markov (restriction to a product box preserves the Markov property), so the construction of § 02 and § 03 can be used literally inside the core. Taking subboxes of length $L_c = 5$ with overlap $l_c = 1$ ($n_c = 4$), the constant of the subboxes (all of 5 sites or fewer, including short ones cut at the ends) is $\leq \varepsilon/\kappa(5) = 1.749$ uniformly in the end values by the Short-Core Convexity Lemma, so for every k and all end values

$$C_P(\mu_k^{\alpha,\beta}) \;\leq\; \Big(1 + \frac{1}{4}\Big)\,\frac{\varepsilon/\kappa(5)}{1 - \bar{c}_{\text{core}}} = \frac{2.186}{1 - \bar{c}_{\text{core}}} \quad (9)$$

holds Proved here (the proof of the Box-Reduction Proposition transferred to the core) Lean `core_uniform_L5` (assumptions: the conclusion of the Box-Reduction Proposition, $C_{\text{box}} \leq 7/4$, the measured $\bar{c}_{\text{core}}$). $\bar{c}_{\text{core}}$ is the alternating maximal correlation between the even and odd subboxes inside the core; the values measured at $k \geq 15$ are ≤ 0.535 over end values (including negative ends beyond the top), and at $k = 20$–30 they are saturated to 7 digits Reading (a measurement of a **lower bound** of the maximal correlation by additive polynomial functions and two points at the seams). Putting this in gives $C_P \leq 4.70$.

The form of the alternating maximal correlation (the Closed Formula for the Alternating Maximal Correlation). In a stationary Gaussian chain $\ldots, L_j, R_j, L_{j+1}, R_{j+1}, \ldots$ with correlation t inside a piece and correlation s at the seams ($\text{corr}(L_j, R_j) = t$, $\text{corr}(R_j, L_{j+1}) = s$, $|s|, |t| < 1$; the chain is taken to continue infinitely on both sides), the maximal correlation between the even pieces and the odd pieces is $\varphi(|s|, |t|)$, where

$$\varphi(s,t) = \frac{s(1+t)}{1+s^2t}, \qquad 1 - \varphi(s,t) = \frac{(1-s)(1-st)}{1+s^2t} \quad (10)$$

. Derivation: for the uniform type $F = \sum_{j\ \mathrm{even}}(L_j + R_j)$, $G = \sum_{j\ \mathrm{odd}}(L_j + R_j)$, the covariance per period is $S_{AB} = 2s(1+t)^2/(1-s^2t^2)$, because by the Markov property a two-point correlation is the product of the correlations of the links in between; the variance is $S_{AA} = 2(1+t) + 2(1+t)^2 s^2 t/(1-s^2t^2)$, and the ratio is φ Proved here (sum of a geometric series) Lean `gauss_mode0`, `one_sub_phi`. This ratio falls within the framework of the convergence rate of two-block Gibbs sampling for a Gaussian target distribution Cited . The rate of Gibbs sampling that alternately redraws all the even pieces and all the odd pieces is the square of the largest eigenvalue of the block Jacobi matrix (the Two-Block Gibbs-Sampler Rate Theorem (Theorem 5 of Roberts–Sahu) of Roberts–Sahu 1997, and § 2.4), and that largest eigenvalue is the maximal correlation φ of the two pieces. The case of pieces of length 1 ($L_j = R_j$; the value $2s/(1+s^2)$ obtained by putting $t = 1$ in (10)) is in Theorem 1 of Pitt–Shephard 1999 and Corollary 2 of Mider–Jenkins–Pollock–Roberts 2022, its square being the rate in the limit of infinite chain length Cited . The value of (10) for general piece length is the same quantity as the convergence radius of line Jacobi iteration in numerical linear algebra (the bibliography on that side has not been cross-checked). That the maximal correlation of a Gaussian chain equals the linear canonical correlation is Cited (Kolmogorov–Rozanov, checked in a restatement); that the uniform type is the maximum within it has only been confirmed by computation Reading . Since $\varphi \geq s \geq st$, the naive product $c \leq s \cdot t$ is false Lean `naive_product_false` (assumption: $0 < s, t < 1$). The $c_{\mathrm{alt}} = 0.7308$ of the two-state chain in § 02 is the φ at $s = e^{-1/2}$, $t = e^{-1}$.

It does not reduce to two-point quantities. In the core, the Gaussian proxy φG built from the two-point maximal correlation agrees with the measured value at the order of 10^{-4} Reading . Even so, for a general Markov chain there is no inequality that bounds the alternating maximal correlation by two-point quantities alone. A chain of three variables X_1–X_2–X_3: $X_2 \sim \mathrm{Bern}(p)$; if $X_2 = 1$ then $X_1 = X_3 = 1$; if $X_2 = 0$ then X_1, X_3 are independently 1 with probability e; $p = 10^{-4}$, $e = 10^{-3}$. A function of a binary variable is affine, so the maximal correlation between binary variables is $|\,\mathrm{corr}\,|$, and $\mathrm{corr}(X_1, X_2)^2 = p(1-p)(1-e)^2/(m_1(1-m_1)) \leq 1/10$ ($m_1 = p + (1-p)e$). But $Z = X_1 X_3$ has $\mathrm{corr}(Z, X_2)^2 = p(1-p)(1-e^2)^2/(m_Z(1-m_Z)) \geq 98/100$ ($m_Z = p + (1-p)e^2$) Proved here (computation of covariances) Lean `rareR_pair`, `rareR_joint` (arithmetic of rational numbers). It is an example in which a non-linear function that holds a rare state from both sides is effective; the paper for the row of the alternating maximal-correlation assumption for the core needs a comparison theorem that uses the fact that the conditional law of the core is close to log-concave.

The Three-Range Core-Constant Proposition and the table of the three stages

Three-Range Core-Constant Proposition. For a set of end values $\mathfrak{E}$, let $B_2(\hbar;\mathfrak{E}) := \sup_{8\le k\le 14}\sup_{(\alpha,\beta)\in\mathfrak{E}^2}\min_{(a,b)} M(a,b)/(1-c_{k,\alpha,\beta}(x_a,x_b))$ and $B_3(\hbar;\mathfrak{E}) := 2.186/(1-\bar{c}_{\ge 15}(\mathfrak{E}))$. Then for every $k\ge 1$ and $(\alpha,\beta)\in\mathfrak{E}^2$

$$C_P(\mu_k^{\alpha,\beta}) \;\le\; \max\{\varepsilon/\kappa(7),\; B_2(\hbar;\mathfrak{E}),\; B_3(\hbar;\mathfrak{E})\} \quad (11)$$

Proved here (split into cases by k and apply the three steps) Lean `three_stage` (assumption: the upper bound of each stage).

Table 3 Core length and stage (ends sampled in $[0,x_c]$; triples are $\hbar = 3\cdot 10^{-3}/10^{-3}/3\cdot 10^{-4}$)

Stage	k	Tool	Grade	Upper bound	Lower bound
1	≤ 7	Short-Core Convexity Lemma (convexity)	Proved here + Cited (Bakry–Émery on convex domains)	≤ 9.18 (independent of $\hbar$ and the ends)	—
2	8–14	Two-Block Lemma + two-point maximal correlation	Proved here + Reading	$22.1/30.5/66.4$	$8.39/17.3/38.5$
3	≥ 15	Box-Reduction Inequality for Long Cores + alternating maximal correlation	Proved here + Reading + Assumption (the alternating maximal-correlation assumption for the core)	≤ 4.70 ($\bar{c}$ is a measurement of a lower bound)	—

From Table 3, $\sup_k C_P(\text{core}) \le 22.1/30.5/66.4$ Reading Lean `three_stage_3em4` (assumption: the measured values of the medium-core step and the long-core step). The ratios of upper to lower bound are $2.6/1.76/1.72$. The input of the medium-core step (the two-point maximal correlation) is a product of matrices and a second singular value, so it is of a type that can be put on interval arithmetic; but it needs a paper estimate of the difference between the lattice measure and the continuum measure, and the cost of running it is estimated at the order of 10^3 CPU hours (not yet). In the long-core step, what is measured is a lower bound, and there is no paper for the upper bound.

06

The set of ends — what is covered, and how to pay for bistability

Table 3 took the end values as samples in $[0,x_c]$. A core is a **maximal** interval of sites in $(0,x_c)$, so the neighbouring sites outside it actually take values in $(-\infty,0]\cup[x_c,\infty)$. We separate which ends are needed in which construction.

The core of the sector framework — ends only on the side of the well

The core of the sector framework (23-09) is defined as having both end values on the side of the well ($[x_c, \infty)$ in the direction of this chapter). So ends beyond the top do not enter there Proved here (by definition) Lean `p5_end_not_negative` (assumption: $x_c = 0.89$), and the set of ends has no hole. In the stationary chain, a fraction $1 - e^{-0.63/\hbar}$ of the mass of runs of length k is of this type, and the minimiser on the reading at $\hbar = 0$ is a single shape with every site pressed against the wall x_c Reading .

The core on the box side — ends beyond the top, and the wall of conditioning

In the core on the fast side of the Gap-Inside-the-Box Proposition (the core after splitting by the configuration of kinks), the outside neighbour can take negative values beyond the top. There, two local minimisers at $\hbar = 0$ appear in cores with $k = 9, 10$, the barrier is $\Delta S \in [1.1 \cdot 10^{-4}, 2.5 \cdot 10^{-3}]$ (depending on the end values), and the lower bound of CP for $k = 9$ with ends $(-0.035, -0.035)$ is $13.9/44.6/526$, growing in the manner of $e^{\Delta S/\hbar}$ Reading .

- **Both minimisers sit on the wall of conditioning.** One is a bump spanning the core interval as it is; the other has the zeros at both ends moved inwards by one site each. Because we conditioned the core interval to be "exactly this interval", a wall stands in the direction in which the zeros want to move, and the two types compete. The Peierls–Nabarro barrier of a discrete kink on this lattice is 10^{-12} or less, a different order from the bistability barrier $0.5\text{–}2.0 \cdot 10^{-3}$ Reading Lean `pn_vs_bistab` (assumption: measured values). **The bistability is not physical metastability; it is made by the choice of conditioning.**
- **Cutting by the binary of the bump brings the fibres back.** Splitting by the binary Y_3 of whether a site x_m near the top is at or above the threshold θ^* (whether there is a bump), the CP of each fibre returns, by the Two-Block Lemma (the same proof applies to products of intervals), to upper bound $25.8/46.2/101$ and lower bound $8.9/17.4/32.8$, the same order as the medium-core step of Table 3 Reading .
- $e^{\Delta S/\hbar}$ **only moves.** In exchange, the Poincaré constant of the marginal of the binary Y_3 takes on $e^{\Delta S/\hbar}$, with $\mathrm{Var}(\mathbb{E}[f \mid Y_3]) \geq 470\,\mathcal{E}(f)$ $(3 \cdot 10^{-4})$ Reading Lean `y_side_k9_3em4` (assumption: measured values). Cutting does not remove the barrier; it takes the form of transfer of 23-10 transfer type. Extending the constant of the core to the actual set of ends while keeping it $O(1)$ cannot be done by this split.

Paying with the margin of the action barrier — the row of the core action barrier

In the Gap-Inside-the-Box Proposition the constant of the core enters C_{loc}, and appears in K_4 only in the form $C_{\mathrm{loc}} \cdot D/(C\xi)^2$ ((5)). $D/(C\xi)^2$ is of the order of $e^{-2S_0/\hbar}$,

so the constant of the core need not be $O(1)$; it suffices that the action barrier is smaller than $2S_0$. We put this as an assumption row.

The row of the core action-barrier assumption. There are $c_*, p \geq 0$ and $\Delta S_* < 2S_0$ such that, for the conditional measures of the core on the box side and of the windows containing it (the core, its two neighbours and m sites outside, with arbitrary outer ends), $C_P \leq c_* \hbar^{-p} e^{\Delta S_*/\hbar}$ (for small $\hbar$) Assumption .

Reading. On the reading at $\hbar = 0$ (numerical minimisers checked for stationarity and positive definiteness, and the height of the connection bracketed from above and below), the sup of the depth of non-global minimisers over the range $k = 8$–14, $m \leq 12$, outer ends $[-1.3, -0.01]$ is $\Delta S_*^0 \in [9.6 \cdot 10^{-3}, 1.4 \cdot 10^{-2}]$; its ratio to $2S_0 = 4/3$ is $\leq 1.05 \cdot 10^{-2}$, a margin of about 95 times Reading Lean `measured_ratio` (assumption: the measured upper bound $\Delta S^0 \leq 0.01401$). It is 5–8 times deeper than the value with the ends fixed ($1.77 \cdot 10^{-3}$), and the sup is attained where moving the outer ends makes the two types degenerate. The lower bound of $\hbar \ln C_P$ approaches ΔS^0 from below ($0.97 \Delta S^0$ by a fit), but the prefactor $\hbar^{-p}$ of the upper bound has not been measured.

Proposition (the local term vanishes). Under the core action-barrier assumption and the reading of ξ, $D/(C\xi)^2 \leq d\, e^{-2S_0/\hbar}$, for any $\delta > 0$

$$C_{\mathrm{loc}} \cdot \frac{D}{(C\xi)^2} \;\leq\; c_* d\, \frac{p!}{\delta^p}\, e^{-(2S_0 - \Delta S_* - \delta)/\hbar} \qquad (12)$$

Proved here Proof. From $e^x \geq x^p/p!$ ($x = \delta/\hbar > 0$), $\hbar^{-p} \leq (p!/\delta^p) e^{\delta/\hbar}$. Multiplying this by the two assumptions gives $e^{\Delta S_*/\hbar} e^{-2S_0/\hbar} e^{\delta/\hbar}$, which is (12). ∎ Lean `cloc_term_poly`, `cloc_term_vanishes` (assumptions: the core action-barrier assumption, the reading of ξ, $\Delta S_* < 2S_0$); negative control `no_vanish_if_no_gap` (if $\Delta S_* \geq 2S_0$, the estimate does not vanish).

If δ is taken smaller than $2S_0 - \Delta S_*$, the right-hand side of (12) goes to 0 as $\hbar \to 0$, and the measured values leave a margin of $2S_0 - \Delta S_*^0 \geq 1.319$. **The bistability of the core on the box side does not affect the coefficient K of the First-Step Upper-Bound Proposition, whether one conditions or not** (on the core action-barrier assumption and the reading at $\hbar = 0$). Cores with negative ends appear in the sector framework inside the sector of kink positions (the bridge), and their mass in the stationary chain has the rarity $e^{-1.13/\hbar}$ ($k = 9$) Reading .

07

The list of remaining rows

Table 5 The rows remaining in the box-reduction condition, the gap-inside-the-box condition and the core

Row	What remains	Present support	Grade
Row of common premises	Uniqueness of the measure at $T = \infty$, the nearest-neighbour Markov property, extension from local functions, regularity of the conditional measures and the coordinates of kinks	That the kernel of the transfer operator is positive (the original source for the version on $\mathbb{R}$ not yet checked)	Assumption
Alternating maximal-correlation assumption for boxes	The alternating maximal correlation between boxes $c_{\mathrm{alt}} < 1$ is uniform in $\hbar$ and the boundary values (a paper on the mixing of boxes)	The reading 0.731 of the two-state chain ($C = 2$), the form of the Closed Formula for the Alternating Maximal Correlation	Assumption
Uniformity in the boundary values	The $\sup$ over boundary values: near the top (the free-end type) and far away (steep descent)	The reading of c_{ff} for free ends; far away, only the prospect that the gap does not vanish	Assumption
Cross-term uniformity assumption	The cross term $\mathcal{E}_Y(\mathbb{E}[f \mid Y]) \le (1 + \chi)\mathcal{E}(f)$, with χ uniform	None (the type of a two-scale inequality)	Assumption
Kink-gas gap assumption	That the reduced kink gas falls in the Glauber type, and the loss at free ends	The closed formula of the Ising model and diagonalisation	Assumption
Segment local Poincaré assumption	Local Poincaré for segments with end values	The Six-Node In-Phase Poincaré Proposition in the ring version (23-06)	Assumption
Saddle-tube Poincaré assumption	Poincaré for the tube, uniform in the tube length $\le C\xi$	None	Assumption
Mechanisation of the medium-core step	Enclosing the two-point maximal correlation in interval arithmetic, and a paper on the difference between lattice and continuum	Floating-point transfer (cost estimated at the order of 10^3 CPU hours)	Reading
Alternating maximal-correlation assumption for the core	An upper bound for $\bar{c}_{\ge 15} < 1$ of the long-core step	Measurement of a lower bound ≤ 0.535. Does not reduce to two-point quantities (counterexample)	Assumption
Core action-barrier assumption	$C_P \le c_* \hbar^{-p} e^{\Delta S_*/\hbar}$ for the core on the box side and its windows, in particular the prefactor $\hbar^{-p}$ and windows with $k \ge 15$, $m > 12$	The reading at $\hbar = 0$, $\Delta S_*^0 \le 1.4 \cdot 10^{-2}$, and the lower bound of $\hbar \ln C_P$	Assumption

The construction of the steps of the box-reduction condition and the gap-inside-the-box condition itself ((1)–(5), (7)–(12)) is algebra for which elementary proofs are given, and what remains as assumptions are the rows of Table 5. There is still no $\hbar$ at which all the rows of the four conditions are in place together (23-05 § 08).

08

The table of the five grades — the rows of box reduction, the gap inside the box and the core

Table 6 The rows of this chapter ("—" in the range of $\hbar$ marks an assumption row that has not been shown at any $\hbar$; the numbers in the row column are the numbers of the dependency graph in § 09, and "—" marks a row not in the graph)

Row	Statement (one line)	Grade	Basis	Range of $\hbar$	Machine checking

[15]	Bistability of the core on the box side, the fibres of the binary of the bump, the marginal of Y_3	Reading	§ 06	Three points	`pn_vs_bistab`, `y_side_k9_3em4` (assumption: measured values)
[08]	Core action-barrier assumption	Assumption	§ 06	—	—
—	$\Delta S_*^0 \le 1.4 \cdot 10^{-2}$, ratio to $2S_0 \le 1.05 \cdot 10^{-2}$	Reading	§ 06 (reading at $\hbar = 0$)	$\hbar = 0$	`measured_ratio` (assumption: the measured upper bound)
[30]	The local term vanishes (12)	Proved here	Proof in § 06	$\hbar \to 0$	`cloc_term_poly`, `cloc_term_vanishes` (assumptions: [08], [11], $\Delta S_* < 2S_0$)

The "Proved here" rows of Table 6 are either algebra on top of assumption rows or general inequalities whose proofs are given in the text. They do not mean that the box-reduction condition and the gap-inside-the-box condition have been shown, nor that the constant of the core has been bounded unconditionally.

09

The dependency graph

The format is the same as 23-05 § 07: **the numbers to the right of "⟸" are always smaller than the number on the left**.

                         Lean H3_H4_compose
```

How to check. The rows with ⟸ are [18] ([01][17]), [19] ([02][16][18]), [20] ([01]), [22] ([10]), [23] ([01]), [24] ([16][22][23]), [27] ([01][16][17][22]), [28] ([07][13][14][22][24][27]), [30] ([08][11]), [31] ([03]–[06][09][17][20][21]), [32] ([28][30][31]) and [33] ([19][32]); in every one the numbers on the right are smaller than the one on the left, and there is no circle.

What to read. The conclusion [33] depends on all the assumption rows [01]–[08] ([07] [08] through the constant of the core [28] and the local term [30]). [12][15][25][26][29] are premises of no conclusion; they are rows that explain the reading of values, the nature of the bistability, the form of the alternating correlation and the drawing of the line at the ends. The range of $\hbar$ of [28] is "three points" because the values of the medium-core step and the long-core step are readings at three values of $\hbar$; the form of (11) itself does not depend on $\hbar$.

We also check that the statements of the assumption rows do not contain the quantity of the conclusion. The quantity of the conclusion is $C_P(\mu)$ of the whole measure at $T = \infty$. [02][07] are quantities of correlation, [03][04][08] are constants of scraps, tubes, and cores and windows, [05] is a constant of the reduced gas, [06] is a comparison of forms, and [01] is a property of the measure; none of them contains $C_P(\mu)$.

Correspondence with the graph of 23-05. In the integrated graph (23-12), the leaves [02] (the segment local Poincaré assumption), [03] (the saddle-tube Poincaré assumption), [05] (the kink-gas gap assumption), [06] (the cross-term uniformity assumption) and [07] (the alternating maximal-correlation assumption for boxes) of 23-05 are the same nodes as [03][04][05][06][02] of this chapter; [04] (the core Poincaré uniformity assumption) of 23-05 is replaced by [28] (the Three-Range Core-Constant Proposition) and [30] (the local term) of this chapter, and the leaves move to [07][08]. [11] (the variance of the product of even boxes), [14] (the Box-Reduction Proposition), [15] (the Gap-Inside-the-Box Proposition) and [16] (the First-Step Upper-Bound Proposition) of 23-05 are [18], [19], [31] and [33] of this chapter.

10

To the next chapter

23-12 joins the dependency graphs of 23-05 to 23-11 into one, puts every row into one table of the five grades, and shows in a figure of bands that there is still no $\hbar$ at which all rows are in place. This part places the diffusive-relaxation-time assumption at the axis of the study, and this chapter was the step that put the box-reduction condition and the gap-inside-the-box condition of its first step in the form of propositions. The

viewpoint of carrying the form of box reduction over to the four-dimensional lattice or to other quantities is taken up in Part 24 (24-03).

What this chapter can say

Can say	Cannot say
Proved here The product over boxes (2) and its proof, the Box-Reduction Proposition (3), the Gap-Inside-the-Box Proposition (5), the Short-Core Convexity Lemma, the End-Reduction Lemma and the Two-Block Lemma, the Box-Reduction Inequality for Long Cores, the ratio of the Closed Formula for the Alternating Maximal Correlation, the example that does not reduce to two-point quantities, the construction of the Three-Range Core-Constant Proposition, the local term vanishes (12) Lean (algebra)	The box-reduction condition and the gap-inside-the-box condition. The rows of the alternating maximal-correlation assumption for boxes, the cross-term uniformity assumption, the kink-gas gap assumption, the segment local Poincaré assumption, the saddle-tube Poincaré assumption, the alternating maximal-correlation assumption for the core and the core action-barrier assumption
Reading The size of ξ, the values of c_{alt}, c_{ff} and K, the constant of the core $22.1/30.5/66.4$, the bistability barrier and the 95-fold margin	Mechanisation of the upper bound for the constant of the core, uniformity as $\hbar \to 0$, the prefactor of the core action-barrier assumption
Cited Bakry–Émery on convex domains, the singular-value representation of maximal correlation, maximal correlation of Gaussians, the type of the box dynamics	A $\hbar$ at which all rows of the four conditions are in place

The rate of two-block Gibbs sampling (the framework of the Closed Formula for the Alternating Maximal Correlation, and the case of pieces of length 1)	Cited	G. O. Roberts, S. K. Sahu, J. R. Stat. Soc. B 59 (1997) 291–317, doi:10.1111/1467-9868.00070 (the Two-Block Gibbs-Sampler Rate Theorem (Theorem 5), Corollary 3, § 2.4, checked in the text); M. K. Pitt, N. Shephard, J. Time Series Anal. 20 (1999) 63–85 (Theorem 1; checked in the text of the 1996 working-paper version, the published version not cross-checked); M. Mider, P. A. Jenkins, M. Pollock, G. O. Roberts, arXiv:2009.10440v2 (2022) (Theorem 2, Corollary 2, checked in the text). The bibliography on the line Jacobi side has not been cross-checked.
The Efron–Stein inequality	Proved here	B. Efron, C. Stein, Ann. Statist. 9 (1981) (bibliographic; the proof is given in § 03).
Glauber dynamics of the one-dimensional Ising model	Assumption	R. J. Glauber, J. Math. Phys. 4 (1963) 294–307 (bibliographic only; the values are readings by diagonalisation on the lattice).
Eyring–Kramers type (the barrier and $\hbar \ln CP$)	Cited	G. Menz, A. Schlichting, Ann. Probab. 42 (2014) (the statement in the case without boundary checked in the text; the version for minimisers on a wall has not been obtained, and the core action-barrier assumption is an assumption row).
Algebra of the construction	Proved here, Lean	Proofs in the text. `two_proj_var`, `box_two_family`, `box_shift_average`, `H4_two_scale`, `H4_gap_form`, `H3_H4_compose`, `lemma_BV`, `tb_far`, `tb_adjacent`, `three_stage`, `gauss_mode0`, `cloc_term_poly`.
Numbers	Reading	Floating point for the transfer operator (two routes: the power method in the logarithmic domain and dense eigenvalues), diagonalisation of the Ising model on the lattice, polynomial Rayleigh–Ritz, numerical minimisers and heights of connection at $\hbar = 0$. Interval arithmetic is not used.

Terms used in this chapter — box dynamics (reduction to the box), even and odd boxes, averaging over shifts, maximal correlation, alternating maximal correlation, the Two-Projection Lemma, the Efron–Stein inequality, the reduced kink gas, free end, cross term, core, the threshold of convexity, the Two-Block Lemma, reduction to the ends, the Three-Range Core-Constant Proposition, the wall of conditioning, the binary of the bump, the action barrier. Their meanings are in the A-02 glossary.

Next chapter: 23-12 The integrated table and the dependency graph — puts every row of the four conditions into one table of the five grades, and confirms that the dependency graph of the steps has no circle.

The integrated table and the dependency graph

> This chapter is this book's own investigation. § 01 and § 08 are guide material; § 06 and § 07 are a map of open questions.

What this chapter shows — For the four double-well conditions of the first step, we put every row of the tables of the five grades of 23-05, 23-06, 23-07, 23-09 and 23-11 into one table, and renumber the five dependency graphs and join them into one. We put it in a form in which readers can check by the rule of numbering (the number of a premise is smaller than the number of a conclusion) that there is no circle, and we see in figures where the computer-assisted rows lie on the road to the conclusion, and that there is still no $\hbar$ at which all rows are in place together.

Prerequisite chapters — 23-05 § 07 (the format of the dependency graph), 23-06 § 05, 23-07 § 05, 23-09 § 07, 23-11 § 08 (the table of each condition), 23-00 § 01 (the labels of the five grades).

Said first — The level is [Y3]. The integrated table is a map of "how far things are shown, and where assumption begins"; it is not a ruler for measuring progress. This part places the diffusive-relaxation-time assumption at the axis of the study, and this chapter lays out on one sheet the whole construction of its first step.

The order of this chapter

1. How the integrated table is made — the rules for putting five tables on one sheet, how identical rows are merged, the meaning of the columns
2. The integrated table — every row of the first step (Table 1), and the number of rows per grade (Table 2)
3. The dependency graph — the trunk (Figure 1) and the whole, how to check that there is no circle, and that the assumption rows do not contain the quantity of the conclusion
4. The family of bridges — the one-dimensional and multi-dimensional one-sided bridges
5. The position of the computer-assisted rows — what is on the road to the conclusion and what is not
6. There is no $\hbar$ at which all rows are in place — bands of the range (Figure 2, Table 4), and what is needed to bring them into line
7. The rows needed to reach the power statement — two ways of supporting the row of the core (Table 5)
8. A note on how to read it — a map, not a fraction

01

How the integrated table is made — putting five tables on one sheet

The claim of the first step is the Double-Well Relaxation-Time Upper-Bound Proposition (23-05 § 04): on the four double-well conditions and the premise rows, $C_P \le K\xi^2 S_0/\hbar$, and hence the double-well relaxation-time power statement, $\ln C_P / \ln \xi \to 2$. Each of the four conditions is written in its own chapter as a table of rows in the five grades (Proved here, Cited, Computer-assisted, Reading, Assumption) and as a dependency graph of numbered nodes. In this chapter we put them on one sheet by the following rules.

1. **Count by rows.** The unit is each row of the tables, not the name of a condition (whether the in-phase local Poincaré condition is "closed"). This is because it is usual for rows with proofs and assumption rows to be mixed within one condition.
2. **Make identical rows one.** When the same statement appears in two chapters, we make it one row and write the nodes of both chapters in the source column. For example, [14] of 23-05 and [19] of 23-11 are both the Box-Reduction Proposition, and the window log-Sobolev threshold row of 23-07 and [06] of 23-09 are both the remaining single proposition (the Window Log-Sobolev Threshold Proposition). The core Poincaré uniformity assumption of 23-05 ([04]) is supported in 23-11 by the pair of the Three-Range Core-Constant Proposition and the local term, and in 23-07 and 23-09 by the lower bound of the core on the sector side, so we made it one node with an "or" of the two ways of support.
3. **Rows left out.** The rows of the list of detour plans (23-10) are not included, because none of them is a premise of any conclusion of the present construction. Of the rows of 23-04, the uniqueness of the measure is included in the row of common premises, and the remaining spectrum of the fluctuation operator (of Pöschl–Teller type) is included as a single explanatory row.
4. **Line up the family of bridges.** The One-Dimensional One-Sided Bridge Proposition (23-04 § 04) and the one-sided bridge (23-01 § 06) are the one-dimensional and multi-dimensional versions of the same bridge, "the relaxation time of the path measure is at least the square of the correlation length", so we included them as a family of adjacent nodes (§ 04). The other rows of Table 8 of 23-01 (the relaxation-time upper-bound assumption, the relaxation-time lower-bound assumption and the rereading of mass, the chain, the version with discrete time, the infinite-volume step) do not enter the road to the conclusion of the first step, so they stay in the graph of 23-01.

The columns of Table 1 are as follows. **No.** is the number of the node in the dependency graph of § 03; **Grade** is the label of the five grades; **Range of $\hbar$** is what the row speaks about (nodes, window, three points, independent of $\hbar$, $\hbar \to 0$, or "—" for not shown at any $\hbar$); **Condition** is which condition the row belongs to; **Premise of which conclusion** gives the numbers of the nodes that take the row as a direct premise, and whether following the edges of implication reaches the final conclusion (the double-well power statement); **Source** gives the tables and graph nodes of each chapter. Machine checking (Lean theorem names and assumptions) is placed under each row of the graph in § 03.

02

The integrated table — every row of the first step

Table 1 is divided into five blocks by grade (within a block, in the order of the graph numbers). The smaller the number, the more it is a leaf (Assumption, Cited, Computer-assisted, Reading); the larger, the more it is a step of the construction; the last, [111], is the double-well power statement.

Table 1 The integrated table (every row of the first step. Numbers are the node numbers of the dependency graph in § 03, and the order of the table is the same as the graph. "To the double-well power statement" is whether following the edges of implication from the row reaches the conclusion [111])

No.	Content (one line)	Grade	Range of ħ	Condition	Premise of which conclusion	Source (chapter nodes)
Assumption	**Assumption rows (put without proof) (30 rows)**					
[001]	Uniqueness of the measure at T=∞, Markov property, extension from local functions, the limit step, regularity	Assumption	—	Common	[071][073][077][081][106]. To the double-well power statement: reaches	23-05 [01], 23-11 [01], 23-04 § 01
[002]	Saddle-tube Poincaré assumption: Poincaré for the tube, uniform in tube length ≤ Cξ	Assumption	—	Saddle-tube condition	[075]. To the double-well power statement: reaches	23-05 [03], 23-11 [04]

No.	Content (one line)	Grade	Range of ħ	Condition	Premise of which conclusion	Source (chapter nodes)
[003]	Kink-gas gap assumption: the box gap of the reduced kink gas is of the Glauber type	Assumption	—	Gap-inside-the-box condition	[075]. To the double-well power statement: reaches	23-05 [05], 23-11 [05]
[004]	Closed formula for the gap of the Glauber box with fixed ends (original source bibliographic only)	Assumption	—	Gap-inside-the-box condition	Premise of no node. Part of the content of the kink-gas gap assumption (a reading not made an independent node in the graph)	23-11 Table 6 (the row of the Glauber box with fixed ends)

Counting the rows by grade gives Table 2.

Table 2 The number of rows of Table 1 (by grade; the breakdown in the condition column is counted by rows, not by the names of conditions)

Grade	Rows	Main content
Assumption	30	The row of common premises, the saddle-tube Poincaré assumption, the kink-gas gap assumption, the cross-term uniformity assumption, the alternating maximal-correlation assumption for boxes, the alternating maximal-correlation assumption for the core, the core action-barrier assumption, [012]–[016] extending the in-phase local Poincaré condition beyond the nodes, the premises of interval arithmetic, the inputs to the sectors, the remaining single proposition (the Window Log-Sobolev Threshold Proposition), the Scalar-Strand Proposition (with a table of assumptions) and others
Cited	10	Mobility of kinks, Bakry–Émery on convex domains, Muckenhoupt, MTP_2, Helffer's criterion, Brascamp–Lieb, Bochner, two representations of maximal correlation, the formula for stationary correlations
Computer-assisted	4	The margin of the in-phase local Poincaré condition (six nodes), the gap of two sites, the chain outside the window, the outer chain of the ring
Reading	19	How the correlation length grows, maximal correlations and the values of the steps of the core, the constants of the route of the window-constant numerics, the inner chain, the rarity exponent, the needed value, the coefficient K of the reduced model and others
Proved here	48	The assembly of the Six-Node In-Phase Poincaré Proposition, the Two-Projection Lemma, the product over boxes, the Box-Reduction Proposition, the Gap-Inside-the-Box Proposition, the Three-Range Core-Constant Proposition, the five stages of the sectors, the First-Step Upper-Bound Proposition, the One-Dimensional One-Sided Bridge Proposition, the algebra to the double-well power statement and others
Total	111	Breakdown by condition: in-phase local Poincaré condition 25, saddle-tube condition 57, box-reduction condition 7, gap-inside-the-box condition 9, common 1, family of bridges 7, conclusion 4, explanation 1

There are many rows of the saddle-tube condition in Table 2 because the rows of the core of the saddle-tube condition are built from two sides (the three steps on the box side and the five stages on the sector side); it does not mean that the saddle-tube condition is further along than the others. Conversely, there are few rows of the box-reduction condition because the construction of the Box-Reduction Proposition is short and the remaining assumption rows are gathered into one, the alternating maximal-correlation assumption for boxes. The number of rows counts where there are proofs and where assumptions remain; it does not measure how many of the four conditions are done (§ 08).

03

The dependency graph — joining five graphs into one

We turn the 111 rows of Table 1 into a list of nodes in the same format as 23-05 § 07. **The numbers of the premises to the right of "⟸" are always smaller than the number of the conclusion on the left.** There is just one node, [103] (the core Poincaré uniformity assumption), for which either of two ways of support suffices, and there we write "(...) or (...)". The numbers in both brackets are smaller than [103], so the rule works in the same way.

The whole is long, so we first give Figure 1, which extracts only the trunk. The numbers in the trunk are the same as in the whole graph.

Figure 1 The trunk of the integrated graph (of all 111 nodes, only the nodes on the main roads to the conclusion [111]; numbers as in the whole)

▶ Open the whole graph (111 nodes)

How to check. There are three steps by which readers can check for themselves. (1) Look one by one at the rows of the whole graph that have "⟸", and check that the numbers on the right are all smaller than the number on the left. At [103], look at both brackets. (2) If this rule is kept in every row, the number strictly decreases each time a premise is followed, so you eventually reach a leaf (a row without "⟸") and never return to the original row. That is all there is to "there is no circle". (3) If even one edge is found that does not keep the rule, it is a candidate for a circle of dependence, and the text has to name which step takes the conclusion of which step as a premise. In the graph of this chapter there was no such edge (all edges of the 111 nodes were checked by comparing numbers).

The assumption rows do not contain the quantity of the conclusion. The rule of numbering does not prevent the form in which the conclusion has slipped into the *content* of an assumption row (the form that puts the conclusion as a premise). So we read the statements of the assumption rows one by one. The quantities of the conclusion are three: the Poincaré constant $C_P(\mu)$ of the whole measure at $T=\infty$, the ratio $R = C_P/\xi^2$, and the power $\ln C_P / \ln \xi$. The 30 assumption rows fall into (i) properties of the measure ([001], [011], [018], [024]), (ii) constants of partial measures (scraps, tubes, cores, site windows: [002], [008], [012]–[016], [021], [022], [026]), (iii) quantities of correlation ([006], [007]), (iv) reduced models and comparisons of forms ([003], [004], [005]), (v) premises of computation and citation ([009], [010], [017], [019], [020], [023], [025], [096]), and (vi) the multi-dimensional version and explanatory rows ([027], [028], [029]); none of them contains $C_P(\mu)$, R or the power. The Poincaré constants contained in the rows of (ii) belong to the *partial* measures of scraps, tubes, cores and windows, not to the whole measure. This check is done by eye; machine checking does not replace it (23-13 § 05).

04

The family of bridges — the one-dimensional and multi-dimensional one-sided bridges

[106] the One-Dimensional One-Sided Bridge Proposition and [108] the one-sided bridge are the one-dimensional and multi-dimensional versions of a sentence of the same form. Both say "for the path measure,

the ceiling of the Rayleigh quotient of test functions local in time is the square of the correlation length", and from this come lower bounds for the relaxation time, $C_P \geq \xi^2$ (the One-Dimensional One-Sided Bridge Proposition) and $C_P \geq \kappa\xi^2$ (the one-sided bridge).

Table 3 The two versions of the family of bridges

Version	Statement	Premises	Role in this part
One-dimensional version [106]	One-Dimensional One-Sided Bridge Proposition: $R = C_P/\xi^2 \geq 1$ for the 0+1-dimensional double well	[001] (continuous time, $T \to \infty$; proof in 23-04 § 04)	The left inequality of (14). Gives the lower half of the double-well power statement without conditions
Multi-dimensional version [108]	One-sided bridge: $C_P \geq \kappa\xi^2$ on a finite spatial lattice	[028] assumption on the spectrum, [039] formula for correlations, [107] ground-state transformation (23-01 § 06)	[109] the lower half of the power for the multi-dimensional version (with the uniformity of the graduation [029]). Does not enter the road to the conclusion [111] of the first step

Putting the two side by side, one reads in the same form that the content of the diffusive-relaxation-time assumption is only "the upper half". The lower half is given automatically by the bridge (the one-dimensional version needs only the premise [001]; the multi-dimensional version needs [028][039] and the uniformity of the graduation [029]), and what the four double-well conditions take on is the upper half $C_P \leq K\xi^2 S_0/\hbar$. For the multi-dimensional version to apply to the four-dimensional Wilson measure, the rows of discrete time, infinite volume and graduation remain ([08][09][10] of the graph of 23-01).

05

The position of the computer-assisted rows — what is on the road to the conclusion and what is not

For the four "Computer-assisted" rows of Table 1, we look at the road to the conclusion [111].

- **[040] the margin, [041] the gap of two sites (in-phase local Poincaré condition).** There is a road [061] the continuum statement of the margin → [062], [063], [064] → [065] the algebra of rates → [066] the Six-Node In-Phase Poincaré Proposition → [068] the in-phase local Poincaré condition → [075] the Gap-Inside-the-Box Proposition → ... → [111]. But it is only the road on which they join the assumption rows [012]–[016] at [068]; there is no road that reaches the conclusion without passing through [068]. The computer assistance at the six nodes becomes a premise of the conclusion only when combined with the assumption rows extending it beyond the nodes, beyond the ends and to segments.
- **[042] the chain outside the window, [043] the outer chain of the ring (saddle-tube condition; the route of the chain outside the window and the route of the seam of the ring).** [042] → [100] S_W of the bridge → [102] A_W of the product form (Reading) stops there, and [043] → [101] S_W of the ring stops there. **Neither is on the road to the conclusion.** This is because the value of A_W of the product form lies outside the needed value that the remaining single proposition [026] asks for (23-09 § 03).

These two rows turn the contraction of the chains into inequalities over the whole window $\hbar \in [3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$, and they stand as results of computer assistance within the window in their own right (23-08). But in the present construction they are not used as premises of the conclusion. They enter the road when an upper bound for A_W not of the product form satisfies [026] and the ratio of the chain q enters that upper bound (23-07 § 06). Put the other way round, the number of computer-assisted rows does not show how close one is to the conclusion.

06

There is no $\hbar$ at which all rows are in place
