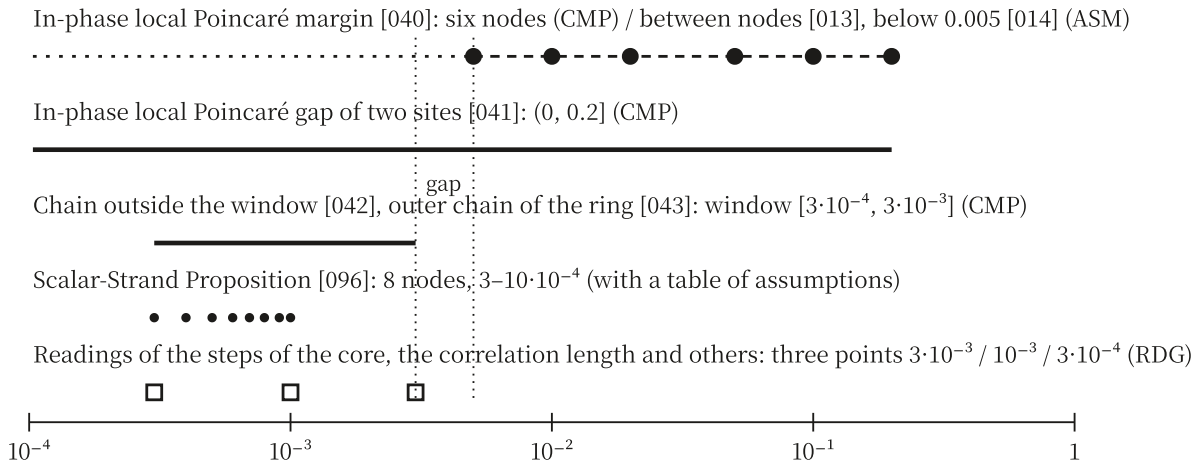
We overlay the range of $\hbar$ of each row on one number line (Figure 2). Assumption rows whose range is "—" ([002], [003], [005], [006] and others, most of the 30 assumption rows) are rows not shown at any $\hbar$, so they are not drawn; only the rows that have a range are drawn.

Figure 2 Bands of the range of $\hbar$ (the horizontal axis is $\log_{10}\hbar$, from 10^{-4} to 1). Solid lines and circles are computer-assisted, dashed lines are assumptions, squares are readings, and small dots are the node values of a proposition with a table of assumptions



There are three things to read from Figure 2. (a) The computer assistance for the margin of the in-phase local Poincaré condition is at six nodes with $\hbar \geq 0.005$, and the smallest node 0.005 is larger than the upper end of the window $3 \cdot 10^{-3}$ (the "gap" between the vertical dotted lines in the figure). (b) The Scalar-Strand Proposition is point values at 8 nodes at the lower end of the window, $[3 \cdot 10^{-4}, 10^{-3}]$, and a little beyond 10^{-3} the two conditions can no longer hold together in the same window (the reading that they do not hold together at $1.35 \cdot 10^{-3}$, 23-09 § 05). (c) The six nodes of the in-phase local Poincaré condition and the 8 nodes of the Scalar-Strand Proposition do not meet, and there is no node of the in-phase local Poincaré condition inside the window. Moreover, the assumption rows whose range is "—" (the saddle-tube Poincaré assumption, the kink-gas gap assumption, the cross-term uniformity assumption, the alternating maximal-correlation assumption for boxes and others) remain assumptions at every $\hbar$. Therefore **there is still not a single $\hbar$ at which all the rows of the four conditions are in place together.**

Table 4 Three kinds of range of $\hbar$ (do not mix them; four kinds together with the three points of 23-04 § 07)

Kind	Range	Which rows	Grade
The nodes of the in-phase local Poincaré condition	$\{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$	[040], [061]–[066]	Computer-assisted, Proved here (between the nodes and below 0.005, Assumption of [013] [014])
The computer-assisted window	$[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$ (25 subintervals)	[042], [043], [100], [101]	Computer-assisted, Proved here
The range of the Scalar-Strand Proposition	8 nodes in $[3 \cdot 10^{-4}, 10^{-3}]$ (no enclosure between the nodes)	[096]	Assumption (a proposition with a table of assumptions)
The three points of reading	$\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$	[044], [046], [047], [052]–[056] and others	Reading

What is needed to bring them into line. To bring them into line over the same range of $\hbar$, one of the following is needed.

1. **Extend the in-phase local Poincaré condition to $\hbar \leq 10^{-3}$.** That is, show row [014] ($\hbar < 0.005$). The type of computer assistance by subintervals cannot be used, because with a fixed ratio the number of subintervals, $\ln(0.005/\hbar)/\ln r$, grows without bound as $\hbar \to 0$; a paper argument uniform as $\hbar \to 0$ is needed (the small-ħ remaining item of 23-06 § 07).
2. **Extend the Scalar-Strand Proposition to $\hbar \geq 0.005$.** This corresponds to the route of the range of ħ (outside the window), a route decided to be outside the scope of this part (23-07 § 02). The form of the Scalar-Strand Proposition itself also stops at $1.35 \cdot 10^{-3}$.

Whichever is done, they only come into line over a fixed range. The double-well power statement is a statement about $\hbar \to 0$, so in the end every row has to be stated in a form uniform as $\hbar \to 0$, and computer

assistance in the window alone cannot reach it. Outside the window, paper asymptotics are needed. The assumption rows whose range is "—" remain at the stage before ranges are brought into line: first being shown at a single $\hbar$.

07

The rows needed to reach the power statement — two ways of supporting the row of the core

Following the graph from the conclusion [111] in the direction of the premises picks up all the leaves the conclusion needs. The only fork is the "or" at [103] (the core Poincaré uniformity assumption), so there are two required sets of leaves (Table 5). This applies to the graph of the first step the way of thinking that counts the sets that reach the conclusion when the assumption rows are put as "provisionally true" (for the list of walls on the side of the four-dimensional lattice, see 23-02 § 06).

Table 5 The leaves needed for the conclusion [111] (for each way of supporting [103]. In either set, every row listed is needed)

Grade of leaf	Support A: the core on the box side ([082] and [084])	Support B: the core on the sector side ([099])
Assumption	15 rows: [001], [002], [003], [005], [006], [007], [008], [009], [010], [011], [012]–[016]	20 rows: [001], [002], [003], [005], [006], [009], [010], [011], [012]–[016], [018], [019], [021], [022], [023], [024], [026]
Cited	[030], [031], [032], [033], [034], [035]	[030], [032], [033], [034], [035], [036]
Computer-assisted	[040], [041]	[040], [041]
Reading	[044], [046], [047]	[044], [055] (and [089], which depends on it)

What to read from Table 5. (1) The assumption rows common to both ways of support are the common premise [001], the rows inside the box [002][003][005], [006] between boxes, and [009]–[016] extending the in-phase local Poincaré condition. These remain whichever road is taken. (2) Support A puts the alternating maximal correlation of the core [007] and the action barrier [008] as assumptions, and needs the readings of the medium-core step and the long-core step, [046][047], to be replaced by upper bounds. Support B puts the remaining single proposition [026] and the inputs to the sectors [019], [021], [022], [024] and Barta's row [023] as assumptions. (3) Both sets still contain "Reading" rows. For the conclusion to become unconditional, every "Assumption" row has to be replaced by a proof, and every "Reading" row by an upper bound (Proved here, Cited or Computer-assisted).

08

A note on how to read it — a map, not a fraction

The integrated table is a map that shows where in the claim of the first step there are proofs and where assumptions remain. A proportion such as "48 of 111 rows are Proved here" does not show progress. There are two reasons. One is that the rows do not have equal weight (the single row [001] holds everything from the uniqueness of the measure to regularity, while the single row [074] is the algebra of a sum of two terms). The other is that many of the "Proved here" rows are algebra that takes assumption rows as input, and as long as one assumption row remains, the conclusion stays conditional (the same as the note after Table 2 of 23-05).

When reading it as a map, the following order helps. (a) Follow the trunk of Figure 1 from the conclusion [111], (b) look at the required set of leaves in Table 5, and (c) trace the "Assumption" rows in it from the source column of Table 1 to the text of each chapter. What remains and its cost are laid out row by row of this table in 23-15.

This part places the relaxation-time assumption at the axis of the study, and has built the upper half of the first step by dividing it into four conditions. This map, which puts the whole on one sheet, is also a map within that way of dividing. Other viewpoints are taken up in Part 24.

What this chapter can say

Can say	Cannot say
The integrated table putting the rows of the five chapters of the first step on one sheet (111 rows: Assumption 30, Cited 10, Computer-assisted 4, Reading 19, Proved here 48), and the dependency graph that keeps the rule of numbering on every edge (no circle)	Any of the 30 assumption rows. Hence the conclusion of the First-Step Upper-Bound Proposition and the double-well power statement of the first step
That the statements of the assumption rows do not contain the quantities of the conclusion $CP(\mu)$, R or the power (a check by reading the statements)	That the assumption rows are compatible with each other, or that none of them is false
The position of the four computer-assisted rows: the two rows of the in-phase local Poincaré condition become premises of the conclusion only on the road where they join [012]–[016], and the two rows of the saddle-tube condition are not on the road to the conclusion	Carrying the computer-assisted results outside the window or to $\hbar \to 0$
That there is no $\hbar$ at which all rows are in place together (by comparing ranges), and the two things needed to bring them into line	Either of the two things to bring them into line. Rows in a form uniform as $\hbar \to 0$
That there are two required sets of leaves for the conclusion (Table 5)	Which of the two ways of support is easier

Sources and reproduction

Item	Kind	Source, tool
The statement, grade and range of each row of Table 1	This book	23-05 Table 2, 23-06 Table 2, 23-07 Table 4, 23-09 Table 5, 23-11 Table 6, 23-04 Table 3, 23-01 Table 8. The original sources of the cited theorems are in the source table of each chapter
Edges of the dependency graph	This book	The "⟸" of each chapter's dependency graph copied as it is, with identical rows merged (the rules of § 01). The "or" at [103] comes from the notes on correspondence in 23-05, 23-07 and 23-11
Checking the rule of numbering, counting the rows, the required set of leaves	Text processing	A small script that, from data copying out the rows and edges of the table, compares the numbers on every edge, counts rows by grade, and collects leaves from the conclusion in the direction of the premises (not a mathematical computation)
Lean theorem names and assumptions	Lean	Under each row of the graph. The list of statements and the limits of checking are in 23-13

Terms used in this chapter — integrated table, dependency graph, node, leaf, trunk, the rule of numbering, circle of dependence, the form that puts the conclusion as a premise, family of bridges, way of support, required set of leaves, bands of the range of $\hbar$ (nodes, window, the range of the Scalar-Strand Proposition, the three points of reading). Their meanings are in the A-02 glossary.

Next chapter: 23-13 Lean statements and the limits of machine checking — looks, through the list of bundles and examples, at what machine checking guarantees, "the conclusion follows from the propositions as written", and what it does not guarantee (the truth of the assumptions, the encoding of the objects, closing by putting the conclusion into a definition, circles of dependence).

Lean statements and the limits of machine checking

> This chapter is a guide. § 01, § 02 and § 05 are established knowledge.

What this chapter shows — We confirm, with the list of bundles of the first step, the convention that what machine checking (Lean) guarantees is only that "the conclusion follows from the propositions as written (the list of assumptions)", and that it guarantees neither that the assumptions are true nor that the real numbers inside Lean represent physical quantities. We look, through examples with their sources withheld, at two types that cannot be detected even when `#print axioms` stays within the three standard axioms (putting the conclusion into a definition, and a circle of dependence), and we give a procedure by which readers can inspect statements themselves.

Prerequisite chapters — A-04 Lean and machine checking (the meaning of the label "Lean"), 23-12 § 03 (the dependency graph and the rule of numbering), 23-08 § 08 (assemblies that put the output of interval arithmetic as an assumption). For how to read Lean itself, see the Lean guide.

Said first — The level is [Y2]–[Y3]. § 01– § 02 and § 06 can be read at [Y2]. This part places the diffusive-relaxation-time assumption at the axis of the study, and Lean is used as a tool to check the algebraic steps of its construction. This chapter shows neither the mass gap nor the continuum limit.

The order of this chapter

1. What machine checking guarantees — the arrow from a list of assumptions to a conclusion (example: the composition of the Double-Well Relaxation-Time Upper-Bound Proposition)
2. The three axioms and `#print axioms` — the criterion of cleanness, why `native_decide` is not used
3. The bundles of the first step — the number of theorems in each bundle, what algebra it is, how the assumptions are put (Table 1), the side of the four-dimensional lattice (Table 2)
4. Assumptions next to theorem names — the discipline of reading, and the fact that the layer of interval arithmetic is outside Lean
5. Four limits — the truth of the assumptions, the encoding of the objects, putting the conclusion into a definition, circles of dependence (Table 3)
6. A procedure for readers to inspect for themselves — six questions
7. Translating conventions — places where the same letter or the same name refers to different quantities (Table 4)
8. How the bundles are divided — by article, paper and subject

---

01

What machine checking guarantees — the arrow from a list of assumptions to a conclusion

Lean is a system in which a mathematical statement is written as a type and its proof as a term of that type, and a small core (the kernel) mechanically checks that the proof matches the statement (Lean guide 01). The rows in this book labelled "`Lean`" refer to theorems that have passed that check. The label guarantees only one thing.

The convention of this book

What is guaranteed in a row labelled "Lean" is that **if all the assumptions written in the statement of the theorem hold, then the conclusion written there holds**. It is not guaranteed that the assumptions hold, that the symbols in the statement represent the quantities of the text, or that the statement means the same as the claim in the text.

As an example, we copy the statement of the theorem for the composition of the First-Step Upper-Bound Proposition (23-05 § 04 Step 3 (composition)).

```
theorem H3_H4_compose (CP Cbox n ca K4 C ξ D hbar S0 : ℝ) (hn : 0 < n) (hca : ca < 1)
    (hh : 0 < hbar) (hS : 0 < S0) (hD : D = hbar / S0)
    (hH3 : CP ≤ (1 + 1 / n) * Cbox / (1 - ca)) (hH4 : Cbox ≤ K4 * (C * ξ) ^ 2 / D) :
    CP ≤ (1 + 1 / n) * K4 * C ^ 2 / (1 - ca) * (ξ ^ 2 * S0 / hbar)
```

How to read it. Everything in the brackets of the first line is a real number (`ℝ`); `CP` and `ξ` are just real numbers with names. `hH3` takes the conclusion of the Box-Reduction Proposition, $C_P \le (1+1/n)C_{\mathrm{box}}/(1-c_{\mathrm{alt}})$, and `hH4` the conclusion of the Gap-Inside-the-Box Proposition, $C_{\mathrm{box}} \le K_4(C\xi)^2/D$, as **assumptions**. What the theorem checked is the algebra by which (13) $C_P \le K\xi^2 S_0/\hbar$ follows from these two and $D = \hbar/S_0$. That `CP` is the Poincaré constant of the path measure at $T=\infty$, and that the conclusions of the Box-Reduction Proposition and the Gap-Inside-the-Box Proposition actually hold (that is, the four double-well conditions and the premise rows), are outside Lean.

This character of "only the arrow" is not a weakness but a premise of how it is used. Many of the "Proved here" nodes in the dependency graph (23-12 § 03) are algebra that takes assumption rows as input, and Lean checks that this algebra has no copying errors or sign errors. Because what enters as an assumption is named in the statement, it can be cross-checked against the list of assumption rows (the integrated table).

02

The three axioms and `#print axioms`

This section summarises existing knowledge (the three axioms of Lean and #print axioms). The introduction is in A-04 § 04.

On top of the type theory of Lean's kernel, the standard toolkit adds three axioms: propositional extensionality `propext` (equivalent propositions are equal), soundness of quotients `Quot.sound` (equivalent elements are equal in the quotient), and choice `Classical.choice` (extracting an element from a proof of existence). Which axioms a theorem depends on is listed by the command `#print axioms theorem_name`.

In the bundles of this book, we put `#print axioms` for the main theorems at the end of each file, and our criterion of cleanness is that **every line of its output is a subset of the three axioms**. Using `sorry`, which skips a proof, adds `sorryAx` to the list, and declaring an `axiom` oneself adds its name, so this criterion is a mechanical confirmation that "the proof has no hole and no arbitrary axiom has been added". In every bundle of Table 1 (the "copy of the axiom output" column of Table 1; including the copies retaken on a second machine on 2026-10-09), we reread that there is not a single axiom name other than the three. Some theorems do not use `Classical.choice` among the three (for example, `tb_range` uses only `propext` and `Quot.sound`).

`native_decide`: why it is not used
`decide` checks a proposition decided by finite case analysis by computation inside the kernel. `native_decide` translates the same computation into a Lean program, runs it as machine code, and trusts the answer. It is fast, but in exchange the range of trust widens from the kernel to the translator and the execution environment, and that trust appears in the list as an additional axiom (depending on the version, an axiom with a different name appears for each declaration). In the bundles of this book we do not use `native_decide`, and we put the criterion of cleanness as "every line of the list is a subset of the three axioms". Looking for the presence or absence of a particular axiom name would miss things when the naming changes between versions.

03

The bundles of the first step — what algebra was checked

The Lean theorems of the first step are divided into files (bundles) by subject. Table 1 lists the main bundles in the order of the chapters that cite them in the text. "Number of theorems" is the number of `theorem` / `lemma` declarations in the file, and the column "Representative theorem" gives the theorem name with that theorem's assumptions in the same column.

Table 1 The main bundles of the first step (the number of theorems is the number of declarations. Copy of the axiom output: ○ = the output of `#print axioms` at the end remains separately, and we reread that every line is a subset of the three axioms. Includes the copies retaken on a second machine on 2026-10-09)

Bundle	Number of theorems	What algebra	Representative theorem (assumptions)	Chapter	Copy of the axiom output

Bundle	Number of theorems	What algebra	Representative theorem (assumptions)	Chapter	Copy of the axiom output
`LatticeGaugeOneScale`	12	The relaxation-time upper-bound assumption, the relaxation-time lower-bound assumption and the rereading of mass (the equality version)	`hup_is_gap_positivity` ($0 < m$, $CP = 1/m^2$, $CP \le K\xi^2$)	23-01	○
`LatticeGaugeHupBridge`	18	The one-sided bridge, the lower half of the power, negative controls	`hup_is_gap_positivity_of_lower` ($0 < m_{\mathrm{lat}}$, $\kappa/m_{\mathrm{lat}}^2 \le CP$, $CP \le K\xi^2$), `first_power_does_not_bridge` (negative control)	23-01	○
`LatticeGaugeDoubleWellTestbed`	7	The skeleton of the finite sum of the One-Dimensional One-Sided Bridge Proposition	`local_rayleigh_ratio_le_one` ($0 < m$, $a_k \ge m$, $c_k \ge 0$, $\sum c_k a_k > 0$)	23-04	○
`LatticeGaugeTwoScalePoincare`	8	Splitting of the variance, curvature of the convex core, values of the reduced two-state model, the band ratio of Glauber	`split_poincare_le` (the splitting formula, two local Poincaré inequalities, the mean difference, additivity of forms, non-negative constants)	23-04, 23-05	○
`LatticeGaugeDoubleWellKramers`	10	From the bracketing of the ratio to the double-well relaxation-time power statement	`power_H_of_kink_ratio` ($0 < K, s, \delta$, $1 \le R \le K/\hbar$, $s/\hbar \le \ln \xi$)	23-04, 23-05	○
`LatticeGaugeH1Assembly`	17	The algebra of rates of the Six-Node In-Phase Poincaré Proposition, the arithmetic of the margin at six nodes, Gershgorin on the ring	`H1_assembly` (seven named ones: decomposition, the fine side, Helffer's criterion, the margin, $0 < \lambda$, the crossing row, the condition on rates)	23-06	○
`LatticeGaugeCoarseSideUniform`	20	Arithmetic of the crossing row, the two-sided form of Muckenhoupt	`T4_paper_numeric` ($\lambda_c \ge 1.3 \times 10^{-4}$)	23-06	○

Bundle	Number of theorems	What algebra	Representative theorem (assumptions)	Chapter	Copy of the axiom output
`LatticeGaugeIntervalQfreeWindow`	150	The linear-fractional map of the Linear-Fractional Lemma, the identity of the tilt, from covering to window, recomputation of the rate-limiting cells	`win_qfree_window_le_of_interval_table` (the table of interval-arithmetic output)	23-08	○
`LatticeGaugeRingUnconditionedWindow`	20	Assembly of the window for the outer chain of the ring	`unc_window_lt_one_of_table` (the table of interval-arithmetic output)	23-07, 23-08	○
`LatticeGaugeRingInnerChain`	22	The ratio at the corner of the wall, S_W of the ring	`sw_inner_le` ($q_{\mathrm{in}} \le 13/10$, $q_{\mathrm{out}} \le 0.998888530$)	23-07	○
`LatticeGaugePartitionFramework`	14	The sector sum, the Gibbs step, composition and the closing condition	`comp_close` ($X > 0$, b, $A \ge 0$, $\ell > 0$, and the three inequalities of Barta, componentwise localisation and Bochner)	23-09	○
`LatticeGaugeRemVProxy`	23	Assembly of the Scalar-Strand Proposition	`path5_conditional` (with the remainder inequality, the proxy ratio, rarity and the arithmetic margin named)	23-09	○
`LatticeGaugeDetourKills`, `…2`	17, 16	The arithmetic of "the line that killed it" for the detour plans	Lemmas for each type (23-10 Table 4)	23-10	○
`LatticeGaugeBoxReduction`	23	The Two-Projection Lemma, even and odd boxes, averaging over shifts, positive and negative controls	`box_shift_average` (the two-family inequality for each shift, $C_{\mathrm{box}} \ge 0$, the sum over overlaps $\le \mathcal{E}$)	23-05, 23-11	○
`LatticeGaugeBoxGap`	18	The Gap-Inside-the-Box Proposition, the algebra of c_{kg}, the composition of the Box-Reduction Proposition and the Gap-Inside-the-Box Proposition	`H3_H4_compose` (the statement of § 01)	23-05, 23-11	○

Bundle	Number of theorems	What algebra	Representative theorem (assumptions)	Chapter	Copy of the axiom output
`LatticeGaugeCoreMixing`, `CoreMaxCorr`, `CoreThreeStage`	15, 20, 18	The three stages of the core (the Short-Core Convexity Lemma, the Closed Formula for the Alternating Maximal Correlation, the Two-Block Lemma, combining the three stages)	`three_stage` (the upper bound of each stage)	23-11	○
`LatticeGaugeCoreActionGap`	15	The vanishing of the local term, drawing the line at the ends	`cloc_term_vanishes` (the core action-barrier assumption, the reading of ξ, $\Delta S_* < 2S_0$)	23-11	○
`LatticeGaugeGlobalLyapunov`	21	The algebra of the Lyapunov criterion and the positive control of the one-dimensional Gaussian	`gauss1d_bbcg`, `gauss1d_equality` (no assumptions)	23-14	○

The theorems of Table 1 are all inequalities and equalities on real numbers, finite sums and sequences. There is no theorem that has measures, operators or spaces of paths as types. The bundle of interval arithmetic (most of the 150 declarations of `IntervalQfreeWindow`) recomputes the formula for the upper bound of the last step cell by cell in rational numbers; there are many declarations, but the content is arithmetic. The index of all bundles is shared with Appendix A-04.

The side of the four-dimensional lattice. The theorems of the roads tried on the four-dimensional lattice (23-02 § 07 Table 4), divided by the type of the object their statements speak about directly, are as in Table 2.

Table 2 The type of object and the character of the theorems on the side of the four-dimensional lattice (rows are theorems; the character symbols correspond to the classification of Table 4 of 23-02: R = reproof, A = arrangement, C = conditional, N = negative control, M = lattice theorem)

Type of object	Number of theorems	Examples
Real numbers (and natural numbers) only	23	`chain_band`, `drain_exponent`
Sequences, real functions	11	`S4_two_sided`, `conditional_scale_bound`
Sums over finite sets and finite groups	8	`intact_frac_le`, `meff_ge_of_corr`
Operators on an inner-product space	1	`tau_int_le`
Lattice gauge fields (quaternions, Haar measure)	3	`one_link`, `hess_gauge`
Total	46	Counted by character (41 rows, counting two paired theorems as one row): R 11, A 15, C 7, N 5, M 3

There are three theorems that have lattice gauge fields as a type, and there is no theorem about expectations, correlations or gaps of the Wilson measure. As for the correspondence of characters, "reproof, arrangement, conditional, negative control, lattice theorem" of Table 4 of 23-02 correspond one to one to R, A, C, N, M of this table.

04

Assumptions next to theorem names

In the text and tables of this part, when we write a theorem name, **we list the assumptions of that theorem in the same column** (example: `H1_assembly` (assumptions: seven named ones)). If only the theorem name is written, it is read at the stage of summary as "settled in Lean", and conditional algebra swells into an unconditional result. In the integrated table (23-12), too, we wrote the theorem names and assumptions under each node of the graph.

In the computer-assisted rows, the Lean column splits into three layers (23-08 § 08): (1) the algebraic core (monotonicity of the linear-fractional map, the identity of the tilt, the algebra from covering to window); (2) recomputation of the rate-limiting cells and of randomly chosen cells (not all cells); (3) the assembly that puts the table of interval-arithmetic output as an **assumption**

and derives the conclusion for the whole window. Interval arithmetic itself (interval evaluation of the map of a step, quadrature, invariant sets, the conventions of rounding) is outside Lean, and its correctness rests on cross-checks and control tests (23-08 § 07). The label of a theorem that puts the table as an assumption is read as "if the output of interval arithmetic is correct, the conclusion for the whole window is correct as algebra".

05

Four limits — what cannot be detected even within the three axioms

Even for a theorem that meets the criterion of cleanness (§ 02), the following four are not guaranteed. The first two restate the convention of § 01; the last two are types in which the way the statement is written itself empties the conclusion.

(1) The truth of the assumptions. A theorem does not prove a single step of its assumptions. If `hH4` of `H3_H4_compose` is false, the conclusion says nothing.

(2) The encoding of the objects. `CP` inside Lean is a real number with a name, and that it is the Poincaré constant of the path measure is a reading of the text. The check passes even if the same name refers to a different quantity in another bundle. For example, a theorem named `measured_ratio` exists in two bundles of the first step (`CoreActionGap` and `HierarchicalLink`), and they are statements about different quantities in different namespaces. A name is no guarantee of content.

(3) Putting the conclusion into a definition. If the desired property is written as it is inside a definition and that definition is taken as an assumption, the conclusion becomes a copy of the assumption, and the proof closes in one line. The following is pseudo-Lean showing only the type.

Putting the conclusion into a definition closes anything (pseudo-Lean, an example of the type)

```
def InSpectrum (E : ℝ) : Prop := E = 0 ∨ c ≤ E          -- write the desired property into the definition of "spectrum"
theorem gap (E : ℝ) (h : InSpectrum E) : E = 0 ∨ c ≤ E := h   -- just returns the assumption as it is
def massGap : ℝ := 1 / 2                                  -- put the value literally, and positivity closes too
```

All three lines pass the check, and the list from `#print axioms` is either empty or within the three axioms. Even so, "spectrum" is not tied to the spectrum of any operator, so there is no mathematical content. One document wrote one of the conjuncts of its main theorem in this type, and another as a number put literally. It is an example in which the theorem name contains "mass gap" and every check passes, yet the statement does not encode the object.

(4) A circle of dependence. Lean checks theorems one at a time. Even if theorem A takes the conclusion of B as an assumption and theorem B takes the conclusion of A as an assumption, both pass the check. Neither conclusion has been derived unconditionally, yet putting the two side by side makes it look "shown". The same holds when proofs are written in prose: one document put the final conclusion, that the gap is positive, as a premise of intermediate steps (clustering, uniqueness of the vacuum), "to be shown later". Drawn as a dependency graph, an edge goes back from a conclusion with a large number to a step with a small number, and the rule of numbering (23-12 § 03) is broken.

Table 3 The four limits, and how this book guards against them

Limit	Visible to the check?	How this book guards against it
(1) The truth of the assumptions	Not visible (assumptions are arguments)	Write the assumptions next to the theorem name (§ 04); count the assumption rows one by one in the integrated table (23-12 Table 1)
(2) The encoding of the objects	Not visible (it only gives names to real numbers)	State the types of the Lean objects in the text ("real numbers, finite sums" of § 03); translate conventions (§ 07); write, chapter by chapter, the correspondence between the quantities of the text and the symbols of the theorem statements
(3) Putting the conclusion into a definition	Not visible (stays within the three axioms)	Copy the theorem statement into the text and read the definitions back (questions 3 and 4 of § 06); give negative-control theorems (examples that collapse when an assumption is removed)
(4) A circle of dependence	Not visible (theorems are checked one at a time)	The rule of numbering of the dependency graph; checking that the assumption rows do not contain the quantity of the conclusion (23-12 § 03)

Negative-control theorems work as a guard against (3). For example, `no_bound_when_c_one` (if the two σ-algebras are the same, $c = 1$, the reduction to the box says nothing) and `first_power_does_not_bridge` (with the first power, the bridge cannot be built) show that the conclusion collapses when an assumption is removed, confirming that the assumption is not decoration but acts on the conclusion.

06

A procedure for readers to inspect for themselves — six questions

When reading a claim labelled Lean, ask the following six in order. They apply equally to the theorems of this book and to theorems of other documents.

1. **Cleanness.** Is every line of the output of `#print axioms` a subset of `propext`, `Classical.choice`, `Quot.sound`? If you do not have the output at hand, it is "unconfirmed".
2. **The list of assumptions.** Write out all the brackets before the colon in the theorem statement (the arguments whose types are propositions). Does a claim that the text calls "unconditional" still have propositional arguments?
3. **Trace back the definition of the conclusion.** Open the definitions of the names that appear in the conclusion (such as `InSpectrum`), and see whether they contain the same sentence as the conclusion. Are the assumption and the conclusion unfoldings of the same proposition?
4. **The type of the object.** Do the objects the claim should speak about (measures, operators, fields) appear as types in the theorem statement? If what appears is only real numbers, natural numbers and finite sums, the tie to the objects lies in the reading of the text.
5. **The direction of dependence.** If the claim joins several theorems, arrange as numbered nodes which theorem takes the conclusion of which theorem as an assumption, and see whether the numbers of premises can be placed smaller than the numbers of conclusions. If not, it is a candidate for a circle.
6. **Negative control.** Is an example given in which the conclusion collapses when one assumption is removed? If not, check for yourself whether that assumption acts on the conclusion.

Example. Applied to `H3_H4_compose` of § 01: (1) a subset of the three axioms; (2) the propositional arguments are the seven `hn`, `hca`, `hh`, `hS`, `hD`, `hH3`, `hH4`; (3) the conclusion is an inequality of real numbers and no tracing back of definitions is needed; (4) the objects are all real numbers; (5) `hH3` and `hH4` are the conclusions of the Box-Reduction Proposition and the Gap-Inside-the-Box Proposition, and in the integrated graph [072], [075] and [104] are smaller than [105]; (6) `no_bound_when_c_one` shows that at $c_{\mathrm{alt}} = 1$ the reduction to the box says nothing (`hca` is not decoration). The answer is "if the Box-Reduction Proposition and the Gap-Inside-the-Box Proposition hold, the inequality of the First-Step Upper-Bound Proposition follows as algebra", and no more.

07

Translating conventions — places where the same letter or the same name refers to different quantities

Lean theorems do not know the meaning of symbols, so the check passes even if the same letter refers to different quantities in different files. Table 4 translates the conventions inside the theorems into the notation table of this book (Appendix A-01) and writes discrepancies as discrepancies. The upper six rows are on the side of the four-dimensional lattice, the lower five on the side of the first step.

Table 4 Conventions inside Lean and the notation of this book

Quantity	Inside Lean	This book	Discrepancy
β	One-link integration $e^{\beta\langle u,M\rangle}$, $\langle u,M\rangle = \frac{1}{2}\mathrm{Re}\,\mathrm{tr}(UM\dagger)$	$\beta = 2N/g^2$	None ($\beta = 4/g^2$ at $N=2$). Against the convention of Shen–Zhu–Zhu, $\beta = 4\beta_{\mathrm{SZZ}}$
tr and angle	Link angle $U = e^{i\vartheta\cdot\sigma}$	$T^a = \sigma^a/2$, $U = e^{i\theta^a T^a}$	$\theta = 2\vartheta$, $C_P^{(\theta)} = 4C_P^{(\vartheta)}$. A constant factor, so it does not affect the power
a	`a` of `drain_exponent`	Lattice spacing	Lean's a is the reciprocal of the bookkeeping length, $1/\xi_{\mathrm{RG}}$
η	The static exponent, the exponent of susceptibility, the exponent of overlap	η_s and η_{dyn} separated by subscripts	Present (the same letter for three quantities)
κ	The one-loop slope, the coefficient of a model, the coefficient of the Casimir term, the contribution of faces sharing no edge	Only the one-loop slope $11/(3\pi^2)$	Present (the same letter for four quantities)
C_P (four dimensions)	A real number with a name	The Poincaré constant of Langevin. The normalisation is named	With the normalisations of the field A and the angle ϑ, $C_P^{(A)} = \beta C_P^{(\vartheta)}$
$\hbar$ and ε	`hbar` (a real number). The lattice spacing enters as a number	$\mathcal{E}(f) = (\hbar/\varepsilon)\sum_i \mathbb{E}\lvert\partial_i f\rvert^2$, $\varepsilon = \frac{1}{2}$	None. The conversion between the readings at $\varepsilon = 0.25$ and at $\varepsilon = \frac{1}{2}$ is not written (23-14 § 05)
The graduation of C_P for the core	C_P of the theorems of the stages of the core	23-11 uses the convention of $\mathcal{E}$, 23-09 the convention of $\hbar\int\lvert\nabla g\rvert^2$	$C^{(23\text{-}09)} = C/\varepsilon = 2C$ (23-11 § 05)

Quantity	Inside Lean	This book	Discrepancy
K	`K` of `power_H_of_kink_ratio`	K of the First-Step Upper-Bound Proposition and $K' = KS_0$	Lean's K is K' of the text (23-05 § 04 Step 5)
Theorem names	`measured_ratio`	—	Different theorems with the same name in two bundles ((2) of § 05)
Reading values	Numerical theorems such as `K_ff_C2`, `three_stage_3em4`	Reading	Arithmetic with measured values put as assumptions. The grade of the values stays "Reading" (it does not become "Proved here" through the Lean label)

08

How the bundles are divided — by article, paper and subject

The bundles (files) are divided by subject (one proposition and its lemmas). It is usual for the theorems cited by one chapter or article to span several bundles, and the "Chapter" column of Table 1 gives the correspondence. There are four disciplines for dividing them.

- **One subject per bundle.** Even mutually dependent subjects such as the Box-Reduction Proposition and the Gap-Inside-the-Box Proposition are put in separate bundles, and the composition goes into a bundle of its own. The boundaries between bundles become the boundaries between nodes of the dependency graph, and one can follow which bundle takes the conclusion of which bundle as an assumption.
- **`#print axioms` at the end.** At the end of each bundle we put `#print axioms` for the main theorems, and keep the output under the same name as the bundle (the "copy of the axiom output" of Table 1).
- **No internal names in names.** Bundle names and theorem names are given by mathematical content (`LatticeGauge…` followed by the name of the subject), and names visible to readers do not contain working names or names of people.
- **Decide the bundles handed to articles and papers.** When an article or paper cites theorems of some bundle, the list of the bundles containing the cited theorems is also placed on the article's side, together with the version of the bundles (the output of which check). If a bundle is later corrected, the list on the side of the citing article is corrected too.

This part places the diffusive-relaxation-time assumption at the axis of the study, and Lean was used for the algebraic steps of the construction of the first step. The viewpoint of doing proof checking in another form (for example, a formalisation that makes the objects themselves types) is taken up in Part 24.

What this chapter can say

Can say	Cannot say
`Lean` The theorems of the bundles of Table 1 pass machine checking in a form that makes the assumptions explicit as arguments. In every bundle of Table 1, every line of the remaining `#print axioms` output is a subset of the three axioms	The truth of the assumption rows. A check of reading Lean's real numbers as quantities of the path measure itself
The Lean theorems of the first step are all statements on real numbers, finite sums and sequences; there is no theorem that has measures or operators as types	A formalisation that makes measures and operators types
The four limits and how to guard against them (Table 3), the six questions for inspection	That a claim that has passed the six questions is true (the questions are necessary checks, not sufficient ones)
That the layer of interval arithmetic is outside Lean, and only the assembly that puts the table as an assumption is inside Lean	Formal verification of the implementation of interval arithmetic

Sources and reproduction

Item	Kind	Source, tool
The declarations and numbers of the theorems of the bundles	Lean	We read the declarations of the source of each bundle (Lean 4, Mathlib) and counted the `theorem` / `lemma` lines. Theorem names and assumptions are in each row of the text
Copy of the axiom output	Lean	We read the copy of the `#print axioms` output of each bundle and counted the absence of axiom names other than the three (`sorryAx` and others), after confirming with a control copy that contains such a name that it would be detected
The three axioms and `#print axioms`	Cited	J. Avigad, L. de Moura, S. Kong, S. Ullrich et al., "Theorem Proving in Lean 4", chapter Axioms and Computation

Item	Kind	Source, tool
The layers of type and the characters on the side of the four-dimensional lattice (Table 2)	This book	The count of theorems in 23-02 § 07 (the same 46 theorems)
Examples of the type that puts the conclusion into a definition and the type of a circle of dependence	This book	A reading of two external documents that claim a construction or a proof (the sources are withheld and only the types are written; no judgement is made on whether the documents are right or wrong)

Terms used in this chapter — machine checking, bundle, the criterion of cleanness, the three axioms, `#print axioms`, `native_decide`, encoding of the objects, putting the conclusion into a definition, circle of dependence, negative-control theorem, translating conventions. Their meanings are in the A-02 glossary.

Next chapter: 23-14 Reconciliation — the numbers of the record and the known numbers — lays out, row by row against the numbers of the record, the distance between each condition of the first step and the nearest known theorem, a summary of the bibliographic checks, and the known numbers used for positive controls.

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time reconciliation, distance to known theorems, bibliography · Kiichi, Shiori and Rin

Reconciliation — the numbers of the record and the known numbers

> This chapter is this book's own investigation. § 01 and § 07 are guide material; § 02 is established knowledge; § 05 is a map of open questions.

What this chapter shows — For each of the four conditions of the first step, how far the nearest known theorem reaches and where it stops. A summary of the results of checking the statements of the known theorems cited in the first step against original sources and secondary sources, and the types of discrepancy that had occurred before the check. We lay out, row by row, the known numbers (closed formulae) used as positive controls against the numbers of the record, and divide them into agreement, conditional agreement, disagreement and not comparable. The nineteen-row cross-check on the side of the four-dimensional lattice is kept as it is.

Prerequisite chapters — 23-05 § 05 (where known theorems reach), 23-12 (the integrated table), 23-13 § 07 (translating conventions).

Said first — The level is [Y3]. Numbers agreeing shows neither that the assumptions are true nor that the mass gap exists. Many of the numbers that agreed are checks that recompute known values by another road. This part places the diffusive-relaxation-time assumption at the axis of the study, and this chapter holds the numbers and tools used in its construction up against outside numbers and tools.

The order of this chapter

1. The conventions of reconciliation — four verdicts, and three things to align
2. Distance to known theorems — for each condition, the nearest known result and what differs (Table 1)
3. Summary of the bibliographic checks — the support of the main citations, and the types of discrepancy (Table 2)
4. The numbers of the record and the known numbers — cross-check against the closed formulae used as positive controls (Table 3)
5. Rows that cannot be compared — numbers with no counterpart to check against
6. The nineteen rows on the side of the four-dimensional lattice — one table of cross-checks (Table 4)

7. A way of reading dependency graphs learned from outside documents — two types

---

01

The conventions of reconciliation — four verdicts, and three things to align

There are four verdicts.

- **Agreement**: the same quantity compared under the same conditions agrees within the error or the digits shown.
- **Conditional agreement**: it agrees, but how it agrees depends on one choice (the lattice spacing, the box, the convention, the form of extrapolation).
- **Disagreement**: compared as the same quantity, it differs beyond the error. Even when the reason is known, we write disagreement.
- **Not comparable**: the quantities or conditions differ, and no counterpart to check against is found.

Before comparing, we align three things: the **convention** (the same CP changes value with the normalisation of the Dirichlet form, Table 4 of 23-13), the **conditions** (the lattice spacing ε, the boundary, whether inside or outside a model), and the **kind of number** (closed formula, computer-assisted upper bound, floating-point reading, lower bound of a family). Especially in the first step, the counterpart is often "a model whose answer is known by a closed formula"; agreement there is a check that the tool works correctly (a positive control), not a check of the claim on the double well.

02

Distance to known theorems — condition by condition

This section summarises existing knowledge (known criteria and theorems for Poincaré inequalities). The introduction is in 1-10 § 08.

Table 1 of 23-05 listed where known theorems reach for the Double-Well Relaxation-Time Upper-Bound Proposition as a whole. Table 1 divides it by condition, and writes in one line the nearest known result for each condition and what differs.

Table 1 The nearest known result for each condition (the grade is the grade of the row citing the known theorem; statements checked in the text)

Condition	Nearest known result	Where it reaches	What differs	Grade

Condition	Nearest known result	Where it reaches	What differs	Grade
The in-phase local Poincaré condition	Poincaré Version of Helffer's Criterion (Proposition 3.1 of Ledoux), Bakry–Émery on convex domains (Kolesnikov–Milman Theorem 1.2)	The two-scale construction of the chain on the coarse side and the bridge on the fine side, the convex core at the bottom of the valley	The inputs to the criterion (the margin, the gap of two sites) are values at each node of $\hbar$, and it gives no input uniform in $\hbar$	Cited
The saddle-tube condition (transport along the family of saddles)	Poincaré version of Eyring–Kramers (Menz–Schlichting Lemma 2.4, Theorems 2.9 and 2.12)	Asymptotics and prefactor of the gap between valleys of a Morse function	**Fixes the dimension**: the constants are not uniform in dimension, and a degenerate family of saddles such as the translations of a kink is outside the assumptions	Cited
The saddle-tube condition (same as above)	Eyring–Kramers for the stochastic Allen–Cahn equation on a fixed interval (Di Gesù–Le Peutrec, Brooks–Di Gesù)	Asymptotics of the gap with the length of the interval fixed short of the bifurcation threshold	**Excludes the family**: the regime in which the interval becomes infinitely long, and the family of translations, are stated by the authors themselves to be outside the scope	Cited
The box-reduction condition	The box dynamics of Glauber dynamics (Propositions 3.4 and 3.5 of Martinelli's lectures)	The type that bounds the whole gap by the box dynamics and the gap inside the box	Discrete spins, in the form of total-variation coupling. The rewriting into one dimension, L^2 and the form of maximal correlation is on this book's side (23-11 § 02)	Cited (type)
The gap-inside-the-box condition	The closed formula for the Glauber dynamics of the one-dimensional Ising model, diffusion of a single interface (Bertini–Brassesco–Buttà Theorem 2.1)	The formula for the gap of a box with fixed ends, the diffusion coefficient D of the position of a single kink	The former is for discrete spins, and that the reduced kink gas falls in that type is an assumption (the kink-gas gap assumption). The latter is a statement at the level of the process, not a statement on the box gap with many kinks	Assumption (the original source of the closed formula has not been checked), Cited

Condition	Nearest known result	Where it reaches	What differs	Grade
The whole (uniform in volume)	A criterion uniform in volume (Bauerschmidt–Dagallier Theorem 2.1)	Applies directly to the lattice of paths, an upper bound uniform in length	**Uniform in volume but doubly exponential**: the value is $CP \le e^{c\xi}$ ($c \approx 1.4 \to 1.8$, read at $\varepsilon = 0.25$, $\hbar = 0.4 \to 0.1$), and since ξ grows exponentially in $\hbar$, it is doubly exponential in $\hbar$. It does not reach the double-well relaxation-time power statement	Cited, Reading (values)
The whole (an analogous case of a theorem of the same type)	The gap of the dynamics of hierarchical $\lvert\varphi\rvert^4_4$ (Bauerschmidt–Bodineau)	A theorem of the same type as the diffusive-relaxation-time assumption: the gap vanishes with the same power as the free field (with a logarithmic correction)	**Hierarchical**: a model of nested boxes, neither the lattice model itself nor the path measure of the double well. Cited as evidence that a question of this type stands as mathematics (23-01 § 06)	Cited

From Table 1, the known tools lie in four places, "asymptotics between valleys with the dimension fixed", "a single kink", "an upper bound uniform in volume but coarse" and "a theorem of the same type in another model", and within the range searched we found no theorem that gives a sharp upper bound on a long path up to the diffusion time of the kink gas, ξ^2/D. No row can replace any one of the four conditions wholesale by a known theorem; they take the form of citing a step within a condition (a criterion, a type, a coefficient).

03

Summary of the bibliographic checks — support, and the types of discrepancy

We picked up every row in the assumption tables of the four conditions of the first step marked "cites a known theorem", and checked it against the original source or a secondary source restating the statement. 55 items were picked up, of which 26 are main items entering the columns of the condition tables directly. Table 2 gives where the 26 main items went.

Table 2 Where the 26 main citations went (level of checking. "Changed into assumptions" means renamed as an assumption row rather than a citation row)

Destination	Items	Content

Destination	Items	Content
Statement checked in the text of the original source	4	Poincaré version of Helffer's criterion (Ledoux), Bakry–Émery on convex domains and Brascamp–Lieb (by a single theorem of Kolesnikov–Milman), Sturm's oscillation theorem
Statement checked in a restatement in a secondary source	8	Muckenhoupt's bracket (in the form of Barthe–Roberto), correlation inequality for MTP_2 (Karlin–Rinott), the type of Lyapunov and local Poincaré, the Poincaré constant of the exponential distribution, IMS localisation, the bathtub principle, the maximal correlation of n steps of a reversible chain, maximal correlation of Gaussians
Proof given in this book (elementary)	7	Decomposition of the variance and the steps around it, the direction of min-max, the ground-state transformation (integration by parts), the lemma of two projections, the Efron–Stein type
Original source needs to be obtained	4	The Poincaré–Miranda theorem, regularity of the weighted Neumann operator on a box, stochastic monotonicity (Herbst–Pitt), the principal eigenvalue of a positive integral kernel on $\mathbb{R}$
Changed into assumptions	3	The cross term (cross-term uniformity assumption), the type of the kink gas (kink-gas gap assumption), Eyring–Kramers for minimisers on a wall (core action-barrier assumption)
Total	26	19 with support (the top three rows)

The 4 items that need to be obtained are counted in the integrated table as "Assumption" rows ([010], [024], part of [001] and others in 23-12 Table 1). The rule of this part is that citations that cannot be checked in the text of the original source do not go into "Cited" (23-00 § 01).

The type of discrepancy — one word of the setting. Between the record before checking and the original sources there were 15 discrepancies. 12 were reattributions that do not change the mathematics (citing the version for convex domains through another theorem, correcting attributions, correcting pages), and 3 needed rewriting of assumption rows. The 3 rewrites were (a) a row that had put regularity of eigenfunctions on a box up to the corners as "standard" (for a box with corners and an asymmetric weight it does not follow from the standard results, so it was split off as an assumption row), (b) a row in which the theorem number of the continuous version of monotonicity in the end values was unconfirmed (left in the row as unconfirmed), and (c) a row that used a logarithmic Sobolev lemma in uncentred form (the restatement of the original source is in centred form).

The discrepancies all arose from **one word of the setting** — whether there is a boundary, whether it is finite, whether it is centred. And they arose not in rows where the record wrote the source as "memory" but in rows where it wrote "standard". Rows written as "standard" have a weak motive to be checked. This is why the five grades of this part have no grade "standard". Every cited theorem is always assigned to one of "statement checked in an original or secondary source (Cited)", "proof given in this book (Proved here)" and "not checked (Assumption)".

04

The numbers of the record and the known numbers — closed formulae used as positive controls

The tools of the first step (criteria, the machinery of interval arithmetic, reduction to the box) were first applied to models whose answers are known by closed formulae, and applied to the double well only after confirming that they work correctly. Table 3 is the list of those cross-checks; the ratio is "record side ÷ known side".

Table 3 Positive controls and calibration of the first step (grades on the record side by label; row numbers continue after Table 4 of § 06)

#	Quantity	Record side	Known side	Ratio	Verdict	Conditions, notes
20	The best constant from applying the criterion of Lyapunov and local Poincaré (of BBCG type) to the one-dimensional Gaussian	Reading 5.828427 by scanning weights ($u = 0.41422$)	Closed formula $3 + 2\sqrt{2}$ ($u = \sqrt{2} - 1$)	1.000000	Agreement	6 digits. 8 digits in the dual form too. Lean `gauss1d_bbcg`, `gauss1d_equality` (no assumptions)
21	The true Poincaré supremum of the same model	Reading 4.4979 (400 finite elements), 4.4994 (800)	The value of the criterion $3 + 2\sqrt{2}$	0.77	Conditional agreement	The loss of the criterion is 1.30 times, and the direction (criterion $\geq$ true value) is right
22	CP of the pure Gaussian $V = x^2/2$ and the right-hand side of the Box-Reduction Proposition	Reading right-hand side 1.10–1.33 ($L = 4$–128)	$CP = 1$ (equality in Bakry–Émery)	1.10–1.33	Agreement	A check of the direction of the inequality. Approaches 1 as the proportion of overlap $\to 0$ Lean `gauss_box_le_one`
23	Both sides of the Box-Reduction Proposition for heat-bath Glauber of the one-dimensional Ising model	Reading holds in all 9 cases, loss 1.17–1.35 times	The gap by diagonalisation over all states	–	Agreement	Rings of 12 and 16 sites, couplings 0.3, 0.6, 1.0. A check of the direction of the inequality

#	Quantity	Record side	Known side	Ratio	Verdict	Conditions, notes
24	The gap of the Glauber box with fixed ends	Reading diagonalisation over all states of small chains	Closed formula $1-\gamma\cos(\pi/(L+1))$	1.00000	Agreement	The 6 digits shown. The same for boundary values $(+,+)$ and $(+,-)$. The original source is bibliographic only
25	Alternating maximal correlation ($C=2$, $\theta=\frac{1}{4}$)	Proved here $\varphi(e^{-1/2},e^{-1})$ of the Closed Formula for the Alternating Maximal Correlation	The closed formula of the two-state telegraph chain, 0.7308	1	Agreement	Two expressions of the same quantity (23-11 § 02)
26	The action of the kink on the lattice	Reading $S_0^{\mathrm{lat}}=0.665266$ ($\varepsilon=\frac{1}{2}$)	The continuum $S_0=2/3$	0.998	Conditional agreement	The difference of 0.2% is due to the lattice spacing. There is no estimate of the difference between continuum and lattice
27	The logarithm of the correlation length $\ln\xi$	Reading two routes: the difference of eigenvalues, and the transfer-operator version of Herring's formula	The semiclassical leading term $\xi\propto\hbar^{1/2}e^{S_0/\hbar}$	–	Conditional agreement	The two routes agree to 6 digits at intermediate $\hbar$. $\ln\xi-S_0^{\mathrm{lat}}/\hbar-\frac{1}{2}\ln\hbar$ settles towards a constant, $-0.774/-0.777/-0.778$, which agrees with the form of the leading term. There is no counterpart for comparing the constant term
28	The diffusion coefficient of a single kink	Reading $D/(\hbar/S_0)=1.00$–1.14	$D=\hbar/S_0$ (the coefficient of the theorem at the level of the process)	1.00–1.14	Conditional agreement	Point values at $\varepsilon=0.25$, $\hbar=0.02$, 0.07, 0.1. Corrections for finite $\hbar$ and the spacing

#	Quantity	Record side	Known side	Ratio	Verdict	Conditions, notes
29	The machinery for fitting the criterion uniform in volume	Reading 1.0049 for the harmonic model	Closed formula 1	1.005	Agreement	A positive control for the transfer-matrix computation applying the criterion to the lattice of paths ($\varepsilon = 0.25$)
30	The machinery of interval arithmetic: the pure Gaussian chain	Computer-assisted every point is inside the enclosure with $\hbar$ kept as an interval	Variance per step $(k-1)/k$, mean $(k-1)s/k$	1	Agreement	With the interval width set to 0, the same as the point machinery to the order of 10^{-12} (23-08 § 07)
31	The machinery of interval arithmetic: another implementation and point values	Computer-assisted upper bound	Reading 75 floating-point recursions, 26 point values of the transfer matrix	—	Agreement	0 outliers. All point values below the upper bound (smallest difference 2.85×10^{-4})
32	The gap of the hierarchical Gaussian free field	—	L^{-2N} at depth N of the nested boxes (known)		Not comparable	A known number put as a counterpart for comparison. The number on the side of the free field of the Langevin dynamics of links has not yet been computed

The rows of agreement in Table 3 are all checks that "the tool worked correctly on a model whose answer is known"; they do not show that the rows on the double well are correct. The conditions of the rows of conditional agreement are the lattice spacing (rows 26 and 28), finite $\hbar$ (row 28), and the missing constant term of the counterpart (row 27). Row 21 measures, on a model whose answer is known, the loss by which the criterion comes out 1.30 times larger than the true value; it serves as a rough guide when comparing the upper bound of the criterion with the needed value on the double well (23-09 § 05).

```
05
```

Rows that cannot be compared — numbers with no counterpart to check against

We list the numbers of the first step for which no counterpart to check against is found. All of them are numbers at the places where the construction comes closest to the upper half of the diffusive-relaxation-time assumption, and only there is there no counterpart.

- **Conversion between the two lattice spacings.** The readings of the diffusion coefficient of kinks and of the lower bound of the ratio R are at spacing $\varepsilon = 0.25$, while the table of correlation lengths and the steps of the First-Step Upper-Bound Proposition are at $\varepsilon = \frac{1}{2}$, and the conversion between the two spacings is not written (the table of ranges in 23-04).
- **The coefficient of $1/\hbar$ of the logarithmic Sobolev constant of the core.** A quantity needed in the Feynman–Kac strand; the Monte Carlo reading and the pathwise upper bound are three orders of magnitude apart (23-09 § 05).
- **The reading of $\sup |\nabla \psi|^2$.** A reading that it is within 0.54 times the threshold; it is not an upper bound. No known value of the same quantity was found in the range searched.
- **The lifting assumption of the Scalar-Strand Proposition.** An assumption that lifts the measured values of the two-site lump linearly beyond the measured range; the counterpart for comparison is the lifted value itself (23-09 § 05).
- **Comparison with the hierarchical free field.** Row 32 of Table 3. The known number L^{-2N} exists, and the number on the record side does not yet.

06

The nineteen rows on the side of the four-dimensional lattice

We keep one table that holds the numbers computed by the record on the side of the four-dimensional lattice (the one-loop slope κ, the shortfall $\delta(b)$, the ratio $m/\sqrt{\sigma}$, upper bounds of mass, C_P and autocorrelation times, strong-coupling thresholds, the exponent of stochastic time) up against existing computations and the numbers of primary lattice sources. The ratio is "record side ÷ existing side", and it is left blank for rows that cannot be compared. The details of each row and the conversion of conventions are in the chapter on the side of the four-dimensional lattice (23-02) and the source tables of Part 5.

Table 4 Cross-checks on the side of the four-dimensional lattice (rows 1–19)

#	Quantity	Record side	Existing side	Ratio	Verdict	Conditions, notes
1	κ (window model)	0.371521	0.371511	1.00003	Agreement	Within the one-loop model

11	Upper bound β=2.60 (APE)	0.558(51)	0.514(8)	1.086	Conditional agreement	$12^3 \times 24$ ($L\sqrt{\sigma} \approx 1.6$) against 24^4
12	Upper bound β=2.60 (flow)	0.501(71)	0.514(8)	0.975	Conditional agreement	12^4 ($L\sqrt{\sigma} \approx 1.6$) against 24^4
13	Ratio m(2.40)/m(2.60)	1.837(302)	1.854	0.991	Conditional agreement	β=2.60 is a small box with $L\sqrt{\sigma} \approx 1.6$
14	Straight-line threshold / SZZ	1/12	1/48 (converted by $\beta = 4\beta_{SZZ}$)	1.000	Agreement	Rederivation of a known result
15	Threshold after one-link integration	$\sqrt{(2/27)} = 0.2722$	—		Not comparable	Threshold of the marginal measure. The constant moves by 3.27 times within the same criterion. Not a claim of a widened range

#	Quantity	Record side	Existing side	Ratio	Verdict	Conditions, notes
16	C_P of the free field	C_P^(A)=ξ², 4C_P(time 0)²	Gaussian measure, ground-state transformation	1	Agreement	Recomputation
17	τ_int/ξ² of Langevin	0.5–1.4	—		Not comparable	No primary source for the same quantity at zero temperature towards the continuum limit was found in the range searched
18	The pole in stochastic time	13/6, −11/3	Baulieu–Zwanziger	1	Agreement	Only one independent primary source
19	Exponent s	−9/22	g₀^{9/11} (Lüscher–Schaefer equation (1.1))	1	Conditional agreement	Conditional on the one-loop leading logarithm and the relaxation-time assumption. Not an independent check

On the side of the four-dimensional lattice there are 6 agreements, 8 conditional agreements, 2 disagreements and 3 not comparable (rows 3 and 4 are two readings of the same disagreement). On the side of the first step (rows 20–32 of Table 3) there are 8 agreements, 4 conditional agreements and 1 not comparable. Read together, the rows of agreement are recomputations of known values or checks of tools on models whose answers are known, and the rows with no counterpart gather, on both sides, at the numbers that come closest to the relaxation-time assumption ($\tau_{\mathrm{int}}/\xi^2$ on the side of the four-dimensional lattice; the coefficient of the core and the lifting assumption on the side of the first step).

07

A way of reading dependency graphs learned from outside documents

We read two outside documents that claim to solve the existence and mass gap of Yang–Mills, and drew from them, not their correctness, but two types useful as **ways of reading the construction of a claim**. We do not give the sources; we write only the types. This book does not judge whether those documents are right or wrong.

1. **The type that puts the conclusion as a premise of intermediate steps.** One document piled up steps in the form of theorems and proofs; intermediate steps (clustering, uniqueness of the vacuum, exponential decay) took as a premise the

positivity of the mass gap, "to be shown later", and the positivity of the mass gap itself was supported by physical relations and dimensional analysis. Read step by step, each step derives its conclusion from its premises, but when the steps are arranged as numbered nodes, an edge goes back from the final conclusion to the intermediate steps, and the rule of numbering is broken. It is a type that is **invisible to step-by-step checking, and visible once arranged in a dependency graph**.

2. **The type with an object for its name and numbers for its content.** The other document closed its main theorem in Lean. Tracing the conjuncts of the main theorem back to their definitions, "lies in the spectrum" was defined as the same proposition as the conclusion, and the value of the gap was a rational number put literally; operators, fields and measures appeared only as names. It is a type that is **invisible even when machine checking passes and the list of axioms is clean, and visible once the definitions are traced back** (23-13 § 05).

These two types should be applied in the same way to the construction of this book. In the integrated graph of the first step, we checked the rule of numbering on every edge, and checked by reading that the statements of the assumption rows do not contain the quantities of the conclusion (23-12 § 03). For the Lean theorems, that there is no name on the side of the conclusion whose definition needs tracing back (only inequalities of real numbers) can be checked by the six questions of 23-13.

This part places the relaxation-time assumption at the axis of the study, and has held the numbers and tools of its first step up against outside numbers and tools. Other viewpoints are taken up in Part 24.

What this chapter can say

Can say	Cannot say
Cited Where the nearest known result for each condition stops (Table 1). Within the range searched, no known theorem gives a sharp upper bound on a long path up to the diffusion time of the kink gas	That no such theorem exists (outside the range searched)
Of the 26 main citations, 19 are supported by an original source, a secondary source or a proof in this book, 4 need to be obtained, and 3 were changed into assumption rows (Table 2). The type of discrepancy is one word of the setting	The statements of the 4 items that need to be obtained
The cross-check of positive controls (rows 20–32 of Table 3): that the tools worked correctly on models whose answers are known	That this shows the rows on the double well are correct

Can say	Cannot say
The nineteen-row cross-check on the side of the four-dimensional lattice (Table 4)	Explaining the disagreement between the slope of the lattice data tables and the one-loop value beyond the reason that it is before asymptotic scaling
The two types drawn from outside documents, and the check of applying them to the construction of this book	Whether the outside documents are right or wrong

The two types	This book	A reading of two outside documents that claim a construction or a proof (sources withheld)

Terms used in this chapter — reconciliation, agreement, conditional agreement, disagreement, not comparable, positive control, calibration, distance to known theorems, one word of the setting, the type that puts the conclusion as a premise of intermediate steps, the type with an object for its name and numbers for its content. Their meanings are in the A-02 glossary.

Next chapter: 23-15 What remains and its cost — the distance to a theorem — lays out what remains and its cost for each assumption row of the integrated table, and

separates the distance within the first step from the distance from the second step on.

What remains and its cost — the distance to a theorem

> This chapter is a map of open questions. It marks the boundary between the parts that close and the parts that do not.

What this chapter shows — That the rows needed to reach the conclusion of the first step (the upper side of the double-well relaxation-time power statement) split two ways at the single fork of the integrated table. For each of the two roads (the core on the box side, the core on the sector side), the assumption and reading rows needed, and the kind of work needed to close each row together with cost estimates. What is needed to produce a $\hbar$ at which all rows are in place. Outside the first step, what the distance from the second step on looks like when measured by three levels of the goal on the four-dimensional lattice, and the meaning of the one line "what is missing is uniformity".

Prerequisite chapters — 23-12 Table 1 (the integrated table) and 23-12 § 07 (the required sets of leaves). The content of each row is in the chapters 23-05 to 23-11. For the second step on, 23-01 and 23-03 § 06.

Said first — The level is [Y3]. Every cost is an estimate, and nothing has been run. We do not add up numbers of rows or hours and read them as "so many tenths to go". The rows do not have equal weight, and only rows expected to close by computation have time estimates; rows whose method is unknown have no estimate at all. This part places the diffusive-relaxation-time assumption at the axis of the study, and what this chapter measures is what remains of the first step on that axis.

The order of this chapter

1. The conventions of this chapter — distance is a list, cost is an estimate
2. The fork and the two roads — the core on the box side, the core on the sector side (Table 1)
3. Comparing the two roads — counting by kind of work (Table 2, Figure 1)
4. Remaining work not on the road to the conclusion — work worth having (Table 3)
5. What is needed to produce a ħ that fits all — why computer assistance in the window cannot reach it / The third branch of the fork (the road of blocks and mixing) (Tables C1 and C2)
6. Conditions common to the four conditions — five premises (Table 4)
7. The distance from the second step on — three levels of the goal, and the number of steps in β (Tables 5 and 6) / Detour: the lesson of ϕ^4_4
8. How to read the distance — a one-line conclusion

01

The conventions of this chapter — distance is a list, cost is an estimate

The "distance" to a theorem is a metaphor. In this chapter we call distance the **list** of those premises of the target proposition that have no proof.

$$\text{distance} \;=\; \{\text{the rows among the premises of the target proposition that have no proof}\} \qquad \text{(a set; we do not}$$

The goal of the first step is the upper side of the double-well power statement for the path measure of the double well, that is, the conclusion of the Double-Well Relaxation-Time Upper-Bound Proposition, $C_P \le K\xi^2 S_0/\hbar$, and $\ln C_P / \ln \xi \to 2$, which follows from it (23-05 § 04). The premises as a whole are the 111 rows of the integrated table (23-12 Table 1), and the rows without proof are the "Assumption" and "Reading" rows. The "Reading" rows are at hand as numbers, but they are not propositions of upper or lower bounds, so as premises of the conclusion they count as rows without proof.

To each row we attach the kind of work needed to close it. There are six: **interval arithmetic** (replace it by a computer-assisted inequality; 23-08), **paper** (write a proof), **bibliography** (check a known theorem in the original source and raise it to "Cited"), **measurement** (measure a quantity not yet measured), **another method** (it is known that the present tools cannot reach it, and another tool is needed), and **method undecided** (it is not yet decided with which tool to attack it). Time estimates are written only for rows with an estimate in the record, and rows with "no estimate" are left blank.

Example. Row [013] of the in-phase local Poincaré condition, between the nodes, has the estimate "24 subintervals, 23–39 hours in total". Row [002] for the tube, on the other hand, has no estimate. It is wrong to read the former as "closer" than the latter. The former is work expected to close if computed; the latter is work for which it is not yet known what would close it. A sum of computing hours does not show the size of the distance.

02

The fork and the two roads — the core on the box side, the core on the sector side

Following the dependency graph of the integrated table from the conclusion [111] in the direction of the premises, there is only one fork with "or": the core Poincaré uniformity assumption (the Poincaré constant of the core is uniform in core length and end values, [103]). This row is supported in two ways (23-12 § 07). For the road of the core on the sector side, the paper "The coarse-chain Poincaré inequality", which came out of this book, supports the core Poincaré uniformity assumption for every $\hbar \in (0,1]$ on the core whose two ends lie in the well: conditional on the paper's proof (Coarse-Chain Dobrushin Theorem (Theorem CC of the paper)) + Computer-assisted ($\hbar \in [10^{-5},1]$ by interval arithmetic over 239 intervals, $\rho_{\text{col}} \le 0.400$) + a paper proof and Computer-assisted (Small-$\hbar$ Coarse-Chain Proposition (Proposition PIN of the paper): $\hbar \le 10^{-5}$, $\rho_{\text{col}} \le 0.874$) + Cited (Poincaré Version of Helffer's Criterion (Proposition 3.1 of Ledoux) in Bobkov–Ledoux 2000) and the Coarse-Chain Brascamp–Lieb Proposition (Proposition BLc of the paper), with no Reading rows. The core on the box side (the core that enters the Gap-Inside-the-Box Proposition on the road of the core on the box side) is not covered.

- **The road of the core on the box side**: supported by the Three-Range Core-Constant Proposition (three stages for the constant of the core, [082]) and the vanishing of the local term as $\hbar \to 0$ ([084]) (23-11 § 05).
- **The road of the core on the sector side**: supported by a uniform lower bound for the gap of the core of the sector framework ([099]) and regularity at the seam (the seam limit assumption) (23-09 § 02).

Whichever road is taken, the rows needed for the conclusion are fixed as one set. Table 1 lists all the "Assumption", "Reading" and "Computer-assisted" rows in the union of the two roads, and writes the work and cost needed to close each row. The table, the graphs and the counts were made from the same single set of data (rows, edges) as the integrated table, with a column of costs added.

Table 1 The assumption, reading and computer-assisted rows needed for the conclusion [111], and the work needed to close them (numbers and contents as in the integrated table. A = the road of the core on the box side, B = the road of the core on the sector side. Every cost is an estimate; nothing has been run)

No.	Content (integrated table)	A	B	Work needed to close it	Kind	Cost estimate	Text
Assumption	**Assumption rows (22 rows)**						
[001]	Uniqueness of the measure at T=∞, Markov property, extension from local functions, the limit step, regularity	○	○	Cite from the original source or show on paper the uniqueness of the measure (the principal eigenvalue of a positive integral kernel on ℝ), the Markov property, extension, the limit step and regularity	Bibliography, paper	Obtaining 1 original source (positive kernel) and paper. No time estimate	23-05
[002]	Saddle-tube Poincaré assumption: Poincaré for the tube, uniform in tube length ≤ Cξ	○	○	The Poincaré constant of the tube is uniform in tube length ≤ Cξ	Method undecided	No estimate (not started)	23-07
[003]	Kink-gas gap assumption: the box gap of the reduced kink gas is of the Glauber type	○	○	Show the box gap of the reduced kink gas without copying the values of the one-dimensional Ising model	Another method	No estimate (a comparison theorem is needed)	23-11
[005]	Cross-term uniformity assumption: cross term $\mathcal{E}_Y(E[f\|Y]) \le (1+\chi)\mathcal{E}(f)$, χ uniform	○	○	χ of the cross term is uniform	Method undecided	No estimate (not started)	23-11
[006]	Alternating maximal-correlation assumption for boxes: the alternating maximal correlation between boxes c_alt < 1 is uniform	○	○	The alternating maximal correlation between boxes c_alt < 1, uniformly	Another method	No estimate (a comparison theorem avoiding the example that does not reduce to two-point quantities is needed)	23-11
[007]	Alternating maximal-correlation assumption for the core: upper bound for the alternating maximal correlation in the core $\bar{c} < 1$ ($k \ge 15$)	○	—	Upper bound for the alternating maximal correlation in the core $\bar{c} < 1$ ($k \ge 15$)	Another method	No estimate (the saturation is only a floating-point reading)	23-11
[008]	Core action-barrier assumption: C_P ≤ c ħ^(−p) e^(ΔS/ħ) for core and window	○	—	C_P ≤ c ħ^(−p) e^(ΔS/ħ) for core and window	Paper, measurement	The prefactor ħ^(−p) has not been measured. The next move is the capacity at the degenerate point (no estimate)	23-11
[009]	Continuous version of Holley's comparison (the tail lemma)	○	○	Continuous version of Holley's comparison	Bibliography	Confirming the version and the theorem number	23-06
[010]	The Poincaré–Miranda theorem (covering by boxes)	○	○	The Poincaré–Miranda theorem	Bibliography	Obtaining 1 original source	23-06

No.	Content (integrated table)	A	B	Work needed to close it	Kind	Cost estimate	Text
[011]	Variance-decomposition row: regularity and density of the functions used	○	○	Regularity and density of the functions used	Bibliography, paper	No estimate	23-06
[012]	Margin row (large-end side): neighbour and end values > 2.5	○	○	Neighbour and end values > 2.5	Paper	No estimate (the road through monotonicity does not close, and the lemma of tangents to a convex tail is far from the margin)	23-06
[013]	Margin row (between the nodes): ħ between the nodes (in uniform form)	○	○	ħ between the six nodes (0.005–0.2)	Interval arithmetic	After one rerun of the frame (30–50 minutes), 24 subintervals, 23–39 hours in total (one core; cut into jobs of at most 25 minutes each, 60–170 jobs)	23-06
[014]	Margin row (small ħ): ħ < 0.005 (in uniform form)	○	○	ħ < 0.005	Paper + interval arithmetic	Interval arithmetic alone would need infinitely many subintervals. On paper it is reduced to the ħ→0 limit of the margin ħρ − 2ħκ ≥ 0.067 of the margin row alone, and the limiting margin is ≥ 0.758 (interval arithmetic + paper). The quantitative uniform Laplace method and a one-dimensional lemma on the ħρ side are needed (not done). With an explicit $\hbar_0$ the infinitely many become finitely many (§ 05). On the upper-end side, ħ∈[0.001949, 0.005] was filled with six subintervals by interval arithmetic (margin ≥ 0.067; the arithmetic on the subintervals in Lean: LatticeGaugeH1HbarInterval). Below that, the estimate of the corner tail does not close with this computing machinery, and the machinery has to be replaced (§ 05)	23-06
[015]	Two-site gap row (large-end side): end values of the two sites > 4	○	○	End values of the two sites > 4	Paper	No estimate	23-06
[016]	Transfer from the ring to scraps (with end values)	○	○	From the statement on the ring to the statement on scraps (with end values)	Paper	No estimate	23-06
[018]	Seam limit assumption, random-end-value assumption, regularity at the seam of the ring	—	○	Seam limit assumption, random-end-value assumption, regularity at the seam	Paper	No estimate	23-07

No.	Content (integrated table)	A	B	Work needed to close it	Kind	Cost estimate	Text
[019]	The small assumptions of the route of the sector input (inputs to the sectors)	—	○	The small assumptions of the route of the sector input (the vertical term, the small assumptions of the sector input, regularity)	Paper	A list only, not started (no estimate)	23-07
[021]	Marginal log-Sobolev input for the window (the form of LSI for the marginals of site windows)	—	○	Marginal log-Sobolev input for the window	Paper	No estimate	23-09

All three strands stop at the shortfall of ¼ in the curvature of the single site at the top	23-09
Reading	**Reading rows (need to be replaced by propositions of upper or lower bounds) (5 rows)**						
[044]	$\ln \xi \geq s/\hbar$ ($\xi \propto \hbar^{1/2} e^{(S_0/\hbar)}$), the size of $D/(C\xi)^2$	○	○	$\ln \xi \geq s/\hbar$ as a lower-bound proposition	Bibliography, paper	Expected to rise to "Cited" if the original source of the semiclassical asymptotics of the tunnelling splitting is checked (no estimate)	23-04
[046]	Two-point maximal correlation of the medium-core step and B_2 (22.1 / 30.5 / 66.4)	○	—	The two-point maximal correlation of the medium-core step ($8 \leq k \leq 14$) as an upper bound	Interval arithmetic, paper	Interval arithmetic for each of the seven values of k and each point of ħ, and a paper on the difference between lattice and continuum (no time estimate)	23-11
[047]	$\bar{c}_{(\geq 15)} \leq 0.535$ (measurement of a lower bound)	○	—	$\bar{c}_{(\geq 15)} \leq 0.535$ as an upper bound	Another method	No estimate (at present only a measurement of a lower bound)	23-11
[055]	$\ell_{min} = 38.3$ / 121.9 / 406.8	—	○	$\ell_{min} = 38.3$ / 121.9 / 406.8 as a lower bound	Interval arithmetic	No estimate	23-09
[089]	Volume locality: ℓ_{min} does not depend on k	—	○	Volume locality: ℓ_{min} does not depend on k	Paper	No estimate	23-09
Computer-assisted	**Computer-assisted rows (done within the nodes and ranges) (2 rows)**						

No.	Content (integrated table)	A	B	Work needed to close it	Kind	Cost estimate	Text
[040]	Margin row: margin $\hbar\rho - 2\hbar\kappa \geq 0.067$ (neighbour and end in $[0,2.5]^2$)	○	○	(Done) computer-assisted at six nodes	—	Closed within the nodes. Outside the nodes, [013][014]	23-06
[041]	Two-site gap row: $\lambda_c \geq 1.3\times10^{-4}$ (ends in $[0,4]^2$)	○	○	(Done) computer-assisted row	—	The range of $\hbar$ as in the column of the integrated table	23-06

What to read from Table 1. (1) The rows common to the two roads are 13 assumption rows and 1 reading row: the common premise [001], the rows inside the box [002][003][005], [006] between boxes, [009]–[016] extending the in-phase local Poincaré condition, and the reading of how the correlation length grows [044]. These remain whichever road is taken. (2) Needed only for the road of the core on the box side are four rows: the alternating maximal correlation of the core [007], the action barrier [008], and the readings of the medium-core step and the long-core step [046][047]. (3) Needed only for the road of the core on the sector side are the remaining single proposition of the route of the window log-Sobolev inequality [026], 7 assumption rows including the inputs to the sectors [019][021][022][024], Barta's row [023] and regularity at the seam [018], and the two reading rows [055][089]. (4) The two computer-assisted rows [040][041] are done within the nodes and ranges, and common to both roads.

03

Comparing the two roads — counting by kind of work

We compare the costs of the two roads not by the number of rows but by the kind of work (Table 2).

Table 2 The assumption and reading rows of Table 1 counted by the kind of work needed to close them (a row with two kinds is counted in both; the two computer-assisted rows are done and excluded)

Kind of work	Common to both roads	A only	B only
Interval arithmetic	1 [013]	1 [046]	2 [023], [055]
Paper	6 [001], [011], [012], [015], [016], [044]	2 [008], [046]	6 [018], [019], [021], [022], [023], [089]
Bibliography	5 [001], [009], [010], [011], [044]	0	0
Measurement	0	1 [008]	0
Another method	3 [003], [006], [014]	2 [007], [047]	1 [024]
Method undecided	2 [002], [005]	0	1 [026]

There are three ways to read it.

First, **the only row with a time estimate is [013], common to both roads** (24 subintervals, 23–39 hours, not run). There are other rows expected to close by interval arithmetic ([046], [023], [055]), but there are as yet no estimates of the number of jobs or the time. And among the common rows is [014] ($\hbar < 0.005$, infinitely many subintervals needed), which is known to be out of reach of interval arithmetic. So neither of the two is a road that "closes given enough computer time".

Second, **the additions of the road of the core on the box side lean towards "another method", and the additions of the road of the core on the sector side lean towards "paper"**. [007][047] of the road of the core on the box side need a comparison theorem bounding the alternating maximal correlation of the core uniformly in k, and it must take a form that avoids the example that does not reduce to two-point quantities (23-11 § 05). Many of the additions of the road of the core on the sector side are papers on the inputs to the sectors, but behind them lies one "method undecided" row, [026]: the remaining single proposition of the route of the window log-Sobolev inequality, the place where all three strands stopped at the shortfall $\frac{1}{4}$ in the curvature of the single site at the top (23-09 § 06).

Third, **the road of the core on the sector side, with more rows, is not necessarily heavier**. The additional papers of the road of the core on the sector side are all rows for which what has to be shown is fixed as a statement. The two additional rows of the road of the core on the box side, [007][047], and the one row of the road of the core on the sector side, [026], are all rows for which "what to show" is fixed but "how to show it" is not. The difference between the two roads is whether these rows of unknown method lie on the side of the maximal correlation of the core or on the side of the curvature at the top.

Figure 1 is the dependency graph for each of the two roads, keeping only the ancestors of the conclusion. From the graph of the integrated table (111 nodes), only the nodes reached by choosing one side of the "or" at [103] and following the direction of the premises are listed, with the same numbers.

> Figure 1 Dependency graph for each road (number, grade, symbol, content; the numbers to the right of $\Longleftarrow$ are premises. The rule of numbering is the same as in the integrated table: the numbers of premises are smaller than that of the conclusion)
> ▶ The road of the core on the box side: the core on the box side (55 nodes)
> ▶ The road of the core on the sector side: the core on the sector side (59 nodes)

Example. In the graph of the road of the core on the box side the premises of [103] are [082][084]; in the graph of the road of the core on the sector side they are [099][018]. The rest of the trunk (the gap of the box and the composition from [104] on) consists of the same nodes in both graphs, and the work before the fork acts in common on both roads.

04

Remaining work not on the road to the conclusion — work worth having

The integrated table contains work that is not on the road to the conclusion yet has been named as remaining. Closing any of it would not move the conclusion [111], but it is worth having for the certainty of the numbers or as material for other roads.

Table 3 Remaining work not on the road to the conclusion (costs copied from the estimates in the record; none has been run)

Remaining work	Row of the integrated table	Work and cost estimate	What could be said if it closed	Text
Putting the inner chain of the ring on interval arithmetic	[053], [054]	With 1–2 rounds of paper study and 1–2 rounds of scripting, build a machine separating the lattice of pins from the lattice of positions and a proposition for the layer of the outward-pushing wall; about 50 jobs, about 42 hours over the 25 subintervals of the window (about 85 hours without the paper on bands)	The coefficient of the inner chain $\bar{q} \approx 1.3$ becomes an upper bound. Not a road that meets the closing condition of the sectors ((7) of 23-09)	23-07 § 03
Extending the pin of the boundary stage to $(0, \frac{1}{2})$	[054]	Part of the machine above (extending the domain of the outer machine)	The condition "pin ≤ 0" on the outer chain is removed	23-07 § 03
The remaining numbers of the route of the window-constant numerics	[052]	About 42 jobs, about 21 hours, for the constants of the window, the minimal weight and the congestion. Since the floor of the product form is 4–5 orders of magnitude above the needed value, the decision is not to run them	The upper bound of the product form becomes Computer-assisted (it does not reach the conclusion)	23-07 § 04

Remaining work	Row of the integrated table	Work and cost estimate	What could be said if it closed	Text
Aligning the thresholds and remeasuring A_W	[056]	Measure A_W with the mark of the defect threshold $\theta_B = 0.57$ (no estimate)	The closing condition (7) of 23-09 has literal meaning	23-09 § 04
Making the rows of the Scalar-Strand Proposition computer-assisted	[025], [096]	12 jobs per node (3 for the bathtub column, 7 for rarity, 2 for non-convex fibres), estimated 60–250 for the nodes. The lower bound of the action difference of non-convex fibres is not yet in the form of interval arithmetic. The lifting assumption remains	The rows of the Scalar-Strand Proposition at the lower end of the window become Computer-assisted. There is no edge of implication to the remaining single proposition [026]	23-09 § 05
Sharpening the constant of the in-phase local Poincaré condition	[066]	Reworking the two-site gap row (no estimate)	$C \le 1.6 \times 10^{10}$ becomes smaller (the form of the conclusion does not change)	23-06 § 07
Conversion between the two spacings	—	Connect the readings at lattice spacing $\varepsilon = 0.25$ with the tables at $\varepsilon = \frac{1}{2}$ (no estimate)	One fewer "not comparable" row in the reconciliation	23-14 § 05
Obtaining bibliography	[010] and others	4 items to obtain (Poincaré–Miranda, elliptic regularity of the Neumann problem on a box, stochastic monotonicity, the principal eigenvalue of a positive integral kernel)	Rows that can be obtained rise from "Assumption" to "Cited"	23-14 § 03

The first three rows of Table 3 are, in amount of computation, larger work than [013] of Table 1. Even so, they are not on the road to the conclusion because closing them does not remove a single "Assumption" row of the integrated table (the same reason as "the two Computer-assisted rows of the saddle-tube condition are not on the road to the conclusion" in 23-12 § 05). The size of the computation and the closeness to the conclusion are different rulers.

05

What is needed to produce a ħ that fits all — why computer assistance in the window cannot reach it

Even if all the rows of Table 1 closed, if the ranges of $\hbar$ in which each row holds do not intersect, the conclusion cannot be stated at even a single $\hbar$. The present ranges are of four kinds (23-12 § 06): the nodes of the in-phase local Poincaré condition $\{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$, the computer-assisted window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$, the nodes in the range of the Scalar-Strand Proposition $[3 \cdot 10^{-4}, 10^{-3}]$, and the three points of reading $\hbar = 3 \cdot 10^{-3}/10^{-3}/3 \cdot 10^{-4}$. The side of the in-phase local Poincaré condition has nothing below 0.005 and the side of the saddle-tube condition has nothing above $3 \cdot 10^{-3}$, so the intersection is empty.

There are only two roads to bring them into line: (a) extend the in-phase local Poincaré condition to $\hbar \le 10^{-3}$ (row [014]), or (b) extend the side of the saddle-tube condition to $\hbar \ge 0.005$. (b) was decided to be outside the scope of this part (the route of the range of ħ, 23-07 Table 1). (a) cannot be reached by interval arithmetic: the width of subintervals shrinks with $\hbar$, and covering down to $\hbar \to 0$ would need infinitely many subintervals. What is needed is another method, writing the asymptotics as $\hbar \to 0$ on paper. That line has come as far as the following form. Of the inputs of the Six-Node In-Phase Poincaré Proposition, the two-site gap row, the crossing row, λ_S and the nesting close for $\hbar \in (0, 0.2]$, and the

condition on the rate is monotone in the margin, so what remains is only to show the margin of the margin row, $\hbar\rho - 2\hbar\kappa \geq 0.067$, as $\hbar \to 0$ [Paper] . The limiting formula is $\kappa_0(a,b) = (H^{-1})_{1,11}/\varepsilon^2$ (the Hessian at the minimiser of the 11-site bridge), and for all ends $(a,b) \in [0,2.5]^2$ there is a unique global minimiser in the interior with $\lambda_{\min} H \geq 0.2$, $\kappa_0 \leq 0.1282$, and in the coarse landscape $U_0''(t^*) \geq 1.943$ [Computer-assisted] (interval arithmetic; the prerequisite paper lemmas — KKT, the truncation $x \leq \max(a,b,1)$, the leading principal minors of Jacobi — are not placed in the book; the action gap g is floating point [Computed]). From this the limit of the margin is $\geq 1.014 - 2 \times 0.1282 = 0.758$ (after paying for Muckenhoupt), larger than the 0.067 of the six nodes, and the true margin at finite $\hbar$ (1.67–1.79) is also nearly flat [Computed] . To bring the $\hbar \to 0$ limit down to finite $\hbar$, the quantitative uniform Laplace method and a one-dimensional lemma on the Muckenhoupt asymptotics on the $\hbar\rho$ side are needed [Assumption] (the constants of the uniform Laplace method are not made explicit in Theorem 2.12 of Katsevich arXiv:2406.12706 [Cited]). If an explicit $\hbar_0$ is obtained, the infinitely many subintervals of [014] become finitely many on $[\hbar_0, 0.005]$ [Reading] (the estimate of $\hbar_0$ is 4×10^{-4}–8×10^{-4}).

Subintervals from the upper end. On the upper-end side of the window $[\hbar_0, 0.005]$, we filled it by extending the same interval-arithmetic machinery as for the six nodes to intervals of $\hbar$. On the $\hbar\kappa$ side, the covariance of the bridge of 11 sites is bounded from above over an interval of $\hbar$ with interpolation in β at three points and a cubic remainder. On the $\hbar\rho$ side, the band of the expectation of the boundary values is extended to an interval of $\hbar$ with the same type, and the forward sums appearing in the Muckenhoupt exponent with band are compared cell by cell at the two ends of $\hbar$, giving a lower bound valid for every $\hbar$ in the interval [Paper] . As a result, on all six subintervals $[0.001949, 0.002281]$, $[0.002281, 0.002668]$, $[0.002668, 0.003122]$, $[0.003122, 0.003653]$, $[0.003653, 0.004274]$, $[0.004274, 0.005]$, the margin $\hbar\rho - 2\hbar\kappa$ exceeds 0.067 for every box of the neighbours and the ends $[0,2.5]^2$ (from the lowest interval up: 0.367, 0.353, 0.321, 0.240, 0.154, 0.077) [Computer-assisted] (float64 with outward widths. The comparison of exponents on the cells over the subintervals, the covering by small pieces and the arithmetic of the margin are in Lean: LatticeGaugeH1HbarInterval, 15 theorems; the numbers were put in for the upper two). Hence the margin of the margin row holds by interval arithmetic for $\hbar \in [0.001949, 0.005]$. It does not overlap with $\hbar_0$ of the quantitative uniform Laplace method (about 5.5×10^{-4} in floating point), and the gap between them remains open. The cost of this machinery grows roughly as the -3.5 power of $\hbar$ [Computed] , and moreover from the next subinterval on, because of the truncation of the weights, the upper bound on the tail at the corner $(a,b) = (2.5, 2.5)$ exceeds the integral, and it does not close on a single weight scale in float64 [Reading] . To join the window, the machinery has to be replaced — keeping the weights as logarithms or revisiting the estimate of the corner tail — or the constants of the quantitative uniform Laplace method have to be sharpened.

Moreover, even if a $\hbar$ that fits all could be produced at a single point, the double-well power statement is a statement about the limit $\hbar \to 0$.

$$\lim_{\hbar \to 0} \frac{\ln CP(\hbar)}{\ln \xi(\hbar)} = 2 \quad (2)$$

(2) does not follow from an inequality on any finite window. Computer assistance in the window only checks the inequality at each $\hbar$ in the window and says nothing about the outside of the window (23-08 § 10). So to close the first step, every row of Table 1 has to be stated "in a form uniform as $\hbar \to 0$", and the role of computer assistance is limited to taking on a finite part within such a uniform proposition (for example, the side $\hbar \geq \hbar_1$).

Example. Even if [013] is closed with 23–39 hours, what is closed is the continuum $0.005 \leq \hbar \leq 0.2$. [014] remains untouched, and the limit of (2) is not a single step closer. What computing time can buy is

"between the nodes", not "$\hbar \to 0$".

The third branch of the fork — the road of block log-Sobolev inequalities

Besides the road of the core on the box side and the road of the core on the sector side, a third candidate has been proposed as a road supporting the fork [103] (the core Poincaré uniformity assumption). It passes neither through the LSI constant A_W of the site windows of the sector framework ([026]) nor through the maximal correlation of the core of the Three-Range Core-Constant Proposition ([007], [046], [047], [082]); in this section we call it the road of blocks and mixing. Many of its steps have no written proof, so this section is not a statement of claims: it sets out the proposed road as a table of rows (Table C1) and a dependency graph. The counts of Tables 1 and 2 and Figure 1 are not changed.

Setting. The object is the conditional measure $\mu_k^{a,b} \propto e^{-S/\hbar}$, with the values a, b outside both ends fixed, on the same core $Q_k = (-x_c, 0)^k$ as in 23-09 ($x_c = 0.89$, Neumann faces, $\varepsilon = \frac{1}{2}$, $V(z) = (z^2-1)^2/8$). The Dirichlet form follows the convention $\mathcal{E}(f) = \hbar \int |\nabla f|^2 \, d\mu$ of 23-09 (the form of the overdamped Langevin dynamics $dz = -\nabla S \, dt + \sqrt{2\hbar}\, dW$), and differs from $(\hbar/\varepsilon)\sum_i \mathbb{E}|\partial_i f|^2$ of 23-11 only by a constant factor ε. So "uniform in $\hbar$" means the same under either convention. The goal is a logarithmic Sobolev inequality (LSI) uniform in the core length k, in $\hbar$ and in all end values; since the Poincaré inequality follows from the LSI Cited , if the goal is shown, the core Poincaré uniformity assumption follows.

Three stages.

1. Block LSI. For blocks of length $\ell_B \geq 12$ (avoiding length 8, just outside the threshold of convexity), an LSI uniform in the end values and in $\hbar$. The inputs are the Hidden-Convexity Proposition below (exactly one minimum on the box), the curvature $\lambda_*(12) \geq 0.255$ at the minimiser for the worst end values, Witten's Morse theory that there are no exponentially small eigenvalues under a single non-degenerate minimum (on a Neumann box), and the Menz–Schlichting decomposition for the case of one minimum.
2. Strong mixing. The optimal path of $\hbar \to 0$ reaches the corner $-x_c$ of the box within 7 steps from every starting point, the chain concentrates around that path with a width of order $\sqrt{\hbar}$, and in the boundary layer at the corner the Doeblin condition holds uniformly in $\hbar$. The conclusion has the form $\mathrm{TV}(n) \leq (1-\delta)^{\lfloor n/10 \rfloor}$, with δ independent of $\hbar$.
3. Combine 1 and 2 by the standard theorem for one-dimensional chains (of the Zegarlinski and Martinelli–Olivieri type: block LSI and strong mixing give an LSI uniform in length).

This road does not take the worst configuration as its entrance. It lies outside the fact that tools evaluating at the worst configuration all stop at the shortfall $\frac{1}{4}$ in the curvature of the single site at the top (23-09 § 06), and it goes after uniformity in $\hbar$ through mixing on average.

Hidden-Convexity Proposition (exactly one minimum on the box)

Let $\varepsilon > 0$, $c > 0$, $l \geq 1$, with end values $a, b \in [-c, 0]$, and with $z_0 = a$, $z_{l+1} = b$,

$$S(z) = \sum_{i=0}^{l} \frac{(z_{i+1} - z_i)^2}{2\varepsilon} + \varepsilon \sum_{i=1}^{l} V(z_i), \qquad V(z) = \frac{(z^2-1)^2}{8} \tag{C1}$$

be considered on the box $Q = [-c, 0]^l$. Then S has exactly one local minimum on Q, and it is the global minimum.

Proved here Proof. Put $z_i = -\sqrt{\rho_i}$ ($\rho_i \in [0, c^2]$, $i = 1, \dots, l$), likewise $a = -\sqrt{\rho_0}$ at the ends, and $b = -\sqrt{\rho_{l+1}}$ (with ρ_0, ρ_{l+1} fixed). With $(z_{i+1} - z_i)^2 = \rho_{i+1} + \rho_i - 2\sqrt{\rho_i \rho_{i+1}}$, the geometric mean $(x, y) \mapsto \sqrt{xy}$ is concave on $[0, \infty)^2$, so $-\sqrt{\rho_i \rho_{i+1}}$ is convex. The end term $-\sqrt{\rho_0}\sqrt{\rho_1}$ is also convex, since $\sqrt{\cdot}$ is concave and the coefficient is ≥ 0. In ρ the linear term is convex, and $V(z_i) = (\rho_i - 1)^2/8$ is strictly convex in ρ_i with second derivative $\frac{1}{4}$. Hence $\tilde{S}(\rho) := S(-\sqrt{\rho})$ is the sum of a convex function and $\varepsilon \sum_i (\rho_i - 1)^2/8$, and is strictly convex on $[0, c^2]^l$. The componentwise $\rho \mapsto -\sqrt{\rho}$ is a homeomorphism from $[0, c^2]^l$ to Q, so local minima correspond to each other. A local minimum of a strictly convex function on a convex set is the global minimum, and there is at most one. S is continuous on the compact Q, so the minimum exists. ∎

What the Hidden-Convexity Proposition says is that an action which is not convex in the coordinates z (the Hessian at the top is not positive definite for lengths 8 and above; next paragraph) is convex in the coordinates $\rho = z^2$, independently of length. But the Poincaré constant and the LSI constant are quantities of the flat metric of z, so the convexity in ρ does not by itself give the Bakry–Émery criterion. The density written in ρ carries the Jacobian $\prod_i (2\sqrt{\rho_i})^{-1}$, and the $\frac{1}{2} \ln \rho_i$ added to the potential is a concave term with second derivative $-1/(2\rho_i^2)$. The lower bound on convexity $\varepsilon/(4\hbar)$ in $\tilde{S}/\hbar$ can cancel this only where $\rho_i \geq \sqrt{2\hbar/\varepsilon}$; in thinner layers convexity is not guaranteed Proved here (a one-line computation). The view is that the non-convexity moves from "the lump at the top of length 8 and above" to "rare thin layers at each site". The proposition in the record (the Closed-Core KKT-Point Proposition), which shows that when the end values are below the box ($a, b \leq -x_c$) the only KKT points on the closed core are the bottom corners, uses a different method based on the convexity of sequences and the KKT conditions, and is not among the ancestors of the conclusion of the road of blocks and mixing.

The threshold of convexity is the first conjugate point of the top. The Hessian of S at the top $z \equiv 0$ is tridiagonal, $\mathrm{tridiag}(-1/\varepsilon,\ 2/\varepsilon + \varepsilon V''(0),\ -1/\varepsilon)$, and with $V''(0) = -\frac{1}{2}$, $\varepsilon = \frac{1}{2}$ it is $\mathrm{tridiag}(-2, \frac{15}{4}, -2)$. For length l the eigenvalues are $\frac{15}{4} - 4\cos\frac{\pi j}{l+1}$ ($j = 1, \dots, l$), and the smallest, $j = 1$, is positive only when $\cos\frac{\pi}{l+1} < \frac{15}{16} = 1 - \frac{\varepsilon^2}{4}$, that is, $l + 1 < \pi/\theta$ ($\cos\theta = 1 - \varepsilon^2/4$) Proved here . With $\theta = 0.3554$, $\pi/\theta - 1 = 7.839$, the smallest eigenvalue is 0.0545 at length 7 and -0.0088 at length 8. The solution of the Euler–Lagrange equation linearised at the top (the Jacobi equation) $-2u_{n-1} + \frac{15}{4}u_n - 2u_{n+1} = 0$ is $\sin(\theta n)$, and π/θ is its first zero, in the language of the calculus of variations the first conjugate point. The statement of the Short-Core Convexity Lemma (23-11 § 05), "convex for length ≤ 7, broken from 8", is exactly the test of whether a conjugate point enters the interval. This length is fixed classically and does not depend on $\hbar$.

Table C1 The rows of the road of blocks and mixing (numbers carry a C to distinguish them from the numbers of the integrated table. Labels are the five grades of Part 23. No row has a cost estimate)

Row	Statement (one line)	Label	Grounds, what remains	Work needed to close it
C01	The threshold of convexity 7.84 is the first conjugate point of the top $\pi/\theta - 1$ ($\cos\theta = 1 - \varepsilon^2/4$)	Proved here	The paragraph above	—

Row	Statement (one line)	Label	Grounds, what remains	Work needed to close it
C02	A core of length $k \le 7$ has $\mathrm{Hess}\, S \ge \kappa(k)$ ($\kappa(7) = 0.0545$) at every configuration; Poincaré uniform in $\hbar$ and the end values (the Short-Core Convexity Lemma, integrated table [076])	Proved here	23-11 § 05. Bakry–Émery on convex domains (Kolesnikov–Milman) is Cited. The LSI form is expected to follow from the same convexity; checking against the literature remains. Not among the ancestors of the conclusion of the road of blocks and mixing (blocks have length 12 or more)	Bibliography (the LSI form)
C03	Hidden-Convexity Proposition: if the end values are $a, b \in [-c, 0]$, there is exactly one local minimum on the box	Proved here	The proof in the box above	—
C04	The curvature at the minimiser for the worst end values $\lambda_*(12) \ge 0.255$, $\lambda_*(16) \ge 0.305$ ($\varepsilon = \frac{1}{2}$, all end values)	Reading	Monotonicity of the minimiser in the end values (Topkis's theorem) and a lower bound per cell by Weyl's inequality. The minimisers at the four corners of each cell come from floating-point optimisation	Interval arithmetic (Computer-assisted if the KKT residuals at the four corners are checked with intervals)
C05	A single non-degenerate minimum $\Rightarrow$ no exponentially small eigenvalues, and at $\hbar \to 0$ the LSI constant is fixed by λ_*	Assumption	Candidates to cite (Helffer–Nier, the Neumann version of Le Peutrec, Menz–Schlichting). The form at the corners of the box has not been checked	Bibliography
C06	The LSI of a block ($\ell_B \ge 12$) is uniform in the end values and in $\hbar$	Assumption	C03, C04, C05, and the line of assembly over the range of finite $\hbar$ and the compactness of the end values	Paper
C07	The optimal path of $\hbar \to 0$ reaches the corner $-x_c$ within 7 steps from every starting point	Reading	A record of solving the path from the top in 50-digit floating point (gradient residual 3×10^{-51}) and checking the signs of the KKT conditions. Uniqueness is C03; monotonicity in the starting point is Topkis's theorem. It is not interval arithmetic, so it is not graded Computer-assisted	Computer-assisted by interval arithmetic (enclosing the existence of the solution in intervals)
C08	Convexity of the one-step action $\kappa_0 \ge 0.055$ ($\hbar \to 0$, all starting points)	Assumption	The record has a line of proof (if there are at most 6 free sites, the second derivative of the one-step action is at least the smallest eigenvalue 0.0545 of the worst tridiagonal matrix of length 7). The book gives no proof. Depends on C01 and C07. $\kappa\hbar \ge 1.88$ measured at finite $\hbar$ ($\hbar = 10^{-2}$–10^{-5}) is Reading	Paper
C09	$\lvert W\hbar - W_0 \rvert = O(\hbar \ln(1/\hbar))$ ($W\hbar = -\hbar \ln \varphi_0$, uniform in $[-x_c, 0]$)	Assumption	A candidate to cite (a limit of Varadhan type). Not yet checked against the original	Bibliography
C10	Concentration to a width $\sqrt{\hbar}$, and the Doeblin condition in the boundary layer at the corner (uniform in the starting point)	Assumption	A line of argument by the constrained Laplace method. What remains is a form uniform in the starting point, and the treatment of the finitely many starting points at which the multiplier of the wall is 0	Paper

Row	Statement (one line)	Label	Grounds, what remains	Work needed to close it
C11	Strong mixing $\mathrm{TV}(n) \le (1-\delta)^{\lfloor n/10 \rfloor}$, with δ independent of $\hbar$	Assumption	The line of assembly on top of C07–C10	Paper
C12	Mixing length $\approx$ 9–10 (total variation $< 10^{-2}$ at the worst end values, $\hbar = 10^{-2}$–10^{-5}); rough Langevin relaxation ≈ 0.46 ($k \ge 16$, $\hbar = 10^{-2}$–10^{-4})	Reading	Numbers for the transfer operator (maximum over 41 end values) and numbers for overdamped Langevin (256 chains, ends at the top). Supporting rows that are not among the ancestors of the conclusion	—
C13	Block LSI + strong mixing ⇒ LSI uniform in length	Assumption	Candidates to cite (Zegarlinski, Martinelli–Olivieri). The version for compact continuous spins has not been checked	Bibliography
C14	The LSI of the core is uniform in k, $\hbar$ and the end values, hence the core Poincaré uniformity assumption	Assumption	Assembly on top of C06, C11, C13	Paper

Dependency graph (the rule of numbering is the same as in Figure 1: the numbers of premises are smaller than that of the conclusion. C02 and C12 are nodes that are not among the ancestors of the conclusion):

Table C2 The quantities of Part 23, and how the road of blocks and mixing treats them

Quantity of Part 23	Meaning	Treatment in the road of blocks and mixing
Core Poincaré uniformity assumption ([103])	The Poincaré constant of the core is uniform in core length and end values (23-09, 23-11)	Follows from the conclusion C14 of the road of blocks and mixing (LSI ⇒ Poincaré). The convention is aligned with $\hbar \int \lvert\nabla f\rvert^2 d\mu$ of 23-09
Window Log-Sobolev Threshold Proposition ([026])	$A_W < A_{\max}(\hbar)$: the one remaining proposition of the route of the window log-Sobolev inequality	Not passed through. If the road of blocks and mixing is chosen, [026], the 6 sector input rows of the road of the core on the sector side ([018], [019], [021]–[024]) and the readings [055], [089] drop out of the ancestors of the conclusion

Quantity of Part 23	Meaning	Treatment in the road of blocks and mixing
A_W	The LSI constant of the marginals of the marks of a site window	Not used
[007], [008], [046], [047], [082]	The core rows of the road of the core on the box side (the Three-Range Core-Constant Proposition and its inputs)	Not used
The common rows ([001], [002], [003], [005], [006], [009]–[016], [044])	The tube, the reduced kink gas, the cross term, the maximal correlation between boxes, the extension of the in-phase local Poincaré condition, and others	Remain

Counts, and what does not close. If the road of blocks and mixing is chosen, the rows without proof among the ancestors of the conclusion [111] are the 13 common assumption rows and 1 reading row ([044]), plus the 8 assumption rows of the road of blocks and mixing (C05, C06, C08, C09, C10, C11, C13, C14) and its 2 reading rows (C04, C07). The number of rows is not smaller than for the road of the core on the box side (15 assumptions, 3 readings) or the road of the core on the sector side (20 assumptions, 3 readings). The difference is in the kind of work: the rows of the road of blocks and mixing divide into bibliography (C05, C09, C13), interval arithmetic (C04, C07) and paper (C06, C08, C10, C11, C14), and none of them falls under "another method" or "method undecided" of Table 2. But this classification comes from reading the line of argument of each row, and there is no guarantee that new obstacles will not appear while writing it out.

The road of blocks and mixing is a road supporting the single row of the fork [103], and the trunk from [104] on is the same as for the road of the core on the box side and the road of the core on the sector side. **The 13 common rows remain even if the road of blocks and mixing is chosen.** Of these, [002] (Poincaré for the tube) and [005] (the χ of the cross term is uniform) are method undecided, and [003], [006] and [014] (the form uniform in $\hbar < 0.005$, which interval arithmetic cannot reach) are rows that need another method (Table 2). So even if the road of blocks and mixing closes, the first step does not close. The problem of "a $\hbar$ that fits all" of § 05 also remains, through [014].

When $\ln(1/\hbar)$ remains in the mixing length. Numerically, the length at which the influence of the worst end values falls below 10^{-2} stays at 9–10 from $\hbar = 10^{-2}$ to 10^{-5}, but the position at which the total variation drops below 0.5 moves slowly, logarithmically, from 5 to 8 Reading . The possibility that a dependence on $\ln(1/\hbar)$ remains has not gone away. If it remains, the constant in the conclusion of the road of blocks and mixing grows polynomially in $\ln(1/\hbar)$ as a function of $\hbar$, and the two statements are treated differently. The power statement (2) is not affected: even if a factor $(\ln(1/\hbar))^p$ multiplies C_P, under $\ln \xi \geq s/\hbar$ of [044] we have $p \ln\ln(1/\hbar)/\ln \xi \to 0$ Proved here (the algebra on top of [044]). On the other hand, the form in $C_P \leq K\xi^2 S_0/\hbar$ of the First-Step Upper-Bound Proposition, in which K does not depend on $\hbar$, does not allow it. The uniformity of K includes the uniformity of the χ of the cross term (the cross-term uniformity assumption, [005]), and if the cross-term uniformity assumption is shown by the standard two-scale argument, χ is expected to come out proportional to the square of the local constant C_{loc}; so if a logarithmic factor enters C_{loc}, the uniformity of χ breaks Assumption . The second term $C_{\mathrm{loc}} D/(C\xi)^2$ of (12) in 23-05 allows a logarithmic factor, since $D/(C\xi)^2$ is small, of order $e^{-2S_0/\hbar}$. Therefore the right goal for the road of blocks and mixing is the core Poincaré uniformity assumption in a form without logarithmic factors, and if a logarithm remains, what can be reached is only the power statement.

06

Conditions common to the four conditions — five premises

Apart from the work row by row in Table 1, there are five premises that bear on all four conditions. None of them disappears when a single row is closed; they are conditions to be written into the statement when putting the first step in a form that can be called "closed".

Table 4 Premises common to the four conditions

Symbol	Premise	Present state	What is needed to close it
C1	Kind of number	The reading rows are floating-point values (the 19 Reading rows of the integrated table)	Replace the reading rows among the premises of the conclusion by upper and lower bounds from interval arithmetic or paper (the reading rows of Table 1)
C2	Bibliography of the cited theorems	Of the 26 main citations, 19 have their statements checked in an original or secondary source. 4 to obtain, 3 rows changed into assumptions (23-14 Table 2)	Obtain the 4 items and check their statements. If they cannot be obtained, they stay "Assumption"
C3	The range of machine checking	Lean covers only algebra and arithmetic. Analytic theorems are input as assumptions (23-13 § 05)	Widening the range of machine checking does not reduce the conditions of the conclusion. What reduces the assumption rows is paper and bibliography
C4	A $\hbar$ that fits all	There is no $\hbar$ at which all rows hold (§ 05)	Another method to extend the in-phase local Poincaré condition to $\hbar \to 0$
C5	Limit and regularity	Existence of the limit $T \to \infty$, regularity, and simplicity of the first eigenvalue are assumptions ([001] of the integrated table)	The same as [001] of Table 1

07

The distance from the second step on — three levels of the goal, and the number of steps in β

The distance of the first step was the list of rows of Table 1. From the second step (the four-dimensional lattice, non-abelian) on, the statements are not divided finely enough to be written as a list of rows. This section lays out what the goal on the four-dimensional lattice looks like when written at three levels, and the number of steps in β, as a rough guide by physical extrapolation. What can be expected to carry over from the first step to the second step and beyond is only the form of the statements and the form of the tools; why the constants and the range of $\hbar$ do not carry over is in 23-03 § 06.

"The mass of the lightest particle is positive" is the statement on the spectrum of the quantum Hamiltonian H, $\mathrm{spec}(H) \subset \{0\} \cup [\Delta, \infty)$, $\Delta > 0$ (4-11). On the road entering from the lattice, the same goal splits into three levels.

$$(\mathrm{T1})\ \ \xi(\beta) < \infty\ (\forall \beta),\ \ \xi(\beta) \to \infty\ (\beta \to \infty); \qquad (\mathrm{T2})\ \ \frac{m_{\mathrm{lat}}(\beta)}{a(\beta)} \to \Delta_{\infty} \in (0, \infty); \qquad (\mathrm{T3})\ \ \text{gap positive in the}$$

Table 5 Three levels of the goal, and their relation to the relaxation-time assumption

Level	Content	What is added to the level above	Status in four dimensions	Relation to the relaxation-time assumption
Lattice target level ((T1) of the formulas)	Correlation length finite at each β, diverging as $\beta \to \infty$	—	Unsolved (lattice correlation-length problem (Chatterjee's Problem 5.1)) Cited	The relaxation-time assumption is a statement that presupposes the latter half of the lattice target level

Level	Content	What is added to the level above	Status in four dimensions	Relation to the relaxation-time assumption
Physical-unit target level ((T2) of the formulas)	m_{lat}/a tends to a positive finite value	How the lattice spacing $a(\beta)$ is determined	Unsolved	If the relaxation-time upper-bound assumption and the one-sided bridge (23-01 § 06) are both in place, the lower half follows
Continuum target level ((T3) of the formulas)	A non-trivial theory on $\mathbb{R}^4$ with positive gap	Existence of the limit (Wilson-loop limit statement), rotation-recovery statement, OS reconstruction statement, non-triviality statement	Unsolved (the problem statement). On the existence of the limit and the axioms side, the committee's assessment is that the construction published on 2026-11-10 shows them as the limit of Wilson's lattice gauge theory (Part 6). The gap is not shown (6-04)	Does not follow even with the relaxation-time assumption and the bridge in place (23-01 § 08)

Next, we measure the gap between the β where there are proofs and the β on the side of the continuum limit by the number of steps that coarsen the lattice by a factor of 2. It is a physical extrapolation that extends two-loop asymptotic scaling, matched to the value $\xi = 1/0.514$ of Lucini–Teper at $\beta = 2.60$; it is not a distance to a theorem.

$$\xi(\beta) \;\propto\; \Big(\frac{6\pi^2\beta}{11}\Big)^{-51/121} e^{3\pi^2\beta/11}, \qquad k = \log_2 \frac{\xi_{\mathrm{target}}}{\xi_{\mathrm{start}}} \tag{4}$$

Table 6 Target correlation lengths, and the β and number of steps needed Reading (values of the two-loop extrapolation. The window end is the end of the numerical window, $\xi = 1.95$; the curvature end is $\xi \approx 0.093$, the end of $\beta < 0.2722$ that comes from the lower bound of the curvature after one-link integration)

ξ_{target}	β (two loops)	From the window end	From the curvature end
10	3.243	2.36	6.75
100	4.136	5.68	10.07
1000	5.022	9.01	13.39
10^4	5.903	12.33	16.72
10^6	7.654	18.97	23.36

The numbers in Table 6 are all finite. Even so, the distance does not shrink, because what a theorem needs is not "up to some target" but "at every target, with the same constants". In metaphor, what is missing is not the number of steps on the staircase but the guarantee of not missing one's footing on any step. Improving the constants of the theorem on the strong-coupling side ($\beta < 1/12$ of Shen–Zhu–Zhu Cited) only widens the range of β in hand and does not touch this uniformity. The curvature end 0.2722 is a threshold that comes from the lower bound of the curvature (Lean), and the step towards the gap is a sketch Assumption .

Put back into the language of the first step, the same thing happens with $\hbar$. As in § 05, however wide the window of $\hbar$ is made, the double-well power statement (2) does not come out; what is needed is a proposition in a form uniform as $\hbar \to 0$. On the four-dimensional lattice, a form uniform as $\beta \to \infty$; in the first step, a form uniform as $\hbar \to 0$ — on every step of the staircase, the shape of what is missing is the same.

Detour: the lesson of φ^4_4 — even if the limit is reached, the place one arrives at may be trivial

A subsection you may skip. For the four-dimensional scalar field ϕ^4, cutting it off on a lattice and taking the limit naturally lands on a Gaussian (the free field) (Aizenman–Duminil-Copin 2021, 7-08) Cited . Even if the limit exists and the mass stays finite, if the interaction has vanished it is not a solution in the sense of the problem statement. This is why the non-triviality statement is written separately in the continuum target level of Table 5, and it is the same caution as the relaxation-time lower-bound assumption being a different statement from non-triviality (23-01 § 06). In metaphor, one may think one has reached the summit and find it is flat ground.

08

How to read the distance — a one-line conclusion

We put the distance of this chapter into a single diagram of arrows.

$$\underbrace{\text{each row of the first step}}_{\text{Table 1}} \xrightarrow{\hbar\to 0 \text{ in uniform form}} \text{power form of Assumption } (\xi^2) \text{ (first step)} \cdots \underbrace{\text{theorems f}}_{\text{in}}$$

The dotted line is not an implication; it shows that a statement of the same form is placed at two steps. None of the arrows of (5) has been proved. In the first step we have gone as far as listing the rows before the arrow, dividing them into two roads and attaching a kind of work to each row; the dividing is an arrangement, not a shortening of the arrow.

In one line, **what is missing is not the number of steps but uniformity: holding with the same constants at every scale**. In the first step it appears as the in-phase local Poincaré condition and the rows of the core uniform as $\hbar \to 0$; on the four-dimensional lattice, as the upper-bound assumption and the bridge uniform as $\beta \to \infty$ — the same thing in different forms.

This part placed the relaxation-time assumption at the axis and divided that uniformity into the rows of the first step. Roads that ask about the same uniformity from viewpoints other than the relaxation-time assumption are taken up in Part 24. A single table that rearranges, for each of the four steps of the staircase, the hurdle, the known reach, whether the tools of this book reach it, and the kind of cost is in 24-07 § 04.

What this chapter can say

Can say	Cannot say
That the rows needed for the conclusion [111] split into two roads at the fork [103]. The road of the core on the box side has 15 assumption rows and 3 reading rows, the road of the core on the sector side 20 assumption rows and 3 reading rows (counted from the data of the integrated table)	Which road is easier. The number of rows does not show weight
The kind of work needed to close each row (interval arithmetic, paper, bibliography, measurement, another method, method undecided), and the cost estimates in the record	Whether the estimates are right. None of them has been run. The cost of rows without estimates
That there is no $\hbar$ at which all rows are in place, that bringing them into line needs another method to extend the in-phase local Poincaré condition to $\hbar \to 0$, and that computer assistance in the window does not reach (2)	The asymptotics of the in-phase local Poincaré condition as $\hbar \to 0$. (2) itself

Can say	Cannot say
Three levels of the goal from the second step on, and the number of steps by the two-loop extrapolation (reading) Reading	Table 6 is a rough guide by extrapolation, not a theorem on the correlation length. This part shows none of the three levels
Setting out the rows of the road of blocks and mixing (block LSI and strong mixing) in Table C1, and showing the Hidden-Convexity Proposition and threshold of convexity = first conjugate point with proofs Proved here . That even if the road of blocks and mixing is chosen the 13 common rows remain, and the first step does not close	The 8 assumption rows and 2 reading rows of the road of blocks and mixing. Whether $\ln(1/\hbar)$ remains in the mixing length

Sources and reproduction

Item	Kind	Source, tool
Numbers, contents and grades of the rows of Table 1	This book	23-12 Table 1. The source of each row is in the source column of the integrated table
Work and cost estimates of Tables 1 and 3	This book	The sections on what remains in each chapter (23-06 § 07, 23-07 § 04, 23-09 § 05, 23-11 § 07). All are estimates; nothing has been run
Counts of Tables 1 and 2 and Figure 1	Text processing	A small script that adds a column of costs to the same row and edge data as the integrated table, chooses one side of [103], and collects nodes from the conclusion in the direction of the premises (not a mathematical computation)
(3), Table 5, lattice correlation-length problem	Cited	A. Jaffe, E. Witten, Quantum Yang–Mills Theory, Clay Mathematics Institute (2000). S. Chatterjee, arXiv:1803.01950 § 5
(4), Table 6	Reading	Two-loop coefficients (source table of 4-06) and the value at $\beta = 2.60$ in Table 1 of B. Lucini, M. Teper, JHEP 0106 (2001) 050, hep-lat/0103027. The extrapolated numbers are copied from the table in the record of the study
The strong-coupling range $\beta < 1/12$	Cited	H. Shen, R. Zhu, X. Zhu, Commun. Math. Phys. 400 (2023) 805–851, arXiv:2204.12737 (source table of 23-01)
Triviality of ϕ^4_4	Cited	M. Aizenman, H. Duminil-Copin, Ann. of Math. 194 (2021) 163 (source table of 7-08)
The rows of the road of blocks and mixing (Table C1), the numerical rows C04, C07, C12	Proved here, Reading, Assumption	The Hidden-Convexity Proposition and C01 are proved in the text. $\kappa_\hbar$ of C04, C07 and C08, and C12, are floating-point numbers from the record (C07 in 50 digits, not interval arithmetic). The candidates to cite for the assumption rows (Helffer–Nier, Le Peutrec, Menz–Schlichting, a limit of Varadhan type, Zegarlinski, Martinelli–Olivieri, Topkis's monotone comparison theorem) have not been checked against the literature

Terms used in this chapter — distance (a list), fork, road of the core on the box side, road of the core on the sector side, kinds of work (interval arithmetic, paper, bibliography, measurement, another method, method undecided), a $\hbar$ that fits all, three levels of the goal, uniformity. Their meanings are in the A-02 glossary.

Next chapter: 23-16 What is not claimed — what this part does not show, what should not be read strongly, and what is not called false either, with a table of correspondence to sentences of the text.

What is not claimed — not shown, not read strongly, not called false

> This chapter is a map of open questions. § 01 and § 06 are guide material.

What this chapter shows — The list of things Part 23 does not claim (fourteen items), and a table matching each item to the sentence in the body, and the chapter, that supports it. The difference between not claiming something and claiming its opposite. For the first-step proposition, the Lean theorems, the computer-assisted results and the readings, examples of how each is misread once its conditions are removed.

Prerequisite chapters — None. This chapter can be read from anywhere. The terms are defined in 23-01 § 05 (the diffusive-relaxation-time assumption, the relaxation-time upper-bound assumption and the relaxation-time lower-bound assumption), 23-00 § 01 (the five labels) and 23-05 (the Double-Well Relaxation-Time Upper-Bound Proposition and the four double-well conditions).

Said first — The level is [Y2]. This book does not solve the problem of Yang–Mills existence and the mass gap. This part contains no construction of the continuum limit and no proof of the mass gap (the existence of the continuum limit is proved in Lean by the construction published on 2026-11-10, along another road — this is the committee's assessment; Part 6. The mass gap is not shown there either; 6-04). This chapter only splits that fact into items and writes them out; it adds no new result. This part places the diffusive-relaxation-time assumption at the axis of the study, and it does not claim that the relaxation-time assumption is the only road or the right road.

The order of this chapter

1. Three meanings — not shown / not read strongly / not called false (Table 1) / Detour: negating a quantifier
2. The fourteen items and the sentences in the body that support them — a table of correspondence (Table 2)
3. On the main problem — the claim of the problem statement, the local-field footnote · weak-existence footnote (footnotes of Jaffe–Witten)

4. On the double-well step — the First-Step Upper-Bound Proposition is algebra on top of four conditions (Table 3)
5. Not reaching is not evidence of falsity — the death of detour plans, the reading for the periodic box, the lower-bound assumption and the free field (Table 4)
6. Conditions fall away in summaries — sentences of the body and one-line summaries (Table 5)
7. Analogies and other documents — what is not judged, and the convention for putting things out

---

01

Three meanings — not shown, not read strongly, not called false

When a mathematical text says "not claimed", there are three meanings. The first is **not shown**. On the main problem, this part shows nothing. The second is **not read strongly**. Whatever has been shown always carries conditions or assumptions, and reading it with the conditions removed gives a sentence that has not been shown. The third is **not called false**. That a method did not reach something is a property of the method, not a claim that the proposition it did not reach is false.

The third becomes clear when written in logical form. Writing "P is claimed" as $\vdash P$, we have

$$\neg(\vdash P) \quad \text{and} \quad \vdash \neg P \quad \text{are different sentences} \ (1)$$

On the left: "we do not have a proof of P". On the right: "we have a proof of the negation of P". The "not claimed" of this chapter always has the meaning on the left. As a metaphor: a road not drawn on a map is not evidence that there is no road there.

Table 1 How the items of this chapter are divided (numbers are the items of Table 2)

Kind	What is not claimed	Item
Not shown	Existence and the mass gap on $\mathbb{R}^4$, the construction of the continuum limit, the double-well relaxation-time power statement for the first step	1, 2, 3, 10
Not read strongly	Computer-assisted results, readings, Lean theorems, lifting, the relation between the relaxation-time assumption and the mass gap	4, 5, 6, 7, 11
Not called false	Propositions a tool did not reach, the upper-bound assumption as read to fail in the periodic box	8, 12, 13
Not judged, not counted	Rederivations of known results, the correctness of other documents, putting unclosed propositions out	9, 14

Detour: negating a quantifier

A subsection you may skip. The negation of "for every f, $Q(f) \le C$" is "for some f, $Q(f) > C$". In symbols, $\neg\forall f\, A(f) \iff \exists f\, \neg A(f)$. To show the upper-bound assumption false, a single sequence of counterexamples f suffices; to show the lower-bound assumption false, one must show "for every f the ratio is $o(\xi^2)$". The latter is a sentence of the same "for every" type as the upper-bound assumption, and it does not come out of listing test functions. That some families did not reach it is a "for every" restricted to a family ($\forall f \in \mathcal{F}$), not a "for every" with the family removed.

02

The fourteen items and the sentences in the body that support them

Table 2 writes, one row at a time, what this part does not claim, and lists the places in the body that support each row. "Support" means that the sentence in that chapter already states the conditions, assumptions and scope, and the row merely copies it onto one line.

Table 2 What is not claimed, and the sentences in the body that support it

Item	What is not claimed	Kind	Supporting sentence in the body (gist)
1	The solution of the problem of Yang–Mills existence and the mass gap. Neither a construction of the continuum limit nor a proof of the mass gap in the limit is here	Not shown	23-01 § 08: in four dimensions, what we have (along the line of this part) are only the theorems of the reflection-positivity preservation statement and the OS reconstruction statement, and the infinite-volume uniqueness statement for small β. Even with the relaxation-time assumption and the bridge, the infinite-volume uniqueness statement, the Wilson-loop limit statement, the rotation-recovery statement, the OS reconstruction statement and the non-triviality statement do not follow
2	Even for the first step (the double well in 0+1 dimensions), the relaxation-time assumption (the double-well power statement) has not been shown. The First-Step Upper-Bound Proposition is algebra on top of four conditions, and each of the four conditions leaves assumption rows	Not shown	23-05 § 08: where the four conditions stand. 23-12 § 07: the assumption rows needed for the conclusion number 15 or 20
3	There is not yet a single $\hbar$ at which all rows of the four conditions hold at once	Not shown	23-12 § 06: the nodes of the in-phase local Poincaré condition and the range of the saddle-tube condition do not intersect. 23-15 § 05

Item	What is not claimed	Kind	Supporting sentence in the body (gist)
4	Computer-assisted results are inequalities inside the windows and nodes that were computed, and say nothing about outside the window or about $\hbar \to 0$	Not read strongly	23-08 § 10: what computer assistance does not say (outside the window, $\hbar \to 0$, the difference between continuum and lattice)
5	Readings (floating point, Monte Carlo, fits, lower bounds over families) are used neither as upper bounds nor as proofs of lower bounds	Not read strongly	23-00 Table 1: what the label "Reading" does not guarantee. 23-12 Table 1: all 19 Reading rows keep the grade "Reading"
6	A Lean theorem checks the algebra from assumptions to conclusion; it does not check that the assumptions are true, nor the reading of real numbers as physical quantities	Not read strongly	23-13 § 05: four limits (truth of the assumptions, the encoding of the objects, putting the conclusion into a definition, circles of dependence)
7	From the first step to the second step on, we only state the prospect that the form of the sentences and the form of the tools lift; there is no theorem of implication	Not read strongly	23-03 § 06: what lifts and what does not (constants and the range of $\hbar$ do not lift)
8	That a tool did not reach something is a property of that tool, not a claim that the proposition it did not reach is false	Not called false	the table of scope in 23-10: the "death" of a detour plan is a property of the tool. 23-02 § 08: where the roads on the four-dimensional lattice stopped
9	Rederivations of known theorems are not counted as results. The correctness of other documents that claim a construction is not judged	Not judged	23-14 § 03: the support of the cited theorems. 23-14 § 07: from outside documents we take only patterns, give the source, and do not judge
10	The record on the side of the four-dimensional lattice (the relaxation-time assumption, the three chains, the sum of shortfalls) also remains assumption	Not shown	23-01 § 05: the three chains are all assumptions. 23-02 § 07: what remained is algebra and readings

Item	What is not claimed	Kind	Supporting sentence in the body (gist)
11	Under the assumption of the one-sided bridge, the upper-bound assumption implies a lower bound on the gap of the lattice in physical units, but the converse is false in general and undecided for the class of Wilson measures. The relaxation-time assumption is not the mass gap itself	Not read strongly	(4) of 23-01 § 06 (the one-sided bridge) and (5) (the Free-Particle-on-a-Circle Counterexample: on the circle, $\Delta > 0$ and $CP = \infty$)
12	The "death" of a detour plan means that the ceiling of that construction does not exceed the needed value, not that the one remaining proposition is false	Not called false	23-10 § 03: the line that killed it is a line of a tool's inequality
13	The reading that the upper-bound assumption fails on the four-dimensional lattice in the periodic box is a conditional reading, resting on numbers from the literature and on the conjecture that "HMC and Langevin are in the same universality class"; it is not a theorem that the upper-bound assumption is false	Not called false	the note in 23-01 § 05 (topological sectors and the order of volume), 23-02 § 05
14	A proposition with assumption rows left is not put out as a result. Only what has had all its conditions closed is put out	Not counted	23-12 § 08: the integrated table is a map, not a fraction of progress

Items 1–10 are the skeleton of the part, and 11–14 were added from the text of the individual chapters. Every row compresses the conditions of the body onto one line, and is written so that reading the body gives the conditions in full.

03

On the main problem — nothing is said about the claim of the problem statement

What the problem statement (0-03) asks is that, for every compact simple gauge group, a quantum Yang–Mills theory on $\mathbb{R}^4$ exists, satisfies the axioms (4-09, 4-10), and has a mass gap.

$$\text{existence (satisfying the axioms)} \quad \wedge \quad \operatorname{spec}(H) \subset \{0\} \cup [\Delta, \infty), \ \ \Delta > 0 \ \text{(2)}$$

This part shows nothing about either part of (2) (item 1). The local-field footnote · weak-existence footnote of the problem statement excludes from solutions limits obtained only by weak existence (compactness) Cited . That subsequential limits come for free from compactness is a matter at that level, and neither uniqueness nor the mass gap follows from it.

The relaxation-time assumption, which this part treats, is a sentence that restates Δ of (2) (the gap in Euclidean time) in terms of the relaxation time C_P of Langevin dynamics. The two are different quantities, and only when the one-sided bridge holds can one cross, in one direction, from the upper-bound assumption to a lower bound on Δ (item 11, 23-01 § 06). We placed the relaxation-time assumption at the axis of the study because it is language that can be computed on the lattice, has the tools of convexity and Poincaré inequalities, and is within reach of machine checking; we do not claim that this restatement is the only road to solving the problem. Other views are placed in Part 24.

04

On the double-well step — the First-Step Upper-Bound Proposition is algebra on top of four conditions

The central sentence of the first step is the First-Step Upper-Bound Proposition: "on the four double-well conditions, $C_P \le K\xi^2 S_0/\hbar$, and hence the double-well power statement" (23-05 § 04). Reading this sentence as "the double-well power statement has been shown for the double well" is too strong (item 2). Beneath the four conditions there are 15 or 20 assumption rows of the integrated table (depending on which of the two roads) and 3 reading rows (23-15 Table 1).

The algebra of the construction is checked in Lean, but when only the theorem name remains in a summary, the conditions fall away. Table 3 lists the theorem names of this part that are easily read strongly once their assumptions are dropped (item 6).

Table 3 Theorem names, assumptions, and what is not to be read strongly

Theorem name	Assumptions (gist)	Not to be read strongly
`H3_H4_compose`	The box product inequality, the box gap inequality, $D = \hbar/S_0$, $n, \hbar$, $S_0 > 0$, $c_{\text{alt}} < 1$	Not "the First-Step Upper-Bound Proposition has been shown". The in-phase local Poincaré condition and the saddle-tube condition are inside the assumption of the box gap

Theorem name	Assumptions (gist)	Not to be read strongly
`power_H_of_kink_ratio`	$0 < K, s, \delta$, $1 \le R \le K/\hbar$, $s/\hbar \le \ln \xi$	Not "the double-well power statement has been shown". $R \le K/\hbar$ is the conclusion of the First-Step Upper-Bound Proposition itself
`H1_assembly`	Seven named ones (decomposition, fine side, Helffer's criterion, margin, $0 < \lambda$, the crossing row, the rate condition)	A proposition at six nodes, not the in-phase local Poincaré condition uniform in $\hbar$
`cloc_term_vanishes`	The core action-barrier assumption, the reading of ξ, $\Delta S_* < 2S_0$	The local term vanishes when the core action-barrier assumption is assumed. The value of the action barrier is a reading at $\hbar = 0$
`path5_conditional`	The remainder inequality, the proxy ratio, rarity, the arithmetic margin (named)	The Scalar-Strand Proposition at the lower end of the window; there is no edge of implication to the one remaining proposition
`win_qfree_window_le_of_interval_table`	Table of interval-arithmetic output	Inequalities inside the window (item 4). Not on the road to the conclusion in the integrated table
`hup_is_gap_positivity_of_lower`	$0 < m_{\mathrm{lat}}$, $\kappa/m_{\mathrm{lat}}^2 \le C_P$, $C_P \le K\xi^2$	The one-sided bridge enters as an assumption. That the bridge holds for the Wilson measure has not been shown (item 11)
`drainExp_eq_zero_iff`	$0 \le \eta \le 2$, $\theta \ge 0$	Algebra of exponents on the side of the four-dimensional lattice. Applying it to physical quantities rests on assumptions (item 10)

Example. `power_H_of_kink_ratio` is the algebra "if the ratio R lies between 1 and $K/\hbar$, and $\ln \xi$ is at least $s/\hbar$, then $\ln C_P / \ln \xi \to 2$". Removing the assumption $R \le K/\hbar$ and writing "the double-well power statement in Lean" gives a sentence that has not been shown. The correct summary is "the double-well power statement follows by algebra from the conclusion of the First-Step Upper-Bound Proposition (Lean)".

05

Not reaching is not evidence of falsity

The death of detour plans (items 8, 12). Of the detour plans aimed at the one remaining proposition of the route of the window log-Sobolev inequality, 13 were

judged "dead" (23-10 § 03). Death means that the ceiling of the upper bound obtained by that construction does not exceed the needed value. It does not mean that the one remaining proposition [026] is false, and it says nothing about the possibility of closing it by another construction.

The reading for the periodic box (item 13). On the four-dimensional lattice, it is reported that in a box with periodic boundary the autocorrelation time of the topological charge grows faster than ξ^2, and together with $\tau_{\text{int}} \le C_P$ this reads as the upper-bound assumption failing in the periodic box (the note in 23-01 § 05). This reading stands on numbers from the literature Reading and on the conjecture that HMC and Langevin are in the same universality class Assumption. So this part does not claim "the upper-bound assumption is false on the four-dimensional lattice" either. What it claims is only that how to correct the statement of the relaxation-time assumption remains as a question.

The lower-bound assumption is not non-triviality. What the lower-bound assumption avoids is only that the physical mass collapses to infinity; it does not ask whether there is interaction. This can be confirmed by computing the relaxation-time assumption in a theory without interaction. For the free field with lattice mass m, the Poincaré constant of the path measure is the largest eigenvalue of the covariance,

$$C_P = \frac{1}{m^2}, \qquad m^2 = 4\sinh^2\frac{1}{2\xi}, \qquad \frac{C_P}{\xi^2} = \frac{1}{4\xi^2\sinh^2(1/2\xi)} = 1 - \frac{1}{12\xi^2} + O(\xi^{-4}) \tag{3}$$

Table 4 C_P/ξ^2 for the free field on the lattice Proved here (values of the closed formula (3))

ξ	C_P/ξ^2	$1 - 1/(12\xi^2)$
1	0.920674	0.916667
2	0.979425	0.979167
8	0.998699	0.998698
64	0.999980	0.999980

The ratio tends to 1 as $\xi \to \infty$, so both the upper and the lower side of the relaxation-time assumption hold. The relaxation-time assumption and the lower-bound assumption are sentences that hold in a theory without interaction, and the non-triviality statement does not follow from the relaxation-time assumption (23-01 § 06).

06

Conditions fall away in summaries — sentences of the body and one-line summaries

The error of reading a claim strongly occurs, in most cases, at the stage of compressing a sentence of the body onto one line. Table 5 sets the conditional sentences of the body

beside one-line versions with the conditions dropped completely. Every sentence in the right column is one this part has not shown.

Table 5 Sentences of the body (conditional) and one-liners with the conditions dropped (every one on the right is wrong, or not shown)

Topic	Sentence of the body	One-liner with the conditions dropped
Chain outside the window	$q_{\text{free}} \le 0.998854904$ over the whole $\hbar$ window $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$ Computer-assisted (assuming IEEE correct rounding, outward widths)	The chain condition of the saddle-tube condition is closed
Chain outside the ring	$q_{\text{out}} < 1$ over the whole window Computer-assisted (conditional on the pin ≤ 0; the boundary stage is a reading of 1.004–1.045)	The seam of the ring is closed
Mixing between boxes	$c_{\text{alt}} = 0.731/0.410/0.138$ ($C = 2/4/8$, values of the reduced model) Reading	The alternating maximal-correlation assumption for boxes holds
In-phase local Poincaré condition	Margin ≥ 0.067 at six nodes (ends $[0, 2.5]^2$) Computer-assisted , constant $C \le 1.6 \times 10^{10}$ (a proposition at the nodes)	The in-phase local Poincaré condition has been shown
First-Step Upper-Bound Proposition	Algebra on top of the four double-well conditions (Lean has the algebra of composing boxes)	The double-well power statement has been shown for the double well
Feynman–Kac strand	A reading of $\sup \lvert\nabla\psi\rvert^2$ from below, 0.433 ± 0.007 (0.54 times the threshold, $\hbar = 10^{-3}$) Reading ; the paper upper bound is about 1000 times the threshold	The assumption of the Feynman–Kac strand falls within the threshold
Periodic box	On numbers from the literature and a conjecture, the upper-bound assumption reads as false in the periodic box	The upper-bound assumption is false in four dimensions

The errors in Table 5 are of two types. One drops the scope (window, nodes, model values); the other drops the grade (Reading, Computer-assisted, Assumption). Both are prevented by keeping the words of the condition in the one-line summary.

07

Analogies and other documents — what is not judged, and the convention for putting things out

Where words are borrowed from the side of physics, they inherit the level of where they were borrowed from. Holography is a conjecture, and a table of correspondences that uses it is a dictionary, not a proved equivalence. The "4" in a complete family existing for $d \le 4$ is a combinatorial number of the lattice, a coincidence unrelated to the dimension of physical spacetime (23-02 § 02). The correspondence between the

first step and the four-dimensional lattice ($\hbar \to 0$ and $\beta \to \infty$) is also an analogy, not a theorem of correspondence (23-03 § 06).

On other documents that claim a construction, this part does not judge correctness (item 9). What we took from outside documents is only patterns for reading dependency graphs (closing by putting the conclusion into a definition, circles of dependence), and even those were written as patterns with the source withheld (23-13 § 05, 23-14 § 07).

Finally, the convention for putting things out (item 14). As long as even one assumption row remains, the propositions of this part are not put out as results. What is put out is only what has had all its conditions closed and has passed machine checking and bibliographic checking. Until then, the text stands as a map of which rows are closed and which are not.

What this chapter can say

Said	Not said
That this part shows nothing about (2) of the problem statement. The fourteen items that are not claimed, and the places in the body that support them (Table 2)	Whether (2) is true. The existence of the continuum limit. A gap uniform in the volume
The assumptions of the theorem names in Table 3 (copies of the statements in each chapter)	The truth of the assumption rows
Proved here That $C_P/\xi^2 = 1 - 1/(12\xi^2) + \cdots$ and the relaxation-time assumption hold for the free field on the lattice (closed formula)	A theorem comparing C_P and ξ^2 for an interacting four-dimensional measure (in neither direction)
The conditions of the reading that the upper-bound assumption fails in the periodic box (numbers from the literature and a conjecture)	That the upper-bound assumption is false, or true, on the four-dimensional lattice

Terms used in this chapter — not shown, not read strongly, not called false, negating a quantifier, the one-sided bridge, the death of detour plans, conditions that fall away in summaries. Their meanings are in the A-02 Glossary.

Next chapter to read: 23-17 Insights and small questions — the views that repeatedly proved useful in studying the first step, and questions that can be settled at the size of an undergraduate thesis.

2026-10-09 · chapter Yang–Mills and the mass gap Part 23 The first road, first half — from the direction of time patterns of insight, discarded hypotheses, small questions · Kiichi, Shiori and Rin

Insights and small questions — views that remain as procedures, and questions that can be settled

> In this chapter, § 01 is guide material, § 02– § 04 are a map of open questions and § 05 is this book's own investigation.

What this chapter shows — The views that repeatedly proved useful while studying the first step, gathered into twelve insights in the form "any problem needs this procedure". For each insight, one small question the reader can check by hand. A table of discarded hypotheses and the reasons. A list of questions that can be settled at the size of an undergraduate thesis, and a worked example that takes one question to the form of a settlement.

Prerequisite chapters — The material for the insights is in the chapters 23-06 to 23-11. At the end of each insight we write the chapter where that view worked. The prerequisites of each question are written in its entry.

Said first — The level is [Y2]–[Y3]. What is listed here are insights and questions before verification, neither theorems nor results. Whichever question is settled, it does not reach a proof of the mass gap. For each question we wrote what does not move even when it is settled.

The order of this chapter

1. How to read the insights — three states, and the criterion for keeping one (Table 1)
2. Twelve insights and small questions — ways of paying, addresses, thresholds, directions, order
3. Discarded hypotheses — the original form, the corrected form, the grounds (Table 2)
4. Questions at the size of an undergraduate thesis — a list of seventeen questions (Table 3)
5. Worked example: one question to the form of a settlement — $1-\lambda_k$ for the Hermite family (Table 4)

01

How to read the insights — three states, and the criterion for keeping one

In the course of a study, "shifts in how things look" get written down apart from results. They fall into three states: **still an insight** (not yet tested), **checked form** (checked once on a small model or a closed formula), and **overlaps the known** (the core was a restatement of a known theorem; not counted as an insight).

There is one criterion for keeping something in this chapter. Not who thought of it or when, but only what can be written in a form that lets us say **another reader who meets a problem of the same type would also need to take this procedure**. For example, "before trimming an upper bound, sort the factors of the needed value into structure and tools" is a procedure that keeps its meaning away from the double well. Conversely, the observation that some number happened to lie near a threshold is not kept.

We read the insights on the side of the four-dimensional lattice in seven patterns (cannot be measured from below / drop to one dimension / drop the units / counterexamples and controls first / look at the power of the difference / the diffusive-relaxation-time assumption is a pair of measure and form / connectedness of the state space). Table 1 shows those seven and how they relate to the twelve insights of this chapter.

Table 1 The seven patterns, and the insights of this chapter (the right column gives the insights of § 02)

Pattern	One line	Insight continuing it in this chapter
Cannot be measured from below	Averages and test functions bound C_P only from below	Before trimming an upper bound, measure one lower bound
Drop to one dimension	Tools for upper bounds on C_P are available in one dimension	The threshold of convexity is decided by whether the parameter enters the Hessian (cut shorter than the threshold)
Drop the units	Make dimensionless ratios the protagonists	What does $1/\hbar$ live in? (the length where $1/\hbar$ lives)
Counterexamples and controls first	First name the models where the proof fails	The wall of conditioning creates minima (count the minima first)
Look at the power of the difference	What fixes the power is not the quantity but what is left after cancellation	Split the ratio of upper bound to reading into a stage of cancellation and a stage of direction
The relaxation-time assumption is a pair of measure and form	Name the normalisation of the Dirichlet form explicitly	Whether the diffusive-relaxation-time assumption is true changes with the coordinates (the Dirichlet form)
Connectedness of the state space	Suspect topology before uniformity of constants	The insight that truth changes with the coordinates, the note in 23-01 § 05

02

Twelve insights and small questions

Are we paying for the same place twice?

In a long chain of inequalities, one bad place (near the top, for the double well) may be paid for by two stages under different names. In the sector framework, the Bochner stage and the Gibbs stage both paid for the same neighbourhood of the top, and the amplification factor of one of them multiplied the whole. Moving the negative curvature to the other side avoids passing through the amplification. In the same pattern, when using gradients in which two terms complement each other, sharing the denominator can sometimes fold $(1+\sqrt{C})^2$ into $(1+C)$ instead. As a procedure: **before tightening a construction, write out place by place what each stage is paying for, and look for double payment** (23-09 § 02, the double-payment type in 23-10). State: checked form.

Small question 1. Compare the best right-hand side, when $\|u\|^2=\|v\|^2=\|w\|^2=1$, of two constructions for the sum of three vectors $u+v+w$: applying $\|u+v\|^2 \le (1+t)\|u\|^2 + (1+1/t)\|v\|^2$ $(t>0)$ twice in a row, and distributing all three terms at once as $\|u+v+w\|^2 \le (1+s_1)\|u\|^2+\cdots$. Where does the twice-in-a-row construction pay for the same quantity twice?

The currency of Poincaré and the currency of entropy

There are situations where one wants to pay for rare events with "rarity". But on the side of the Poincaré inequality, rarity is not a currency. Poincaré looks at the speed of exit, and putting mass on a rare state cancels the mass in both the variance and the Dirichlet form. Rarity can be a currency only on the side of entropy (the logarithmic Sobolev inequality), but there one pays instead $\ln(1/\nu)$ for the rarest state on which test functions can concentrate. As a procedure: **decide between the entropy type and the variance type by setting two rarities side by side (the rarity of the defect one wants to pay for, and the rarity of the states on which test functions can concentrate)** (the currency-mix-up type in 23-10). State: checked form (the two-point model).

Small question 2. Consider the measure $\pi=(1-p,p)$ on two points $\{0,1\}$ and the Dirichlet form with flip rate 1, $\mathcal{E}(f)=\pi_0\pi_1(f_1-f_0)^2$. Show that the Poincaré constant does not depend on p. Check, by citing the known formula for the two-point space (Diaconis–Saloff-Coste), that the logarithmic Sobolev constant grows at the rate $\ln(1/p)$ as $p\to 0$.

What does $1/\hbar$ live in? — read the loss on the same length as the quantity it multiplies

On the plateau at the top, the test function that produces a constant of size $1/\hbar$ was not a function of the collective linear coordinate $\sum z_j$ but of the radius from the corner at the top, $\sum z_j^2$. Choosing the linear collective coordinate gets the direction wrong. Also, $1/\hbar$

lives on the length of the plateau $\ell \approx 0.34/\hbar$, and when measuring a loss it must be measured on the same length as the quantity it multiplies. As a procedure: **before splitting into two scales, check whether the function that produces the lower bound lives on the coarse coordinate or on the fibre** (the type of the address of 1/ħ in 23-10, 23-09 § 06). State: still an insight (in a form supported by numerical readings).

Small question 3. For the measure $\mu \propto e^{-V(|z|)/\hbar}$ on $\mathbb{R}^k$ with $V(r) = (r^2-1)^2/8$, compare the ratios $\mathrm{Var}(\cdot)/\mathcal{E}(\cdot)$ ($\mathcal{E}(f) = \hbar \int |\nabla f|^2 d\mu$) of the linear function $f = z_1 + \cdots + z_k$ and the radial function $g = |z|^2$, for $k = 1$ and $k = 2$, up to the leading term as $\hbar \to 0$. For $k = 2$, when μ concentrates on an annulus, which function captures the slow direction?

The wall of conditioning creates minima

When conditioning by fixing the ends of an interval exactly, all the minima at $\hbar = 0$ may lie on the wall. The "slowness" or "bistability" one then sees is not a property of the model but a shadow created by the conditioning (the bistability at the negative end of the core was the shadow of confining, inside the interval of the core, a configuration in which the kink wants to shift by one site). As a procedure: **each time the way of cutting sectors or conditioning changes, make the first check a count of the $\hbar = 0$ minima lying on the wall** (23-11 § 06). State: checked form.

Small question 4. Where does the measure $\mu_\hbar \propto e^{-V/\hbar}\mathbf{1}_{[0,b]}$, $V(x) = (x^2-1)^2/8$ restricted to the interval $[0, b]$ ($0 < b < 1$), concentrate as $\hbar \to 0$? Near there, approximate $\mu_\hbar$ by an exponential distribution, and write the behaviour of the Poincaré constant of $\mu_\hbar$ (Dirichlet form $\hbar \int f'^2 d\mu$) as $\hbar \to 0$ in terms of $|V'(b)|$. What changes when the wall is moved to $b = 1$?

Before closing the inside uniformly, first write what multiplies it on the outside

In nested estimates, one can get stuck trying to bound an inner constant by $O(1)$. But if, in the outer formula, that constant is multiplied by a small factor, the accuracy needed inside is much looser. In the proposition for the box gap, the local term is multiplied by $e^{-2S_0/\hbar}$, so the constant of the core did not need to be $O(1)$; size $e^{\Delta S/\hbar}$ ($\Delta S < 2S_0$) was enough. As a procedure: **before closing the inside uniformly, first write what multiplies that quantity in the outer formula, and fix the accuracy needed inside by its ratio to the outer scale** (23-11 § 06). State: checked form (the reading of the action barrier is the value at $\hbar = 0$).

Small question 5. Write the condition on B needed for $K(\hbar) = A + e^{-2S_0/\hbar}B(\hbar)$ to be bounded as $\hbar \to 0$. If it has the form $B(\hbar) \le c\,\hbar^{-p} e^{\Delta S/\hbar}$, what must the relation among ΔS, $2S_0$ and p be? What is needed in the exact case $\Delta S = 2S_0$?

The sup over a parameter is attained just outside the threshold

When bounding the constant of a core of length k uniformly in k, the hard case was not a long core but just outside the threshold where convexity is lost ($k = 8$, both ends at the top). Inside the threshold convexity makes it free; far outside it saturates by reduction to the box; and one point in between attains the sup. As a procedure: **when stuck on a sup over a parameter, first find where the threshold is, then name the value just outside it and bound it separately** (23-11 § 05). State: checked form (the threshold is a closed formula).

Small question 6. Find the smallest k for which $\kappa(k) = 8\sin^2\big(\pi/(2(k+1))\big) - \frac{1}{4}$ is negative (the same formula as in 23-09 § 06). How does $\kappa(k)$ behave as $k \to \infty$? Are "the threshold is at $k = 8$" and "the sup is attained at $k = 8$" the same thing or different things?

The threshold of an excluded set is fixed by the mass the downstream inequality allows

When excluding a bad set and estimating on the rest, where to put the threshold is decided not by the convenience of the bad set but by what the downstream inequality, which receives the mass of that set, allows. In the sector framework, the threshold of the window mark and the threshold of the defect disagreed, so the only set determined by the mark that contained the defects was the whole space, and the closing condition, taken literally, gave nothing. As a procedure: **check literally that each of the conditions being composed holds on the same definition of the threshold, and work the threshold back from the mass the downstream can pay** (23-09 § 04). State: checked form (one line of measurability).

Small question 7. At one site $z \in \mathbb{R}$, consider the mark $\sigma = \mathbf{1}\{z \le -\theta_\sigma\}$ and the defect set $N = \{-\theta_B < z \le -\theta_\sigma\}$ ($\theta_\sigma < \theta_B$). List all sets determined by the value of σ (sets measurable with respect to σ) that contain N. What changes if $\theta_\sigma = \theta_B$?

The threshold of convexity is decided by whether the parameter enters the Hessian

When stuck on a sup over end values, the road divides according to whether the end value enters the Hessian. If the end value enters a nearest-neighbour quadratic coupling only linearly, the Hessian does not depend on it, and convexity is uniform in the end value. So cutting shorter than the threshold of convexity makes the sup over end values free, and the whole price moves to the side of the correlation across the cuts (the maximal correlation). As a procedure: **when stuck at the end of a parameter, first check whether that parameter enters the Hessian; if it does not, cut shorter than the threshold of convexity, and account separately only for the correlation at the seams** (23-11 § 05). State: checked form.

Small question 8. For $S(x_1, \dots, x_k) = \sum_{j=0}^{k} \frac{(x_{j+1} - x_j)^2}{2\varepsilon} + \varepsilon \sum_{j=1}^{k} V(x_j)$ and the measure $e^{-S/\hbar}$ with $x_0 = a$ and $x_{k+1} = b$ fixed, check that the Hessian does not depend

on a, b. When $V'' \geq -\frac{1}{2}$ (the value at the top of $V = (x^2-1)^2/8$), write the range of k for which the smallest eigenvalue of the Hessian is positive, in terms of ε (compare with $\kappa(k)$ of small question 6 at $\varepsilon = \frac{1}{2}$).

Split the ratio of upper bound to reading into a stage of cancellation and a stage of direction

When an upper bound U and a reading from below L are far apart, looking at the ratio U/L as a single number does not tell where one is losing. Inserting between them "the quantity along the same path before the cancellation is discarded", R, and splitting into R/L (the stage of cancellation) and U/R (the stage of direction), for the Feynman–Kac strand the former was around 1.2 and the latter over 1000, so almost all the loss was at the stage where the scalar Grönwall discards direction (23-09 § 05). As a procedure: **split the gap between an upper bound and a reading into ratios per stage before choosing the target of improvement**. State: checked form (ratios of readings).

Small question 9. For $\dot{X} = -CX$, $C = \mathrm{diag}(\lambda, \Lambda)$ $(0 < \lambda < \Lambda)$, with initial value $g = (0, 1)$ (the stiff direction), compare the true value of $\int_0^T |X_t|\, dt$ with the upper bound coming from the scalar Grönwall $|X_t| \leq e^{-\lambda t}|g|$. How does the ratio grow with Λ/λ? What is recovered when estimating with the matrix kept as it is?

Before trimming an upper bound, measure one lower bound

When tightening the construction of an upper bound through many stages still does not reach, first measuring one lower bound of the same quantity with a test function tells whether the problem lies in the technique or in the target. If the lower bound exceeds the target, improving the upper bound is pointless. In the sector framework, it turned out that the lower bound on the propagation constant lay at several times the needed value, which changed the meaning of the work of trimming the floor of the upper bound. As a procedure: **before trimming the floor of an upper bound, put a stage that sets the needed value beside the lower bound on the best constant** (23-09 § 03, 23-10 § 02). State: checked form.

Small question 10. On a single road of L cells (uniform distribution, $\mathcal{E}(f) = \frac{1}{L}\sum (f_{i+1} - f_i)^2$), show with the single test function $f_i = i$ that the target "$CP \leq L^2/12$" is false $(\mathrm{Var}(f)/\mathcal{E}(f) = L(L+1)/12)$. Compare also with the true value $1/(2(1-\cos(\pi/L)))$ (23-00 § 04).

Obstacles do not vanish but move — record, line by line, where they moved

Changing the formulation can make an obstacle seem to vanish while it appears elsewhere in the same form. In the first step, a single number — the curvature at one site at the top falls short of the coupling by $\frac{1}{4}$ — came back three times in different forms: the Poincaré constant of the lump of the core, the contraction ratio on the slope approaching

1, and the ratio of the tail pinned at the top exceeding 1 (the common wall of 23-09 § 06). As a procedure: **each time the formulation changes, record line by line "where the obstacle moved", and check whether the formula where it moved can be written with the same number**. If it can, that is not a defect of the tool but the structure of the object. State: checked form (the formula of the common wall).

Small question 11. Find in closed form the smallest eigenvalue of the tridiagonal matrix $M_k = \mathrm{tridiag}(-2,\ 4 - \frac{1}{4},\ -2)$ ($k \times k$, Dirichlet at both ends), and compare it with $\kappa(k)$ (small question 6). How is the failure of diagonal dominance, $\frac{15}{4} < 4$, related to the smallest eigenvalue becoming negative for $k \geq 8$?

Whether the diffusive-relaxation-time assumption is true changes not only with the measure but with the coordinates (the Dirichlet form)

The diffusive-relaxation-time assumption is not a sentence about a measure but about a pair of a measure and a Dirichlet form. Even for the same equilibrium measure, depending on which variables the dynamics moves independently, the size of the gap can be $O(1)$ or inversely proportional to the square of the side of the volume. In a dynamics with a conserved quantity (a quantity only handed between neighbours), its unevenness is smoothed out only by diffusion. As a procedure: **before asking about the relaxation-time assumption, name the coordinates of the dynamics, and first check whether that dynamics has a conserved quantity and at what length the conservation breaks** (23-01 § 05; for how to compare with the length at which conservation breaks, see Part 24). State: still an insight (checked form in the free-field approximation).

Small question 12. For the product measure of L independent standard normals, compare the gaps of (a) the dynamics that moves each coordinate independently by Ornstein–Uhlenbeck, and (b) the dynamics that hands quantity between neighbours and keeps the sum $\sum x_i$ (on the measure with the sum fixed). Check that the gap of (b) has the form $4\sin^2(\pi/(2L))$, and that it is unrelated to the static correlation length (here 0).

03 Discarded hypotheses — the original form, the corrected form, the grounds

Discarded hypotheses and the reasons for discarding them are information for avoiding the same errors. The upper six rows of Table 2 were discarded in the study of the first step, and the lower four on the side of the four-dimensional lattice.

Table 2 Discarded hypotheses and corrected insights

Original form	Corrected form	Grounds
Local Poincaré comes from a convex core	The action of an excursion out of the core is much smaller than S_0, and exponentially many excursions fit into an interval of length ξ	The reading of the action of excursions (towards the two scales of 23-06 § 03)

Original form	Corrected form	Grounds
Convexity improves away from the wall	The opposite. Pressing the end against the wall lowers the variance and raises the Hessian; moving it away removes only this help	Comparison of the Hessian for each end value (23-06 § 04)
Making the lumps larger lets the chain be built from the convexity of each lump	The worst convexity of a lump decreases with the length of the lump, and the coupling between lumps does not decrease	The formula of the common wall (23-09 § 06)
The contraction can be bounded by the smallest eigenvalue of the time-averaged operator	False. What can be used is only the time average of the smallest eigenvalue, and this discards direction	The algebra of the counterexample (Lean `mbar_bound_false`, 23-09 § 05)
If the pointwise reading is singular at rare configurations, the true gradient is singular too	What fixes the upper limit of the true gradient is not the pointwise minimum but the decay rate of the flow of derivatives	The representation $\nabla \psi = \int \mathbb{E}[J_t^{\top} \nabla G]\, dt$ (23-09 § 05)
The road of sharpening constants can lower $\hbar$ indefinitely	It stops at the convex radius (about 0.45); beyond that the error terms become genuinely large	The reading of the margin at the nodes (towards the $\hbar < 0.005$ row of 23-06 § 07)
$C_P \asymp \xi^2$ usually holds	The relaxation-time assumption is a specific claim, the dynamical exponent $z = 2$	$z \approx 2.17$ for the heat bath of the two-dimensional Ising model
Abelian counterexamples show that "non-abelianness is essential"	"An input that forbids a second small parameter" is essential	Three-dimensional $\mathbb{Z}_2$ keeps a single scale even though it is abelian (17-12)
The holographic density is not log-concave	The sign is the opposite ($W'' = -2B''$)	The judgement of the one-dimensional model
Gauge-fixed numbers are a property of confinement	Numbers for compact $U(1)$ in four dimensions; not measured for $SU(2)$	23-02 § 04

There are two types of error, and both occur at the stage of raising something to a one-line summary. One drops the conditions (group, model, range); the other confuses "a pointwise quantity" with "a quantity over the measure". Of the upper six rows of Table 2, four are of the latter type.

04

Questions at the size of an undergraduate thesis — a list of seventeen questions

A "small question" is one that satisfies three things. The form of the answer (exists / does not exist, the value of a constant, whether an inequality holds) is fixed in advance. The tools are at hand (python3 with NumPy and SciPy, a SAT solver, interval arithmetic, Lean and Mathlib, a literature search). There is a prospect that a third- or fourth-year student

of mathematics or physics can settle it within the period of an undergraduate thesis. The first column of Table 3 gives the short name of each question.

Table 3 Seventeen questions ("What does not move when settled" are the rows of this part that do not change even if the question is settled)

No.	Question	One line	Tools	Form of settlement	What does not move when settled
1	Complete families of k=3 cells	Does a complete family of $k = 3$ cells exist in $d = 9$?	SAT, Lean	A construction in the periodic box, or a record refuting satisfiability of the box	That one-link integration is a single step only (23-02 § 02)
2	Largest dimension with a complete family	The largest dimension in which a complete family exists, $d_{\max}(k)$	Exhaustive search, paper	A table for $k = 3, 4, 5$, and the reason the upper bound $3k + 1$ is not sharp	Same as above. Non-existence with period 2 (Lean `no_perfect_k4_d9`, `no_perfect_k5_d8`, assumption: period 2) already exists
3	Constant of the Hermite family	The constants of $1 - \lambda_k$ for the Hermite family (the worked example of § 05)	Paper, python3	The two terms and the remainder of (5)	That test functions bound C_P only from below
4	SU(N) version of the ratio on forests	The $SU(N)$ version, and the Lean statement, of the ratio of functions on the forest saturating at $1/\lambda_1(G)$	Paper, Lean	The statement of Poincaré for products of Haar	The relaxation-time upper-bound assumption (it only closes one family of test functions for the relaxation-time lower-bound assumption on the four-dimensional lattice)
5	C_P(β) on the two-dimensional lattice	$C_P(\beta)$ in the link variables of two-dimensional lattice YM	Paper, python3	The power as $\beta \to \infty$	The relaxation-time assumption in four dimensions (two dimensions is a control)
6	Curvature after one-link integration	The best constant of the curvature after one-link integration, $c^* \in [21, 27]$	Global optimisation, interval arithmetic	c^* and the configuration, a computer-assisted lower bound	That one cannot get out from the strong-coupling side

No.	Question	One line	Tools	Form of settlement	What does not move when settled
7	The N^{−3} coefficient of the column model	The coefficient $C \approx 320$ of N^{-3} in the column model, analytically (finite-size expansion of the XX chain)	Paper, python3	A closed formula agreeing to 4 digits or more	The logic of the arrows of the tube estimate (the tube inequality)
8	Sign of 1/P in the column model	In the column model, the sign of $1/P$ at finite u	python3	A table of signs for $u = 0.1 \sim 0.3$	Same as above
9	Gauge dependence of the shortfall	How much does the shortfall c_2 change with the choice of gauge in the block transformation?	python3	A table of c_2 for each gauge, and whether $c_2 > 0$ is kept for positive kernels	The arrow of the sum of shortfalls (it does not move if $c_2 \neq 0$)
10	C_P and ξ² of the O(3) σ model	C_P and ξ^2 of the two-dimensional $O(3)$ sigma model	python3, literature	The slope, and whether a logarithm is present when the scale is changed	The relaxation-time assumption in four dimensions (an asymptotically free control)
11	C_P/ξ² of three-dimensional Z_2 gauge theory	C_P/ξ^2 of the three-dimensional $\mathbb{Z}_2$ gauge theory	python3	A table, and the correspondence with the dynamical exponent on the dual Ising side	The relaxation-time assumption in the non-abelian case
12	Volume monotonicity of C_P(V)	Monotonicity in volume of $C_P(V)$, and boundary conditions (find all eigenvalues of the generator on small lattices)	python3	A counterexample to monotonicity, or a proof	The question itself of the order of volume in which the relaxation-time assumption is stated (the note in 23-01 § 05)

No.	Question	One line	Tools	Form of settlement	What does not move when settled
13	Dynamical exponent of four-dimensional SU(2)	Collect the primary sources on the dynamical exponent of local algorithms for four-dimensional $SU(2)$	Literature	A table of about ten primary sources (exponent, observable, box, boundary)	The conditions of the reading for the periodic box (the part that is a conjecture)
14	Interval arithmetic for the maximal correlation of the core	Bound from above, by interval arithmetic, the two-point maximal correlation of the medium-core step ($8 \le k \le 14$)	Interval arithmetic, paper	Computer-assisted upper bounds at each point of k and $\hbar$, and a paper on the difference between lattice and continuum	[007] of the road of the core on the box side (the side $k \ge 15$) and [014] (23-15 Table 1)
15	Power of the prefactor for the core and window	Read the power of the prefactor $\hbar^{-p}$ of C_P for the core and the window by the capacity of the degenerate point	python3, paper	The value of p (a reading), and the form of the capacity formula	The side of the action barrier $\Delta S < 2S_0$ (only one of the conditions of small question 5)
16	Comparison for the alternating maximal correlation of boxes	A comparison theorem showing the alternating maximal correlation between boxes $c_{\mathrm{alt}} < 1$, avoiding examples that do not reduce to two-point quantities	Paper	An upper bound on c_{alt} uniform for the reduced model	The rows of the in-phase local Poincaré condition and the saddle-tube condition (only [006] moves)

No.	Question	One line	Tools	Form of settlement	What does not move when settled
17	Length set by a conservation-breaking term	In the dynamics with conservation of small question 12, when a small term that breaks the conservation is added, the length at which the gap departs from the square of the side	Paper, python3	The relation between the strength of the breaking term and the length	The relaxation-time assumption in four dimensions (the smallest model for the questions of Part 24)

For every question, before starting, we put a stage of searching for whether an answer to the same question exists. Write the question in one sentence in the form of a theorem, search with combinations of words from both mathematics and physics, follow the references of reviews to the text of the primary sources, and judge it as one of: the same answer, a close but different result, or not found. If nothing is found, write "not found in the range searched", and leave the words and materials searched in the source table.

05

Worked example: one question to the form of a settlement — $1-\lambda_k$ for the Hermite family

To see the size of a question, we carry the question "constant of the Hermite family" to the end. The Poincaré constant of the standard normal distribution is $C_P=1$, with equality at $f=x$ (1-10). Let λ_k be the maximum of the ratio $\operatorname{Var}(f)/\mathcal{E}(f)$ over the family $F_k=\operatorname{span}\{x^3,\dots,x^{2k+1}\}$, which does not contain x.

Normalising the Hermite polynomials to $\mathbb{E}[h_m h_n]=\delta_{mn}$ gives $h_n'=\sqrt{n}\,h_{n-1}$, so the variance and the Dirichlet form of an odd function $f=\sum_{j=0}^{k}u_j h_{2j+1}$ are diagonal.

$$\operatorname{Var}(f)=\sum_{j=0}^{k}u_j^2,\qquad \mathcal{E}(f)=\sum_{j=0}^{k}(2j+1)\,u_j^2 \tag{1}$$

The condition for being in the family is the single linear constraint "the coefficient of the monomial x is 0", $\sum_j w_j u_j=0$, with $w_j=(-1)^j\sqrt{(2j+1)!!/(2j)!!}$. Finding the minimum μ_k of $\mathcal{E}/\operatorname{Var}$ under the constraint by Lagrange multipliers leaves an equation in one variable [Cited] (the secular equation for stationary values of a quadratic form under a linear constraint, Golub 1973).

$$g_k(\mu) := \sum_{j=0}^{k} \frac{w_j^2}{2j+1-\mu} = 0, \qquad 1 < \mu_k < 3, \qquad \lambda_k = \frac{1}{\mu_k} \tag{2}$$

Setting $\mu_k = 1 + \varepsilon$, the $j = 0$ term is $-1/\varepsilon$ and balances the rest.

$$\frac{1}{\varepsilon} = S_k + O(\varepsilon), \qquad S_k := \sum_{j=1}^{k} \frac{(2j+1)!!}{(2j)!!\, 2j} \tag{3}$$

S_k closes by a generating function. Splitting each term in two by $(2j+1)!!/(2j)!! = (2j+1)\binom{2j}{j}4^{-j}$, and using the partial-sum identity $\sum_{j=0}^{k}\binom{2j}{j}4^{-j} = (2k+1)\binom{2k}{k}4^{-k}$ (by induction on k) and the value $\ln 2$ at $x = 1$ of $\ln \frac{2}{1+\sqrt{1-x}} = \sum_{j\ge 1}\binom{2j}{j}\frac{x^j}{2j\,4^j}$, gives

Proved here

$$S_k = 2\sqrt{\frac{k}{\pi}} + (\ln 2 - 1) + O(k^{-1/2}) \tag{4}$$

Substituting into (3) and expanding $1 - \lambda_k = \varepsilon - \varepsilon^2 + \cdots$ fixes the two terms Proved here .

$$1 - \lambda_k = \frac{\sqrt{\pi}}{2\sqrt{k}} - \frac{\pi \ln 2}{4k} + O(k^{-3/2}), \qquad \frac{\sqrt{\pi}}{2} = 0.886227, \quad \frac{\pi \ln 2}{4} = 0.544397 \tag{5}$$

Table 4 λ_k and a check of (5) Reading (values from solving for the roots of (2) numerically)

k	λ_k	$\sqrt{k}(1-\lambda_k)$	$k\left(1-\lambda_k-\frac{\sqrt{\pi}}{2\sqrt{k}}\right)$
1	0.555556	0.4444	−0.4418
10	0.774921	0.7118	−0.5517
1000	0.972524	0.8689	−0.5489
10^4	0.991192	0.8808	−0.5459
10^6	0.999114	0.8857	−0.5446
(5)	$\to 1$	0.8862	−0.5444

What does not move when it is settled is the fact that test functions bound C_P only from below. Enlarging the family keeps $\lambda_k < 1$ and only approaches 1 at the rate $k^{-1/2}$; that the limit is 1 can be said only from an input outside the family (Gaussian convexity, $V'' = 1$). The settlement of a small question often takes this form.

This part placed the relaxation-time assumption at the axis of the study, and this chapter gathers the views that repeatedly proved useful on that basis. Questions that stand on views other than the relaxation-time assumption are placed in Part 24.

What this chapter can say

Said	Not said
In which stage of which chapter of the body each of the twelve insights worked (the chapter at the end of each insight), and the state of each insight (still an insight, checked form)	That the insights work outside the first step (the four-dimensional lattice, other problems). Every insight is a view before verification
Proved here The formula for the threshold in small questions 6 and 11 ($\kappa(k) < 0 \iff k \geq 8$), and the skeleton of the derivation of (4)(5)	The value of the coefficient of the remainder $O(k^{-3/2})$ in (5)
Reading The numbers of Table 4	Table 4 consists of floating-point values of the roots of (2), not propositions of upper or lower bounds
The list of seventeen questions, and what does not move when they are settled	No question, even when settled, shows anything about the mass gap, the continuum limit or the relaxation-time assumption. "The size of an undergraduate thesis" is a prospect

Sources and reproduction

Item	Kind	Source / tools
Material for the twelve insights	This book	The sections of the chapters given at the end of each insight (23-06 to 23-11)
The two-point logarithmic Sobolev constant of small question 2	Cited	P. Diaconis, L. Saloff-Coste, Logarithmic Sobolev inequalities for finite Markov chains (bibliographic data not checked; the statement has not been checked in the original. It is an object to be checked on the side of the question)
The lower two rows of Table 2 (the heat bath of the two-dimensional Ising model, the holographic density)	This book	The record of hypotheses discarded in this book's study. The z of the two-dimensional Ising model is from M. P. Nightingale, H. W. J. Blöte, Phys. Rev. Lett. 76 (1996) 4548 (abstract only)
Questions 1–13 of Table 3	This book	The fourteen small questions of this book's study, minus the one that became the test bed. Questions 14–17 come from the remaining rows of 23-09 to 23-11
The secular equation (2)	Cited	G. H. Golub, Some modified matrix eigenvalue problems, SIAM Review 15 (1973) 318–334 (bibliographic data only)
Table 4	Reading	Bisection for the roots of (2), cross-checked against the generalised eigenvalues of the Gram matrix of monomials for $k \leq 6$

Terms used in this chapter — the three states of an insight, paying twice, the currency of Poincaré and the currency of entropy, the length where $1/\hbar$ lives, the wall of conditioning, the threshold of convexity, the stage of cancellation and the stage of direction, the moving of obstacles, dynamics with conservation, small questions. Their meanings are in the A-02 Glossary.

Next chapter to read: Part 24 The first road, second half — views other than the relaxation-time assumption, and a list of material for new views that take the relaxation-time assumption as given. To go on to the appendices, A-01 Table of notation.

Entrance to Part 24 — what we take over from Part 23

> This chapter is a guide (the entrance to this part).

This part is a record of the study. The theorems that have been machine-checked are in Parts 20–22, and the current list of premises is in 28-04.

What this chapter shows — Where Part 24, "Further considerations", stands; the sentences it takes from Part 23; the map of its nine chapters (title, one line, level, and what each chapter can say); the words fixed in this part; and what this part does not treat.

Prerequisite chapters — 23-00 (the entrance to Part 23), 23-01 § 05 (the diffusive-relaxation-time assumption), 23-01 § 06 (what the diffusive-relaxation-time assumption gives and does not give).

Said first — The level is [Y2]. This page is a map and proves nothing. No chapter of Part 24 shows the mass gap. We write neither that the relaxation-time assumption was wrong nor that it was the right road.

The order of this chapter

1. Where this part stands — what to think about after the study of Part 23
2. Sentences taken from Part 23 — five sentences and their labels (Table 1)
3. Map of the part — the nine chapters, and what each can say (Figure 1, Table 2, Table 3)
4. Words fixed in this part — the local diffusive-relaxation-time assumption and the ratio form, the threshold, the length at which conservation breaks
5. What is not treated, the table of notation, returning to Part 23

01

Where this part stands — what to think about after the study of Part 23

Part 23 restated the problem of the mass gap in terms of quantities that can be computed on the lattice and are within reach of machine checking — a power relation between the relaxation time C_P of Langevin dynamics and the correlation length ξ (the relaxation-time assumption) — and used that restatement as a foothold for its study. Setting up the relaxation-time assumption as a sharp sentence made it possible to name where the relaxation-time assumption fails. Which test functions obstruct the upper half of the relaxation-time assumption (the relaxation-time upper-bound assumption) came together as a single pattern. This is not "the relaxation-time assumption was wrong"; the order of events is "because the relaxation-time assumption was set up, the nature of how it breaks became visible".

Part 24 is the "further considerations" that start from there. First we see that what obstructs the relaxation-time assumption comes together in one form — a global quantity not reflected in the gap slows relaxation on a length other than the correlation length (24-01, 24-02). Next, keeping the relaxation-time assumption as a premise, we define two candidates that restate the relaxation-time assumption so as to avoid that form (the relaxation-time assumption for each topological sector, and the local relaxation-time assumption with windows or boxes limited to a few times the ruler), and examine which part the one-sided bridge needs for the mass gap (24-03, 24-04). From there we go on to two views that do not pass through the relaxation-time assumption: that on a lattice with continuous time the gap is exactly the Poincaré constant of the vacuum measure (24-05), and that on groups one needs tools that pay with rarity instead of convexity (24-06). Finally we state where being four-dimensional matters, limited to the two points "the dimensionless coupling" and "topology" (24-07), and close with questions and what is not claimed (24-08).

Many sentences of this part are estimates, and we distinguish them by adding one estimate label, Estimate, to the five labels of Part 23 (Proved here, Cited, Computer-assisted, Reading, Assumption). An estimate is an opinion offered as material for judgement; it carries neither a proof nor numbers.

02

Sentences taken from Part 23

Table 1 lists the five sentences that Part 24 takes from Part 23 and uses. Labels and statements remain as in Part 23; this part only cites equation numbers and sections, and does not copy the proofs.

Table 1 Sentences taken from Part 23

Sentence	Label	Place in Part 23	Chapters that use it

Sentence	Label	Place in Part 23	Chapters that use it
The trade of the restatement: the quantity of the problem statement is the gap in Euclidean time; the quantity of the relaxation-time assumption is the relaxation C_P in Langevin time (a quantity defined by a supremum, bounded from below by a single test function, and whose upper bound can be built from parts). The two are different quantities	Convention	23-01 § 04 (the three C_P)	24-01, 24-04, 24-05
The relaxation-time assumption is the power statement $\lim \ln C_P / \ln \xi = 2$. The halves of the band statement are written the upper-bound assumption and the relaxation-time lower-bound assumption	Assumption	23-01 § 05	All chapters
The one-sided bridge: on a lattice with continuous time, $C_P \geq \kappa \hbar^2 / \Delta^2$. Under the assumption of the bridge, the upper-bound assumption is a stronger sentence than the gap of the lattice in physical units (there is also a version in the form of a paper, before external checking)	Proved here (continuous time), Assumption (on Wilson's lattice with discretised time, the time-step comparison assumption ((D) in the paper "one-sided bridge"))	23-01 § 06 (Lean `hup_is_gap_positivity_of_lower`, assumptions: $0 < m$, $\kappa / m^2 \leq C_P$, $C_P \leq K \xi^2$)	24-04, 24-05
The converse is false in general: for a free particle on a circle, $\Delta > 0$ holds while $C_P = \infty$ (the Free-Particle-on-a-Circle Counterexample)	Proved here	23-01 § 06	24-01, 24-04

Sentence	Label	Place in Part 23	Chapters that use it
In the four-dimensional periodic box, the upper-bound assumption reads as broken by the freezing of the topological charge (on original sources for $SU(3)$ and above, and a reading that extends a conjecture). The note on topological sectors and the order of volume	Assumption , Reading	the note in 23-01 § 05, 23-02 § 05	24-01, 24-03, 24-07

03

Map of the part — the nine chapters, and what each can say

The nine chapters of Part 24 and the table of notation

0. **24-00 Entrance — what is taken from Part 23** [Y2] (this page)
1. 24-01 One form that obstructs the diffusive-relaxation-time assumption — a nearly conserved global quantity [Y3]
2. 24-02 Choosing the ruler and the coordinates again — the length at which conservation breaks [Y3]
3. 24-03 Two ways to repair the relaxation-time assumption — the sector assumption and the local assumption [Res] (summary at [Y3])
4. 24-04 Which form of the relaxation-time assumption the one-sided bridge needs [Res] (summary at [Y3])
5. 24-05 Making time continuous — the Hamiltonian lattice and the vacuum measure [Y3]
6. 24-06 Paying with rarity instead of convexity — renormalisation on groups and log-Sobolev [Res] (summary at [Y3])
7. 24-07 Because it is four dimensions — the dimensionless coupling and topology [Y3]
8. 24-08 Questions, and what is not claimed [Y2]–[Y3]

24-09 Table of notation for the first road, second half (a reference page)

Together with Part 23, this part forms the second half of "The first road — from the direction of time" (the second road is Part 25, the meeting of the two roads is Part 26, and the conditional statements are Part 27). The order of the chapters is: the form of

the breakage (24-01, 24-02), restatements that keep the relaxation-time assumption as a premise (24-03, 24-04), views that do not pass through the relaxation-time assumption (24-05, 24-06), what is specific to four dimensions (24-07), and questions (24-08). From 24-01 to 24-05 is a single chain in which the conclusion of each chapter becomes the question of the next. 24-06 is not a consequence of the chain but a chapter of tools needed to show any of the statements of 24-03 to 24-05, and on the line of the argument it is placed as a branch.

```

```

Table 2 One line for each chapter, and what that chapter can say

Chapter	One line	What this chapter can say
24-01	Puts in one table, together with their strength, that the number of kinks, the winding number, the flux, the topological charge and the flux through the box are all of the same pattern: "a global quantity not reflected in the gap slows relaxation on another scale"	That the five examples are of the same pattern is a classification (an estimate). The numbers carry the label of each row
24-02	Splits the length to compare with C_P into three rulers, and sets out that the type of relaxation changes with the choice of coordinates (the Dirichlet form), together with numbers for the two-dimensional strip and the test beds	The length at which conservation breaks is a reading on the two-dimensional $U(1)$ strip. Restating what to compare with is a candidate. CP^{N-1} is a conditional reading at one volume and one correlation length

Chapter	One line	What this chapter can say
24-03	Defines the relaxation-time assumption conditioned on topological sectors, and the local relaxation-time assumption with windows or boxes limited to a few times the ruler, and states them in the ratio form against a massless reference	The two relaxation-time assumptions have definitions, and the local relaxation-time assumption has content only in the ratio form. There is no inequality shown at any β
24-04	States that the one-sided bridge uses only the part of the upper-bound assumption that is local in time, and sets out the bridge on a window, the threshold of the ratio form and three references	The threshold of the bridge depends on the reference and the family, and the band between the threshold and 1 is undecided. Everything rests on the local-excitation moment assumption and the assumptions of the One-Sided Bridge Proposition (Theorem 3.1 of the paper)
24-05	Sets out that on a lattice with continuous time the gap is tied, as the exact reciprocal, to the Poincaré constant of the vacuum measure at a single time, and why the tools needed there do not apply	The gap is the Poincaré constant of the vacuum measure itself, and the identity does not make the problem easier
24-06	States that on groups the tools of convexity cannot, in principle, stand at weak coupling, that the non-convex places are pushed into places of small probability, and the tools that pay with rarity and candidate rules	A chapter of tools. The ceiling of convexity has a proof; the class of measures that pay with rarity is a candidate. Results on hierarchical models imply nothing for four dimensions
24-07	Limits what matters in four dimensions to two points, the dimensionless coupling and topology, and sets out the four hurdles and why the third hurdle stayed open for so long, from what primary sources written before the published construction say	The two points are an estimate of a property of the critical dimension. Freezing for $SU(2)$ is undecided. Results in two dimensions imply nothing for four dimensions
24-08	The table of questions, the list of candidate rules, the sixteen items that are not claimed	Questions, and what is not claimed. Candidate rules are candidates

Table 3 lists the material that came up in Part 23 and that the chapters of this part take up as body text.

Table 3 Material taken over from Part 23, and the chapters that take it up

04

Words fixed in this part

The local relaxation-time assumption and the ratio form. The sentence that states the Poincaré constant $C_P^{\mathrm{loc}}(c)$, with test functions limited to those supported in a window (or box) of c times the ruler ℓ, by its ratio $K_{\mathrm{rel}}(c)$ to the massless reference on the same window with the same graduation (24-03 § 03). The form "bounded by some constant" also holds for the free field and is empty, so we use the ratio form.

The threshold K_*. The value of the threshold such that, if the ratio is below it, the one-sided bridge gives a lower bound on the mass under the assumptions. Depending on the choice of reference it changes: 0.342κ (scalar), 0.502κ (gauge quotient), about 0.62κ (colour singlet of $SU(2)$) (24-04 § 06; the numbers are readings for the free-field reference).

The length at which conservation breaks ℓ_*. The length at which a global quantity not reflected in the gap begins to relax through the breaking of conservation rather than through local transport. It is a ruler different from the static correlation length, and the values measured on the two-dimensional $U(1)$ strip are not proportional to the correlation length (24-02 § 01, § 03).

05

What is not treated, the table of notation, returning to Part 23

What is not treated. Part 24 does not touch the ultraviolet side — the existence of the continuum limit, the recovery of rotations, the OS axioms, non-triviality (the Wilson-loop limit statement, the rotation-recovery statement, the OS reconstruction statement and the non-triviality statement of Part 23, 23-01 § 02). Only 24-07 § 05 sets out, from primary sources, how far the third hurdle has been reached as a difficulty specific to four dimensions, and even there construction is not treated. The existence of the

continuum limit is read in Volume 2 (from Part 6) through the construction published on 2026-11-10 (a Lean formalisation that builds a theory satisfying the Wightman axioms as the limit of Wilson's lattice in four dimensions; the committee's assessment is that it is proved in Lean).

Notation. The notation of Part 24, and its correspondence with symbols of the same letter in Part 23, are in 24-09 Table of notation for the first road, second half. In particular Δ is reserved for the gap of the Hamiltonian $E_1 - E_0$, and the mass in physical units is written m_{phys}.

Returning to Part 23. The map of Part 23 is in 23-00 § 01, what is not claimed in 23-16, and the small questions in 23-17.

Next chapter to read: 24-01 One form that obstructs the diffusive-relaxation-time assumption — a nearly conserved global quantity — sets out, in one table with five

examples, the pattern in which a global quantity not reflected in the gap slows relaxation on another scale.

One form that obstructs the diffusive-relaxation-time assumption — a nearly conserved global quantity

> This chapter is this book's own investigation. The established knowledge it builds on is in 2-10 and 5-09.

What this chapter shows — We set out five examples that obstruct the upper half of the diffusive-relaxation-time assumption (the relaxation-time upper-bound assumption), and see that all of them fall into a single pattern: "a global quantity not reflected in the gap slows relaxation on a scale other than the correlation length". The five examples are the number of kinks in the double well, the winding number of a particle on a circle, the flux in the two-dimensional $U(1)$ strip, the topological charge in the four-dimensional periodic box, and the flux through a box. What differs is the strength (logarithmic, power or exponential, infinite) and the event that does the breaking. How the upper-bound assumption fails in this pattern is decided by the single line $\tau_{\mathrm{int}} \le C_P$. Using the charge of a subregion, we separate two accounts, "transport" and "breaking of conservation", in preparation for the local diffusive-relaxation-time assumption of 24-03.

Prerequisite chapters — 23-01 §05 ((13) for the relaxation-time assumption, (14)(15) for the upper-bound assumption, the note on topological sectors), 23-01 §06 (the Free-Particle-on-a-Circle Counterexample), 23-02 §05 ($\tau_{\mathrm{int}} \le C_P$), the detour in 2-10 (conserving dynamics). The notation is collected in 24-09.

Said first — The level is [Y3]. Calling the five examples one pattern is a classification, not a theorem Estimate . The numbers in each example are numbers under conditions, with a label on each row. This chapter does not claim that the upper-bound assumption is false. The row for the four-dimensional periodic box rests on numbers from original sources for $SU(3)$ and above, and on a reading that extends a conjecture attached to observations with open boundaries to the slowness of topology in the periodic box; for $SU(2)$ it is not settled even at the level of a reading. None of the examples breaks the mass gap.

The order of this chapter

1. The type of a nearly conserved global quantity — three conditions, and the one line by which the upper-bound assumption fails ((1)–(3))
2. Five examples in one table — Table 1, and three rows moved below (Table 2)
3. Three strengths — logarithmic, power or exponential, infinite (Table 3)
4. Two accounts for the charge of a subregion — the transport coefficient d and the coefficient of breaking of conservation h ((4)–(7))
5. The wall of the first step is a scaled-down version of this pattern — the $\frac{1}{4}$ at the top, and the correspondence with the types of breakage in Part 23 (Table 4)
6. What cannot be said — extending the conjecture, $SU(2)$, two dimensions, power and exponential
7. Table of the five grades and the dependency graph — Table 5

01

The type of a nearly conserved global quantity — three conditions, and the one line by which the upper-bound assumption fails

The relaxation-time assumption is the power statement $\lim \ln C_P / \ln \xi = 2$ ((13) of 23-01), and its upper half (the upper-bound assumption) is "for every test function f, $\mathrm{Var}(f) \le C\, \xi_{\mathrm{RG}}^2\, \mathcal{E}(f)$" ((15) there). Since it is a statement about every f, it collapses if there is even one function whose ratio $\mathrm{Var}/\mathcal{E}$ grows faster than ξ^2. Because Part 23 set up the relaxation-time assumption as a sharp sentence, we can name what such a function looks like. The answer of this chapter is the following pattern.

Pattern (an estimate)

For a pair of a measure μ and a Dirichlet form $\mathcal{E}$, there is a global quantity Q such that

(i) $\mathrm{Var}_\mu(Q)$ is large (it grows with the volume or the length of the window).

(ii) $\mathcal{E}(Q)$ is small. Q is handed to neighbours through the flux of a conservation law, or changes only through rare configurations.

(iii) Q is not reflected in the gap Δ. It does not belong to the family of time-integrated single-time functions ($\mathcal{F}_1$ in 24-04), or if it does, it does not overlap the excitations of the gap.

Then the time for Q to relax is fixed not by the correlation length ξ but by the scale of the events that break Q.

(iii) is the condition that separates this pattern from the mass gap. Since the quantity is not reflected in the gap, the gap may stay positive however slow the relaxation is. The smallest example of this separation was the Free-Particle-on-a-Circle Counterexample of Part 23 (a free particle on a circle; the gap is positive and $C_P = \infty$).

The one line by which the upper-bound assumption fails. If the dynamics is reversible (the generator L is self-adjoint on $L^2(\mu)$, $-L \geq 0$), then the integrated autocorrelation time of any observable f does not exceed C_P. Writing ν_f for the spectral measure of $-L$ for $\tilde{f} = f - \mu(f)$ (supported on $[\lambda_1, \infty)$, $\lambda_1 = 1/C_P$), we have

$$\tau_{\mathrm{int}}(f) := \int_0^\infty \frac{\mathrm{Cov}(f(0), f(t))}{\mathrm{Var}\, f}\, dt = \frac{\int \lambda^{-1}\, d\nu_f(\lambda)}{\int d\nu_f(\lambda)} \;\leq\; \frac{1}{\lambda_1} = C_P \quad (1)$$

Proved here (one only integrates $\lambda^{-1} \leq \lambda_1^{-1}$ over $\lambda \geq \lambda_1$; equality holds when $\tilde{f}$ lies in the slowest eigenspace). In Lean the version with a finite spectral sum is checked (LatticeGauge.FourDTrial.tau_int_le_CP, assumptions: weights ≥ 0, each eigenvalue $\geq \lambda_1 > 0$, sum of weights > 0). The version that does not use the dynamics is the definition of the supremum itself:

$$\frac{\mathrm{Var}_\mu(Q)}{\mathcal{E}(Q)} \;\leq\; C_P \quad (2)$$

Proved here. Hence, if the relaxation time of Q ($\tau_{\mathrm{int}}(Q)$ for (1), the static ratio for (2)) grows at least as $c\,\xi^p$ ($p > 2$) along a sequence with $\beta \to \infty$, then $C_P \leq K\xi^2$ fails for every constant K. In the range where the correlation length ξ and the bookkeeping length ξ_{RG} are comparable up to constant factors, this is the negation of the upper-bound assumption.

$$\tau_{\mathrm{int}}(Q) \leq C_P, \quad \tau_{\mathrm{int}}(Q) \geq c\,\xi^p \ (p > 2), \quad \xi \to \infty \qquad \Longrightarrow \qquad \neg\,\exists K:\ C_P \leq K\xi^2 \quad (3)$$

Proved here Lean LatticeGauge.FourDTrial.not_hup_of_fast_tau (assumptions: $0 < c$, $2 < p$, $\xi_n \to \infty$, $\xi_n > 0$, and for each n, $\tau_n \leq C_n$ and $c\,\xi_n^p \leq \tau_n$). Exponential growth $\tau \geq c\,e^{\alpha\xi}$ includes $p = 3$ ($e^x \geq x^3/6$). The caution in the converse direction is also one line. That τ is small for a fast quantity does not support the upper-bound assumption. For an observable whose weight lies on fast modes, τ_{int} stays small however large C_P is (negative control tau_small_but_CP_large).

Let us check the level of this one line. Of the two assumptions on the left of (3), Lean takes only inequalities between sequences of real numbers; that τ_n is the autocorrelation time of a reversible dynamics and that C_n is the Poincaré constant of the Wilson measure lie outside Lean. What supports the second assumption of (3) in four dimensions is the Monte Carlo numbers of the original sources Cited, reinterpreted across the difference of algorithms as Langevin autocorrelations, and that reinterpretation is an assumption (§ 06 (a)).

02

Five examples in one table

Table 1 sets out, in the same columns, five examples that satisfy the three conditions of the pattern. The columns are: the quantity outside the family (the Q of the pattern), the event that moves it (the breaking of conservation), the relation between the scale of slowness and the correlation length, the strength, the numbers measured and their labels, and the chapter where the body text is. The label on a row is the label of that row's numbers; the classification "falls into the same pattern" itself is Estimate on every row.

Table 1 Five examples that obstruct the upper-bound assumption (the strength is how C_P/ξ^2 grows; the conditions on the numbers are in each row's para

Example	Quantity outside the family	What moves it (breaking of conservation)	Scale of slowness and correlation length	Strength	Numbers measured and la
(a) Double well in 0+1	The number of kinks (which well the path is in), the position of a kink in the window	Creation and annihilation of kink pairs (tunnelling), motion across the window	Same origin as ξ. The overall ratio is $S_0/\hbar \approx \ln \xi$. The local ratio is ω_b/m even for the shortest window	Logarithmic	One-site ratio $= \omega_b/m$ Proved here, 4.61, 21.6, 638 Reading, overall rati Assumption
(b) Free particle on a circle	The winding number (integral of the increments of the lifted angle)	Never breaks (continuous paths)	Infinite	Infinite	$C_P = \infty$ with $\Delta = \hbar^2/2 >$ Proved here
(c) The two-dimensional $U(1)$ strip	Flux dipoles, the topological charge Q of the strip	Wrapping of a single plaquette (a barrier of height 2β)	$\ell_c \propto e^{0.916\beta}$, $\xi_{XY} \approx 2\beta$	Exponential in ξ_{XY}	$\ell_c = 3.29$ to 139, $\tau(Q)/\xi_{XY}^2$ $= 0.4 \to 24$ Reading

Example	Quantity outside the family	What moves it (breaking of conservation)	Scale of slowness and correlation length	Strength	Numbers measured and la
(d) Four-dimensional periodic box	The smoothed topological charge Q	Small instantons slipping through the lattice (dislocations)	Faster than ξ^2 in original sources for $SU(3)$ and above. For $SU(2)$, one primary source, close to a^{-2}	Power or exponential ($SU(3)$ and above)	Numbers of the original sources Cited , reading the upper-bound assumption Assumption
(e) Flux through a box	Functionals moved by gauge transformations at the sites on the boundary of the box	They enter the test space if the boundary gauge transformations are not divided out	2.22 to 2.53 times the value of the reference box	Constant factor	Difference between the t choices Proved here , factor Reading

(a) The number of kinks in the double well. In the path measure in 0+1 dimensions (23-04, $V = (x^2-1)^2/8$, $S_0 = 2/3$), which well the path is in changes only when a kink (a path moving from valley to valley) enters. The weight of a kink $e^{-S_0/\hbar}$ fixes the correlation length $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$, and the diffusion of kinks fixes the scale $\xi^2 S_0/\hbar$ on the upper side of C_P, so the slow quantity and the correlation length are born from the same event. The ratio C_P/ξ^2 is of order $S_0/\hbar \approx \ln \xi$, so the band form of the upper-bound assumption fails only by a logarithm while the double-well relaxation-time power statement survives ((14) of 23-04, the accounting for a dilute gas of kinks) Assumption . The same pattern appears in local ratios with limited windows. In a window of a single time, the Poincaré constant of the marginal ψ_0^2 moves by the ground-state transformation to the gap of $(H - E_0)$, and its ratio to the harmonic oscillator with the curvature of the bottom is **exactly** ω_b/m (when ψ_0 is the Schrödinger ground state) Proved here . With the transfer on the lattice $\varepsilon = \frac{1}{2}$, at $\hbar = 0.3,\ 0.15,\ 0.08$ it is $4.61,\ 21.6,\ 638$, 1.04 to 1.05 times ω_b/m Reading . The detailed behaviour of this ratio (lengthening the window moves it to $(\omega_b/m)^2$) is treated in 24-04.

(b) The winding number of a particle on a circle. This is the Free-Particle-on-a-Circle Counterexample of Part 23. For the path lifted to the real line, $\tilde{x}(\tau)$, the integral of its increments with weight w, $f = \int w\, d\tilde{x}$, has $\mathrm{Var}(f) = \hbar \int w^2$ and $\mathcal{E}(f) = \hbar \int w'^2$, and lengthening the window makes the ratio as large as one likes. The winding number never breaks for continuous paths, so the strength is infinite. This f is a functional supported in a window of length L; with the window fixed the ratio is finite, but lengthening the window makes it unbounded Proved here . The winding number is not a time-integrated single-time function, so it satisfies condition (iii) of the pattern.

(c) The flux and the topological charge of the two-dimensional $U(1)$ strip. In a strip of width 2 with the links on the outer boundary fixed, if the links are moved by Langevin, the angles of the plaquettes (the flux) are only handed between neighbours, and unevenness of the flux is smoothed out by diffusion. Because the group is compact, a "wrapping", in which the angle of a single plaquette crosses π, changes the total flux (the topological charge Q of the strip) by one, and conservation is broken. The length at which conservation breaks, ℓ_C, is $3.29,\ 9.88,\ 24.7,\ 53.6,\ 139$ at $\beta = 2, \dots, 6$; the slope of $\ln \ell_C$ is $0.916(21)$, and the ratio to the static length $\xi_{XY} = -1/\ln(I_1(\beta)/I_0(\beta))$ (2.78 to 10.9) opens from 1.2 to 12.8 Reading . When the strip is longer than ℓ_C, relaxation is fixed by the time for Q to move by one, and $\tau(Q)/\xi_{XY}^2$ is about 0.4 at $\beta = 4$ and about 24 at $\beta = 8$ (strip length 32) Reading . Conditions: two-dimensional $U(1)$, width 2, outer boundary frozen, gauge quotient of link Langevin, strip length ≤ 256, τ_{int} as a reading of an upper bound on the gap, fit of the form $A/M^2 + B$. The length at which conservation breaks is discussed in detail in 24-02.

(d) The topological charge in the four-dimensional periodic box. The smoothed topological charge Q cannot move between sectors in the continuum limit; on the lattice it changes only when a small instanton, of the size of the lattice spacing, slips through the lattice (a dislocation). In the periodic box, the autocorrelation time of Q is reported to grow clearly faster than ξ^2 (Del Debbio–Panagopoulos–Vicari 2002 with local heat bath and overrelaxation, Schaefer–Sommer–Virotta 2011 with HMC, Bonanno–Bonati–D'Elia 2021 with local algorithms; if a power, the exponent is about 5, or else exponential in $1/a$, and all three write that power and exponential cannot be distinguished by the data) Cited . The groups in all three are $SU(3)$ and above. For $SU(2)$, the primary sources measuring the dependence of $\tau_{\mathrm{int}}(Q)$ on the lattice spacing number one in the range searched (Abe–Morikawa–Suzuki 2025; HMC, periodic, a small box with side about $2.2/\sqrt{\sigma}$, three lattice spacings), which reports growth close to a^{-2} Cited . The original sources treating $SU(2)$ with heat-bath algorithms were all observations on the side of "freezing not strong enough to measure". The conditions for using this, through (3), in a reading of the upper-bound assumption are collected in § 06.

(e) Flux through a box. An example in which the same pattern appears not through slowness of the dynamics but through the choice of the family of test functions. When measuring the reference for the local Poincaré constant in a four-dimensional box (the value for the massless free gauge field), dividing by gauge transformations at all sites of the box makes the test space functions of the plaquette angles; leaving the gauge transformations at the boundary sites of the box undivided lets a field passing uniformly through the box (a flux whose divergence lies only on two faces) into the test space. The latter value is 2.22 (side 4) to 2.53 (side 12) times the former, which returns roughly to the gauge-fixed value Reading (one-colour Gaussian approximation, $\beta = 1$, canonical graduation, floating point). In a contractible box, the space divided at all sites coincides with the space of functions of the plaquettes Proved here (24-03 § 03). The numbers in this row are numbers for the free field of the reference, not for the target measure. Regarding it as a member of the pattern is Estimate : the flux through the boundary of the box is, seen from inside the box, "a global quantity not reflected in the gap that moves the ratio by one choice of family".

There are three rows that satisfy the conditions of the pattern but were moved below the table of five examples (Table 2). Each has its body text in another chapter, and here we copy only the labels.

Table 2 Three rows moved below Table 1

Example	Quantity outside the family	Slowness	Label	Body text
Conserving dynamics (Gaussian chain)	The total of the field	$\xi^4/2$ for the component at wavenumber $1/\xi$, $C_P = \infty$ for the infinite chain	Proved here	the detour in 2-10
Flux through the plaquettes of the layers of a hierarchical lattice (Gauss approximation, link coordinates)	Flux of each layer	Smallest eigenvalue $\beta \cdot 4\sin^2(\pi/2^{N+1})$. The same slowness even when the layers are decoupled and the static correlation set to 0	Proved here (sector decomposition and the Neumann Laplacian of the two-dimensional dual lattice), Reading (cross-check for $N \le 4$)	24-02
Centre sectors of a small periodic box	Sign of the Polyakov loop	Long autocorrelation under heat bath. A finite-volume artefact that vanishes as the box grows; not the Langevin C_P	Reading	24-08 (questions)

The upper side of the hierarchical-lattice row is checked in Lean (HierLink.lam_le, bundle LatticeGaugeHierarchicalLink; no assumptions: $4\sin^2(\pi/2^{N+1}) \le \pi^2/4^N$. That the smallest eigenvalue equals this expression is outside Lean).

03

Three strengths — logarithmic, power or exponential, infinite

Rearranging the five examples by how the ratio of slowness C_P/ξ^2 (or $\tau(Q)/\xi^2$) grows with the correlation length, the pattern is one but the strengths divide into three.

Table 3 One form, three strengths

Strength	Example	The breaking event and the origin of the correlation length	Effect on the relaxation-time assumption and the upper-bound assumption
Logarithmic	(a) Double well	The same event (kinks) produces the slow quantity and ξ	The band form of the upper-bound assumption fails by a logarithm; the double-well power statement survives Assumption
Power or exponential	(c) the two-dimensional strip, (d) the four-dimensional periodic box	The event that breaks the slow quantity (wrapping, dislocation) and the origin of ξ are different	In (c), $\tau(Q)/\xi_{XY}^2$ grows with β inside the two-dimensional toy Reading . In (d), the upper-bound assumption reads as false under the conditions of § 06 ($SU(3)$ and above)
Infinite	(b) the rotor, and the conserving dynamics and layer flux of Table 2	There is no breaking event	$C_P = \infty$ while $\Delta > 0$ Proved here
(constant factor)	(e) Flux through a box	Not the dynamics but the choice of family	Moves the denominator of the local ratio by a factor of 2.2 to 2.5 Reading

The middle row of Table 3 is the row that matters in four dimensions. In the double well the slow quantity and the correlation length are born from the same kink, so the exponents match and only a logarithmic difference remains. In the two-dimensional strip, the correlation length (the inverse string tension) grows only linearly in β, whereas the wrapping that breaks conservation is an event crossing a barrier of height 2β, and its length grows exponentially in β. Whether the same split occurs in four dimensions, and if so why, is the question of 24-07.

04

Two accounts for the charge of a subregion — the transport coefficient and the coefficient of breaking of conservation

In infinite volume the total topological charge Q is not in L^2, so what goes into (2) of the pattern is the charge of a subregion R. Writing its ratio $\mathrm{Var}/\mathcal{E}$ split into two coefficients makes clear what the local relaxation-time assumption of 24-03 asks.

Setting. Take a translation-invariant lattice measure μ in four-dimensional infinite volume, and the Dirichlet form of link Langevin $\mathcal{E}(f) = \sum_\ell \mathbb{E}|\nabla_\ell f|^2$. The smoothed charge density $q(x)$ is taken to depend only on links within distance r_s of x (made by finitely many smoothings; the Gaussian tail of the Wilson flow is treated separately as a truncation error). The gradient field $J_\ell(x) := \nabla_\ell q(x)$ is 0 for $|x - x_\ell| > r_s$. Put its sum $\bar{J}_\ell := \sum_x J_\ell(x)$ (the gradient of the total charge) and its first moment $D_\ell := \sum_x (x - x_\ell) J_\ell(x)$ (the dipole), and define three coefficients by

$$\chi_t := \sum_y \mathrm{Cov}\big(q(0), q(y)\big), \qquad h := \sum_{\ell \in \text{unit cell}} \mathbb{E}|\bar{J}_\ell|^2, \qquad d := \sum_{\ell \in \text{unit cell}} \mathbb{E}|D_\ell \cdot e_1|^2 \tag{4}$$

Proved here (definitions; by cubic symmetry $\mathbb{E}[D \otimes D]$ is taken to be of the form d times the identity matrix). χ_t is the topological susceptibility in lattice units, h is the density of **breaking of conservation** (in the continuum $\bar{J} = 0$ by topological invariance; only

on the lattice is it non-zero, on dislocation configurations), and d is the coefficient of **transport**. The coefficient of the boundary layer g is the quantity per unit area obtained by subtracting the volume term from $\mathcal{E}$ of the charge cut off by a half-space.

A sharp box. For a box of side R, assuming cluster decay $\sum_z |z|\,|\operatorname{Cov}(q(0),q(z))| < \infty$ Assumption (an assumption equivalent to a gap, so beware of circularity when bringing this back to arguments about the gap),

$$\operatorname{Var}(Q_R) = \chi_t |R| - b|\partial R| + o(|\partial R|), \qquad \mathcal{E}(Q_R) = \sum_\ell \mathbb{E}\Big|\sum_{x\in R} J_\ell(x)\Big|^2 = h|R| + g|\partial R| + O(R^2 r_s^2) \quad (5)$$

(b is the one-sided first moment of the correlation). Note the form of the denominator. The sum over densities of the squared gradients, $\sum_{x\in R}\mathbb{E}|J_\ell(x)|^2$, is not $\mathcal{E}(Q_R)$. It is a quantity that drops the cancellation in the sum $\sum_x J_\ell(x)$ (that in the continuum the total charge does not move locally), and it leaves a volume term even in a perfectly conserving theory. The correct volume term is the density h of $|\sum_x J_\ell(x)|^2$. Inserting $|R| = R^4$ and $|\partial R| = 8R^3$ gives

$$\frac{\chi_t}{h} - \frac{\chi_t R - 8b}{hR + 8g} = \frac{8(g\chi_t + bh)}{h(hR+8g)} \quad (6)$$

Proved here (algebra) Lean LatticeGauge.LocalH.subregion_gap_identity (assumptions: $0 < h$, $0 < hR + 8g$). As $R \to \infty$ the ratio returns to the overall ratio of the periodic box, $\operatorname{Var}(Q)/\mathcal{E}(Q) = \chi_t/h$, and the leading ratio $\chi_t R^4/(hR^4 + gS)$ does not exceed χ_t/h (subregion_ratio_le, assumptions: $0 \le \chi_t$, $0 < h$, $0 \le g$, $0 < R^4$, $0 \le S$).

A smooth window. With $Q_w := \sum_x w(x)q(x)$ and $w(x) = W(x/R)$, we have $\nabla_\ell Q_w = w(x\ell)\bar{J}_\ell + \nabla w(x\ell)\cdot D_\ell + O(R^{-2})$; the cross term vanishes by $\sum \nabla(w^2) = 0$, and

$$\frac{\operatorname{Var}(Q_w)}{\mathcal{E}(Q_w)} = \frac{\chi_t R^2}{hR^2 + d\lambda_W}\big(1 + O(\xi^2/R^2)\big), \qquad \lambda_W := \frac{\|\nabla W\|^2}{\|W\|^2}, \qquad R_*^2 := \frac{d\lambda_W}{h} \quad (7)$$

Assumption (an estimate on top of cluster decay and the definitions of h, d; λ_W is $4\pi^2$ for the Dirichlet window on the unit four-dimensional cube). The two regimes divide at the crossing length R_*. For $R \ll R_*$ the ratio is $\chi_t R^2/(d\lambda_W)$, proportional to R^2; this is the same **transport** type as conserving dynamics (the detour in 2-10). For $R \gg R_*$ the ratio is χ_t/h, the **barrier** type (breaking of conservation). Reading $D_{\text{eff}} := d/\chi_t$ and $r \propto h/\chi_t$ gives $R_*^2 \approx D_{\text{eff}}/r$, a four-dimensional candidate for the "length at which conservation breaks" of 24-02 Estimate .

The two coefficients bear on different questions. The necessary condition for the global upper-bound assumption is $\chi_t/h \lesssim \xi^2$, which asks about the coefficient of breaking of conservation h. The local relaxation-time assumption of 24-03 is the condition obtained by putting (7) into a window of side $c\xi$, and in the regime where h is small it asks about the transport coefficient d (24-03 § 05). The values of h, g and d on the four-dimensional lattice are not in this book.

05

The wall of the first step is a scaled-down version of this pattern

The first step of Part 23 stopped at the common wall: the curvature at one site at the top falls short of convexity by $\frac{1}{4}$ ((11) of 23-09: the diagonal $4 - \frac{1}{4} = \frac{15}{4}$ does not reach the sum of couplings 4). This wall can be read as a 0+1-dimensional scaled-down version of the pattern of this chapter Estimate . The reason is the following correspondence.

Condition (ii) of the pattern was "Q changes only through rare configurations". In the double well, the configurations in which Q (which well) changes are those where the path crosses the plateau at the top, which is exactly where the Hessian of the action has a negative direction. Tools that rely on convexity (Bakry–Émery, Brascamp–Lieb, diagonal dominance) produce a shortfall on these configurations, and the shortfall can be paid only by the rarity (entropy) of the plateau (23-10 currency-mix-up type). That is, $\frac{1}{4}$ is the local face of "on the configurations of the event that breaks a nearly conserved quantity, convexity falls short". What corresponds to this in four dimensions are the configurations where the topological charge changes (dislocations of the size of the lattice spacing, which break the smoothness condition). The prospect of meeting a wall of the same pattern in four dimensions comes from here Estimate .

Table 4 The pattern of this chapter, and its correspondence with the notes and types of breakage of Part 23

Place in Part 23	What is said there	Reading in terms of this chapter's pattern
the note in 23-01 § 05	The topological charge cannot move between sectors, and in the periodic box the upper-bound assumption reads as false under a conjecture. Correcting the relaxation-time assumption into a statement per sector or a local statement is a candidate direction	Row (d) of Table 1. The two corrected forms are in 24-03
the paragraph on the pattern in 23-01 § 06	Relaxation is slower than the gap when a quantity not local in time, not reflected in the gap, is carried by diffusion	Exactly (i)–(iii) of the pattern. This chapter increased the examples to five and divided them by strength

Place in Part 23	What is said there	Reading in terms of this chapter's pattern
23-10 summit-curvature type (one source)	The only source of the shortfall is the curvature at one site at the top	The configurations of the breaking event gather in one place (§ 05)
23-10 currency-mix-up type	Poincaré is the speed of exit; rarity is the currency of entropy. After conditioning, no rarity is left to pay with	The "rare configurations" of (ii) of the pattern cannot be paid for in the Poincaré ratio. Conditioning on sectors moves the rarity into a quantity between sectors (C_{trans} of 24-03)
23-10 transfer type	Another column gets heavier by as much as one got lighter	The sector diffusive-relaxation-time assumption does not remove the obstruction but pushes it into a single quantity between sectors (24-03 § 04)

06

What cannot be said

(a) **Extending the conjecture.** The conjecture "HMC and Langevin are in the same dynamical universality class" is, in the original source (Lüscher–Schaefer 2011), a phrase attached to the observation that with open boundaries for $SU(3)$ the autocorrelation grows as a^{-2}. The same source writes that with periodic boundaries algorithms that integrate Langevin also have difficulty crossing topological sectors, but as grounds it cites original sources on heat bath and HMC, and has no periodic-boundary numbers of its own Cited . Putting row (d) of Table 1 into (3) to say "the upper-bound assumption reads as false in the periodic box" is **a reading that extends the conjecture to the slowness of topology with periodic boundaries** Assumption . Between the Dirichlet form of heat bath and that of Langevin there is only the one-directional one-link comparison $\mathcal{E}_{\text{HB}} \le c_1 \mathcal{E}_L$, and a lower bound on the Langevin C_P does not follow directly from the slowness of heat bath. No primary source stating the relation between HMC and Langevin as a theorem was found in the range searched.

(b) $SU(2)$ **is undecided.** The groups in the original sources are $SU(3)$ and above. There is one primary source for $SU(2)$, and its numbers lie on the side close to a^{-2}. In a rough semiclassical accounting (taking the action of a dislocation as a constant multiple of the one-loop instanton action), with the constant fitted to the numbers for $SU(3)$, $SU(2)$ falls right near the boundary $z = 2$ (24-07). **For $SU(2)$, whether freezing of the topological charge breaks the relaxation-time assumption is not settled.**

(c) **Two dimensions and four.** Row (c) is numbers for a two-dimensional $U(1)$ toy, and two-dimensional $U(1)$ is a trivial theory in the continuum limit. It says nothing about exponents in four dimensions, non-abelian, $\beta \to \infty$.

(d) **Power or exponential.** The three original sources for row (d) themselves write that "power and exponential cannot be distinguished by the data". The "power or exponential" of Table 3 copies that phrasing.

(e) **The pattern is a classification.** That the five examples fall into one pattern is not a theorem. Row (e) is numbers for the free field of the reference, not for the target measure. The coefficients h, g, d of (4)–(7) are only definitions; there are no four-dimensional values.

(f) **The mass gap.** None of the examples breaks the gap. Condition (iii) of the pattern is what guarantees this, and what this chapter says goes only as far as "there is slowness that is not caught in the form of the upper-bound assumption".

07

Table of the five grades and the dependency graph

We put the rows of this chapter into one table in the format of the five grades (23-00 § 01), with the estimate label Estimate added. The symbols of the rows are the same as the nodes of the dependency graph below.

Table 5 Rows on nearly conserved quantities ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	Cluster decay $\sum_z \lvert z\rvert \lvert \mathrm{Cov}(q(0), q(z))\rvert < \infty$	Assumption	Premise of (5)	Infinite volume	—
2	A reading that extends the conjecture to the slowness of topology in the periodic box	Assumption	§ 06 (a)	Periodic box	—
3	$\tau(Q)$ faster than ξ^2 in the periodic box for $SU(3)$ and above	Cited	§ 02 (d), three original sources	$SU(3), SU(4), SU(6)$, periodic	—
4	One primary source for $SU(2)$, close to a^{-2}	Cited	§ 02 (d)	HMC, small box, three points	—
5	Overall ratio of the double well $C_P/\xi^2 \approx S_0/\hbar$	Assumption	(14) of 23-04	$\hbar \to 0$	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
6	ℓ_c and $\tau(Q)/\xi_{XY}^2$ of the strip	Reading	§ 02 (c)	Two-dimensional $U(1)$, $\beta = 2..6$ (also 8 for $\tau(Q)$)	—
7	Reference with the boundary gauge frozen is 2.22 to 2.53 times	Reading	§ 02 (e)	One-colour Gaussian, $\beta = 1$, side ≤ 12	—
8	$\tau_{\mathrm{int}} \leq CP$ for reversible dynamics	Proved here	(1)	Reversible semigroup	tau_int_le_CP (assumptions: weights ≥ 0, eigenvalues $\geq \lambda_1 > 0$)
9	Free-Particle-on-a-Circle Counterexample: $CP = \infty$ with $\Delta > 0$	Proved here	(23) of 23-01	Circle, all $\hbar$	rotor_ratio_unbounded (assumption: $0 < r$; only the arithmetic of the skeleton)
10	One-site ratio $= \omega_b/m$	Proved here	§ 02 (a) (ground-state transformation)	Schrödinger ψ_0	one_slice_ratio (assumptions: $0 < \varepsilon, m, \omega$; only the algebra of the ratio)
11	The subregion ratio formula (6), and ratio $\leq \chi_t/h$	Proved here	(5)(6) (on top of row 1)	Infinite volume	subregion_gap_identity, subregion_ratio_le (assumptions: positivity)
12	(3): if τ grows as ξ^p ($p > 2$), the upper-bound assumption fails	Proved here	(3)	Sequences with $\xi \to \infty$	not_hup_of_fast_tau (assumptions: $\tau_n \leq C_n$, $c\xi_n^p \leq \tau_n$, $p > 2$)
13	The upper-bound assumption reads as false in the periodic box ($SU(3)$ and above)	Assumption	Reading obtained by putting rows 3 and 2 into row 12	Periodic box	—
14	The five examples are one pattern	Estimate	§ 01– § 03	—	—

How to check: on each "⟸" row, see by eye that the numbers on the right are smaller than the one on the left. There are no circles. The row of the primary source for $SU(2)$ is a premise of no row. That is how the unsettled reading for $SU(2)$ appears on the graph. Among the leaves of the row "the upper-bound assumption reads as false in the periodic box" is an assumption row (the reading that extends the conjecture to the slowness of topology in the periodic box), and this is why the label of that row is "Assumption".

Strictly, the statement "the upper-bound assumption reads as false in the periodic box" contains the quantity of the conclusion CP, but among its premises, the reading that extends the conjecture and the numbers of the original sources for SU(3) and above do not contain CP. The numbers of the original sources are numbers for Monte Carlo autocorrelations, and the reading that extends the conjecture is a reading about the universality class of dynamics; the only passage that reaches CP is the single one through the row τ_int ≤ C_P.

What this chapter can say

Said	Not said
Proved here $\tau_{\mathrm{int}} \leq CP$ (reversible dynamics), the static lower bound (2), the algebra of (3), the Free-Particle-on-a-Circle Counterexample, the one-site ratio ω_b/m, the subregion ratio formula (6)	A lower bound on $\tau(Q)$ satisfying the second assumption of (3) in four dimensions. Four-dimensional values of h, g, d

Said	Not said
Reading ℓ_c and $\tau(Q)$ for the two-dimensional $U(1)$ strip, the factor for the boundary gauge, the lattice ratios for the double well	All are floating-point and Monte Carlo numbers within conditions, not propositions of upper or lower bounds. The two-dimensional numbers imply nothing for four dimensions
Cited $\tau(Q)$ faster than ξ^2 in the periodic box for $SU(3)$ and above (three original sources), one primary source for $SU(2)$	Power or exponential. Whether $z > 2$ for $SU(2)$
Assumption The upper-bound assumption reads as false in the periodic box ($SU(3)$ and above, on top of a reading that extends a conjecture)	That the upper-bound assumption is false. The same reading for $SU(2)$
Estimate That the five examples are one pattern, and that the wall of the first step is a scaled-down version of this pattern	Turning the classification of the pattern into a theorem

Terms used in this chapter — nearly conserved global quantity, breaking of conservation, the transport coefficient d and the coefficient of breaking of conservation h, the crossing length R_*, wrapping, the topological charge of the strip, flux through a box. The notation is in 24-09.

Next chapter to read: 24-02 Choosing the ruler and the coordinates again — is the length to compare with the static correlation length, or the length at which conservation breaks? The two forms that restate the relaxation-time assumption to avoid the pattern are in 24-03.

Choosing the ruler and the coordinates again — the length at which conservation breaks

> This chapter is this book's own investigation. § 06 is a map of open questions.

What this chapter shows — The diffusive-relaxation-time assumption was a sentence comparing the relaxation time CP with the square of one length ξ. We split the rulers that could play the role of that ξ into three: the static correlation length, the length at which conservation breaks ℓ_*, and the time for the global quantity to move by one. On a hierarchical lattice we see that, even for the same equilibrium measure, whether the diffusive-relaxation-time assumption is true changes with the coordinates used to move it (the choice of Dirichlet form) ($C_P = 1/\beta$ in tree coordinates, the square of the side in link coordinates). We state that the length at which conservation breaks, measured at five points on the two-dimensional $U(1)$ strip, is not proportional to the static length; that it comes from the same wrapping as one step of the topological charge; and that splitting the relaxation rate into a "raw rate" and a "static fluctuation" reveals the factor the paper prediction had dropped. Finally we set out a candidate correction that compares with $\max(\xi^2,\ \text{the time for the global quantity to move by one})$, and that on the two-dimensional CP^{N-1} test bed the freezing of the topological charge splits with N while the ratios of local quantities did not (conditionally).

Prerequisite chapters — 24-01 (the pattern, the two accounts of (4)–(7), row (c) of Table 1), 23-01 § 05 ((13) for the relaxation-time assumption and the note on topological sectors), 23-01 § 07 (the bookkeeping length ξ_{RG} and the logarithmic factor), the detour in 2-10 (conserving dynamics), "Differences other than constants" in 2-10 (the choice of variables). The notation is collected in 24-09.

Said first — The level is [Y3]. The numbers in this chapter are numbers for the Gauss approximation on a hierarchical lattice and for two-dimensional models (the $U(1)$ strip, CP^{N-1}). Two-dimensional numbers imply nothing about four-dimensional Yang–Mills. "Correcting what to compare with" is a candidate restatement, shown in no model Estimate . This chapter shows neither the mass gap nor whether the relaxation-time assumption is true.

The order of this chapter

1. Three rulers — the static correlation length, the length at which conservation breaks, the time for the global quantity to move by one ((1)(2))
2. Choosing the coordinates again — tree coordinates and link coordinates, conservation of flux (Table 1, (3)–(5))
3. The two-dimensional $U(1)$ strip — the length at which conservation breaks at five points (Table 2, (6))
4. Two faces of the same wrapping — the flux dipole and the topological charge ((7))
5. Raw rate and static fluctuation — the factor the paper prediction had dropped ((8)(9))
6. Correcting what to compare with — $\max(\xi^2, \tau_{\mathrm{glob}})$ ((10))
7. The two-dimensional CP^{N-1} test bed — freezing splits with N, local ratios do not (Table 3, Table 4)
8. What cannot be said
9. Table of the five grades and the dependency graph — Table 5

01

Three rulers — what length is the ξ of the diffusive-relaxation-time assumption?

The relaxation-time assumption is the power statement $\lim \ln C_P / \ln \xi = 2$ ((13) of 23-01), comparing the relaxation time C_P with the square of one length ξ. Part 23 took this ξ to be the correlation length $1/m_{\mathrm{lat}}$ and used the bookkeeping length ξ_{RG} in its place (23-01 § 07). But in the pattern of 24-01, what fixes the slowness is not the correlation length but "the scale of the events that break the global quantity Q". So we split the candidates for what to compare with into three.

(a) The static correlation length ξ. The length over which two-point correlations decay, fixed by the equilibrium measure alone. In four dimensions $\xi = 1/m_{\mathrm{lat}}$. In the two-dimensional $U(1)$ strip, one row of the strip becomes a one-dimensional chain of rotors in axial gauge, and the length over which Wilson loops decay with area (the inverse string tension),

$$\xi_{XY} = -\frac{1}{\ln\bigl(I_1(\beta)/I_0(\beta)\bigr)} \ \approx\ 2\beta \qquad (\beta \text{ large}) \ (1)$$

plays this role (I_ν is a modified Bessel function. The formula is a standard computation, and this book has not checked the original source Assumption).

(b) The length at which conservation breaks ℓ_*. The global quantity (charge) Q_R in a subregion R changes by two routes: the route of transport, flowing out through the boundary (taking time of order R^2), and the route of conservation breaking inside the region (dislocations, wrapping). The length at which the two balance is ℓ_*. The crossing length R_* of (7) in 24-01 was its static version. A candidate definition written with quantities of the measure alone is

$$S := \sup_R \frac{\mathrm{Var}(Q_R)}{\mathcal{E}(Q_R)}, \qquad \ell_* := \inf\Big\{ R : \ \frac{\mathrm{Var}(Q_R)}{\mathcal{E}(Q_R)} \ \geq \ \frac{S}{2} \Big\} \quad (S = \infty \text{ implies } \ell_* = \infty) \ (2)$$

Estimate . Putting in the estimate $\mathrm{Var}/\mathcal{E} \approx \chi_t R^2/(hR^2 + d\lambda_W)$ of (7) in 24-01 gives $S = \chi_t/h$, and the ratio reaches half of it when $hR^2 = d\lambda_W$, that is, $\ell_* = R_*$ Assumption (on top of the estimate (7)). If conservation never breaks ($h = 0$), then $S = \infty$ and $\ell_* = \infty$, which agrees with the flux of the layers in the Gauss approximation of § 02 below (where conservation holds exactly). Strictly, a definition of the form "the supremum of R with $\mathrm{Var}/\mathcal{E} \leq KR^{2}$", comparing the ratio with R^2, does not fix a length: under the estimate (7) the ratio divided by R^2 decreases in R, so the set of R satisfying the condition is a half-line open upwards or empty, and the supremum is infinite or undefined. (2) avoids this by cutting at half the saturation value.

(c) The time for the global quantity to move by one τ_{glob}. A time, not a length. Its representative is the integrated autocorrelation time $\tau_{\mathrm{int}}(Q)$ of the topological charge Q in the periodic box, and for reversible dynamics $\tau_{\mathrm{int}}(Q) \leq C_P$ ((1) of 24-01).

The three can take different values within the same model. In the 0+1-dimensional double well, the slow quantity (the number of kinks) and the correlation length are born from the same kinks, and the three differ only by logarithms (24-01 Table 3). In the two-dimensional strip of § 03, (a) grows linearly in β while (b)(c) grow exponentially, and the three move apart. Fixing the model does not automatically fix which ruler the relaxation-time assumption is a sentence about.

What this section can say: (2) is a candidate definition, and the four-dimensional value of ℓ_* is not in this book. The ξ_{XY} of (1) is used only as the static length of the strip; it does not stand in for the four-dimensional correlation length.

02

Choosing the coordinates again — tree coordinates and link coordinates

The denominator of the Poincaré constant $C_P = \sup \mathrm{Var}(f)/\mathcal{E}(f)$ is a Dirichlet form, and it is not fixed until one decides the variables whose gradients it measures. We saw in Part 2 that changing variables by a constant factor changes C_P by a constant factor ("Differences other than constants" in 2-10: a factor β depending on whether one measures by link angles or by the field). In this section we give an example where the choice of coordinates changes the **type** of growth of C_P.

Stage. A hierarchical lattice replaces the lattice by nested boxes so that one step of renormalisation can be written down. For gauge fields, Ito (1984) built a three-dimensional lattice on which the recursion of the Migdal–Kadanoff approximation holds exactly, and wrote that the extension to higher dimensions is left to the reader Cited . This book defines for itself a four-dimensional version that coarsens by factors of two (each layer a two-dimensional periodic lattice of side $L = 2^N$, with the bonds of level r identified across 4^r layers), and treats only the Gauss approximation on it ($U(1)$, or linearisation to one component of the Lie algebra of $SU(2)$) Assumption (the four-dimensional construction is this book's extension).

Tree coordinates. Taking the values of the plaquettes (the holonomies at the nodes) as variables, in the Gauss approximation the configuration space is a linear subspace S, the equilibrium measure is the density $e^{-\beta|x|^2/2}$ on S, and the Hessian of the Langevin potential is βI on S.

$$\text{tree coordinates (Gauss approximation)}: \qquad \lambda_1 = \beta, \qquad C_P = \frac{1}{\beta} \qquad (\text{every number of levels } N) \ (3)$$

Proved here Proof. It is an Ornstein–Uhlenbeck process with unit metric and drift matrix βI, so the gap of the generator is β. ∎ Lean `HierLink.tree_no_decay` (bundle LatticeGaugeHierarchicalLink; assumption: $0 < \beta$; only the arithmetic that the ratio is 1). Increasing the number of levels, that is, making the lattice however large, does not slow relaxation in these coordinates. Even if the correlation length grows under the non-abelian flow, the coarse levels are expected to stay close to Haar with $C_P = O(1)$ Estimate , and **in tree coordinates the relaxation-time assumption is false or empty**.

Link coordinates. What the relaxation-time assumption of Part 23 names is Langevin in the link variables (23-01 § 04). The link generator in the Gauss approximation is $\beta\, D\Pi D^*$ (D is the exterior derivative from links to plaquettes, Π the projection of the identification), and its smallest positive eigenvalue is

$$\lambda_{\min}(N) = 4\sin^2\frac{\pi}{2^{N+1}}, \qquad 4^N \lambda_{\min}(N) \ \longrightarrow \ \pi^2 \qquad (N \to \infty) \ (4)$$

Proved here (paper: splitting functions of the layers into sectors by the hierarchical projection, the block operator for sector k becomes the Neumann Laplacian of the two-dimensional dual lattice of side 2^{k+1}, and the minimum is the value for sector $k = N -$

1 with side 2^N) Reading (agreeing with the direct full spectrum for $N \le 2$, and with a separate implementation by sectors for $N = 3$, 4). The gap of the generator is $\beta\lambda_{\min}$, which shrinks inversely with the square of the side. Lean `HierLink.lam_le` (no assumptions: $4\sin^2(\pi/2^{N+1}) \le \pi^2/4^N$; an upper bound in the direction of slowness; that $\lambda_{\min}$ is *equal* to this expression is outside Lean), `HierLink.measured_scaled` (with the interval of the measured $\lambda_{\min}(4)$ as assumption, $4^4\lambda_{\min} \in (9.83, 9.84)$).

Table 1 Coordinates and gap (Gauss approximation, one component of $U(1)$, this book's four-dimensional extension; the gap

N	Side $L = 2^N$	Tree coordinates	Link coordinates (metric of the original lattice)	$4^N\lambda_{\min}$	Link coordinates (metric per class)	Gauge quotient on the four-dimensio
1	2	1	2.000000	8.0000	2.000000	2.0000
2	4	1	0.5857864	9.3726	0.8768944	0.5857864
3	8	1	0.1522409	9.7434	0.2575235	—
4	16	1	0.0384294	9.8379	0.0667663	—

Labels of Table 1: the tree-coordinate column is Proved here by (3). Link coordinates (metric of the original lattice) are Proved here Reading , the closed formula (4) agreeing with computation. The metric per class (moving identified bonds as one variable) is computation only Reading , 1.0–1.74 times the metric of the original lattice. The gauge quotient on the four-dimensional original lattice agrees with the metric of the original lattice to 10^{-9} for $N \le 2$ Reading . The lowest eigenvector lies, for all N, in the same sector (the contrast between the four top-level groups of layers) Reading .

The slowness comes from conservation of flux. When links move, the values of the plaquettes (the flux) are only handed between neighbours.

$$\frac{d}{dt}F = d\Big(\frac{d}{dt}A\Big), \qquad \sum_{p\in\text{block}} F_p = 0 \quad \text{(when the boundary bonds are fixed; Stokes)} \tag{5}$$

Unevenness of the flux is smoothed out only by diffusion, which takes time of the square of the side (the conserving dynamics of Part 2, the model B type, the detour in 2-10). The decisive point is the last column of Table 1. If the layers are decoupled and every bond made an independent variable per layer, then statically the plaquettes are almost independent (only the constraint on the total) and the correlation length is 0, yet the smallest eigenvalue is $4\sin^2(\pi/L)$ and the same L^{-2} type remains Proved here . Hence **this slowness does not come from the correlation length**. The static correlation of plaquettes in the Gauss approximation decays masslessly, of order $-\beta^{-1}R^{-4}$; β does not flow (the Gauss-approximation face of the coupling being dimensionless in four dimensions, 24-07), and the correlation length is only cut off by the volume Proved here .

Consequence. The relaxation-time assumption is not a sentence about the measure alone but **a sentence about the pair (measure, Dirichlet form)** Estimate . Tree coordinates and link coordinates have the same equilibrium measure, yet in the former C_P does not depend on the number of levels, and in the latter it grows as the square of the side. In Part 2, "C_P changes by a constant factor with the coordinates" did not change the power of the growth, but here the power itself (N^0 versus 4^N) changes. The relaxation-time assumption of Part 23 names Langevin in the link variables, so it already meets this point. Reinterpreting heat-bath or overrelaxation numbers as C_P of link Langevin is an assumption (2-10 § "Do not identify heat bath with Langevin"). And even in link coordinates, conservation holds exactly in the Gauss approximation, so ℓ_* of (2) is infinite, and comparing "$C_P \propto L^2$" with the correlation length has no meaning. What should be compared is a quantity outside the Gauss approximation: at what length the compactness or non-abelianness of the group breaks the conservation of flux. The next section is the first measurement of it.

What this section can say: hierarchical models lack translation and rotation invariance, and imply nothing about four-dimensional Yang–Mills. The four-dimensional construction is this book's extension of the three-dimensional construction of the original source. The numbers are numbers for the Gauss approximation, with $N \le 4$.

03

The two-dimensional $U(1)$ strip — the length at which conservation breaks at five points

Model. We cut one layer of the previous section into a narrow strip. Plaquettes (x, y), $x = 0, \dots, M-1$, $y = 0, 1$ (width $W = 2$); all links on the outer boundary are fixed at angle 0, and the inner links are moved by the Langevin dynamics $d\theta_\ell = -\partial_\ell S\, dt + \sqrt{2}\, dB_\ell$ for the action $S = -\beta\sum_p \cos\varphi_p$ (unit metric). Gauge transformations at inner vertices do not change the plaquette angles φ_p, so on gauge-invariant functions the link generator reduces to a diffusion on φ, whose metric is the Neumann Laplacian of the dual graph of the plaquettes Proved here . The equilibrium measure is the product of independent $e^{\beta\cos\varphi}$ per plaquette conditioned on $\sum_p \varphi_p \equiv 0 \pmod{2\pi}$, and there is almost no static correlation between plaquettes.

In the Gauss approximation conservation holds exactly. With $\sin\varphi \to \varphi$, the smallest gap is $\beta \cdot 4\sin^2(\pi/2M) \approx \beta\pi^2/M^2$, inversely proportional to the square of the strip length Proved here (Lean `ConsLen.neumann_gap_lower` , `ConsLen.neumann_gap_upper` , bundle LatticeGaugeConservationLength; assumption: $1 \le M$; $4/M^2 \le 4\sin^2(\pi/2M) \le \pi^2/M^2$. That the gap equals this expression is outside Lean).

If the group is compact, conservation breaks. An event in which the angle of a single plaquette crosses $\pm\pi$ (a wrapping) changes by one the sum of the angles reduced to $(-\pi, \pi]$,

$$Q := \frac{1}{2\pi}\sum_p [\varphi_p] \;\in\; \mathbb{Z} \quad (6)$$

(the topological charge of the strip, an integer because the outer boundary is fixed). A wrapping is a rare event crossing a barrier of height 2β. We measure two quantities: $\lambda_X := 1/\tau_{\mathrm{int}}(X)$ for the flux dipole $X = \sum_p w_p[\varphi_p]$ ($w_p = \cos(\pi(x+\frac{1}{2})/M)$, the slowest mode of the Gauss approximation), and $\lambda_Q := 1/\tau_{\mathrm{int}}(Q)$ for the topological charge. For reversible dynamics $\tau_{\mathrm{int}} \le C_P$ ((1) of 24-01), so both are read as **upper bounds on the gap**. The length at which conservation breaks is defined by fitting $\lambda_X = A/M^2 + B$ and setting $\ell_c := \sqrt{A/B}$ (the length at which the diffusion rate A/M^2 equals the saturation value B).

Table 2 Five points for the two-dimensional $U(1)$ strip (width 2, outer boundary frozen, gauge quotient of link Langevin, strip length $M \le 256$; λ_Q is a weighted mean over M with $\mathrm{Var}\, Q \ge 0.5$; $E := \mathbb{E}\,[\varphi_p]^2$; errors by Madras–Sokal and the covariance of the fit)

β	ξ_{XY}	ℓ_c	Paper estimate	λ_Q	$\tau(Q)$	$\pi/\sqrt{E\lambda_Q}$	$\rho = \ell_c/\frac{\pi}{\sqrt{E\lambda_Q}}$	ℓ_c/ξ_{XY}
2	2.78	3.29(20)	3.53	0.769(21)	1.30	4.10	0.80(5)	1.2
3	4.75	9.88(39)	8.28	0.224(13)	4.46	10.0	0.985(50)	2.1
4	6.82	24.7(9)	19.6	0.0579(29)	17.3	23.9	1.03(5)	3.6
5	8.87	53.6(3.1)	47.7	0.0127(10)	79	58.5	0.92(6)	6.0
6	10.90	139(14)	118	0.00276(32)	362	139	1.00(11)	12.8

Every label in Table 2 is Reading . "Paper estimate" is the value, by numerical integration, of a capacity estimate with a test function (the length at which the two terms of an upper bound become equal, using a test function whose return from wrapping is optimised by capacity; for large β, $e^{\beta}\sqrt{\pi/(6\beta)}$) Assumption (an estimate on top of the independence approximation), and is of the same order as the measured ℓ_c.

Slopes. With a weighted straight line over $\beta = 2, \dots, 6$:

- The slope of $\ln \ell_c$ is $a = 0.916(21)$. Split into intervals: $0.988(34)$ for $\beta = 2$ to 4, $0.834(46)$ for 4 to 6.
- The slope of $-\ln \lambda_Q$ is $b = 1.355(18)$. Split into intervals: $1.286(28)$ and $1.520(57)$ (difference 3.7σ).
- The slope of ln of the combination $\pi/\sqrt{E\lambda_Q}$ is $0.884(9)$, and 0.879 to 0.884 on every interval.

Reading Lean `ConsExp.lc_slope_2_6` (bundle LatticeGaugeConservationExponent; assumptions: $\ell_c(2) \in [3.09, 3.49]$, $\ell_c(6) \in [125, 153]$, the measured 1σ intervals; conclusion: $a \in [3/4, 1]$), `ConsExp.lamQ_slope_2_6` (with the 1σ intervals of $\lambda_Q(2)$ and $\lambda_Q(6)$ as assumptions, $b \in [5/4, 3/2]$). The bundles guarantee only interval arithmetic.

Not proportional to the static length. The static length $\xi_{XY} \approx 2\beta$ is linear in β and grows only about fourfold over the five points. The length at which conservation breaks, $\ell_c \propto e^{0.92\beta}$, grows 42-fold, and the ratio ℓ_c/ξ_{XY} opens from 1.2 to 12.8 Reading . Of the three rulers of § 01, (a) and (b) move apart exponentially within the same model. When the strip is longer than ℓ_c, relaxation stops depending on the strip length and is fixed by the time for Q to move by one.

Conditions: two-dimensional $U(1)$, width 2, outer boundary frozen, gauge quotient of link Langevin with unit metric, $\beta = 2, \dots, 6$, strip length $M \le 256$, τ_{int} as a reading of an upper bound on the gap, fit of the form $A/M^2 + B$ (for $\beta = 2$, $\chi^2/\mathrm{dof} = 3.3$, and the form does not fit). Nothing is said about the exponent as $\beta \to \infty$.

04

Two faces of the same wrapping — the flux dipole and the topological charge

The ρ column of Table 2 shows that the two quantities are one process. The relaxation of the flux dipole X falls as M^{-2} at the rate $\mu_1(M)/E$ ($\mu_1 \approx \pi^2/M^2$), with the Gauss stiffness replaced by $1/E$, while the relaxation rate λ_Q of the topological charge Q does not depend on the strip length. The length at which the time for diffusion to cross a length ℓ equals the time for Q to move by one is

$$\frac{\pi^2}{E\,\ell^2} = \lambda_Q \quad\Longleftrightarrow\quad \ell = \frac{\pi}{\sqrt{E\,\lambda_Q}} \quad (7)$$

Proved here (algebra) Lean `ConsExp.lc_eq_iff` (assumptions: $0 < E$, $0 < \lambda$, $0 < \ell$), and its ratio ρ to the measured ℓ_c is 0.80 to 1.03 over the five points Reading . **The length at which conservation breaks reads as the distance the flux crosses by diffusion while the topological charge moves by one.** The flux dipole departing from M^{-2} and the topological charge relaxing are two faces of the same wrapping.

A single point at $\beta = 8$ supplements this reading. Up to strip length 64, X keeps M^{-2} (ratio to the Gauss stiffness 0.86 to 1.03), but at strip length 32, $\tau_{\mathrm{int}}(Q) = 5.3(1.7) \times 10^3$ (run length 10^6, $\mathrm{Var}\, Q = 0.145$), and a slow mode at about $1/380$ of the value for X appears Reading . Because $\mathrm{Var}\, Q$ is small (a sector where $Q \neq 0$ is rare), this point is not included in the slopes.

What this section can say: ℓ_c is the length of the bend in the relaxation of X, not the length of a bend in the gap itself (including Q, the upper bound on the gap at $\beta = 4$ already saturates at $M \approx 8$ to 16). We do not claim that the topological charge of the strip is the same thing as the four-dimensional topological charge.

05

Raw rate and static fluctuation — the factor the paper prediction had dropped

The paper prediction before measuring was "$\lambda_Q \propto \beta e^{-2\beta}$" (the Kramers rate for the barrier 2β), so the slope b should have been near 2. The measured $b = 1.355(18)$ is gentler, and moreover split before and after β (bottom of Table 2). To find where the split comes from, we divide the relaxation rate into two factors. Q can be regarded as a chain of ± 1 jumps with a restoring force, so from the total jump rate $WM\nu$ (ν is the rate of wrapping per plaquette) and the variance $\mathrm{Var}\, Q \approx WM\, E/(4\pi^2)$ comes

$$\lambda_Q = \kappa \cdot \frac{2\pi^2\, \nu}{E}, \qquad E = \mathbb{E}\,[\varphi_p]^2 \quad (8)$$

this form Assumption (the chain picture; κ is a correction for the raw count. It is a different quantity from the comparison constant κ of the One-Sided Bridge Proposition (Theorem 3.1 of the paper) (24-09)). The ν in the numerator is the **raw rate** (a quantity of the dynamics), and the E in the denominator is the **static fluctuation** (a quantity of the measure). Taking logarithms gives

$$\Delta \ln \lambda_Q = \Delta \ln \nu - \Delta \ln E \quad (9)$$

Proved here (algebra) Lean `ConsExp.lamQ_log_split` (assumptions: $0 < \kappa$, each quantity positive).

Counting the raw number of wrappings ν_{raw} (the number of times $\pm\pi$ is crossed), we found the following Reading .

- $\kappa = \lambda_Q E/(2\pi^2 \nu_{\mathrm{raw}})$ is constant at $0.167,\ 0.165,\ 0.158,\ 0.167$ for $\beta = 3, 4, 5, 6$ (the raw count also counts back-and-forth trips near π, so the effective crossings are about $1/6$ of it).
- The slope of the raw rate $-d \ln \nu_{\mathrm{raw}}/d\beta$ is $1.73,\ 1.75,\ 1.79$ on the intervals $3 \to 4,\ 4 \to 5,\ 5 \to 6$, agreeing within 1–3% with the slope $2 - 1/\beta$ of the Kramers rate $\beta e^{-2\beta}$ ($1.71,\ 1.78,\ 1.82$ at the midpoints of the intervals).
- The slope of the static factor $\ln(1/E)$ is $0.38,\ 0.27,\ 0.21$, decreasing with β (approaching the Gauss value $1/E \approx \beta$).

From (9), $b = (\text{slope of the raw rate}) - (\ln(1/E)\ \text{slope})$, and since the latter decreases with β, b increases with β. This is what the split really is. **The paper prediction had dropped the static factor $1/E$.** The corrected form is $\lambda_Q \propto \beta e^{-2\beta}/E$ (for large β, $\propto \beta^2 e^{-2\beta}$, $b \to 2 - 2/\beta$), in the same direction as the measured b Estimate . In the combination $\pi/\sqrt{E\lambda_Q}$, E cancels and only $\nu^{-1/2}$ remains, so the slope is half the slope of the raw rate (about 0.88) and constant over all intervals. That is the third slope at the bottom of Table 2.

Strictly, this split is a check added after seeing the split in the data; it was not among the pre-registered predictions. Also, nothing can be said from these five points about the exponent as $\beta \to \infty$ (whether $b \to 2$).

What to keep as a view Estimate : the relaxation rate of a global quantity splits into the product of "the rate of events" (dynamics, barrier) and "the static fluctuation that measures how much one event moves the global quantity" (measure). The one-loop accounting that the original sources write for the four-dimensional topological charge (24-07 § 02) also counts only the exponent of the density of events. Whether the static factor moves the reading of the exponent has not been checked in four dimensions.

06

Correcting what to compare with — $\max(\xi^2, \tau_{\mathrm{glob}})$

In the strip, measuring $\tau(Q)$ with the static length ξ_{XY} as the ruler, $\tau(Q)/\xi_{XY}^2$ is about 0.4 at $\beta = 4$ and about 24 at $\beta = 8$ (strip length 32) Reading . Since $C_P \geq \tau_{\mathrm{int}}(Q)$, C_P/ξ_{XY}^2 also grows with β. "$C_P \lesssim \xi^2$", with only the static correlation length as the ruler, tends to fail with β inside this toy (row (c) of the pattern in 24-01). So we put forward, as a candidate, a form that adds the time of the global quantity to what is compared with.

$$C_P \asymp \max\left(\xi^2,\ \tau_{\mathrm{glob}}\right), \qquad \tau_{\mathrm{glob}} := \left(\text{the time for the global quantity to move by one}\right) \quad (10)$$

Estimate . This is one direction for correcting the relaxation-time assumption. The other direction is to restrict the side of test functions to families local in time and space (24-03 § 02), where, as long as the box is smaller than ℓ_*, the time of the global quantity is expected not to enter (§ 07).

(10) has three weaknesses. (i) If τ_{glob} is defined by $\tau_{\mathrm{int}}(Q)$ of the same dynamics, (10) is close to a restatement of $\tau_{\mathrm{int}}(Q) \le C_P$ and has no content. To give it content, τ_{glob} must be fixed independently of the dynamics. Candidates are the split of § 05 (barrier rate and static fluctuation, $\tau_{\mathrm{glob}} \approx E/(2\pi^2\kappa\nu)$), or making the diffusion time ℓ_*^2/D from the static ℓ_* of (2) Estimate . (ii) The strip numbers see only the lower side of (10), $C_P \ge \tau_{\mathrm{glob}}$, and not a single number bounds C_P from above. At $\beta = 4$, $\tau(Q) \approx 17$ against $\xi_{XY}^2 \approx 46$, and whether C_P is on the side of ξ_{XY}^2 has not been measured. (iii) In four dimensions the candidate for τ_{glob} is the topological charge in the periodic box, whose measurements are the heat-bath and HMC numbers of the original sources, and reinterpreting them for Langevin is an assumption (24-01 § 06).

What this section can say: (10) is a candidate restatement, shown in no model. Nor do we propose replacing the relaxation-time assumption of Part 23 with (10). The order of the account is: because the relaxation-time assumption was set up sharply, we could name the places where a single thing to compare with is not enough.

07

The two-dimensional CP^{N-1} test bed — freezing splits with N, local ratios do not

Why this model. The two-dimensional CP^{N-1} model shares two points with four-dimensional Yang–Mills — a dimensionless coupling, and instantons with no scale (24-07) — and lets one vary N, which plays the role of the size of the group. There are primary sources reporting that in the periodic box the autocorrelation of the topological mode grows like $\exp(1.72\,\xi)$ for $\xi = 2$ to 6 ($N = 21$, Hasenbusch 2017), and worsens with N (Del Debbio–Manca–Vicari 2004, Berni–Bonanno–D'Elia 2019) Cited . It is also reported that with open boundaries the growth returns to $z \approx 1$ Cited .

Setting. The action is Hasenbusch's form $S = -\beta N \sum_{x,\mu}(\bar{z}_{x+\mu} z_x \lambda_{x,\mu} + \mathrm{c.c.} - 2)$ ($z_x \in \mathbb{C}^N$, $|z_x| = 1$, $\lambda \in U(1)$), and the topological charge is the sum of plaquette angles $Q = \frac{1}{2\pi}\sum \theta_{\mathrm{plaq}}$. The dynamics is heat bath (sites and links) mixed with n_{ov} overrelaxation steps; it is **not Langevin**. The autocorrelations measured here are in units of heat-bath sweeps, and reinterpreting them as the Langevin C_P is an assumption (2-10). The local quantities are three for a box of side R: the energy E_B, the topological charge of the box q_B, and the "magnetisation" of the box m_B.

The two-dimensional reference differs in character from four dimensions. The reference of the ratio form K_{rel} of 24-03 (the box value for the massless free field) diverges in two dimensions not only with the box size R but logarithmically in the lattice side L (the constant part of the continuum kernel $-\frac{1}{2\pi}\ln|z|$ sits on the box average) Proved here . Removing the box average makes it finite, about 0.0548 by extrapolation in $1/R^2$ Reading . Moreover, even for mean-zero quantities the free-field Langevin autocorrelation grows with $\ln L$ Reading (in a box with $R = 16$, from 36 to 119 as the lattice side goes from 64 to 1024). So the ratios of this test bed are **ratios of autocorrelations with the lattice side fixed at $L = 64$**, $K_{\mathrm{rel}}(c;\mathrm{qty}) := \tau(\mathrm{qty}_B(c\xi))/\tau^{\mathrm{free}}(D_B(c\xi))$ (D_B is the first Neumann mode of the free-field box, with the same algorithm and the same L) and $K_{\mathrm{glob}} := \tau(Q^2)/\tau^{\mathrm{free}}(D_B(4\xi))$, quantities different from the static ratios of 24-03.

Positive control. With two runs (run length 70000 sweeps) at $N = 21$, $\beta = 0.70$, $L = 44$, $n_{\mathrm{ov}} = 6$, it passed with $\tau_{\mathrm{int}}(Q^2) = 160(26)$ (0.80 times 199(18) of Hasenbusch's Table II, inside the band [139, 259] fixed in advance), an energy difference of -9×10^{-6}, and a ξ difference of -0.1% Reading .

Table 3 Core pairs and pure heat-bath pairs ($L = 64$, periodic, $\xi \approx 4$; K is three values at $c = 1, 2, 4$; one run each, some runs shortened from the registered length)

N	β	n_{ov}	ξ_{2nd}	$\tau(Q^2)$	Changes of Q / measurements	K_{glob}	$K_{\mathrm{rel}}(E_B)$	$K_{\mathrm{rel}}(m_B)$	$K_{\mathrm{rel}}(q_B)$
21	0.70	6	3.738(14)	154(46)	527 / 30600	Undefined (the reference τ^{free} is 0.33–0.54)			
2	1.140	6	4.25(8)	0.50	93123 / 99000	Same as above			
21	0.70	0	3.76(6)	3874(2810)	120 / 41400	55	0.32, 0.11, 0.038	0.68, 0.59, 0.51	1.71, 1.74, 2.27
10	0.80	0	4.62(8)	70.9(10.3)	24347 / 81000	1.01	0.35, 0.13, 0.049	0.83, 0.78, 0.57	1.51, 1.11, 0.83
2	1.140	0	4.89(24)	0.73	133493 / 144000	0.010	0.26, 0.084, 0.030	0.66, 0.41, 0.25	0.21, 0.062, 0.022

Every label in Table 3 is Reading . $\tau(Q^2)$ for $N = 21$, $n_{\mathrm{ov}} = 0$ has a run length of only about 11τ and is treated as a lower bound.

What can be read.

1. **The freezing of the topological charge splits with N.** At $\xi \approx 4$, $\tau(Q^2)$ for $N = 21$ against $N = 2$ is 154 against 0.50 with overrelaxation (about 300 times), and 3874 against 0.73 with pure heat bath (about 5000 times; the former treated as a lower bound) Reading .
2. **The ratios of local quantities are small regardless of N.** For the pure heat-bath pairs, K_{rel} for the energy and the magnetisation is almost the same at $N = 2, 10, 21$ (0.03–0.35 for E_B, 0.25–0.83 for m_B), and the ratios of one-step Rayleigh quotients (the ratio of $1/(1-\rho(1))$ to its free-field value) are all 1.1 or below Reading . The verdict at the freezing point was on the side of "freezing of topology does not break the local ratios up to box 4ξ". Conditions: $L = 64$, a single point $\xi \approx 4$, one run each, a post-hoc cell (below). There is only one freezing point, ($N = 21$, $\xi \approx 4$), and $K_{\mathrm{glob}} = 55$ has a 1σ width of 15–95 from the error of one run, so whether it exceeds the decision threshold 30 is within that error. **It is a weak reading at one point.**

3. **ℓ_* grows with N.** Table 4 lists the length at which the autocorrelation of the topological charge of the box catches up with the global value.

Table 4 Autocorrelation of the topological charge of the box $\tau(q_B(R))$ and the global $\tau(Q)$ (pure heat bath, $L = 64$)

N	$R = 2$	4	8	16	32	$\tau(Q)$	$\tau(q_B(32))/\tau(Q)$	Exponent for $R \to 2R$
21	3.08	9.82	38.9	160	738	4071	0.18	1.67, 1.98, 2.04, 2.21
10	3.01	8.72	24.7	58.4	113	222	0.51	1.54, 1.50, 1.24, 0.95
2	0.98	1.21	1.39	1.51	1.53	1.55	0.99	0.30, 0.20, 0.12, 0.02

Reading For $N = 2$ the autocorrelation of the box charge saturates at the global value at $R \approx 8$ to 16; for $N = 10$ it begins to bend at $R = 32$; for $N = 21$ it still grows as R^2 at $R = 32$. The box charge takes time R^2 through transport across the boundary (the route (b) of § 01), and the length at which it catches up with the global value is the reading of ℓ_*. **In this model and this range, freezing does not break the ratios for boxes smaller than ℓ_*, and rides only on quantities on scales beyond ℓ_*** Estimate . That in Table 3 only $K_{\mathrm{rel}}(q_B)$ of the box charge splits with N ($0.022 \to 0.83 \to 2.27$ at $c = 4$) we read as a reflection of this difference in catching-up length. In the language of 24-03, the local diffusive-relaxation-time assumption asks about the transport coefficient d and the global relaxation-time assumption about the coefficient of breaking of conservation h (24-03 § 05), so this is one two-dimensional face of the prospect that local ratios are unaffected by freezing. It also agrees in direction with the conclusion of 24-04 that what the one-sided bridge needs is the local side (24-04), but the ratios here are ratios of autocorrelations, not the ratio of the bridge's threshold (a static ratio).

What should be disclosed.

- **The registered verdict could not be defined.** The verdict registered in advance was the ratio for dynamics mixed with overrelaxation ($n_{\mathrm{ov}} > 0$), but overrelaxation makes the autocorrelation of the free-field reference oscillate, and $\tau^{\mathrm{free}}(D_B)$ came out at 0.33 to 0.54, below 1. By the rule that a ratio with a denominator below 2 is not defined (added before the main runs), all the registered ratios were "undefined". Readings 2 and 3 above are numbers for pure heat-bath pairs added as a separate cell after the registration was fixed.
- **The dynamical exponent $z_Q(N)$ cannot be read.** For each N there is only one point in ξ. The decision script printed a negative exponent for $N = 21$, but the second point was an artefact in which the script returned a small autocorrelation for a series where the topological charge never changed (only rounding error), and it was discarded.
- **The topological charge for $N = 2$ carries an ultraviolet label.** For $N = 2$ the two definitions of the topological susceptibility (the sum of plaquette angles and the triangle definition of Berg–Lüscher) differed by 13–14%, and for $N = 10, 21$ by 0.1–3% Reading . We understand that the lattice topological susceptibility for $N = 2$ (the same model as $O(3)$) is known to have an ultraviolet problem Assumption (from memory; the original source was not obtained). $N = 2$ may fail to freeze because it is on the side where the lattice scale (the ultraviolet) fixes Q Estimate . If so, the speed for $N = 2$ is not "weak freezing" but a shadow of "Q not being a topological charge in the continuum sense", and the analogy with $SU(2)$ (24-07) carries this reservation.
- Some runs were shortened from the registered length (because of an upper limit on the time of one run), and the statistics are rough. The negative control with open boundaries was not run.

What this section can say: numbers for the two-dimensional CP^{N-1}, this action and these algorithms (heat bath and overrelaxation), $L = 64$, a single point $\xi \approx 4$; nothing is said about four dimensions, $SU(N)$, the relaxation-time assumption or the mass gap.

08

What cannot be said

(a) Two dimensions and four. The numbers of § 03– § 07 are numbers for the two-dimensional $U(1)$ strip and the two-dimensional CP^{N-1}. Two-dimensional $U(1)$ is a trivial theory in the continuum limit, and neither set of numbers implies anything about exponents in four dimensions, non-abelian, $\beta \to \infty$.

(b) Readings of upper bounds. λ_X and λ_Q are readings as upper bounds on the gap (lower bounds on C_P), not the gap itself. ℓ_c is the length of the bend in the relaxation of the flux dipole and depends on the form of the fit $A/M^2 + B$.

(c) Candidates. The ℓ_* of (2) and the thing to compare with of (10) are candidates, shown in no model. The strip numbers see only the lower side of (10).

(d) The hierarchical lattice. The results are numbers for the Gauss approximation, and the four-dimensional construction is this book's extension of the three-dimensional construction of the original source. Hierarchical models lack translation and rotation invariance and imply nothing for four-dimensional Yang–Mills.

(e) Conditions of the test bed. The CP^{N-1} ratios are ratios of autocorrelations of heat-bath dynamics, conditional quantities with $L = 64$ fixed, and different from the static ratios of 24-03. For each N there is one point in ξ, one freezing point, and the verdict on local

ratios is a weak reading at one point on a cell added after registration; the registered verdict could not be defined. $z_Q(N)$ has not been read.

(f) Afterthought. The split into raw rate and static fluctuation in § 05 is a check added after seeing the split.

(g) The analogy with $SU(2)$. Using the split of freezing with N as a two-dimensional analogy of the borderline reading for $SU(2)$ is an estimate, and $N = 2$ carries an ultraviolet label (24-07).

Table of the five grades and the dependency graph

Table 5 Rows of this chapter ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	The Gauss approximation (abelian linearisation), and the four-dimensional extension of the hierarchical lattice	Assumption	§ 02	$N \le 4$	—
2	$\lambda_1 = \beta$ in tree coordinates ((3))	Proved here	§ 02	Gauss approximation, all N	`HierLink.tree_no_decay` (assumption: $0 < \beta$; arithmetic of the ratio)
3	$\lambda_{\min}(N) = 4\sin^2(\pi/2^{N+1})$ in link coordinates ((4))	Proved here	Sector decomposition of § 02	Gauss approximation	`HierLink.lam_le` (no assumptions; only the direction of the upper bound)
4	Cross-check for $N \le 4$, metric per class, gauge quotient on the original lattice	Reading	Table 1	$N \le 4$ (gauge quotient $N \le 2$)	`HierLink.measured_scaled` (measured interval as assumption)
5	L^{-2} remains even with the layers decoupled (conservation of flux)	Proved here	(5), Table 1	Gauss approximation	—
6	The relaxation-time assumption is a sentence about the pair (measure, Dirichlet form)	Estimate	§ 02	—	—
7	Gauss gap of the strip $\beta \cdot 4\sin^2(\pi/2M)$	Proved here	§ 03	Width 2, outer boundary frozen	`ConsLen.neumann_gap_lower/upper` (assumption: $1 \le M$)
8	$\tau_{\mathrm{int}} \le CP$	Proved here	(1) of 24-01	Reversible dynamics	`LatticeGauge.FourDTrial.tau_int_le_CP` (assumptions: weights ≥ 0, eigenvalues $\ge \lambda_1 > 0$)
9	Five points of the strip: ℓ_c, λ_Q, slopes a, b	Reading	Table 2	Conditions of § 03	`ConsExp.lc_slope_2_6`, `lamQ_slope_2_6` (1σ intervals as assumptions)
10	Algebra of (7)	Proved here	§ 04	—	`ConsExp.lc_eq_iff` (assumptions: $0 < E, \lambda, \ell$)
11	$\rho = 0.80$ to 1.03 (two faces)	Reading	Table 2	Five points	—
12	Algebra of the split (9)	Proved here	§ 05	—	`ConsExp.lamQ_log_split` (assumptions: $0 < \kappa$, positivity)
13	The raw rate within 1–3% of the Kramers slope, κ constant (added afterwards)	Reading	§ 05	$\beta = 3..6$	—
14	The paper prediction had dropped $1/E$	Estimate	§ 05	Strip	—
15	$\tau(Q)/\xi_{XY}^2$ goes $0.4 \to 24$	Reading	§ 06	$\beta = 4, 8$	—
16	Compare with $\max(\xi^2, \tau_{\mathrm{glob}})$ ((10))	Estimate	§ 06	—	—
17	Passing the positive control for CP^{N-1}	Reading	§ 07	$N = 21$, $L = 44$	—
18	$\tau(Q^2)$ splits with N	Reading	Table 3	$L = 64$, $\xi \approx 4$	—
19	Local ratios are small regardless of N	Reading	Table 3	Post-hoc cell, one point, weak	—
20	The length at which the box charge catches up with the global one grows with N	Reading	Table 4	$L = 64$	—
21	$N = 2$ may fail to freeze because it is on the side where the ultraviolet fixes Q	Estimate	§ 07	—	—
22	Freezing rides only on quantities on scales beyond ℓ_*	Estimate	§ 07	This model, this range	—

What the machine-checking column guarantees is only arithmetic, algebra and comparisons of intervals. That eigenvalues equal closed formulas, the spectral representation of $\tau_{\mathrm{int}} \le CP$, the fits and the Monte Carlo lie outside Lean (23-13).

How to check: see by eye that on every "⟸" the numbers on the right are smaller than the number on the left. There are no circles. The conclusion nodes of this chapter (the relaxation-time assumption is a sentence about a pair of measure and form; the correction of what to compare with; freezing rides only on quantities beyond the length at which conservation breaks) are all "Estimate", and there is neither a four-dimensional node nor a node for the mass gap. The two-dimensional readings (the nodes from the five points of the strip onwards) are premises of none of the four-dimensional rows.

What this chapter can say

Said	Not said
Proved here On the hierarchical lattice in the Gauss approximation, the gap in tree coordinates is β and the gap in link coordinates is $\beta \cdot 4\sin^2(\pi/2^{N+1})$, and the slowness comes from conservation of flux	The gap of non-linear, non-abelian hierarchical lattices. Implications for four-dimensional Yang–Mills
Reading The length at which conservation breaks, ℓ_c, at five points of the two-dimensional $U(1)$ strip with slope $0.916(21)$; that it is not proportional to the static length; $\ell_c \approx \pi/\sqrt{E\lambda_Q}$	The exponent as $\beta \to \infty$. Two ways to repair the relaxation-time assumption — the sector assumption and the local assumption

This chapter is this book's own investigation. The established knowledge it builds on is in 2-10 and 5-09.

What this chapter shows — We define two forms that restate the diffusive-relaxation-time assumption so as to avoid the pattern of 24-01 (a nearly conserved global quantity). The local relaxation-time assumption is a sentence about the Poincaré constant $C_P^{\mathrm{loc}}(c)$ over functionals supported in a window of length $c\ell$; it is fixed by the marginal law on the window alone, and returns unconditionally to the global C_P as $c \to \infty$. But the form "$C_P^{\mathrm{loc}} \le K(c)\ell^2$ for some $K(c)$" holds even for the massless free field and is empty, so it must be stated by the ratio K_{rel} to the massless value on the same box. The sector relaxation-time assumption is a sentence about the Poincaré constant in each sector of the smoothed topological charge; it pushes the obstruction to the relaxation-time assumption into a single quantity between sectors, C_{trans}, but it does not become a bridge to the mass gap. Seen through the charge of a subregion, the local relaxation-time assumption asks about the transport coefficient d, and the global relaxation-time assumption about the coefficient of breaking of conservation h.

Prerequisite chapters — 24-01 (the pattern, and the two accounts of (4)–(7)), 23-01 § 05 ((13)–(15) for the relaxation-time assumption and the relaxation-time upper-bound assumption, the note on topological sectors), 23-01 § 06 (the setting of the One-Sided Bridge Proposition (Theorem 3.1 of the paper)), 23-11 § 02 (the Box-Reduction Proposition and the closed box C_{box}). Notation in 24-09.

Said first — The level is [Res]; only § 01 is written to be readable at [Y3]. The core of this chapter is definitions, and **neither of the two relaxation-time assumptions has been shown at any** β. What has been shown are properties of the definitions (being a quantity of the marginal on the window, not being dense, monotonicity, the limit), an inequality for the decomposition of the variance by sectors, and values for the free-field reference. The definition on the four-dimensional Wilson measure is a copy of the definition on the path measure with continuous time, and the existence of the infinite-volume measure is a premise row.

The order of this chapter

1. Summary — a section readable at [Y3]
2. Definition of the local relaxation-time assumption — the algebra of time-averaged functionals $\mathcal{D}$, the window families $\mathcal{D}_c$, the Local Poincaré Constant Properties Proposition ((1)–(4))
3. The ratio form and the gauge-quotient reference — the emptiness of the absolute form, K_{rel}, gauge-invariant references, the note on 0+1 ((5)–(7), Table 1)
4. The sector relaxation-time assumption — cuts at regular values, the reflecting form, the Sector Poincaré Constant Proposition and the sandwich, three weaknesses ((8)–(11))
5. Open boxes and closed boxes, two coefficients — local asks d, global asks h, Table 2 (the order of volume and $a \to 0$)
6. Table of the five grades — Table 3 / dependency graph
7. What cannot be said

01

Summary

A section readable at [Y3]. The relaxation-time assumption is a sentence about "every test function", so if the relaxation of a quantity of the pattern of 24-01 (a winding number, the topological charge) grows faster than ξ^2, that alone breaks the upper half (the upper-bound assumption) ((3) of 24-01). Such a quantity is global, local neither in time nor in space. So we restrict the test functions in two ways and restate the relaxation-time assumption.

The local relaxation-time assumption. Restrict the test functions to those depending only on configurations inside a window of length $c\ell$ (in four dimensions, a spacetime box of side $c\ell$). ℓ is a ruler given from outside, independently of the gap; in four dimensions it is the bookkeeping length ξ_{RG}. The supremum $C_P^{\mathrm{loc}}(c)$ is fixed by the marginal distribution on the window alone, increases monotonically as the window widens, and returns exactly to the global C_P as $c \to \infty$. But in a four-dimensional box, C_P^{loc} is finite, of order the square of the side of the box, even for the massless free field. Merely satisfying "$C_P^{\mathrm{loc}} \le K\ell^2$" says nothing, so we ask that the ratio K_{rel} to the massless value on the same box be sufficiently smaller than 1.

The sector relaxation-time assumption. In the periodic box, divide configurations into sectors by the value of the smoothed topological charge, and measure the Poincaré constant in each sector. Splitting the variance into within sectors and between sectors, the global C_P is sandwiched: above by the sum of "the worst constant within a sector" and "the quantity between sectors C_{trans}", and below by C_{trans}. Assuming the sector relaxation-time assumption, the upper-bound assumption becomes the same as $C_{\mathrm{trans}} \lesssim \xi^2$. The obstruction does not vanish; it only moves into one quantity.

What is asked. Writing the ratio for the charge of a subregion with two coefficients ((7) of 24-01), the local relaxation-time assumption needs the **transport** coefficient of the charge d not to be too small, and the global upper-bound assumption needs the coefficient of **breaking of conservation** of the charge h not to be too small. In four dimensions, the freezing of the topological charge acts on the h side, so the local relaxation-time assumption is expected not to be affected by freezing Estimate . But the local relaxation-time assumption does not become a part of the chain that builds the upper-bound assumption; it is a separate sentence (the dependency graph of § 06). That what the one-sided bridge needs is the side local in time (under the assumptions of the one-sided bridge) is treated in the chapter on the bridge, 24-04.

02

Definition of the local diffusive-relaxation-time assumption

Setting. We use the same setting as the one-sided bridge of Part 23 ((17) of 23-01): a finite spatial lattice, the configuration space of one time $\mathcal{Q}$ (a finite-dimensional connected Riemannian manifold with metric M), $H = -\frac{\hbar^2}{2}\Delta_M + V$ with the ground-state assumption ((A1) in the paper; discrete spectrum, simple ground state $\psi_0 > 0$, $\Delta = E_1 - E_0 > 0$), μ the stationary path measure with $T = \infty$ (one-time distribution ψ_0^2, transition $e^{-\tau A}$, $A = (H - E_0)/\hbar$), and $m = \Delta/\hbar$. We take the collection of test functions to be the following **algebra of time-averaged functionals**.

$$\mathcal{D} := \Big\{ f = \Phi\Big(\int h_1(\tau) F_1(q(\tau))\, d\tau, \dots, \int h_k(\tau) F_k(q(\tau))\, d\tau \Big) \Big\}, \qquad \mathcal{E}_G(f) = \hbar \int \mathbb{E}\big\langle d_{q(\tau)} f,$$

Here $\Phi \in C_b^\infty(\mathbb{R}^k)$, $F_i \in C^\infty(\mathcal{Q})$ (up to polynomial growth for $\mathcal{Q} = \mathbb{R}^n$), and the weights $h_i \in L^\infty(\mathbb{R})$ have **bounded support**. $d_{q(\tau)} f = \sum_i \partial_i \Phi \cdot h_i(\tau)\, dF_i(q(\tau))$, and the metric G satisfies the metric comparison assumption of the one-sided bridge ((A3) in the paper). The global Poincaré constant is defined as $C_P := \sup_{f \in \mathcal{D},\, \mathcal{E}(f) > 0} \mathrm{Var}(f)/\mathcal{E}(f)$ **over** $\mathcal{D}$. The test functions of the one-sided bridge, $f_T = \int_0^T F(q)\, d\tau$, belong to this $\mathcal{D}$.

Definition of the local Poincaré constant

For a ruler of length $\ell > 0$ and $c > 0$, put the window $W_c := [0, c\ell]$ and

$$\mathcal{D}_c := \{ f \in \mathcal{D} : \text{ every weight } h_i \text{ has support in } W_c \}, \qquad C_P^{\mathrm{loc}}(c) := \sup_{f \in \mathcal{D}_c,\, \mathcal{E}(f) > 0} \frac{\mathrm{Va}}{\mathcal{E}}$$

ℓ is not the length fixed by the gap, $\xi = \hbar/\Delta$, but a length given from outside (in four dimensions, the bookkeeping length ξ_{RG}).

ℓ is not fixed by the gap because, when a lower bound on the gap is derived from the local relaxation-time assumption in 24-04, the argument would be circular if the gap entered the length of the window. Since the measure is stationary, the position of the window does not affect the value (the interval $[a, a + c\ell]$ gives the same value).

Local Poincaré Constant Properties Proposition

(i) $C_P^{\mathrm{loc}}(c)$ is fixed only by the marginal law of the path on the window, $\mu|_{W_c}$, and the Dirichlet form inside the window.

(ii) $\mathcal{D}_c$ is not dense in $L^2(\mu)$.

(iii) If $c \le c'$, then $C_P^{\mathrm{loc}}(c) \le C_P^{\mathrm{loc}}(c') \le C_P$.

(iv) $\lim_{c \to \infty} C_P^{\mathrm{loc}}(c) = C_P$. This limit needs no assumption.

Proved here Proof. (i) $f \in \mathcal{D}_c$ is fixed only by the values of the path inside the window (the path is continuous, and $\int h F(q)\, d\tau$ is the limit of Riemann sums over points inside the window). For $\tau \notin W_c$, $d_{q(\tau)} f = 0$, so $\mathcal{E}(f) = \hbar \int_{W_c} \mathbb{E}\langle \cdots \rangle\, d\tau$, and both the variance and the Dirichlet form are expectations under the marginal law on the window.

(ii) The closure of $\mathcal{D}_c$ lies in $L^2(\mathcal{F}_{W_c})$, the space of functions measurable with respect to the σ-algebra $\mathcal{F}_{W_c}$ generated by the path inside the window. The value $F(q(\tau_0))$ at a time τ_0 outside the window (F non-constant) is not measurable with respect to $\mathcal{F}_{W_c}$: with $s > 0$ the distance from the end of the window, the conditional expectation is of the form $\psi_0^{-1} e^{-sA}(F\psi_0)$, which under the ground-state assumption does not coincide with F itself.

(iii) If $c \le c'$, then $\mathcal{D}_c \subseteq \mathcal{D}_{c'} \subseteq \mathcal{D}$, and the supremum over a subset is smaller.

(iv) The weights in $\mathcal{D}$ have bounded support, so taking the window as $[-c\ell/2, c\ell/2]$ by stationarity, $\mathcal{D} = \bigcup_c \mathcal{D}_c$. If $b < C_P$, there is $f \in \mathcal{D}$ whose ratio exceeds b, and that f lies

in $\mathcal{D}_c$ for some c, so $C_P^{\mathrm{loc}}(c) > b$. Together with the monotonicity of (iii), the limit is C_P . ∎

Lean LatticeGauge.LocalH.local_le_global (assumptions: bounded above, non-empty, subset) and local_approaches_global (assumptions: $S = \bigcup_c S_c$, bounded above, non-empty; conclusion: every b smaller than $\sup S$ is exceeded by $\sup S_c$ for some c) check only the part of (iii)(iv) about suprema of sets of real numbers. The path measure, $\mathcal{D}$ and $\mathcal{E}$ are outside Lean.

(iv) holds without assumptions because C_P was defined over $\mathcal{D}$. The assumption "local functions form a core of the form" is not needed for this limit. The question of the core remains only when one identifies $C_P(\mathcal{D})$ with the gap of the generator of the equation of stochastic quantisation (the SPDE of Langevin dynamics) (the gap of the generator of the closure of the form on $\mathcal{D}$ is $1/C_P(\mathcal{D})$, and whether it coincides with the generator of the SPDE is the question of the core).

The local relaxation-time assumption. On the definition of the local Poincaré constant, we write the local relaxation-time assumption at two levels.

$$(\xi^2)_c^{\mathrm{loc}}: \ \lim \frac{\ln C_P^{\mathrm{loc}}(c)}{\ln \ell} = 2, \qquad (\xi^2)\!\uparrow_c^{\mathrm{loc}}(K): \ C_P^{\mathrm{loc}}(c) \le K\,\ell^2 \quad (3)$$

(left: the power statement for families with $\ell \to \infty$; right: the absolute form of its upper half). Two things follow in one line from the Local Poincaré Constant Properties Proposition Proved here . First, the global upper-bound assumption $C_P \le K\ell^2$ implies $(\xi^2)\!\uparrow_c^{\mathrm{loc}}(K)$ with the same constant for every c ((iii)). Second, if $(\xi^2)\!\uparrow_c^{\mathrm{loc}}(K)$ holds for every c with **a K uniform in c**, it returns by (iv) to the global upper-bound assumption. So the local relaxation-time assumption has content different from the global upper-bound assumption only when stated with **a single c** fixed.

A version local in space too. On an infinite spatial lattice (or a spatial lattice containing the box), take the product $B \times W_c$ of a spatial box B and a window, and define in the same form the family $\mathcal{D}_{B,c}$, with F_i restricted to single-time functions depending only on variables in B, and $C_P^{\mathrm{loc}}(B,c)$. (i)–(iv) of the Local Poincaré Constant Properties Proposition hold with the same proof, and the marginal in (i) is the law of the field on $B \times W_c$. The local relaxation-time assumption on the four-dimensional Wilson measure copies this definition onto a spacetime box B_c of side $c\ell$ ($\ell = \xi_{\mathrm{RG}}$), treating time and space alike, and the σ-algebra generated by the links in the box; the Dirichlet form is that of link Langevin, $\mathcal{E}(f) = \mathbb{E}\sum_\ell |\nabla_\ell f|^2$. What is presupposed at the copying stage is the existence and uniqueness of the infinite-volume Wilson measure (the infinite-volume uniqueness statement of Part 23) Assumption .

03

The ratio form and the gauge-quotient reference

The absolute form is empty. The right-hand form of (3), $(\xi^2)\uparrow_c^{\mathrm{loc}}(K)$, holds on a four-dimensional spacetime box, local in space too, even for the massless free field. Writing $C_P^{\mathrm{loc},0}(R)$ for the local Poincaré constant of the infinite-volume massless free scalar field (one component, canonical graduation) on a spacetime box B_R of side R,

$$\frac{R^2}{4\pi^2} \;\le\; C_P^{\mathrm{loc},0}(R) \;\le\; R^2 \qquad (4)$$

Proved here . The gradient Poincaré constant of a Gaussian measure equals the operator norm of the covariance compressed to the subspace spanned by the family (a transcription to subspaces of the Covariance-Compression Lemma (Lemma 2.2 of Hairer–Stuart–Voss–Wiberg) of Hairer–Stuart–Voss–Wiberg 2005) Cited , so $C_P^{\mathrm{loc},0}(R) = \|P_B(-\Delta)^{-1}P_B\|$. In four dimensions $(-\Delta)^{-1}$ is finite (transient) and its kernel is continuous, of the type $1/(4\pi^2|z|^2)$, so the Schur estimate $\sup_x \sum_{y\in B} G(x-y) \le \int_{|z|<2R} d^4z/(4\pi^2|z|^2) = R^2$ gives the upper side, and the value with the Dirichlet ground state of the box as test function gives the lower side. Hence, reading $\ell = R/c$, $(\xi^2)\uparrow_c^{\mathrm{loc}}(K)$ holds with $K = c^2$, and **the form "$C_P^{\mathrm{loc}}(c) \le K(c)\ell^2$ for some $K(c)$" says nothing about the gap**. This is the negative control of this definition (the massless free field). In numbers, $\Gamma(R) := C_P^{\mathrm{loc},0}(R)/R^2$ is $0.0802,\ 0.0768,\ 0.0756,\ 0.0750,\ 0.0747,\ 0.0744$ at $R = 4, 6, 8, 10, 12, 16$; the correction is $1/R^2$ with no logarithmic correction, and $\Gamma_\infty = 0.0740$ Reading (floating point, numerical integration of the heat kernel on the infinite lattice, extrapolation from $R \le 16$; within relative $2\cdot 10^{-3}$ of an independent route via periodic lattices). The massless field itself satisfies $K(c) = 0.0740\,c^2$.

One line of contrast with lower dimensions. For massless fields in two spacetime dimensions the infrared diverges and $C_P^{\mathrm{loc}} = \infty$; localising only to a time window on a finite spatial lattice, the constant mode gives $C_P^{\mathrm{loc}} \approx T/(2m)$ $(mT \ll 1)$, which diverges as $m \to 0$. A massless field has a finite local constant in spacetime dimension three or more when localised in space too, and the four-dimensional setting of Part 24 is exactly that case Proved here .

Definition of the ratio form

Put the ratio of the local Poincaré constant of the target measure μ (the Wilson measure, or the path measure in continuous time) on the box $B_{c\ell}$ to the value of the massless reference with a Dirichlet form on the same lattice, the same box and the same graduation as

$$K_{\mathrm{rel}}(c) := \frac{C_P^{\mathrm{loc}}(B_{c\ell};\mu)}{C_P^{\mathrm{loc},0}(c\ell)}, \qquad (\xi^2)\uparrow_c^{\mathrm{rel}}(K) : \ K_{\mathrm{rel}}(c) \le K \quad (\beta \ge \beta_0 \text{ uniformly}, \ \ell = \xi_{\mathrm{RG}}$$

The local relaxation-time assumption is this sentence at **a single** c; it is not required uniformly in c.

It corresponds to the constant of the absolute form by $K(c) = K_{\mathrm{rel}}\,\Gamma\,c^2$ Proved here . In the ratio form the constant K becomes an absolute number independent of the box size, and "sufficiently smaller than 1" has meaning.

Why it is not required uniformly in c. For the free field of mass m the ratio is a function of mR alone, $r(mR)$, and is $0.932,\ 0.825,\ 0.623,\ 0.359,\ 0.0772$ at $mR = 0.5,\ 1,\ 2,\ 4,\ 12$ Reading (agreeing within 0.3% for boxes of side 4 to 12). When the box is smaller than the correlation length ($mR \to 0$) the ratio tends to 1. An asymptotically free theory is close to a free field at short distance, so a sentence requiring $K < 1$ uniformly down to $c \to 0$ is expected to be false Estimate . For a field whose action is a convex perturbation $\frac{1}{2}\phi(-\Delta)\phi + \sum U(\phi_x)$ (U convex), the Brascamp–Lieb inequality gives $K_{\mathrm{rel}} \le 1$ Assumption (the statement of the inequality in the original source has not been checked in this part). What the bridge needs is not that the ratio is below 1 but that it is below the threshold K_*, and the threshold moves with the choice of reference: 0.342κ (scalar), 0.502κ (gauge quotient, one-colour linearisation), $\approx 0.62\kappa$ (colour singlet of $SU(2)$, leading term). The threshold, and that the band $[K_*, 1)$ is undecided, are treated in 24-04.

The reference for gauge fields is taken on the gauge quotient. For four-dimensional gauge fields, the value of the reference changes with the test space in which it is measured. The target Wilson measure is gauge invariant, and the Poincaré constant of a non-gauge-invariant function is infinite along gauge orbits, so the numerator of the ratio is finite only on gauge-invariant functions. So the reference in the denominator is also measured on gauge-invariant functions of the same box.

$$V_F := \{\text{gradients of functions of the plaquette angles of the box}\} = d^*\big(\ell^2(P_R)\big), \qquad V_Q :=$$

If the box is contractible, $V_F = V_Q$ Proved here (the cubical complex is contractible with zero first homology, so cycles in the graph of the box are boundaries of 2-chains of plaquettes). In non-contractible regions (with holes), $V_F \subsetneq V_Q$. Gauge-fixed references (Feynman gauge and so on) depend on the fixing parameter α, with $\Gamma_Q \le \Gamma_{\text{Landau}} \le \Gamma_{\alpha=1}$, and moreover $\Gamma_\alpha \ge \alpha/(\lambda_D^{\mathrm{int}} R^2)$, so they become infinite as $\alpha \to \infty$ (removing the fixing) Proved here . The numbers are in Table 1.

Table 1 References for the four-dimensional box (one-colour Gaussian approximation, $\beta = 1$, canonical graduation, floating point, extrapolation from $R \le 16$; λ_W is the Dirichlet value of the box within the test

space times R^2)

Reference	Test space	Γ_∞	$\lambda_{W,\infty}$	As a reference
Scalar (one component)	All functions on the box	0.0740 Reading	$4\pi^2 = 39.5$	Not used for gauge fields
Feynman gauge ($\alpha = 1$)	All functions of the links of the box	0.0740 Reading	39.5	Depends on α; not intrinsic
Gauge quotient	$V_Q = V_F$ (functions of plaquette angles)	0.0277 Reading	72.0 Reading	Independent of α. This one is used
Variant with the boundary gauge frozen	Divided only by gauge transformations at inner sites	2.22 to 2.53 times the gauge quotient (side 4 to 12) Reading	—	Not gauge invariant (flux through the box enters)

The last row of Table 1 is (e) of Table 1 in 24-01. Gauge transformations at the boundary sites of the box also act on links inside the box, so gauge-invariant observables of the box (Wilson loops and so on) lie in the space divided at all sites. **"Dividing by gauge transformations at all sites of the box" is part of the definition**, and leaving it out moves the numbers by a factor of 2.2 to 2.5. Every reference is a number for a free field; this book has not measured a single ratio for the target Wilson measure.

Note on 0+1. In 0+1 dimensions there is no finite massless reference (for a free particle $C_P^{\mathrm{loc}} = \infty$). The reference always has a scale, and for the double well we take the harmonic oscillator with the curvature of the bottom (angular frequency ω_b). Its ratio for the shortest window (a single time) is **exactly** ω_b/m (when ψ_0 is the Schrödinger ground state) Proved here :

$$K_{\mathrm{rel}}(\text{single time}) = \frac{\varepsilon/(2m)}{\varepsilon/(2\omega_b)} = \frac{\omega_b}{m} \quad (7)$$

(ε is the time step. The numerator is the Poincaré constant of the marginal ψ_0^2, which moves to the gap of $(H - E_0)$ by the ground-state transformation. This identity is the same as the formula for the vacuum measure in 24-05.) Lean LatticeGauge.LocalHDoubleWell.one_slice_ratio (assumptions: $0 < \varepsilon, m, \omega$; only the algebra of the ratio). In the double well, tunnelling gives $m \ll \omega_b$, so the ratio does not become 1 even for short windows; on the lattice $\varepsilon = \frac{1}{2}$ it is 4.61 ($\hbar = 0.3$) to 638 ($\hbar = 0.08$) Reading . Hence "the ratio tends to 1 at short distance" is not a fact that follows from the ratio form but **an assumption depending on a property of the theory, asymptotic freedom (being close to a free field at short distance)** Assumption . The three regimes of the ratio as the window is lengthened are treated in 24-04.

04

The sector diffusive-relaxation-time assumption

Setting. Take the periodic box $\Lambda_L = (\mathbb{Z}/L)^4$, the configuration space $\mathcal{M} = G^{\text{links}}$ (a compact connected manifold with a bi-invariant metric), the Wilson measure μ (smooth positive density), and $\mathcal{E}(f) = \int |\nabla f|^2 d\mu$. For the topological charge we use the lattice charge Q_s smoothed by the Wilson flow (flow time s) or by finitely many smoothings. The smoothing map is smooth and the charge density is a polynomial in matrix elements, so $Q_s \in C^\infty(\mathcal{M})$.

Definition of sectors, and of the form reflecting at the walls

Take the cuts $\theta_n \in (n-1, n)$ at **regular values** of Q_s (by Sard's theorem almost all values are regular, so they can be taken arbitrarily close to $n - \frac{1}{2}$).

$$I_n := \{\theta_n \le Q_s < \theta_{n+1}\}, \quad \mu_n := \mu(\,\cdot\,|I_n), \quad \mathcal{E}_n(f) := \int_{I_n} |\nabla f|^2 d\mu_n \;\; (f \in H^1(I_n)),$$

(only for n with $\mu(I_n) > 0$). No boundary condition is imposed on $\mathcal{E}_n$. Its generator is Langevin reflecting at the walls (Neumann).

Because the cut is at regular values, the closure of a sector is a compact manifold with smooth boundary, and the walls are smooth hypersurfaces of codimension 1. Cutting by a geometrically defined integer-valued charge (piecewise constant and discontinuous), the form can be defined as H^1 on open sets, but the regularity of the walls is unknown and (i) below cannot be said. This is why this chapter uses a smoothed charge.

Sector Poincaré Constant Proposition (sector Poincaré constants and the decomposition of the variance)

(i) $C_P^{\text{sec}}(n) < \infty \iff I_n$ is connected.

(ii) With N the sector index, for smooth f,

$$\mathcal{E}(f) = \sum_n \mu(I_n)\, \mathcal{E}_n(f), \qquad \operatorname{Var} f = \sum_n \mu(I_n) \operatorname{Var}_{\mu_n} f + \operatorname{Var}\big(\mathbb{E}[f \mid N]\big) \quad (9)$$

(iii) For the quantity between sectors $C_{\text{trans}} := \sup_f \operatorname{Var}(\mathbb{E}[f|N])/\mathcal{E}(f)$,

$$C_{\text{trans}} \;\le\; C_P \;\le\; \sup_n C_P^{\text{sec}}(n) + C_{\text{trans}} \quad (10)$$

(iv) $C_P^{\text{sec}}(n) \le C_P$ does not hold in general.

Proved here Proof. (i) The closure of a sector is compact with smooth boundary and the density is positive and smooth, so the resolvent of the Neumann operator is compact (Rellich's theorem Assumption : the statement in the original source has not been checked in this part). The multiplicity of the zero eigenvalue equals the number of connected components, so a positive gap is the same as connectedness. (ii) The walls have measure 0, so the Dirichlet form splits into a sum over sectors, and the variance is the sum of the expectation of the conditional variance and the variance of the conditional expectation. (iii) The left is $\mathbf{Var}(\mathbb{E}[f|N]) \le \mathbf{Var}\, f$; the right uses the Poincaré inequality in each sector on the first term of (9) and closes with $\sum_n \mu(I_n)\mathcal{E}_n = \mathcal{E}$. (iv) Functions on sectors may jump at the walls (they are not in $H^1(\mathcal{M})$), so if conditioning creates a new bottleneck, $C_P^{\mathrm{sec}}(n) > C_P$ is possible. ∎ Lean LatticeGauge.LocalH.sector_split (assumptions: weights ≥ 0, the inequality in each sector, the two formulas of (9), $\mathbf{Var}(\mathbb{E}[f|N]) \le C_{\mathrm{trans}}\mathcal{E}$; conclusion: the right of (10)), trans_le_total (assumptions: weights and sector variances ≥ 0, (9); conclusion: the inequality for the numerator on the left of (10)). The identity (9) itself, Rellich, and the measure are outside Lean.

The sector relaxation-time assumption and its corollary. The sector relaxation-time assumption is the sentence that, in a box with fixed physical side, the Poincaré constant within a sector is bounded by the square of the correlation length.

$$(\xi^2)\uparrow^{\mathrm{sec}}: \quad L = \lambda\,\xi_{\mathrm{RG}} \text{ gives } \sup_n C_P^{\mathrm{sec}}(n) \le K(\lambda)\,\xi_{\mathrm{RG}}^2 \qquad \Longrightarrow \qquad \big(\,(\xi^2)\uparrow \iff C_{\mathrm{trans}} \lesssim$$

Proved here (from (10); $\lesssim$ is up to replacing constants). The sector relaxation-time assumption pushes the obstruction to the relaxation-time assumption **exactly** into the quantity between sectors C_{trans}. It does not remove the obstruction but only moves it into one quantity, the same form as the transfer type in 23-10. The physical reading of C_{trans} is the rate of dislocations, and statically $C_{\mathrm{trans}} \ge \mathbf{Var}(\mathbb{E}[Q_s|N])/\mathcal{E}(Q_s)$.

It does not connect to the bridge. What follows from (10) and the one-sided bridge ((17) of 23-01, with corrections for finite T in periodic time) goes only as far as $\kappa/m^2 \lesssim \sup_n C_P^{\mathrm{sec}}(n) + C_{\mathrm{trans}}$, and no gap comes out unless C_{trans} is bounded Proved here . The Langevin gap within a sector, $1/C_P^{\mathrm{sec}}(n)$, is a fifth quantity of time, and the conditioned measure μ_n has no transfer operator (the constraint on the total charge breaks the Markov property in time). A "physical gap within a sector" of the type of the one-sided bridge does not stand by definition; to set it up one would need a treatment of superpositions of θ vacua, which has not been formulated Estimate .

Three weaknesses. (a) *The walls of conditioning can create artificial bistability.* In the core on the box side of Part 23, two local minima appeared on the walls of conditioning the interval to "exactly this interval", giving rise to a bistability that was

not physical metastability (23-11 § 06). The walls of sectors lie on dislocation configurations of small measure, so we expect the harm to be small, but this has not been checked Estimate . That it is unknown whether sectors are connected in (i) of the Sector Poincaré Constant Proposition is the extreme form of this weakness. (b) *When the physical volume is made large, the obstruction remains even with the sector fixed.* With β fixed and $L \to \infty$, the charge of a half box can move even within a sector I_n. With the coefficients of (5) in 24-01, the conditional variance is of order $\chi_t V/4$ and the Dirichlet form of order $hV/2 + g\,|\mathrm{face}|$, and the ratio tends to $\chi_t/(2h)$ as $V \to \infty$, the same order as the overall ratio of the periodic box χ_t/h Assumption (on the definitions of h, g and the accounting for the conditional variance of a normal distribution with the sum of the two halves fixed). Fixing the sector stops only the one mode of the total charge; the modes of the charges of subregions remain. Hence the sector relaxation-time assumption is expected to have content different from the upper-bound assumption only when the box is smaller than the crossing length (subregions within a sector are in the transport regime), that is, **to have meaning only in the order in which the physical volume is fixed** Estimate . (c) *The path measure with $T = \infty$ has no sectors.* The four-dimensional charge is a quantity integrated over time, and for $T = \infty$ it is not in L^2.

Correspondence with the splitting of the first step. (9) is the same splitting as the splitting of the variance in the first step (local Poincaré within a phase, and transport between phases, 23-05 § 01), with phase ↔ sector and kink ↔ dislocation Estimate . It is one concrete destination of "the two-scale splitting is expected to lift" in 23-03 § 06. But in the first step, the time for transport between phases (diffusion of kinks) is read to be of order $\xi^2 S_0/\hbar$ ((14) of 23-04 Assumption), and fits into the form of the double-well relaxation-time power statement. The four-dimensional quantity between sectors C_{trans} is exactly a quantity of the pattern of 24-01, and there is no prospect yet that it fits into the same form.

05

Open boxes and closed boxes, two coefficients

Local asks about the transport coefficient; global asks about the coefficient of breaking of conservation. The charge Q_w in a smooth window of (7) in 24-01 belongs to the local family of a box of side $R = c\xi$. Putting (7) into the local relaxation-time assumption (absolute form), the necessary condition is $\chi_t c^2\xi^2/(hc^2\xi^2 + d\lambda_W) \le K\xi^2$, and in the regime where h is small (the crossing length R_* much longer than $c\xi$),

$$\frac{\chi_t (c\xi)^2}{d\,\lambda_W} \le K\xi^2 \iff \chi_t c^2 \le K\,d\,\lambda_W, \qquad \text{that is} \qquad D_{\mathrm{eff}} := \frac{d}{\chi_t} \ge \frac{c^2}{K\lambda_W} \quad (12)$$

Proved here (algebra) Lean LatticeGauge.LocalH.transport_requirement (assumptions: $0 < d$, $0 < \lambda_W$, $0 < \xi$). In the ratio form, K is read as $K_{\mathrm{rel}}\Gamma c^2$. On the other hand, the necessary condition for the global upper-bound assumption is (2)(6) of 24-01 with $R \to \infty$,

$$\frac{\chi t}{h} \lesssim \xi^2 \quad (13)$$

Assumption (on top of (5) of 24-01). (12) and (13) bear on different coefficients. **The local relaxation-time assumption asks about the transport coefficient of the charge d, and the global relaxation-time assumption about the coefficient of breaking of conservation of the charge h.** The freezing of the four-dimensional topological charge can be read as the appearance of h vanishing quickly in the continuum limit (dislocation configurations becoming rare), so what it affects is the side of (13). The prospect that the local relaxation-time assumption is unaffected by freezing comes from here Estimate . There are no four-dimensional lattice values for d and h.

Closed boxes and open boxes. The Box-Reduction Proposition of Part 23 (23-11 § 02) is a reduction bounding the global C_P by a box constant C_{box}, and C_{box} was the constant of a conditioned measure **with the boundary values fixed** (with sup over the boundary values). We call this a closed box. The box of the local relaxation-time assumption is a marginal box without fixing the boundary, and we call it an open box. In four dimensions, if the boundary links are fixed, the integer part of the topological charge inside the box is expected to change only through dislocations inside the box (in the continuum, the charge of the box is the sum of the Chern–Simons value on the boundary and a winding number) Estimate . Hence for closed boxes of size $\chi t (c\xi)^4 \gtrsim 1$, C_{box} is expected to inherit the time of the dislocation barrier Estimate . In open boxes the charge flows in and out through the boundary, and relaxation is of the transport type of (12) Assumption .

The difference between closed and open boxes has the same form as the difference between periodic and open boundaries. Open boundaries remove the topological obstruction only inside a finite box with fixed physical side (the autocorrelation time of Q^2 with open boundaries grows roughly in proportion to the length in the time direction, § 5.3 of Lüscher–Schaefer 2011 Reading). This is the transport type of (12) restated in the language of boxes. A reading of the consequence Estimate : if, under the reading that extends the conjecture (§ 06 (a) of 24-01), the upper-bound assumption reads as false in four dimensions, then even when the local relaxation-time assumption holds, the four-dimensional version of the Box-Reduction Proposition fails at the stage of closed boxes. The place where it breaks is not "relaxation inside the box" but "the passage between sectors inside a closed box".

Table 2 The order of volume and $a \to 0$, and the corrections expected to work

Order	Taken first	Corrections expected to work	Corrections expected not to work	Label
$a \to 0$ with the physical side fixed	Continuum limit of a finite box	Open boundaries, the sector relaxation-time assumption	—	Cited (original sources on open boundaries), Estimate
Volume to infinity first (the order of this book)	Infinite-volume lattice measure	The local relaxation-time assumption (open boxes)	Open boundaries, the sector relaxation-time assumption	Assumption (accounting for the charge of a subregion), Estimate

The original source writes that the scaling of the autocorrelation of algorithms implementing Langevin ($1/a^2$ in lattice units) "is expected to hold on infinite lattices and on finite lattices with open boundaries", and excludes transitions changing topology with periodic boundaries from the analysis as lattice artefacts (the footnote of Lüscher–Schaefer, Non-renormalizability of the HMC algorithm, 2011) Cited . The second row of Table 2 points the same way as this wording, but the object of the original source is the autocorrelation of local quantities, not the local relaxation-time assumption itself.

06

Table of the five grades

We put the rows of this chapter into one table in the format of the five grades, with Estimate added. The symbols of the rows are the same as the nodes of the dependency graph, and one row of 24-01 (the row of cluster decay) is carried over.

Table 3 Rows on the sector relaxation-time assumption and the local relaxation-time assumption ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	Existence and uniqueness of the infinite-volume Wilson measure	Assumption	The infinite-volume uniqueness statement of Part 23	$\beta \geq \beta_0$	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
2	Rellich's theorem (compactness of the Neumann resolvent)	Assumption	Sector Poincaré Constant Proposition (i) (the statement in the original source has not been checked)	Smooth boundary	—
3	Poincaré constant of a Gaussian measure = norm of the compressed covariance	Cited	(4), Hairer–Stuart–Voss–Wiberg 2005	Gaussian	—
4	Local Poincaré Constant Properties Proposition (i)–(iv)	Proved here	Proof in § 02	Continuous time, finite spatial lattice, $T = \infty$	local_le_global, local_approaches_global (assumptions: bounded above, non-empty, $S = \bigcup S_c$; only the supremum part)
5	That the proof of the Local Poincaré Constant Properties Proposition goes through in the same way for boxes of the four-dimensional Wilson measure	Assumption	End of § 02 (the treatment of domains is not written out)	Four dimensions, infinite volume	—
6	Properties of the four-dimensional local Poincaré constant	Proved here	On rows 1, 4, 5	Four dimensions	—
7	The absolute form holds with $K = c^2$ for the massless free field	Proved here	(4)	Four-dimensional spacetime, local in space too	—
8	$\Gamma_\infty = 0.0740$, $\Gamma_{Q,\infty} = 0.0277$, $\lambda_W^Q = 72.0$, 2.22 to 2.53 times with the boundary frozen	Reading	§ 03, Table 1	Free field, one-colour Gaussian, $\beta = 1$, $R \le 16$	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
9	$V_F = V_Q$ in contractible boxes; gauge-fixed references depend on α and diverge as $\alpha \to \infty$	Proved here	(6)	Contractible box	—
10	Ratio for the shortest window $= \omega_b/m$	Proved here	(7)	0+1, Schrödinger ψ_0	one_slice_ratio (assumptions: $0 < \varepsilon, m, \omega$)
11	The ratio tends to 1 at short distance	Assumption	The note on 0+1 in § 03 (depends on asymptotic freedom)	Four dimensions	—
12	Local relaxation-time assumption (ratio form): $K_{\mathrm{rel}}(c) \le K$ at a single c	Assumption	(5)	$\beta \ge \beta_0$	—
13	Sector Poincaré Constant Proposition (i): sector constant finite $\iff$ sector connected	Proved here	§ 04 (on top of row 2)	Periodic box, cuts at regular values	—
14	The sandwich (10)	Proved here	(9)(10)	Periodic box	sector_split, trans_le_total (assumptions: weights ≥ 0, the inequality in each sector, the two formulas of (9))
15	Corollary (11): under the sector relaxation-time assumption, the upper-bound assumption $\iff C_{\mathrm{trans}} \lesssim \xi^2$	Proved here	(11)	Box with fixed physical side	—
16	What comes out of sectors goes only as far as $\kappa/m^2 \lesssim \sup_n C^{\mathrm{sec}}_P + C_{\mathrm{trans}}$	Proved here	§ 04 (on top of the one-sided bridge)	Finite box	—
17	Cluster decay (row 1 of Table 5 in 24-01)	Assumption	(5) of 24-01	Infinite volume	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
18	(12): local asks d; (13): global asks h	Proved here	(12) (algebra), (13) on top of row 17	Four dimensions	transport_requirement (assumptions: $0 < d, \lambda_W, \xi$)
19	Ratio for half boxes within a sector $\to \chi t$ $/(2h)$	Assumption	Weakness (b) of § 04	$L \to \infty$ with β fixed	—
20	Alternating maximal-correlation assumption for four-dimensional boxes: maximal correlation < 1 between families of closed boxes, uniform in β	Assumption	Premise of the four-dimensional version of the Box-Reduction Proposition	Four dimensions, families of 2^4 colours	—
21	Gap assumption for closed four-dimensional boxes: $C_{\mathrm{box}}(c\xi_{\mathrm{RG}}) \le K' \xi_{\mathrm{RG}}^2$ for closed boxes	Assumption	§ 05 (the row where the topological barrier is expected to enter)	Four dimensions	—
22	Four-dimensional multi-family box reduction $C_P \le C(c)$ $C_{\mathrm{box}}/(1 - c_{\mathrm{alt}})$	Assumption	Four-dimensional version of the one-dimensional Box-Reduction Proposition (not written out)	Four dimensions	—
23	Relaxation-time upper-bound assumption	Proved here	Algebra on top of rows 20, 21, 22	Four dimensions	—

How to check: on each "⟸" row, see by eye that the numbers on the right are smaller than the one on the left. There are no circles. The leaves marked "Assumption" number ten (the existence of the infinite-volume measure, Rellich's theorem, the transcription to four dimensions of the proof of the properties of the local Poincaré constant, the reading of the ratio at short distance, the local relaxation-time assumption, cluster decay, the ratio of half boxes, the alternating maximal correlation of four-dimensional boxes, the gap of closed four-dimensional boxes, the four-dimensional multi-family

box reduction); the "Cited" leaf is the row of the Gaussian Poincaré constant, and the "Reading" leaf is the row of the reference numbers.

Two things are read from this graph. First, **the local relaxation-time assumption enters nowhere in the chain that builds the upper-bound assumption.** A reduction of the type of the Box-Reduction Proposition uses closed boxes (the gap assumption for closed four-dimensional boxes), whereas the boxes of the local relaxation-time assumption are open boxes. The local relaxation-time assumption is not a part of the upper-bound assumption but a separate sentence. Where the local relaxation-time assumption is used is in the graph of the bridge in 24-04. Second, the place where the upper-bound assumption is expected to break in four dimensions is concentrated in the single row of the gap assumption for closed four-dimensional boxes. The statement of this row contains only the constant of closed boxes C_{box} and not the global C_P, so it is not of the form that puts the conclusion among the premises.

07

What cannot be said

(a) The two relaxation-time assumptions are **candidate definitions; at no β is there an inequality shown for the target gauge theory**. What has been shown are properties of the definitions (the Local Poincaré Constant Properties Proposition and the Sector Poincaré Constant Proposition) and values of the free-field reference. Nor do we claim "the right way to correct" the relaxation-time assumption.

(b) The local relaxation-time assumption on the four-dimensional Wilson measure is a copy of the definition on the path measure in continuous time, and the existence of the infinite-volume measure and the treatment of domains (that the proof of the Local Poincaré Constant Properties Proposition goes through in the same way for four-dimensional boxes) are premise rows.

(c) The accounting for the charge of a subregion (transport in open boxes, barrier in closed boxes) is an estimate on top of cluster decay and the formal coefficients h, g, d, with no four-dimensional lattice values.

(d) The four-dimensional multi-family box reduction has not been written. The harm of sector walls, and how the sector relaxation-time assumption breaks when the physical volume is made large, are estimates.

(e) There is no evidence that the local relaxation-time assumption holds in four dimensions. There is only the accounting "freezing acts on the h side, and the local relaxation-time assumption asks about d".

(f) Every number in Table 1 is a number for the free field of the reference (one-colour Gaussian, $\beta = 1$, floating point, extrapolation); not a single ratio K_{rel} for the target

measure has been measured. The threshold depends on the reference and on the family of test observables, and the bridge says nothing about fields in the band $[K_*, 1)$ (24-04).

(g) "The ratio tends to 1 at short distance" is an assumption depending on asymptotic freedom; in the 0+1 double well this reading does not hold ((7)).

What this chapter can say

Said	Not said
Proved here The definition of the local Poincaré constant and the Local Poincaré Constant Properties Proposition (a quantity of the marginal on the window, not dense, monotone, returns unconditionally to C_P as $c \to \infty$; in continuous time, on a finite spatial lattice, $T = \infty$, under the assumptions of the one-sided bridge)	The treatment of domains on the four-dimensional Wilson measure (the copy). The question of the core (identification with the generator of the SPDE)
Proved here The local relaxation-time assumption in absolute form holds even for the massless free field on a box in four-dimensional spacetime, local in space too ($K = c^2$)	That the local relaxation-time assumption in ratio form holds for the target theory
Proved here That the family of plaquette functions and the gauge quotient coincide for contractible boxes; that gauge-fixed references depend on the parameter; the ratio for the shortest window ω_b/m	References for $SU(2)$ at finite β. Values for families of large four-dimensional loops
Reading Reference numbers $\Gamma_\infty = 0.0740$, $\Gamma_{Q,\infty} = 0.0277$, $\lambda_W^Q = 72.0$, 2.22 to 2.53 times with the boundary frozen	Not propositions of upper or lower bounds. Numbers for free fields, not for the target measure
Proved here The definition of sectors (cuts at regular values, the reflecting form), finite $\Longleftrightarrow$ connected (on top of Rellich), the sandwich (10), corollary (11), the bridge inequality from sectors	Whether sectors are connected. Estimates of C_{trans}. The treatment of θ vacua
Estimate That the local relaxation-time assumption is expected not to be affected by freezing; that closed boxes are expected to inherit the barrier; that the sector relaxation-time assumption is expected to have meaning only in the order with the physical volume fixed	None of them is a theorem

Terms used in this chapter — the algebra of time-averaged functionals $\mathcal{D}$, window, the local Poincaré constant $C_P^{\mathrm{loc}}(c)$, the ratio form K_{rel}, the massless reference and Γ, the gauge-quotient reference, sectors and the reflecting form, the quantity between sectors C_{trans}, open boxes and closed boxes, the transport coefficient d and the coefficient of breaking of conservation h. The notation is in 24-09.

Next chapter to read: 24-04 Which form of the relaxation-time assumption the one-sided bridge needs — the threshold K_* at which a lower bound on the gap comes out of the local relaxation-time assumption in ratio form, and the size of box at which the bridge sees the mass.

Which form of the relaxation-time assumption the one-sided bridge needs

This chapter is this book's own investigation. The established knowledge it builds on is in 5-09 and 2-10.

What this chapter shows — Which part of the diffusive-relaxation-time assumption the one-sided bridge of Part 23 uses, and nothing more. On the family of time-integrated single-time functions, the supremum of the Poincaré constant is fixed exactly by the gap, so what the bridge needs is only the part of the relaxation-time upper-bound assumption that is local in time. That a lower bound on the gap in finite spatial volume follows from the local relaxation-time assumption with a limited window; that in infinite volume the local relaxation-time assumption must be stated as a ratio to a massless reference; that its threshold changes with the choice of reference (scalar, gauge quotient, colour singlet of $SU(2)$); and that the bridge sees the mass only when the box is at least 4–5 times the correlation length. In the 0+1-dimensional double well, the ratio does not become 1 even for the shortest window.

Prerequisite chapters — 23-01 § 05 ((13) for the diffusive-relaxation-time assumption, (14)(15) for the upper-bound assumption), 23-01 § 06 ((17) of the one-sided bridge, the identity (18), the bridge (19), (20) of the time-step comparison assumption ((D) in the paper "one-sided bridge")), 23-01 § 06 (5) (the Free-Particle-on-a-Circle Counterexample), 24-03 (definitions of the local relaxation-time assumption and the ratio form). The notation is collected in 24-09.

Said first — The level is [Res]; only the summary in § 01 is [Y3]. This chapter does not show the mass gap. Neither the relaxation-time assumption, nor the upper-bound assumption, nor its local version has been shown at any β. What we show is the logical form of which part of which assumption the bridge uses, and values for free-field references. The window argument consists of sentences about the stationary path measure with $T = \infty$ on a lattice with continuous time and a finite spatial lattice; the infinite-volume version further rests on the local-excitation moment assumption and on the infinite-volume ground-state transformation identity. The values of the references are readings from floating-point computation and extrapolation.

The order of this chapter

1. Summary [Y3] — the bridge uses only the part of the upper-bound assumption local in time
2. The one-sided bridge and the family local in time — the supremum is exactly ξ^2; correspondence with the paper ((1)–(3))
3. Limiting the window — monotonicity of the window factor, the In-Window Supremum Proposition, the lower bound in finite volume ((4)–(10), Table 1)
4. "Some $K(c)$" is empty — the massless free field as a negative control, and the ratio form ((11)(12))
5. The bridge in infinite volume and the threshold — the local-excitation moment assumption, transfer to the ratio ((13)–(16))
6. Three references — scalar, gauge quotient, colour singlet (Table 2); the box at which the bridge sees the mass
7. Note on 0+1 dimensions — even for the shortest window the ratio is ω_b/m ((17), Table 3)
8. Which part of which assumption each conclusion needs — Table 4
9. What cannot be said
10. Table of the five grades and the dependency graph — Table 5

01

Summary [Y3] — the bridge uses only the part of the upper-bound assumption local in time

In 23-01 § 06 of Part 23, we showed the one-sided bridge $C_P \geq \kappa\hbar^2/\Delta^2$ for the path measure on a lattice with continuous time. The test function is the single one $f_T = \int_0^T F(q(\tau))\,d\tau$, the time integral of a function of the configuration at one time, $F = \psi_1/\psi_0$. Setting this one function beside $C_P \leq C\xi_{\mathrm{RG}}^2$ of the upper-bound assumption gives a lower bound on the gap of the lattice in physical units, $m_{\mathrm{phys}}^2 \geq \kappa/C$ ((19) of 23-01). The question of this chapter is which part of the upper-bound assumption is used there.

The answer comes in three stages.

First stage. On the family $\mathcal{F}_1$ of "functions of one time averaged with time weights", the supremum of $\mathrm{Var}\,/\mathcal{E}$ is exactly $\xi^2 = \hbar^2/\Delta^2$ in the canonical graduation Proved here . Hence the upper-bound assumption restricted to this family is the same as "the gap of the lattice in physical units is at least $C^{-1/2}$". The content of the upper-bound assumption beyond the gap lies only outside this family — in functions not local in time, such as winding numbers and the topological charge (the Free-Particle-on-a-Circle Counterexample of 23-01, the pattern of 24-01). The bridge uses only the part of the upper-bound assumption local in time.

Second stage. From the local relaxation-time assumption with the time window limited to length $c\ell$ (ℓ is a ruler given from outside, independently of the gap; in four dimensions it is the bookkeeping length ξ_{RG}), too, a lower bound on the gap in finite spatial volume follows, $m_{\mathrm{phys}} \geq \sqrt{1/c^2 + \kappa/K} - 1/c$ Proved here . As $c \to \infty$ it returns to the $\sqrt{\kappa/K}$ of Part 23.

Third stage. Going local in space too and on to infinite volume, a sentence of the form "the local Poincaré constant in the box is at most $K(c)\ell^2$" becomes empty, because the four-dimensional massless free field also satisfies it for some $K(c)$ Proved here . So we state it by the ratio K_{rel} to the value of the massless free field (the reference) on the same box with the same graduation. Under the local-excitation moment assumption, if the ratio is below the threshold $K_* = \kappa/(\lambda_W \Gamma)$, a lower bound on the gap follows Proved here (algebra on top of the assumption). The threshold changes with the choice of reference: 0.342κ for the scalar, 0.502κ for the gauge quotient (one-colour linearisation), and about 0.62κ for the colour singlet of $SU(2)$ (leading term, second chaos; a test value, so a lower value of the usable threshold) Reading . Examining free fields with mass, the bridge sees the mass only when the side of the box is at least about 4.2 times (scalar) to 5.2 times (gauge quotient) the correlation length Reading . For fields whose ratio lies in the band $[K_*, 1)$ between the threshold and 1, this bridge says nothing.

Finally we place a note on 0+1 dimensions. In the double well, even for the shortest window (a single time), the ratio is exactly ω_b/m and does not become 1 Proved here . "At short distance the ratio is close to 1" is not a fact that follows from the ratio form; in four dimensions it is an assumption depending on asymptotic freedom Assumption .

As a metaphor, the bridge looks only at "the time for the hand of the clock to go round once", not at the slowness of "the gear that counts how many times the hand has gone round". The upper-bound assumption is a sentence about the whole, gear included, and what the bridge needs is only the part about the hand.

02

The multidimensional one-sided bridge and the family local in time — the supremum is exactly ξ^2

The setting is the same as the one-sided bridge in 23-01 § 06. Space is a finite lattice, the configuration space at one time is Q, the Hamiltonian is $H = -\frac{\hbar^2}{2}\Delta_M + V$, with the ground-state assumption ((A1) in the paper; discrete spectrum, ground state $\psi_0 > 0$ non-degenerate and smooth, $\Delta = E_1 - E_0 > 0$), the stationary path-measure assumption ((A2) in the paper; the stationary path measure with $T = \infty$), and the metric comparison assumption ((A3) in the paper; comparison of the Langevin metric, $\kappa = 1/\lambda_G$). $m = \Delta/\hbar$, $\xi = 1/m$, $A = (H - E_0)/\hbar$.

We set the family local in time as follows.

$$\mathcal{F}_1 = \left\{ f_{h,G_1} = \int_{\mathbb{R}} h(\tau)\, G_1(q(\tau))\,d\tau \ :\ h \text{ bounded with bounded support},\ G_1 \text{ is a function on } Q \text{ that is smooth} \right\} \quad (1)$$

The f_T of the one-sided bridge is the case $h = \mathbf{1}_{[0,T]}$, $G_1 = \psi_1/\psi_0$.

The supremum of the one-sided bridge (best within the family local in time)

Under the assumptions of the one-sided bridge and the canonical choice $G = M^{-1}$ ($\kappa = 1$),

$$\sup_{f \in \mathcal{F}_1} \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} = \xi^2 = \frac{\hbar^2}{\Delta^2}, \quad (2)$$

and the supremum is not attained (for every $f \in \mathcal{F}_1$ the ratio is strictly smaller than ξ^2).

Proved here Proof. Let ν_φ be the spectral measure of A for $\varphi = (G1 - \langle G1 \rangle)\psi 0$; ν_φ lies on $[m, \infty)$. From the formula for correlations and Plancherel's theorem,

$$\mathrm{Var}(f) = \int d\nu_\varphi(a) \int_{\mathbb{R}} |\hat{h}(k)|^2 \frac{2a}{a^2 + k^2} \frac{dk}{2\pi}, \qquad \mathcal{E}(f) = \int d\nu_\varphi(a) \int_{\mathbb{R}} |\hat{h}(k)|^2 \, 2a \, \frac{dk}{2\pi} \quad (3)$$

(the right from the identity (18)). For $a \geq m$, $2a/(a^2 + k^2) \leq 2a/m^2$, with equality only at $k = 0$, so the ratio is smaller than ξ^2. That the supremum is ξ^2 is seen by taking $T \to \infty$ in the f_T of the one-sided bridge. ∎ For a general metric, the metric comparison assumption and the reverse comparison $G \geq \lambda'_G M^{-1}$ sandwich the supremum between $\kappa\xi^2$ and ξ^2/λ'_G. Lean `EuclideanPath.GapBridge.local_rayleigh_le` (assumptions: $0 < m$, $m \leq a_k$ for each k, $0 \leq c_k$; conclusion: $m^2 \sum_k c_k/a_k \leq \sum_k c_k a_k$) and `fourier_weight_le` (assumption: $0 < m \leq a$; conclusion: $2a/(a^2 + k^2) \leq 2a/m^2$) check only the finite sums and the pointwise inequality of this proof.

Consequence. The sentence of the upper-bound assumption restricted to $\mathcal{F}_1$, "for every $f \in \mathcal{F}_1$, $\mathrm{Var}(f) \leq C\xi_{\mathrm{RG}}^2 \, \mathcal{E}(f)$", is by (2) the same as $\xi^2 \leq C\xi_{\mathrm{RG}}^2$, that is,

$$\text{The upper-bound assumption on } \mathcal{F}_1 \iff m_{\mathrm{phys}} = m\,\xi_{\mathrm{RG}} \geq C^{-1/2} \text{ (canonical, each } \beta)$$

Proved here . Right to left also follows from (2). Everything by which the upper-bound assumption is stronger than the gap of the lattice in physical units (the conclusion of 23-01 § 06) lies outside $\mathcal{F}_1$. For a free particle on a circle (the Free-Particle-on-a-Circle Counterexample), the winding-number functional $\int w \, d\tilde{x}$ lies outside $\mathcal{F}_1$ and produces $C_P = \infty$, while the supremum over $\mathcal{F}_1$ remains ξ^2.

Correspondence with the paper. The one-sided bridge, (2) and the Free-Particle-on-a-Circle Counterexample are collected in the paper (list of papers, PDF) “The inverse squared spectral gap bounds the Langevin Poincaré constant of Euclidean path measures from below” (Kiichi, Shiori and Rin). The one sentence of its abstract is "for Euclidean path measures stationary over all time on a finite-dimensional configuration space, the Poincaré constant of the stochastic quantisation (Langevin) Dirichlet form on time-averaged smooth functionals satisfies $C_P \geq \kappa(\hbar/\Delta)^2$". The one-sided bridge corresponds to Theorem 3.1 of the paper, (2) to Proposition 4.1, and the Free-Particle-on-a-Circle Counterexample to Proposition 5.1 ($C_P = \infty$ even on the family of time-averaged smooth functionals $\mathcal{D}_0$). This book only cites the equation numbers, and leaves the proofs to 23-01 § 06 and the paper. The paper has not been checked by outside mathematicians.

03

Limiting the window — monotonicity of the window factor, the supremum within the window, the lower bound in finite volume

The definition of the local relaxation-time assumption is in (1)–(3) of 24-03 § 02. We copy only the form used here. The ruler $\ell > 0$ is a length given from outside, independently of the gap (in four dimensions, the bookkeeping length ξ_{RG}). Using the ξ fixed by the gap as the ruler would be circular when deriving a lower bound on the gap. For $c > 0$, write $\mathcal{D}_c$ for the family of time-averaged functionals whose weights are supported in a window of length $c\ell$, and put

$$C_P^{\mathrm{loc}}(c) = \sup_{f \in \mathcal{D}_c} \frac{\mathrm{Var}(f)}{\mathcal{E}(f)}, \qquad (\xi^2)\uparrow_c^{\mathrm{loc}}(K) : \;\; C_P^{\mathrm{loc}}(c) \leq K\ell^2 \quad (4)$$

$C_P^{\mathrm{loc}}(c)$ is fixed only by the marginal law of the path on the window, increases monotonically in c, and returns to the global C_P as $c \to \infty$ (24-03).

The window factor, and its monotonicity

Write $\varphi(x)$ for the bracket on the right of (17) of the one-sided bridge (the φ without argument is the vector of § 02, a different quantity; the notation follows 24-09).

$$\varphi(x) = 1 - \frac{1 - e^{-x}}{x}, \qquad g(x) = \frac{\varphi(x)}{x^2} = \frac{x - 1 + e^{-x}}{x^3} \qquad (x > 0) \ (5)$$

The ratio for a window T is $\kappa\xi^2\varphi(T/\xi) = \kappa T^2 g(mT)$. $\varphi(x) = x/2 + O(x^2)$, $\varphi(x) \to 1$ $(x \to \infty)$, and the values are $\varphi(1) = 0.368$, $\varphi(4) = 0.755$, $\varphi(10) = 0.900$ Proved here (values of the closed formula).

Window-Factor Monotonicity Proposition (the window factor decreases)

g is strictly decreasing on $(0, \infty)$.

Proved here Proof. Since $x - 1 + e^{-x} = \int_0^x \int_0^u e^{-v}\, dv\, du = x^2 \int_0^1 (1-t)e^{-xt}\, dt$, $g(x) = \frac{1}{x}\int_0^1 (1-t)e^{-xt}\, dt$. It is the product of the positive strictly decreasing function $1/x$ and the positive strictly decreasing function $\int_0^1 (1-t)e^{-xt} dt$, so it strictly decreases. ∎ Lean `LatticeGauge.LocalH.wr_strictAntiOn` (no assumptions; conclusion: g is strictly decreasing on $(0, \infty)$. In Lean it is closed via the sign of the derivative $g'(x) = h(x)/x^4$, $h(x) = 3 - 2x - (3+x)e^{-x} < 0$).

The Window-Factor Monotonicity Proposition has two uses. First, in the family where the weight is fixed to the indicator of the window $\mathbf{1}_{[0,T]}$ and only the single-time function varies, the supremum is attained exactly at the lowest excitation $a = m$ and equals $T^2 g(mT) = \xi^2 \varphi(T/\xi)$ Proved here (the ratio of weighted averages over the spectral measure does not exceed the maximum of the ratios per component; that the maximum is attained at $a = m$ is exactly the monotonicity of g). Second, it turns the window-limited upper-bound assumption $\kappa T^2 g(c\, m_{\mathrm{phys}}) \le K\ell^2$ $(T = c\ell)$ into an inequality on one number. g is a continuous strictly decreasing bijection from $(0, \infty)$ to $(0, \infty)$, so

$$\kappa\,(c\ell)^2\, g(c\, m_{\mathrm{phys}}) \le K\ell^2 \iff m_{\mathrm{phys}} \ge \frac{1}{c}\, g^{-1}\!\Big(\frac{K}{\kappa c^2}\Big) \ (6)$$

From $e^{-x} \ge 1 - x + x^2/2 - x^3/6$ $(x \ge 0)$ comes $g(x) \ge 1/(2x) - 1/6$, and the explicit form

$$m_{\mathrm{phys}} \ge \frac{3\kappa c}{6K + \kappa c^2} \ (7)$$

is obtained Proved here . Lean `LatticeGauge.LocalH.gap_lower_of_window` (assumptions: $0 < \kappa, c, K, \ell, m$, $\kappa(c\ell)^2 g(c\ell m) \le C_P$, $C_P \le K\ell^2$; conclusion: $3\kappa c/(6K + \kappa c^2) \le m\ell$). (7) is sharp for $c\, m_{\mathrm{phys}} \lesssim 1$, and for $c\, m_{\mathrm{phys}} \gtrsim 3$ the approximation on the right becomes weak, so for large c we use the next form.

Letting the weight inside the window vary too — the In-Window Supremum Proposition

In-Window Supremum Proposition (supremum of the family local in time within a window)

Under the assumptions of the one-sided bridge and the canonical choice, the supremum over elements of $\mathcal{F}_1$ whose weights are supported in $[0, T]$ is

$$\sup_{f \in \mathcal{F}_1,\ \operatorname{supp} h \subset [0,T]} \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} = \Psi_T(m) := \frac{1}{m^2 + \omega_0^2}, \qquad \omega_0 \tan\frac{\omega_0 T}{2} = m, \quad \omega_0 \in \Big(0, \frac{\pi}{T}\Big) \ (8)$$

For a general metric (the metric comparison assumption) the left-hand side is at least $\kappa\Psi_T(m)$.

Proved here Proof [Res]. Splitting φ into eigencomponents φ_k of A (eigenvalues a_k), $\mathrm{Var} = \sum_k \|\varphi_k\|^2 \langle h, e^{-a_k|s-t|} h\rangle$ and $\mathcal{E} = 2\|h\|^2 \sum_k a_k \|\varphi_k\|^2$ (the identity (18)). The ratio of weighted averages does not exceed the maximum of the ratios per component, so $\mathrm{Var}/\mathcal{E} \le \max_k \langle h, K_{a_k} h\rangle / \|h\|^2$, where K_a is the integral operator with kernel $e^{-a|s-t|}/(2a)$ restricted to $[0, T]$, the compression of $(a^2 - \partial^2)^{-1}$ on the real line. $a \mapsto (a^2 - \partial^2)^{-1}$ is decreasing as an operator, so the maximum is at $a = m$. The largest eigenvalue of K_m is fixed, since the eigenfunction satisfies $u'' = -\omega^2 u$ with the

boundary conditions $u'(0) = m\,u(0)$ and $u'(T) = -m\,u(T)$, by $\omega\tan(\omega T/2) = m$ for the first symmetric solution $u = \cos(\omega(t - T/2))$, and its value is $1/(m^2 + \omega^2)$. Equality is attained at $G_1 = \psi_1/\psi_0$, $h = \cos(\omega_0(t - T/2))$. ∎

The root ω_0 satisfies $\omega_0^2 \le 2m/T$ by $\tan z \ge z$, and also $\omega_0 < \pi/T$, so

$$\max\Big(\frac{1}{m^2 + \pi^2/T^2},\ \frac{1}{m^2 + 2m/T}\Big) \ \le\ \Psi_T(m) \ <\ \frac{1}{m^2} \quad (9)$$

Proved here . The value for the indicator weight, $T^2 g(mT)$, is strictly smaller than $\Psi_T(m)$ (cos is not constant); as $T \to 0$ both are $\approx T/(2m)$, and as $T \to \infty$, $\Psi_T = 1/m^2 - O(T^{-2})$ and $T^2 g = 1/m^2 - O(T^{-1})$.

Table 1 Two values of the window supremum ($m = 1$)

T	Indicator weight $T^2 g(T) = \varphi(T)$	Weight also varied $\Psi_T(1)$	Grade
1	0.368	0.369	The left column is Proved here (closed formula); the right column is Reading (numerical values of the root formula, agreeing within relative 2.5×10^{-5} with the largest eigenvalue of the kernel by the midpoint rule)
4	0.755	0.775	
10	0.900	0.935	

Lower bound in finite spatial volume

Combine the local relaxation-time assumption (4) with the In-Window Supremum Proposition. From $\kappa\Psi_{c\ell}(m) \le C_P^{\mathrm{loc}}(c) \le K\ell^2$ and $\Psi_{c\ell}(m) \ge 1/(m^2 + 2m/(c\ell))$ of (9), $\mu = m\ell = m_{\mathrm{phys}}$ satisfies $\mu^2 + 2\mu/c \ge \kappa/K$, and

$$m_{\mathrm{phys}} \ \ge\ \sqrt{\frac{1}{c^2} + \frac{\kappa}{K}} - \frac{1}{c} \qquad (c > 0) \quad (10)$$

Proved here (under the assumptions of the one-sided bridge). Lean `LatticeGauge.LocalH.gap_lower_of_local_window` (assumptions: $0 < \kappa, c, K, \ell, m$, $\kappa/(m^2 + w^2) \le CP$, $w^2 \le 2m/(c\ell)$, $CP \le K\ell^2$; conclusion: (10)), `local_bound_tendsto` (no assumptions; conclusion: the right-hand side of (10) tends to $\sqrt{\kappa/K}$ as $c \to \infty$). As $c \to \infty$ it returns to (19) of 23-01, and as $c \to 0$ it is $\approx c\kappa/(2K)$. (10) is stronger than (7) for every c.

For the free field, both directions. For a Gaussian path measure the Poincaré constant equals the norm of the covariance operator Cited (Hairer–Stuart–Voss–Wiberg 2005, Lemma 2.2), and $C_P^{\mathrm{loc}}(c) = \Psi_{c\ell}(m)$ holds exactly even over the whole window family $\mathcal{D}_c$ Proved here (the largest eigenvalue of the covariance compressed to the window is the value of the In-Window Supremum Proposition). Hence for the free field, besides "$(\xi^2)\uparrow_c^{\mathrm{loc}}(K) \Rightarrow$ (10)", also "$m_{\mathrm{phys}} \ge K^{-1/2} \Rightarrow (\xi^2)\uparrow_c^{\mathrm{loc}}(K)$ for every c" holds ($\Psi < 1/m^2$). One also sees that localisation is not trivial: $C_P^{\mathrm{loc}}(c) < CP$ holds strictly for every finite c, and as $c \to 0$ it is $\approx c\ell/(2m) \to 0$.

Conditions of this section. (4)–(10) are sentences on a lattice with continuous time, a finite spatial lattice, $T = \infty$, and the three assumptions of the one-sided bridge (ground state, stationary path measure, metric comparison). On Wilson's lattice, which also discretises time, the time-step comparison assumption ((20) of 23-01) remains, and the window version has not yet been written on top of it.

04

"Some $K(c)$" is empty — the massless free field as a negative control, and the ratio form

Now go local in space too. On an infinite spatial lattice, write $C_P^{\mathrm{loc}}(B_R)$ for the local Poincaré constant with only functionals supported in a spacetime box B_R of side $R = c\ell$ allowed to vary (the version of 24-03 § 03 that is local in space too; (11) below is the same inequality as (4) of 24-03). The plain local relaxation-time assumption is "$C_P^{\mathrm{loc}}(B_{c\ell}) \le K(c)\,\ell^2$". But in four dimensions this form says nothing about the gap.

Negative control (the massless free field)

For the massless free scalar field in four-dimensional spacetime and infinite volume (canonical graduation, $\hbar = 1$),

$$\frac{R^2}{4\pi^2} \ \le\ C_P^{\mathrm{loc}}(B_R) \ \le\ R^2. \quad (11)$$

Hence "$C_P^{\mathrm{loc}}(B_{c\ell}) \le K(c)\ell^2$" holds with $K(c) = c^2$, and the gap is 0.

Proved here Proof. The Gaussian Poincaré constant is the norm of the covariance compressed to the box Cited (previous section). The covariance $(-\Delta)^{-1}$ is transient in four dimensions and hence finite, with continuum kernel $1/(4\pi^2|z|^2)$. Above, by the Schur estimate, the norm is at most $\sup_x \sum_{y\in B_R} G(x-y) \le \int_{|z|<2R} \frac{d^4z}{4\pi^2|z|^2} = R^2$ (the asymptotics of the lattice kernel replaced by the continuum kernel; this step is Assumption). Below, take the Dirichlet ground state w of the box as test direction; from $\langle w, Gw\rangle\langle w, -\Delta w\rangle \ge \|w\|^4$ (Cauchy–Schwarz), $C_P^{\mathrm{loc}} \ge 1/\lambda_D(B_R) \approx R^2/(4\pi^2)$ (π^2/R^2 for each of the four directions of the spacetime box). ∎

In numbers, the ratio $\Gamma(R) := C_P^{\mathrm{loc},0}(B_R)/R^2$ decreases as $0.0802,\ 0.0768,\ 0.0756,\ 0.0750,\ 0.0747,\ 0.0744$ at $R = 4, 6, 8, 10, 12, 16$; the correction is $1/R^2$ with no logarithmic correction, and by extrapolation $\Gamma_\infty = 0.0740$ Reading (floating point; numerical integration of the lattice heat kernel agreeing with an independent route via periodic lattices within relative 2×10^{-3}; extrapolation from $R \le 16$; one component). This is inside the paper sandwich $[1/(4\pi^2),\ 0.1125]$, 2.92 times the Dirichlet value $1/(4\pi^2) = 0.0253$. Since the continuum kernel is homogeneous of degree -2, the compression being exactly proportional to R^2 is as expected.

One line of contrast with lower dimensions as well. For a massless field in two spacetime dimensions the infrared diverges and $C_P^{\mathrm{loc}} = \infty$, and even in finite spatial volume with only the time window localised, the constant mode grows as $\approx T/(2m)$. A massless field has a finite local constant only in spacetime dimension three or more when localised in space too, and the four-dimensional setting of Part 24 is exactly that case Proved here .

The ratio form

So we state the local relaxation-time assumption as a ratio to the massless free field (the reference) on the same lattice, the same box and the same graduation.

$$K_{\mathrm{rel}}(c) = \frac{C_P^{\mathrm{loc}}(B_{c\ell};\mu)}{C_P^{\mathrm{loc},0}(c\ell)}, \qquad C_P^{\mathrm{loc},0}(R) = \Gamma(R)\,R^2, \qquad (\xi^2)^{\mathrm{rel}}_{\uparrow c}(K):\ \ K_{\mathrm{rel}}(c) \le K \quad (12)$$

(uniformly in $\beta \ge \beta_0$, $\ell = \xi_{\mathrm{RG}}(\beta)$). The constant K becomes an absolute number. We set it as **a sentence at a single** c, and do not require it uniformly in c. The ratio $r(mR)$ for the free field of mass m tends to 1 as $mR \to 0$, so a sentence requiring $K < 1$ uniformly down to short distances becomes false for theories close to free fields Estimate . Requiring a K uniform in c returns to the global upper-bound assumption as $c \to \infty$ (24-03).

For a field with a convex interaction added (action $\frac12\langle\Phi, -\Delta\Phi\rangle + \sum_x U(\Phi_x)$, U convex), the Hessian is at least $-\Delta$, so the Brascamp–Lieb inequality gives $K_{\mathrm{rel}} \le 1$ Assumption (the bibliographic data of the inequality have not been checked). Convex fields lie in the band $[0, 1]$. What the bridge needs, as the next section shows, is the part of it below the threshold.

05

The bridge in infinite volume and the threshold — the local-excitation moment assumption and transfer to the ratio

In infinite volume, the single-time function $F = \psi 1/\psi 0$ is neither local nor explicit. Instead we assume that local observables in a box produce low-energy excitations.

Local-excitation moment assumption

There is a local observable O supported in a spatial box of side $c\ell$ such that the spectral measure ν_φ, with respect to the generator of the transfer A, of $\varphi = (O - \langle O\rangle)\Omega$ (Ω is the vacuum) satisfies

$$\frac{M_3}{M_1} := \frac{\int a^3\, d\nu_\varphi(a)}{\int a\, d\nu_\varphi(a)} \ \le\ m_\infty^2 + \frac{\gamma}{(c\ell)^2} \quad (13)$$

m_∞ is the infinite-volume gap in lattice units, and γ a constant independent of β.

Assumption It has not been shown for any interacting model. Assumption (13) contains the quantity of the conclusion m_∞, but it appears only in a comparison from above and does not imply $m_\infty > 0$. It is a sentence that has meaning even for $m_\infty = 0$ (a property of approximation, that low-energy excitations can be approached by local observables), and the massless free field satisfies it with $\gamma = d\pi^2$.

Proved here It holds for the free field. On one-particle states $\nu_\varphi = \sum_p |\hat{w}_p|^2/(2\omega_p)\,\delta_{\omega_p}$, $M_3/M_1 = m_0^2 + \langle w, -\Delta w\rangle/\|w\|^2 \le m_0^2 + d\pi^2/(c\ell)^2$ (w is the Dirichlet ground state of the spatial box, d the spatial dimension).

By Jensen's inequality, the ratio for a window T is bounded as $\ge \kappa/(M_3/M_1 + \pi^2/T^2)$. Treating the spacetime box isotropically and putting $\lambda_W := \gamma + \pi^2$,

$$C_P^{\mathrm{loc}}(B_R) \;\ge\; \frac{\kappa}{m_\infty^2 + \lambda_W/R^2} \quad (14)$$

and from this and the local relaxation-time assumption $C_P^{\mathrm{loc}} \le K\ell^2$, $m_{\mathrm{phys}}^2 \ge \kappa/K - \lambda_W/c^2$ Proved here (on top of (13) and the infinite-volume ground-state transformation identity). Lean `LatticeGauge.LocalH.gap_lower_dirichlet` (assumptions: $0 < \kappa, c, K, \ell$, $0 < m^2 + \lambda$, $\kappa/(m^2+\lambda) \le C_P$, $\lambda \le \gamma/(c\ell)^2$, $C_P \le K\ell^2$; conclusion: $\kappa/K - \gamma/c^2 \le (m\ell)^2$).

Transferring to the ratio form (12), from $C_P^{\mathrm{loc}} \le K_{\mathrm{rel}}\Gamma R^2$ and (14),

$$(m_\infty R)^2 \;\ge\; \lambda_W\Big(\frac{K_*}{K_{\mathrm{rel}}} - 1\Big), \qquad K_* := \frac{\kappa}{\lambda_W\,\Gamma} \quad (15)$$

Proved here (algebra on top of (13) and the infinite-volume identity). Lean `LatticeGauge.LocalHReference.ratio_bridge` (assumptions: $0 < \lambda_W, \Gamma, R, K_{\mathrm{rel}}$, $\kappa/(m^2 + \lambda_W/R^2) \le C$, $C \le K_{\mathrm{rel}}\Gamma R^2$; conclusion: (15)), `kstar_correspondence` (assumptions: $0 < \lambda_W, \Gamma, c$; conclusion: when $K(c) = K_{\mathrm{rel}}\Gamma c^2$, $K(c) < \kappa c^2/\lambda_W \iff K_{\mathrm{rel}} < K_*$), `ratio_bridge_vacuous_of_ge` (assumption: $K_* \le K_{\mathrm{rel}}$; conclusion: the right-hand side of (15) ≤ 0).

How to read it. If $K_{\mathrm{rel}} < K_*$, the right-hand side is positive, and the lower bound on the mass

$$m_\infty\,\ell \;\ge\; \frac{\sqrt{\lambda_W}}{c}\sqrt{\frac{K_*}{K_{\mathrm{rel}}} - 1} \quad (16)$$

follows. If $K_{\mathrm{rel}} \ge K_*$, (15) is empty. A reference satisfies its own Dirichlet lower bound ($\Gamma \ge 1/\lambda_W$, the same Cauchy–Schwarz as on the left of (11)), so for every reference $K_* \le \kappa$ Proved here . Lean `LatticeGauge.LocalHReference.kstar_le_kappa` (assumptions: $0 \le \kappa$, $0 < \lambda_W, \Gamma$, $1 \le \lambda_W\Gamma$; conclusion: $K_* \le \kappa$). For a field with ratio 1 ($K_{\mathrm{rel}} = 1$) the bridge does not stand (`rel_one_no_bridge`, negative control).

The λ_W in (15) needs care. λ_W is "the value of M_3/M_1 attainable within the allowed family of local observables", a number fixed once the family of test observables is chosen. The reference Γ in the denominator and the λ_W of the lower bound in the numerator must be taken over the same family. In the next section, this point moves the threshold.

06

Three references — scalar, gauge quotient, colour singlet

Table 2 sets out the values for each choice of reference. Every row is a number for a free-field reference; not a single ratio K_{rel} for the target Wilson measure has been measured.

Table 2 Three references and thresholds (four dimensions, canonical graduation; numbers are readings from floating-point computation and extrapolation)

Reference	Family of test observables	Γ_∞	λ_W (times R^2)	$\lambda_W\Gamma$	Threshold K_*/κ	Box at which the bridge sees the mass	Conditions

Reference	Family of test observables	Γ_∞	λ_W (times R^2)	$\lambda_W\Gamma$	Threshold K_*/κ	Box at which the bridge sees the mass	Conditions
Scalar	All functions of the field in the box (best is linear)	0.0740	$4\pi^2 \approx 39.5$	2.92	0.342	$mR \approx 4.2$	One component, extrapolation from $R \le 16$ Reading
Gauge quotient	Quotient by gauge transformations at **all** sites of the box = functions of the plaquette angles of the box	0.0277	72.0	1.99	0.502	$mR \approx 5.2$ (transverse Proca waves)	Gaussian for one colour component, $\beta = 1$, extrapolation from $R \le 16$ ($R \le 14$ for λ_W) Reading
Colour singlet of $SU(2)$	Colour singlets (leading term is the second chaos), a family including loops the size of the span of the box	$\Gamma_Q/2 \approx 0.0138$	115–117 (test value)	About 1.6	About 0.62 (lower value)	—	Leading term ($\beta \to \infty$), independent Gaussians for three colours, first-order test, extrapolation from $R \le 10$ Reading

Lean `LatticeGauge.LocalHReference.kstar_measured` (assumption: measured $\Gamma \in [0.0739, 0.0741]$; conclusion: $0.34 < K_* < 0.344$), `LatticeGauge.GaugeReference.kstar_gauge_measured` (assumptions: measured $\Gamma_Q \in [0.02762, 0.02772]$, $\lambda_W^Q \in [71.8, 72.1]$; conclusion: $0.5 < K_*^Q < 0.505$), `LatticeGauge.WilsonLoopReference.kstar2_measured` (assumptions: measured $\lambda^{(2)} \in [115, 118]$, $\Gamma_Q \in [0.02762, 0.02772]$; conclusion: $0.61 < K_*^{(2)} < 0.63$). All three are arithmetic with measured numbers as assumptions; the numbers themselves are outside Lean.

Why the threshold changes with the reference

Gauge-fixed values are not references. The value for the gauge-fixed free gauge field (Feynman gauge) is $\Gamma = 0.0740$, the same as the scalar, but it changes when the gauge-fixing parameter α is changed, and when the fixing is removed ($\alpha \to \infty$) it becomes infinite in the directions of gauge transformations within the box Proved here (with test functions in the directions of the image of the gauge, $\Gamma_a(\alpha) \ge \alpha/(\lambda_D^{\mathrm{int}} R^2)$). The target Wilson measure is not gauge-fixed, so the numerator of the ratio is finite only on gauge-invariant functions. The denominator is measured on the same space. Lean `LatticeGauge.GaugeReference.gauge_param_unbounded` (assumptions: $0 < \lambda_D, R$, $\alpha/(\lambda_D R^2) \le \Gamma_a(\alpha)$; conclusion: Γ_a is unbounded in α).

Gauge-invariant observables can only have high momentum. The test space of the gauge quotient is the divergence-free fields (transverse waves) on the graph of the box. If the box is contractible, this coincides exactly with the space of functions of the plaquette angles of the box Proved here (the first homology of the cubical complex is 0, so closed paths are boundaries of sums of plaquettes). Under the divergence-free constraint one cannot build a positive field pointing the same way over the whole box (the optimal test direction for the scalar). The optimal direction becomes a transverse wave of large momentum: $\lambda_W^Q = 72.0$ is 1.82 times the scalar $4\pi^2$, and Γ_Q is 0.374 times the scalar Reading. The threshold of the ratio relaxes, $0.342 \to 0.502$, but this is because Γ shrinks by more than λ_W grows ($0.502/0.342 = 1/(0.374 \times 1.82)$); the condition rewritten for the local Poincaré constant itself, $C_P^{\mathrm{loc}} < \kappa R^2/\lambda_W$, tightens from $0.0253\kappa R^2$ to $0.0139\kappa R^2$ Reading.

Divide by the gauge transformations at the boundary of the box too. If one divides only by gauge transformations at inner sites of the box and freezes the gauge at the boundary sites, flux passing uniformly through the box enters the test space, and the value returns roughly to the gauge-fixed value, 2.2–2.5 times Γ_Q Reading. Gauge-invariant observables of the box (Wilson loops) are invariant under transformations at all sites, so "dividing by gauge transformations at all sites" is part of the definition of the reference (the row "flux through a box" in 24-01).

What the one-colour approximation tacitly assumed. Linearising to one colour component, linear combinations of plaquette angles inside the box alone span the whole transverse test space, and neither large loops nor plaquettes reaching outside the box are needed Proved here (the angle of a rectangular loop is the sum of the angles of the

plaquettes inside). But the gauge invariants of $SU(2)$ (colour singlets) have no linear term in the expansion around the identity Proved here . A linear term $\sum c_\ell^a A_\ell^a$ must also be invariant under constant gauge transformations (global colour rotations $SO(3)$), and $SO(3)$ has no fixed vector in $\mathbb{R}^3$, so $c = 0$. The trace of a loop $\frac{1}{2}\operatorname{tr} U_C = \cos(|\theta_C|/2) = 1 - |\theta_C|^2/8 + \cdots$ starts at second order in the angles. Lean `LatticeGauge.WilsonLoopReference.no_linear_singlet` (assumption: a linear form invariant under the two rotations $\operatorname{diag}(-1,-1,1)$, $\operatorname{diag}(1,-1,-1)$; conclusion: the coefficients are 0).

The reference is exactly half. In the leading term ($\beta \to \infty$, independent Gaussians for three colours), functions that are colour singlets lie in the second chaos and above. The eigenvalues of the Ornstein–Uhlenbeck generator of a Gaussian measure are sums of one-particle eigenvalues in the eigencoordinates of the covariance, so the minimum on the second chaos is twice the one-particle minimum, and the Poincaré constant is $\Gamma_Q/2$ Proved here (equality at $f_w = \sum_a (\langle w, A^a\rangle^2 - \mathbb{E})$, with w the optimal transverse direction). The value of the first-order test is $\lambda_W(f_w) = \lambda(w) + 1/C(w)$, and by Cauchy–Schwarz $\lambda(w) < \lambda_W(f_w) \le 2\lambda(w)$ Proved here . In the four-dimensional box $\lambda^{(2)}R^2 \to 115$ to 117 (about 1.6 times λ_W^Q), and the threshold is $K_*^{(2)} = 2/(\lambda^{(2)}\Gamma_Q) \approx 0.62\kappa$ Reading . $\lambda^{(2)}$ is a test value (a value from above), so the threshold obtained is a lower value of the usable threshold. Lean `chaos2_gamma`, `chaos2_lambda` (assumptions: $0 < n, g$ and the Wick moments as formulas; conclusion: algebra of the ratio), `chaos2_bracket` (assumptions: $0 < C$, $1 \le \lambda C$; conclusion: $\lambda < \lambda + 1/C \le 2\lambda$).

Large loops are needed. To get this value, loops the size of the span of the box are needed. With the family of plaquettes only, $\{\operatorname{tr} U_p\}$, the reference in the leading term vanishes as $1/R^2$ (in two dimensions, from 0.29 times to 0.035 times $\Gamma_Q/2$ for $R = 4 \to 12$), and even adding loops up to 2×2 it is 0.12 times ($R = 12$), so the bridge speaks only of the lattice scale Reading . Including all rectangles spanning the box, it agrees with $\Gamma_Q/2$ to all digits in two dimensions, while flat rectangles alone give 0.73 times in three dimensions Reading . There are no values for large loops in four dimensions (including non-flat ones and products of lassos).

Box at which the bridge sees the mass

The ratio for the free field of mass m, $r(mR) = C_P^{\mathrm{loc}}(R;m)/C_P^{\mathrm{loc}}(R;0)$, collapses within 0.3% for $R = 4$ to 12 onto a function of mR alone Reading . For the scalar $r = 0.932,\ 0.825,\ 0.623,\ 0.359,\ 0.0772$ ($mR = 0.5, 1, 2, 4, 12$); for the transverse waves of the gauge quotient (Proca) $r_Q = 0.950,\ 0.842,\ 0.721,\ 0.610,\ 0.514,\ 0.434$ ($mR = 1, \ldots, 6$). The ratio falls to the threshold at $mR \approx 4.2$ for the scalar and $mR \approx 5.2$ for transverse waves (both by linear interpolation) Reading . **The bridge sees the mass only when the side of the box is at least 4–5 times the correlation length.** Transverse waves have large momentum, so they notice the mass later.

Put the other way, for fields whose ratio lies in the band $[K_*, 1)$, this bridge says nothing. Free fields of mass $mR < 4.2$ (with the scalar reference) also fall in this band, so the bridge misses fields that do have mass. Whether there is another argument (outside Jensen's inequality and Dirichlet test functions) that sees the mass for fields in the band is not settled.

07

Note on 0+1 dimensions — even for the shortest window the ratio is ω_b/m

We try the ratio form on the 0+1-dimensional double well $V(x) = (x^2-1)^2/8$ ($V''(\pm 1) = 1 = \omega_b^2$, $S_0 = 2/3$). In 0+1 dimensions there is no finite massless reference (a free particle has no stationary measure and $C_P^{\mathrm{loc}} = \infty$). There is no choice but to take as reference the harmonic oscillator ω_b with the curvature of the bottom, and the ratio sentence becomes "if $K_{\mathrm{rel}}(T) < \kappa$ then $m > \omega_b$" Proved here (from the lower bound of the In-Window Supremum Proposition and the decrease of Ψ_T in m. The threshold is κ, and its difference from the four-dimensional 0.342κ is exactly the Dirichlet loss of the spatial box). Lean `LatticeGauge.LocalHReference.gap_gt_ref_of_ratio` (assumptions: Ψ is monotone non-increasing, $0 < \kappa$, $0 < \Psi(\omega_b)$, $\kappa\Psi(m) \le C \le K\Psi(\omega_b)$, $K < \kappa$; conclusion: $\omega_b < m$).

The window of a single time can be computed in closed form. On a lattice with time step ε, the Langevin generator for the single-time marginal ψ_0^2 and $\mathcal{E}_1(f) = (\hbar/\varepsilon)\int \psi_0^2 |f'|^2$ is, by the ground-state transformation,

$$L = -\frac{2}{\varepsilon\hbar}\,\psi_0^{-1}(H - E_0)\,\psi_0, \qquad C_P^{\mathrm{loc}}(1) = \frac{\varepsilon}{2m}, \qquad K_{\mathrm{rel}}(1) = \frac{\omega_b}{m} \quad (17)$$

Proved here (when ψ_0 is the Schrödinger ground state; the reference is $\varepsilon/(2\omega_b)$). This is exactly the identity of 24-05. Lean `LatticeGauge.LocalHDoubleWell.one_slice_ratio` (assumptions: $0<\varepsilon, m, \omega$; conclusion: $(\varepsilon/(2m))/(\varepsilon/(2\omega)) = \omega/m$).

The behaviour as the window is lengthened divides, on top of the In-Window Supremum Proposition, into three regimes Proved here .

Table 3 The ratio $K_{\mathrm{rel}}(T)$ for the 0+1-dimensional double well (three regimes of the value $\Psi_T(m)/\Psi_T(\omega_b)$ of the $\mathcal{F}_1$ part)

Window	Ratio	Order for $m \propto e^{-S_0/\hbar}$
$T \to 0$ (a single time)	ω_b/m	$e^{S_0/\hbar}$
$1/\omega_b \ll T \ll \xi$	$\omega_b^2 T/(2m)$	$T\, e^{S_0/\hbar}$
$T \gg \xi$	$(\omega_b/m)^2$	$e^{2S_0/\hbar}$

The crossover is the window at which $\Psi_T(m)$ becomes half of $1/m^2$: $\omega_0 = m$, that is $\tan(mT/2) = 1$, $T_\times = \pi/(2m)$ Proved here . Lean `LatticeGauge.LocalHDoubleWell.crossover_root`, `crossover_half` (assumption: $0<m$; conclusion: at $T = \pi/(2m)$, $m\tan(mT/2) = m$ and the value is half. Uniqueness of the root is outside Lean).

The lattice values (time step $\varepsilon = \frac{1}{2}$, transfer kernel as Trotter's symmetric product, $\hbar = 0.3,\ 0.15,\ 0.08$) are $K_{\mathrm{rel}}(1) = 4.61,\ 21.6,\ 638$ and $K_{\mathrm{rel}}(1)\cdot m = 1.04,\ 1.04,\ 1.05$ for the window of a single time Reading (the deviation from (17) comes from ψ_0 of the time-discretised transfer and the discretisation of the reference). The crossover on the lattice is $k_\times m\varepsilon = 1.571$ to 1.574 ($\pi/2 = 1.5708$) Reading . Extending the functionals in the window from sums of one-point functions to multi-point functions raises the ratio further: the direct value for a window of two times is 1.02, 1.09, 1.34 times the $\mathcal{F}_1$ value, and the lower bound for a window of eight times with a family up to three-point products is at least 1.07, 1.27, 2.12 times Reading (lower bounds; the smaller $\hbar$, the more they rise with each widening of the family, and they have not saturated).

The ratio sentence "if $K_{\mathrm{rel}} < \kappa$ then $m > \omega_b$" correctly fails for the double well, whose gap is small because of tunnelling ($K_{\mathrm{rel}} \geq 4.6 > \kappa = 1$ for every window). 0+1 is not an analogue of the four-dimensional ratio but a negative control showing that the ratio form responds correctly to non-convexity.

What to take from this note to four dimensions. The non-convexity of the double well does not depend on the length of the window; it shows up in the ratio from the shortest window, as the bimodality of the single-time distribution. Hence "at short distance the ratio is close to 1" (the reason § 04 did not require uniformity in c) is not a fact that follows from the ratio form. Expecting it in four dimensions is an assumption depending on asymptotic freedom, that the theory is close to a free field at short distance Assumption .

08

Which part of which assumption each conclusion needs

Table 4 The part of the relaxation-time assumption each conclusion needs, and the other assumptions needed

Conclusion	Part of the relaxation-time assumption needed	Other assumptions needed	Grade
Lower bound on the gap of the lattice in physical units, in finite spatial volume, at each β	The local relaxation-time assumption on a window $c\ell$ ((4)), or the upper-bound assumption restricted to $\mathcal{F}_1$	The assumptions of the one-sided bridge (continuous time, finite spatial lattice, $T = \infty$). On Wilson's lattice with discretised time, the time-step comparison assumption remains, and the window version has not been written	Proved here ((6)(10)), Assumption (the time-step comparison assumption)
Lower bound on the gap of the lattice in physical units in infinite volume	$K_{\mathrm{rel}}(c) < K_*$ at a single c (ratio form (12))	the local-excitation moment assumption, the infinite-volume ground-state transformation identity, κ uniform in β, test observables from the family of colour singlets (including loops spanning the box)	Assumption
Speed of passage between sectors	The sector diffusive-relaxation-time assumption and the quantity between sectors C_{trans} (24-03)	Unrelated to the mass gap	Estimate

Conclusion	Part of the relaxation-time assumption needed	Other assumptions needed	Grade
The upper-bound assumption itself	All f	The stage of closed boxes (24-03)	Assumption (in the four-dimensional periodic box, on the side that reads as false on the numbers of original sources for $SU(3)$ and above and a reading that extends a conjecture)

The point of Table 4 is that **the conclusion of no row needs the global upper-bound assumption**. What the one-sided bridge uses is only the part of the upper-bound assumption local in time (finite volume), or the ratio form of the local relaxation-time assumption (infinite volume). The rest of the upper-bound assumption — the sentence about functions not local in time — is where quantities like the topological charge can obstruct the upper-bound assumption (24-01), and the bridge does not pass through there Proved here (the first row of Table 4), Estimate (the reading of the second row onwards).

The Jaffe–Witten exposition of the problem writes that "new ideas are needed to prove a mass gap uniform in the volume of spacetime" Cited . The local relaxation-time assumption ties the size of the box to the bookkeeping length and stands as a sentence independent of the volume, so it is one form of stating "uniform in the volume" in the language of Poincaré Estimate . But there are no tools to show it.

09

What cannot be said

- The local-excitation moment assumption has not been shown for any interacting model. The infinite-volume ground-state transformation identity is also an assumption. The infinite-volume bridge (15)(16) is algebra on top of these two.
- The values of Table 2 are readings from floating-point computation and extrapolation ($R \le 16$ for the scalar and transverse waves, $R \le 10$ for the colour singlet). 0.62κ is a threshold obtained from the value of a first-order test, a lower value of the usable threshold. The colour singlet is in the approximation of the leading term ($\beta \to \infty$) with independent Gaussians for three colours; there are no values for $SU(2)$ at finite β. Nor are there values for large loops in four dimensions.
- "The bridge sees the mass only when the box is at least 4–5 times the correlation length" is a linear interpolation of the ratios for massive **free fields**. There are no values of the ratio for interacting fields.
- For fields in the band $[K_*, 1)$, the bridge says nothing. Another argument that sees the mass within the band is undecided.
- "At short distance the ratio is close to 1" is an assumption depending on asymptotic freedom; it does not follow from the ratio form (it is false for the 0+1 double well).
- The window argument consists of sentences on a lattice with continuous time; on Wilson's lattice with discretised time, the time-step comparison assumption remains.
- Every conclusion goes only as far as a lower bound on the gap of the lattice in physical units at each β. The limit of $m_{\mathrm{phys}}(\beta)$, the continuum limit, and the existence of the infinite-volume measure do not follow. None of the mass gap, the relaxation-time assumption, the upper-bound assumption or the local relaxation-time assumption has been shown.

10

Table of the five grades and the dependency graph

We set out the rows of this chapter in the format of the five grades (23-00 § 01) with Estimate added. The symbols of the rows are the node numbers of the dependency graph below.

Table 5 Rows of this chapter ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	Existence and uniqueness of the infinite-volume measure	Assumption	23-01 § 02	$\beta \ge \beta_0$	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
2	The ground-state assumption, the stationary path-measure assumption, the metric comparison assumption: discrete spectrum, stationary measure with $T = \infty$, comparison of metrics	Assumption	23-01 Table 6	Continuous time, finite spatial lattice	—
3	Properties of the local C_P (fixed by the window marginal alone, monotone in c, C_P as $c \to \infty$)	Proved here	24-03	Continuous time	`local_le_global`, `local_approaches_global` (assumptions: bounded, non-empty, union of the families is the whole)
4	$(\xi^2)\uparrow_c^{\mathrm{rel}}(K)$: $K_{\mathrm{rel}}(c) \le K$ at a single c	Assumption	(12)	—	—
5	$(\xi^2)\uparrow_c^{\mathrm{loc}}(K)$: $C_P^{\mathrm{loc}}(c) \le K\ell^2$ (finite spatial volume)	Assumption	(4)	—	—
6	The local-excitation moment assumption: moment ratio of excitations by local observables	Assumption	(13)	—	—
7	Infinite-volume ground-state transformation identity	Assumption	§ 05	—	—
8	κ uniform in β	Assumption	23-01 § 06	Expected to hold in the field graduation	—

The check for circles is only to see that on every "⟸" the numbers on the right are smaller than the number on the left. Among the assumption rows, only the local-excitation moment assumption contains the quantity of the conclusion (the gap m_∞), and there m_∞ appears only in a comparison from above and does not imply $m_\infty > 0$, as checked in § 05. The node of the massless free field is a negative control that does not enter any conclusion; it records why the form "some $K(c)$" was discarded. "At short distance the ratio is close to 1" is an assumption, and the two gap lower bounds of the conclusions do not depend on it (because c was fixed to a single value).

What this chapter can say

Said	Not said
That the supremum over the family local in time $\mathcal{F}_1$ is exactly ξ^2 in the canonical graduation, and that the upper-bound assumption on $\mathcal{F}_1$ is the same as a lower bound on the gap of the lattice in physical units (continuous time, finite spatial lattice, $T = \infty$) Proved here	The same sentence on Wilson's lattice with discretised time (the time-step comparison assumption remains). Making time continuous — the Hamiltonian lattice and the vacuum measure

> This chapter is this book's own investigation. § 04 and § 06 are a map of open questions.

What this chapter shows — That on a lattice with continuous time, the gap of the Hamiltonian Δ is tied to the Poincaré constant of the vacuum distribution at one time $\nu = \psi_0^2$ exactly by $\Delta = \hbar^2/(2C_P(\nu))$ (with a proof). That this is the reverse side of $T = \infty$ for the one-sided bridge of Part 23, and the same formula as the ratio ω_b/m for the shortest window in 24-04. The road that treats the gap directly on the Hamiltonian lattice of Kogut–Susskind, and why local-to-global gap theorems do not apply there. That for the $SU(2)$ colour singlet, at leading order the Poincaré constant of the vacuum measure is halved and the lowest gauge-invariant test space is two-particle. What is needed to measure the constant of the vacuum measure.

Prerequisite chapters — 23-01 § 04 (the three CP of Table 3), 23-01 § 06 ((17) of the One-Sided Bridge Proposition (Theorem 3.1 of the paper), the identity (18)), 24-04 (the supremum (2) over the family local in time, (17) for the 0+1 window, the colour singlet), 2-05 § 08 (the one-dimensional ground-state transformation). The notation is collected in 24-09.

Said first — The level is [Y3]. The identity of this chapter only restates the gap as "the Poincaré constant of a certain measure"; it does not make the problem easier. The vacuum measure cannot be written explicitly, and there is no tool that bounds its Poincaré constant uniformly in the coupling. This chapter does not show the mass gap. It sets out one view that does not pass through the diffusive-relaxation-time assumption, and lists what that view needs.

The order of this chapter

1. The gap is the Poincaré constant of the vacuum measure — the Gap and Vacuum Measure Proposition ((1)–(4)), an example checked by hand
2. Three Poincaré constants — the path measure, the family local in time, the vacuum measure (Table 1, (5)(6))
3. The lattice version in 0+1 — the single-time window, and the discrepancy when time is discretised
4. The Hamiltonian lattice of Kogut–Susskind — the road that treats the gap directly, the Electric–Magnetic Splitting Frustration Proposition, where the tools do not apply (Table 2)
5. The $SU(2)$ colour singlet and two particles — the constant is halved at leading order ((7)(8))
6. The road to measuring the constant of the vacuum measure — what is needed
7. What cannot be said
8. Table of the five grades and the dependency graph — Table 3

01

The gap is the Poincaré constant of the vacuum measure

The setting is the same as for the one-sided bridge of Part 23. Space is a finite lattice, the space of configurations at one time is Q ($\mathbb{R}^n$, or a compact connected Riemannian manifold), the metric of the kinetic term is M, the Hamiltonian is $H = -\frac{\hbar^2}{2}\Delta_M + V$, and we place the ground-state assumption ((A1) in the paper: the spectrum is discrete, the ground state ψ_0 is non-degenerate, smooth and positive, $\Delta = E_1 - E_0 > 0$). We set the vacuum distribution at one time, and the Dirichlet form and Poincaré constant on it, as

$$\nu = \psi_0^2 \, d\mathrm{vol}, \qquad \mathcal{E}_\nu(F) = \int_Q \psi_0^2 \, |dF|^2_{M^{-1}} \, d\mathrm{vol}, \qquad C_P(\nu) = \sup_F \frac{\mathrm{Var}_\nu(F)}{\mathcal{E}_\nu(F)} \quad (1)$$

(F is a smooth, non-constant function on Q). In gauge theory we restrict F to gauge-invariant functions, and Δ is the gap on the gauge-invariant subspace.

Gap and Vacuum Measure Proposition

Under the ground-state assumption,

$$\Delta = \frac{\hbar^2}{2\, C_P(\nu)} \quad (2)$$

holds, and the supremum in (1) is attained at $F = \psi_1/\psi_0$.

Proved here Proof. The map $U : F \mapsto F\psi_0$ is an isometry from $L^2(\nu)$ to $L^2(d\mathrm{vol})$, and takes the constant 1 to ψ_0. Hence $\langle F \rangle_\nu = 0 \iff F\psi_0 \perp \psi_0$, and then $\|F\psi_0\|^2 = \mathrm{Var}_\nu(F)$. For smooth F, the identity of the ground-state transformation ((18) of 23-01)

$$\big\langle F\psi_0, \, (H - E_0)\, F\psi_0 \big\rangle = \frac{\hbar^2}{2}\, \mathcal{E}_\nu(F) \quad (3)$$

holds. Since $H - E_0$ is at least Δ on the orthogonal complement of ψ_0 (min-max), for smooth F with $\langle F \rangle_\nu = 0$ we have

$$\Delta \; \mathrm{Var}_\nu(F) \;\le\; \frac{\hbar^2}{2}\, \mathcal{E}_\nu(F), \qquad \text{that is} \qquad \frac{\mathrm{Var}_\nu(F)}{\mathcal{E}_\nu(F)} \le \frac{\hbar^2}{2\Delta} \quad (4)$$

Adding a constant changes neither side, so (4) holds for every smooth F. Equality is attained at $F = \psi_1/\psi_0$ (smooth by the ground-state assumption, with $F\psi_0 = \psi_1$, and the left-hand side of (3) is $\Delta\|\psi_1\|^2$). For $Q = \mathbb{R}^n$, the finiteness of the Dirichlet integral of ψ_1/ψ_0 is checked by the truncation lemma (Lemma 3.3) of the paper "one-sided bridge" (list of papers). ∎

In other words, the generator of Langevin dynamics on the vacuum distribution is unitarily equivalent, by the ground-state transformation, to $-(2/\hbar^2)\, \psi_0^{-1}(H - E_0)\, \psi_0$. Restatements of this type are well known (the restatements of stochastic quantisation and of supersymmetric quantum mechanics). The Gap and Vacuum Measure Proposition writes the gap part of it in this book's convention (1).

Calibration (one harmonic oscillator). For $Q = \mathbb{R}$, $M = 1$, $V = \frac{1}{2}\omega^2 x^2$, $\hbar = 1$, the gap is $\Delta = \omega$, so (2) gives $C_P(\nu) = 1/(2\omega)$. ψ_0^2 is the normal distribution with variance $1/(2\omega)$, and this agrees with the fact that the Poincaré constant of a one-dimensional normal distribution equals its variance (with equality for linear functions). The row for the vacuum C_P in Table 3 of 23-01 ($1/(2m)$ for the free field) is this value Proved here .

Example 1 (checked by hand on two sites). On the two-site lattice of Example 6 of 23-01 ($\hbar = M = 1$, $V = \frac{1}{2}x^{\mathsf{T}}Kx$, the normal mode $u = (x_1 + x_2)/\sqrt{2}$ with angular frequency m_0, $v = (x_1 - x_2)/\sqrt{2}$ with angular frequency $\sqrt{m_0^2 + 2}$), ν is the independent normal distribution with variance $1/(2m_0)$ for u and variance $1/(2\sqrt{m_0^2 + 2})$ for v. The Poincaré constant is the larger of the two variances, $1/(2m_0)$, and (2) gives $\Delta = m_0$, which agrees with the gap of Example 6 of 23-01 Proved here . If $m_0 = \frac{1}{2}$, then $C_P(\nu) = 1$, the path measure has $C_P = \xi^2 = 4$, and $4 = 4\,C_P(\nu)^2$ ((5) in the next section).

02

Three Poincaré constants

Three quantities are called by the same symbol C_P. With the Gap and Vacuum Measure Proposition, the relations among the three line up in one table.

Table 1 Three Poincaré constants (lattice with continuous time, canonical graduation. The free-field column has $\hbar = 1$ and mass m)

Quantity	Which measure, which functions	Relation to the gap	Free field	Grade
C_P	Path measure, all functionals	One-sided $C_P \geq \kappa\hbar^2/\Delta^2$	$1/m^2$	Proved here (the one-sided bridge of 23-01)
$\sup_{\mathcal{F}_1}$	Path measure, time-integrated single-time functions	$= \hbar^2/\Delta^2 = (2C_P(\nu)/\hbar)^2$	$1/m^2$	Proved here (combining (2) of 24-04 with (2) of this chapter)
$C_P(\nu)$	The vacuum distribution at one time	$= \hbar^2/(2\Delta)$	$1/(2m)$	Proved here (the Gap and Vacuum Measure Proposition)

The equality in the second row

$$\sup_{f \in \mathcal{F}_1} \frac{\mathrm{Var}(f)}{\mathcal{E}(f)} = \left(\frac{2\,C_P(\nu)}{\hbar}\right)^2 \quad (5)$$

makes exact, on the family local in time and with interaction, the statement of 23-01 § 04 that "for the free field $C_P^{(\beta)} = 4(C_P^{(\alpha)})^2$" Proved here . In 23-01 this rereading was written as an analogy from the form of the free field. Under the assumptions of the one-sided bridge, restricted to the family local in time, it is an equality, not an analogy. The amount by which the path C_P stated by the diffusive-relaxation-time assumption exceeds $(2C_P(\nu)/\hbar)^2$ comes from functions that are not local in time (winding numbers and the topological charge).

Restated in physical units. Setting $\hbar = 1$ in lattice units and converting to physical units by the bookkeeping length ξ_{RG}, (2) becomes

$$m_{\mathrm{phys}} = m\,\xi_{\mathrm{RG}} = \frac{\xi_{\mathrm{RG}}}{2\,C_P(\nu)}, \qquad m_{\mathrm{phys}} \geq c \iff C_P(\nu) \leq \frac{\xi_{\mathrm{RG}}}{2c} \quad (6)$$

Proved here . The mass gap (that the gap in physical units of the lattice stays positive) is the same as the Poincaré sentence "the Poincaré constant of the vacuum measure is bounded by the first power of the bookkeeping length". It is a Poincaré sentence that does not pass through the relaxation-time

assumption, and the growth is the first power, not the square (in terms of the dynamical exponent, the type $z = 1$). But this is a restatement, and there is no new information on either side. An upper bound on $C_P(\nu)$ needs every F, and the difficulty is exactly that of a lower bound on the gap.

The topological problem does not arise for the vacuum measure. On ν we vary only single-valued functions at one time. For a free particle on the circle, ν is the uniform distribution on the circle and $C_P(\nu) = 1$ is finite (Wirtinger's inequality for the circle of circumference 2π), and (2) gives $\Delta = \hbar^2/2$ of the Free-Particle-on-a-Circle Counterexample of 23-01. And the winding-number functional that made $C_P = \infty$ for the path measure (the angle of the lift, integrated in time) is not a function on ν Proved here . The four-dimensional topological charge is also a quantity fixed by an integral in time, so it is not among the functions on the vacuum distribution at one time Estimate . The boundary is the same as the inside and outside of $\mathcal{F}_1$ in 24-04.

03

The lattice version in 0+1 — the single-time window

For the 0+1-dimensional double well of 24-04 § 07, the local Poincaré constant of the single-time window of the chain with time discretised at width ε was exactly $C_P^{\mathrm{loc}}(1) = \varepsilon/(2m)$ when ψ_0 is the Schrödinger ground state ((17) of 24-04). The Dirichlet form of the window $(\hbar/\varepsilon)\int \psi_0^2 |F'|^2$ is $\hbar/\varepsilon$ times $\mathcal{E}_\nu$ of (1), so this is exactly the value $C_P(\nu) = \hbar^2/(2\Delta)$ of the Gap and Vacuum Measure Proposition multiplied by $\varepsilon/\hbar$ Proved here . The ratio ω_b/m for the shortest window is this identity for the target (the double well) divided by that for the reference (the harmonic oscillator).

When time is discretised, the single-time distribution of the chain is the square of the top eigenvector of the transfer kernel (the symmetric Trotter product), and differs slightly from the Schrödinger ψ_0^2. On lattices with $V = (x^2-1)^2/8$, $\varepsilon = \tfrac{1}{2}$, $\hbar = 0.3,\ 0.15,\ 0.08$, the ratio of the direct value of the single-time window to $\varepsilon/(2m_{\mathrm{tr}})$ (m_{tr} from the second eigenvalue of the transfer) is $1.006,\ 1.013,\ 1.019$, and the ratio with the reference discretised too, $K_{\mathrm{rel}}(1)\cdot m_{\mathrm{tr}}$, is $1.037,\ 1.044,\ 1.050$ Reading . The identity is a statement in continuous time, and on a lattice with discretised time it is an approximation. This difference is the smallest form of the reason why the time-step comparison assumption of Part 23 ((D) in the paper "one-sided bridge", (20) of 23-01) remains.

04

The Hamiltonian lattice of Kogut–Susskind

This section summarises existing knowledge (the Hamiltonian lattice of Kogut–Susskind). The introduction is in 5-03 § 07.

The Hamiltonian of gauge theory with time continuous and only space made a lattice is the Kogut–Susskind lattice. The configuration space is the product of copies of the group, one per spatial link, $Q = G^{\{\text{spatial links}\}}$ (a compact connected manifold), and setting the metric of the kinetic term to $M = g^{-2}\cdot$ (the bi-invariant metric) to match the form of the one-sided bridge, we have

$$H_{\mathrm{KS}} = \frac{g^2}{2}\sum_{\ell} E_\ell^2 + \frac{1}{g^2}\sum_{p}\left(2 - \operatorname{tr} U_p\right) \qquad (\hbar = 1,\ G = SU(2)) \tag{7}$$

E_ℓ^2 is the Laplace–Beltrami operator on the group of the link ℓ with its sign changed (the square of the electric field), U_p is the product around a plaquette, and the second term is the magnetic term. The

conventions for the coefficients differ in the literature; here they are matched to the form of the one-sided bridge. Physical states are gauge-invariant functions (the Gauss law), and H_{KS} commutes with gauge transformations, so ψ_0 is automatically gauge invariant. On this lattice, the quantity in the problem statement is exactly the gap of H_{KS} on the gauge-invariant subspace, and by the Gap and Vacuum Measure Proposition it can be written as the Poincaré constant of the vacuum distribution at one time $\nu = \psi_0^2 \cdot \mathrm{Haar}$.

The road that treats the gap directly on this lattice is one of the rows of the "table of other roads" in the table of materials of 24-00. Table 2 sets out how far it has reached and where it stopped.

Table 2 Roads that treat the gap of the Hamiltonian lattice directly (the grades of the primary sources are in the source table)

Tool	Statement (summary)	Does it apply to the Kogut–Susskind lattice?	Grade
Local-to-global gap theorems (of Knabe's type, Gosset–Mozgunov)	For a frustration-free, translation-invariant local Hamiltonian, if the local gap of the open chain of length n exceeds a threshold $(6/(n(n+1))$ in Gosset–Mozgunov), the gap survives uniformly in the volume in the thermodynamic limit (one dimension; extended to the two-dimensional square lattice)	Does not apply. The splitting into the electric term and the magnetic term is not frustration-free (the Electric–Magnetic Splitting Frustration Proposition)	Cited (statement checked in the abstract), Proved here (the Electric–Magnetic Splitting Frustration Proposition)
Perturbation (Yarotsky)	For a classical lattice system with a relatively bounded quantum perturbation added, the gap and exponential decay of correlations	Strong coupling (the electric term dominating) is expected to fit the perturbative type. Not checked against the assumptions	Cited (abstract), Estimate
Results on the gap at weak coupling (the continuum-limit side)	—	Not found within the range searched (two searches with short terms)	—

Electric–Magnetic Splitting Frustration Proposition (the splitting into electric and magnetic parts is not frustration-free)

Let $g > 0$ and let the spatial lattice have at least one plaquette. When (7) is regarded as the sum of the local terms $h_\ell = \frac{g^2}{2} E_\ell^2$ and $h_p = \frac{1}{g^2}(2 - \operatorname{tr} U_p)$, $h_p - c_p$ has no eigenvector whatever constant c_p is subtracted. Hence there is no state that realises the ground states of all the local terms at once, and this splitting is not frustration-free.

Proved here Proof. h_p is a multiplication operator on $L^2(Q, \mathrm{Haar})$, and the multiplying function $2 - \operatorname{tr} U_p$ is a non-constant real-analytic function on Q. If $(h_p - c_p)\psi = 0$, then the support of ψ lies in the level set $\{2 - \operatorname{tr} U_p = c_p g^2\}$, but a level set of a non-constant real-analytic function has Haar measure 0, so $\psi = 0$. ∎ That the electric term and the magnetic term do not commute is equally elementary (E_ℓ^2 is a differential operator and does not commute with multiplication by $\operatorname{tr} U_p$). Whether a splitting that groups the electric and magnetic terms by sector also fails to be frustration-free is an expectation from their not commuting, and has not been shown Estimate . Nor have we checked the fact that the local Hilbert space $L^2(SU(2))$ is infinite-dimensional against the setting of the theorems.

Tools on the side of the vacuum measure. Moving the gap to $CP(\nu)$ by the Gap and Vacuum Measure Proposition does not increase the tools available. We list three reasons.

- ν cannot be written explicitly. $-2\ln\psi_0$ is the "action" of ν, and it is not local either. A criterion of Bakry–Émery type, which bounds the Poincaré constant by convexity, needs a lower bound on $\mathrm{Hess}(-\ln\psi_0)$. The result of Brascamp–Lieb type, that the ground state of a convex potential is log-concave, is from memory, and its bibliographic data have not been checked Assumption . Moreover, the magnetic term of (7) is a non-constant smooth function on a compact group, so its Hessian is at most 0 at a maximum point, and it cannot be uniformly convex Proved here . Whether a criterion with the Ricci curvature of the group added works uniformly as $g \to 0$ is expected to meet an obstacle of the same type as the convexity-ceiling lemma of 24-06 Estimate .
- To set up on ν an argument of the local-to-global type for Glauber dynamics (from the Poincaré constants of local boxes and strong spatial mixing to a gap uniform in the volume, of the type in Martinelli's lectures), spatial mixing with respect to the boundary values of ν is needed. Since ν is not explicit, this is expected to be harder than for the Wilson measure Estimate (the statements of theorems of that type are from memory, not checked in the originals Assumption).
- Taking the temporal lattice spacing to 0 first (the Hamiltonian limit) is a different order of limits from Wilson's isotropic lattice. That both orders lead to the same continuum limit is an assumption Assumption (the background in 23-02).

05

The $SU(2)$ colour singlet and two particles

In 24-04 § 06 we saw, for the reference on a four-dimensional spacetime box, that "the $SU(2)$ colour singlet has no linear term, and the reference is exactly halved". We state the same thing on the side of the vacuum distribution at one time.

At leading order ($g \to 0$, the three colour components independent Gaussians), the vacuum distribution ν is a Gaussian measure on the transverse fields of the spatial links; writing ω_k for the one-particle angular frequencies of the free Hamiltonian, the Langevin generator of the Dirichlet form (1) is unitarily equivalent to $-2(H - E_0)$ by the ground-state transformation of the Gap and Vacuum Measure Proposition ($\hbar = 1$). The eigenvalues of $H - E_0$ are sums of one-particle angular frequencies $\sum_k n_k\omega_k$ (n_k is the number of particles), and the eigenspaces correspond to the Wiener chaos ($n = \sum n_k$ gives the n-th chaos). On a finite spatial lattice, let the smallest angular frequency be $\omega_{\min} > 0$ (modes with $\omega = 0$, such as the constant mode of a periodic box, are treated separately).

A gauge-invariant function must be invariant under constant gauge transformations (global colour rotations $SO(3)$). A function in the first chaos $\sum c_k^a A_k^a$ is a vector in the colour index a, and $SO(3)$ has no fixed vector in $\mathbb{R}^3$, so the only invariant one is 0 Proved here . Hence the lowest test space of gauge-invariant functions is the second chaos (two particles), the smallest eigenvalue on it is $2\omega_{\min}$, and equality is attained at $F_w = \sum_a(\langle w, A^a\rangle^2 - \mathbb{E})$, with the two particles placed in the same lowest mode w and contracted in colour Proved here . Reread through the Gap and Vacuum Measure Proposition, this is

$$C_P(\nu \,|\, \text{colour singlet}) = \frac{C_P(\nu)}{2}, \qquad \Delta_{\text{singlet}} = 2\,\omega_{\min} \qquad \text{(leading order)} \quad (8)$$

Proved here (at leading order, three independent Gaussian colours, on a finite spatial lattice with $\omega_{\min} > 0$). The lowest gauge-invariant excitation is at the two-particle threshold, and the Poincaré constant is half the one-particle constant. The reference $\Gamma_Q/2$ for the spacetime box in 24-04 is the same mechanism seen through the local Poincaré constant of the spacetime box. Lean

`LatticeGauge.WilsonLoopReference.no_linear_singlet` (assumption: a linear form invariant under two rotations; conclusion: the coefficients are 0), `chaos2_gamma` (assumption: $0 < n, g$ and the Wick moments as formulas; conclusion: the algebra by which the ratio is halved).

In physics it is said that "the lightest glueball is a bound state of two gluons". One can read (8) as the local Poincaré version of its leading order Estimate . However, a physical mechanism is not a proof (the table of physical mechanisms in 24-07), and (8) is a statement in the form of the leading order. In infinite volume $\omega_{\min} \to 0$, so the right-hand side of (8) also goes to 0. The mass gap does not appear at leading order; what the leading order fixes is only the form "the gauge-invariant test space begins at two particles". How (8) changes for $SU(2)$ at finite g has not been computed at all.

06

The road to measuring the constant of the vacuum measure — what is needed

By the Gap and Vacuum Measure Proposition, measuring the Poincaré constant of the vacuum distribution is the same as measuring the gap. We set out the roads to measuring it by how far the machinery of the first step of Part 23 can be used.

- **0+1 dimensions.** The machinery of the first step (the lattice eigenvalue problem of the transfer kernel, and the generalised eigenvalues of the weighted lattice Laplacian) computes the local Poincaré constant of the single-time window directly, and agreed with $\varepsilon/(2m_{\mathrm{tr}})$ within a factor of 1.006–1.019 (§ 03) Reading . In 0+1, the machinery measures $C_P(\nu)$ as it is.
- **Samples.** ν is not explicit, so samples are needed. The marginal distribution on a single-time slice of an anisotropic Wilson lattice with small temporal lattice spacing is expected to approach ν in the Hamiltonian limit Estimate . If the time step is finite, that slice is ψ_0^2 of the transfer kernel, and the discrepancy of § 03 (1–2% at $\varepsilon = \frac{1}{2}$ in 0+1) enters.
- **Test functions.** Since we restrict to gauge-invariant functions, we take them from polynomials in Wilson loops. As in 24-04 § 06, loops of the size of the span of the box are needed.
- **Graduation.** $\mathcal{E}_\nu$ of (1) is measured in the metric of the kinetic term $M^{-1} = g^2 \cdot$ (the bi-invariant metric). Unless the Langevin graduation is matched to this, the coefficient in (2) is off by a factor κ.
- **Direction.** The Rayleigh quotient on samples gives only a lower bound on $C_P(\nu)$, that is, an **upper bound** on the gap (the side obtained by placing a single test function). A lower bound on the gap needs every F, and the asymmetry between the relaxation-time upper-bound assumption and the relaxation-time lower-bound assumption of Part 23 ((15) of 23-01) appears as it is. The road to measuring is a road that measures the easy side of the gap.

This chapter places no computation. A computation that bounds the Kogut–Susskind gap of a small periodic lattice in intervals, truncating the representations of the electric field, stays at the numbers of a finite box, and does not become a bridge to a gap uniform in the volume Estimate .

07

What cannot be said

- The Gap and Vacuum Measure Proposition is an identity, and we do not claim it has made the problem easier. There is no tool that bounds $C_P(\nu)$ uniformly in β (or g).

- Local-to-global gap theorems do not apply to the splitting of the Kogut–Susskind lattice into electric and magnetic parts (the Electric–Magnetic Splitting Frustration Proposition). That they do not apply to a splitting grouped by sector is an expectation and has not been shown.
- We have not checked the application of strong-coupling perturbative results to the Kogut–Susskind lattice. Results on the weak-coupling side were not found within the range searched.
- That the order taking the Hamiltonian limit first gives the same continuum limit as Wilson's lattice is an assumption.
- (8) is a statement at leading order (three independent Gaussian colours), and there is no value at finite g. The correspondence with glueballs is an estimate.
- This chapter does not show the mass gap. Nor does it show anything about the relaxation-time assumption.

08

Table of the five grades and the dependency graph

Table 3 The rows of this chapter ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking

The check for circles is only to see that on every "⟸" the numbers on the right are smaller than the number on the left. The conclusions of this chapter are the Gap and Vacuum Measure Proposition and the three relations that follow from it (the three constants, physical units, the 0+1 window), and the leading-order statement for two particles; there is no node for the mass gap. None of the assumption rows (the ground-state assumption, log-concavity, mixing, the order of limits) contains a lower bound on the gap.

What this chapter can say

What is said	What is not said
That on a finite spatial lattice with continuous time, the gap is tied to the Poincaré constant of the vacuum distribution at one time by $\Delta = \hbar^2/(2C_P(\nu))$ (under the ground-state assumption) Proved here	A way to bound $C_P(\nu)$ uniformly in β. Any claim that the problem has become easier
The relation among the three Poincaré constants, and that on the family local in time the free-field rereading of 23-01 becomes an equality Proved here	The size of the amount by which the path C_P exceeds $(2C_P(\nu)/\hbar)^2$
That the 0+1 single-time window is this identity Proved here ; the discrepancy when time is discretised Reading	Whether the time-step comparison assumption holds on the four-dimensional Wilson lattice

What is said	What is not said
That the splitting of the Kogut–Susskind lattice into electric and magnetic parts is not frustration-free Proved here	Whether it holds for splittings grouped by sector. The application of strong-coupling perturbation. Weak-coupling results
That at leading order the lowest test space of the colour singlet is two-particle, and $CP(\nu)$ is halved Proved here	Values at finite g. The correspondence with glueballs (an estimate)

Terms used in this chapter — the vacuum measure ν, the ground-state transformation, the Gap and Vacuum Measure Proposition, the three Poincaré constants, the Hamiltonian lattice (Kogut–Susskind), frustration-free, local-to-global gap theorems, the colour singlet and the second chaos, the Hamiltonian limit. Their meanings are in A-02 Glossary and 24-09.

Next chapter to read: 24-06 Paying with rarity instead of convexity — that convexity is not enough on groups, as a story of tools that pay with rarity.

Paying with rarity instead of convexity — renormalisation on groups and log-Sobolev

> This chapter is this book's own investigation. § 02 and § 08 are established knowledge; § 05 and § 07 are a map of open questions.

What this chapter shows — From here on the subject is tools. 24-01 to 24-05 dealt with "what to compare, and which diffusive-relaxation-time assumption to restate". To show any statement, a tool that bounds the relaxation constant from above is needed. On flat space the centre of such tools is convexity (Bakry–Émery, Brascamp–Lieb), and for scalar hierarchical models a theorem of the same type as the diffusive-relaxation-time assumption has been shown, with uniform convexity of the conditional measure at each scale as the entrance. In this chapter: (1) we look at what the convexity tools need and where they break, in three places: the summit in 0+1 dimensions, the antipode on the group, and the induction hypothesis of the hierarchical model. On a group, by the Convexity Ceiling Lemma on closed manifolds (with a proof), convexity cannot hold in principle at weak-coupling scales. (2) Between flat ϕ^4 and the group, the convex and non-convex places are reversed, and the wall does not vanish but is pushed into a place of probability $e^{-c\beta}$. (3) We then list tools that pay with rarity instead of convexity (the currency of entropy, Lyapunov conditions, field-dependent constants), and see that the margin of the action barrier in Part 23 is "an example where rarity paid". (4) We place as a candidate "the class of measures that pay with rarity", rewritten in the form of rules, and check that the "coupling window" left between the ultraviolet side and the strong-coupling side is a restatement of the second difficulty of the third step. (5) We add one section on the road of stochastic quantisation.

Prerequisite chapters — 23-09 § 06 (the one-site curvature at the summit, $\frac{15}{4}$ and 4), 23-10 currency-mix-up type, 23-11 § 06 (the margin of the action barrier), 24-02 § 02 (tree coordinates and link coordinates), 24-07 § 05 (the three roots). From Part 1, 1-05 (manifolds) and 1-04 ($SU(2)$). Notation is in 24-09.

Said first — The level is [Res]; the summary in § 01 is [Y3]. Proofs are placed only for the lemma, corollary and proposition of § 03; the rest is copied from the originals (Cited) or estimates (Estimate). The results for hierarchical models imply nothing for four-dimensional Yang–Mills. The "rules" of § 07 are candidates, and none of them promises a prospect of closing the third step (the continuum limit). This chapter shows neither the mass gap nor the relaxation-time assumption. A note on notation: in this chapter the lower bound on the Bakry–Émery curvature is written κ_{BE}, a different quantity from the comparison constant κ of the One-Sided Bridge Proposition (Theorem 3.1 of the paper) (24-09). The rate of rarity is written s ($\mu(B) \le e^{-s}$). It is the quantity written ℓ in 23-09 and 23-10 of Part 23; in Part 24 we changed the letter because ℓ is used for the ruler of length.

The order of this chapter

1. Summary [Y3] — the convexity ceiling, the reversal of places, the currency of rarity
2. What the convexity tools need — Bakry–Émery, Brascamp–Lieb, the induction hypothesis of the hierarchical model
3. The convexity ceiling on closed manifolds — the Convexity Ceiling on Groups Lemma, the No Concentration at the Identity Corollary, the One-Link Wilson Weight Proposition (with proofs)
4. The convex and non-convex places are reversed — ϕ^4 and the group; the wall goes to where the probability is small (Figure 1)
5. Carrying the hierarchical induction over to the group — applies, changes, does not apply (Table 1)
6. Tools that pay with rarity — currency, Lyapunov, field-dependent constants, the example of the action barrier (Table 2)
7. If it were made into rules — the class of measures that pay with rarity — objects, rules, candidate first theorems, the coupling window
8. The road of stochastic quantisation — subcriticality $d < 4$, and the direction of rebuilding where the objects live
9. What cannot be said
10. Table of the five grades and the dependency graph — Table 3

01

Summary [Y3] — the convexity ceiling, the reversal of places, the currency of rarity

This section is a ten-paragraph summary for readers at [Y3]. The proofs and the conditions of the originals are in § 02 onwards.

1. A hierarchical model replaces the lattice by nested boxes so that one step of renormalisation can be written down. For the four-dimensional hierarchical scalar $|\phi|^4$, both the equilibrium properties (the book by Bauerschmidt–Brydges–Slade) and the slowness of relaxation of the stochastic dynamics (Bauerschmidt–Bodineau: the gap vanishes with the same power as for the free field) are theorems Cited . The latter is a statement of the same type as the relaxation-time assumption.
2. The method of Bauerschmidt–Bodineau takes as its entrance the hypothesis that at each scale "the measure of the fine fluctuations, with the coarse field held fixed, is uniformly convex" Cited . The original itself names convexity at large fields as the main issue in extending the method beyond hierarchical models.
3. The group $SU(2)$ is a closed space (the three-dimensional sphere). On a closed space, imposing convexity bounds the oscillation of the potential by the square of the diameter, and the measure cannot leave the range of a constant multiple of the uniform distribution (the Convexity Ceiling Lemma of § 03) Proved here . At weak coupling the measure needs to gather near the identity, so the convexity hypothesis cannot hold in principle at weak-coupling scales.

4. For ϕ^4 on flat space, large fields are convex by nature, and what is not convex is small fields (between the two wells). On the group it is the reverse: near the identity (small fields) is convex, and the far hemisphere (large fields) is necessarily non-convex (§ 04) Proved here .
5. However, the probability of being on the non-convex side is small, of the order of $e^{-\beta}$ (the One-Link Wilson Weight Proposition of § 03) Proved here . The wall does not vanish; it is pushed into a place of small probability.
6. The wall of the first step of Part 23 (that the one-site diagonal at the summit $\frac{15}{4}$ falls short of the sum of couplings 4 by $\frac{1}{4}$) also took the form of paying for the lack of convexity with the rarity of the plateau. The Poincaré inequality is a currency that measures the speed of exit, and what can pay with rarity is the currency of entropy (23-10 currency-mix-up type). A step that pays with rarity needs to pass through an inequality of log-Sobolev type.
7. Tools that pay with rarity instead of convexity include Lyapunov conditions (a drift that returns from the bad set) and field-dependent constants. The estimate of the action barrier in Part 23 was an example where the cost of the bistability of the core could be paid by the rarity of the local term (a margin of about 95 times, on the $\hbar = 0$ reading).
8. The one-link measure has a single well, and its relaxation constant does not get exponentially worse in β. A wall of the $\frac{1}{4}$ type of the double well does not come back for one link Estimate .
9. Rewritten in the form of rules, this becomes "the class of measures that pay with rarity" (§ 07). On the ultraviolet side it seems possible to write a form in which the class closes at each step of coarse-graining, but at the confinement scale the rate of rarity runs out, and a "coupling window" remains between it and the curvature tools of the strong-coupling side. This is a restatement of the second difficulty of the third step (24-07 § 06) Estimate .
10. The road of stochastic quantisation (SPDE) uses the same Langevin dynamics, but its aim is the construction of the measure, and the solution theory is subcritical only for $d < 4$ Cited . It gives tools neither for the four-dimensional relaxation-time assumption nor for the local diffusive-relaxation-time assumption.

02

What the convexity tools need — Bakry–Émery, Brascamp–Lieb, the induction hypothesis of the hierarchical model

This section summarises existing knowledge (Bakry–Émery, Brascamp–Lieb, the inductive hypothesis of hierarchical models). The introduction is in 5-11 § 02.

Most tools that bound the relaxation constants (the Poincaré constant, the log-Sobolev constant) **from above** take as their entrance a lower bound on the second derivative of the potential, that is, convexity. We list three.

Bakry–Émery. For a probability measure $\mu = e^{-V} d\mathrm{vol}/Z$ on a Riemannian manifold M,

$$\mathrm{Ric} + \mathrm{Hess}\, V \;\geq\; \kappa_{\mathrm{BE}}\, g \quad (\kappa_{\mathrm{BE}} > 0) \qquad \Longrightarrow \qquad \mathrm{Ent}_\mu(f^2) \leq \frac{2}{\kappa_{\mathrm{BE}}} \int |\nabla f|^2 d\mu, \quad CP \leq \frac{1}{\kappa_{\mathrm{BE}}} \;(1)$$

Cited (the single-scale case of Theorem 3.6 of the review by Bauerschmidt–Bodineau–Dagallier). The condition is a lower bound **at every point**.

Brascamp–Lieb. On $\mathbb{R}^n$, if $\operatorname{Hess} V > 0$ then $\operatorname{Var}_\mu(f) \le \mathbb{E}_\mu \langle \nabla f, (\operatorname{Hess} V)^{-1} \nabla f \rangle$ Cited (the form used by Lemma 2.7 of Bauerschmidt–Bodineau). This too uses convexity at each point.

The hierarchical induction. Bauerschmidt–Bodineau split the Gaussian covariance by scale as $C = C_0 + \cdots + C_N$, form the renormalised potential $e^{-V_{j+1}(\phi)} = \mathbb{E}_{C_j} e^{-V_j(\phi+\zeta)}$ (**addition** of fields $\phi + \zeta$), and place the following hypothesis Cited (arXiv:1809.02075 § 2.3).

$$\text{(A1)} \qquad C^{1/2} \big(\operatorname{Hess} V_j(\phi)\big) C^{1/2} \;\ge\; -\varepsilon_j \, Q \qquad (\text{for all } \phi,\ \varepsilon_j < 1) \ (2)$$

Here Q is the projection onto the space of coarse fields, and ε_j is the notation of the original (different from the lattice spacing ε in 0+1 dimensions). Under (A1) and two structural hypotheses, the Brascamp–Lieb quadratic form is handed on at each step as $D \le C/(1-\varepsilon) + D_+/(1-\varepsilon)^2$, and the product over all steps is bounded by $\exp\big(2 \sum_l (\varepsilon_l + O(\varepsilon_l^2))\big)$ (Theorem 2.1, Corollary 2.2) Cited . The conclusion is a spectral gap (of Poincaré type), not a log-Sobolev result. The form that flows log-Sobolev over many scales is later work by the same authors (the Polchinski flow, § 05). The original writes that "to extend this method beyond hierarchical models, convexity rather than probabilistic estimates is needed, and convexity at large fields is the main issue" Cited .

Three places where it breaks. (a) The summit of the 0+1-dimensional double well. In one row of the Hessian of the action of the core, at the summit the diagonal $4 - \frac{1}{4}$ falls short of the sum of the couplings to the neighbours 4 ((11) of 23-09), and on the face where every site is at the summit, the smallest eigenvalue of a lump of length $k \ge 8$ is negative Proved here . Every convexity tool had to pay for this $\frac{1}{4}$ with the rarity of the plateau. (b) The opposite hemisphere of the group. In the One-Link Wilson Weight Proposition of § 03 we see that the Bakry–Émery curvature of the one-link Wilson weight is negative on the far hemisphere. (c) (A1) of the hierarchical induction. For group-valued fields, the natural reading of (A1) is "Bakry–Émery for the measure on the fibre with the coarse field held fixed" Estimate , and by the Convexity Ceiling Lemma of § 03 it cannot hold at weak-coupling scales.

What this section can say: (1)(2) and Theorem 2.1 are copies of the statements of the originals. The reading in (c) (reading (A1) on the group as Bakry–Émery on the fibre) is an estimate, and this book has no exact formulation of the induction on the group.

03

The convexity ceiling on closed manifolds — the ceiling lemma, no concentration at the identity, the one-link weight

Convexity Ceiling Lemma

Let M be a compact connected Riemannian manifold without boundary of diameter D, $V \in C^2(M)$, $K \ge 0$. If $\operatorname{Hess} V \ge -K\, g$, then

$$\operatorname{osc} V := \max_M V - \min_M V \;\le\; \frac{K D^2}{2}. \ (3)$$

Proved here Proof. Let p be a maximum point of V (M is compact). For any $q \in M$, take a minimising geodesic $\gamma : [0, L] \to M$ from p to q (unit speed, $L = d(p, q) \le D$) (it exists by the Hopf–Rinow theorem, since a compact manifold is complete). Setting $h(t) := V(\gamma(t))$, since p is a maximum point on a manifold without boundary, $h'(0) = dV_p(\gamma'(0)) = 0$. Along the geodesic, $h''(t) = \operatorname{Hess} V(\gamma'(t), \gamma'(t)) \ge -K$. Integrating gives $h'(t) \ge -Kt$, and integrating once more gives $h(t) \ge h(0) - Kt^2/2$. At $t = L$, $V(q) \ge \max V - KL^2/2 \ge \max V - KD^2/2$. Since q is arbitrary, (3) follows. ∎

There is no Lean check (the one-dimensional version "if $h'' \ge -K$ and $h'(0) = 0$ then $h(0) - h(x) \le Kx^2/2$" is kept as a candidate). The key of the proof is that "the first derivative vanishes at a maximum point", and here the **absence of boundary** (being closed) is what works. Flat $\mathbb{R}^n$ has no maximum point, so the same estimate does not follow.

No Concentration at the Identity Corollary (on $SU(2)$, a convex measure cannot gather at the identity)

Take $SU(2)$ as the unit three-dimensional sphere S^3 (bi-invariant metric, $\mathrm{Ric} = 2g$, diameter π), and suppose $\mu = e^{-V}\, d\mathrm{Haar}/Z$ satisfies $\mathrm{Ric} + \operatorname{Hess} V \ge 0$. Then $\operatorname{osc} V \le \pi^2$, and for every Borel set A

$$\mu(A) \;\le\; e^{\pi^2}\,\mathrm{Haar}(A), \qquad \mu\big(\{\theta \le r\}\big) \;\le\; e^{\pi^2}\,\frac{2}{3\pi}\,r^3 \quad (4)$$

(θ is the geodesic distance from the identity, $e^{\pi^2} \approx 1.9 \times 10^4$). In particular the one-link Wilson weight ($\operatorname{osc} V = 2\beta$) does not satisfy $\mathrm{Ric} + \operatorname{Hess} V \ge 0$ for $\beta > \pi^2/2$.

Proved here Proof. Since $\operatorname{Hess} V \ge -\mathrm{Ric} = -2g$, using the Convexity Ceiling Lemma with $K = 2$ and $D = \pi$ gives $\operatorname{osc} V \le \pi^2$. Since $Z = \int e^{-V}\, d\mathrm{Haar} \ge e^{-\max V}$, the density is $e^{-V}/Z \le e^{\max V - \min V} \le e^{\pi^2}$. The Haar distribution of class functions is $\frac{2}{\pi}\sin^2\theta\, d\theta$ ($\theta \in [0, \pi]$), and from $\sin\theta \le \theta$, $\mathrm{Haar}(\theta \le r) \le \frac{2}{\pi} \cdot \frac{r^3}{3}$. The Wilson weight $V = \beta(1 - \cos\theta)$ has $\operatorname{osc} V = 2\beta$, so if $2\beta > \pi^2$ it contradicts the inequality stated before (4). ∎

How to read (4). At weak coupling, the Wilson measure gathers most of its probability in a ball of radius of order $\beta^{-1/2}$. The right-hand side of (4) gets small like r^3, so when β is large, a measure with convexity of Bakry–Émery type cannot do that. The content of the lemma is that once convexity is imposed, the measure cannot move further from Haar than a constant factor e^{π^2}.

One-Link Wilson Weight Proposition

On the unit $S^3 = SU(2)$, let $V_\beta = \beta(1 - \cos\theta)$ and $\mu_\beta = e^{-V_\beta}\, d\mathrm{Haar}/Z_\beta$.

(i) $\mathrm{Ric} + \operatorname{Hess} V_\beta = (2 + \beta\cos\theta)\, g$. Hence the Bakry–Émery condition holds only when $\beta < 2$, and then $\kappa\mathrm{BE} = 2 - \beta$.

(ii) When $\beta > 2$, the set where the condition fails, $N_\beta := \{\cos\theta < -2/\beta\}$, lies in the hemisphere far from the identity, and on it $V_\beta \ge \beta + 2$.

(iii) For $\beta \ge 2$,

$$\mu_\beta(N_\beta) \;\le\; \frac{54\pi}{25}\, e^{-3/2}\, \beta^{3/2} e^{-\beta} \;<\; 1.52\, \beta^{3/2} e^{-\beta}. \tag{5}$$

Proved here Proof. (i) A function f of θ alone on the unit sphere has, in geodesic polar coordinates $g = d\theta^2 + \sin^2\theta\, g_{S^2}$, $\mathrm{Hess}\, f = f''\, d\theta^2 + f' \cot\theta\, (g - d\theta^2)$ (the radial direction from the second derivative along geodesics, the spherical directions from the second fundamental form $\cot\theta$ of the sphere of constant θ). For $f = \beta(1-\cos\theta)$, $f'' = \beta\cos\theta$ and $f' \cot\theta = \beta \sin\theta \cot\theta = \beta\cos\theta$, so $\mathrm{Hess}\, V_\beta = \beta\cos\theta\, g$. On the unit S^3, $\mathrm{Ric} = 2g$. The minimum is $2-\beta$ at $\theta = \pi$. (ii) If $\cos\theta < -2/\beta < 0$ then $\theta > \pi/2$, and $V_\beta = \beta(1-\cos\theta) > \beta + 2$. (iii) On N_β, $e^{-V_\beta} \le e^{-\beta-2}$, and the Haar measure is at most 1, so $\int_{N_\beta} e^{-V_\beta} \le e^{-\beta-2}$. For the denominator, on the ball of $r = \beta^{-1/2} \le 1$, $1 - \cos\theta \le \theta^2/2$ gives $V_\beta \le \frac{1}{2}$, and for $\theta \le 1$, $\sin\theta \ge \theta - \theta^3/6 \ge \frac{5}{6}\theta$ gives $\mathrm{Haar}(\theta \le r) \ge \frac{2}{\pi} \cdot \frac{25}{36} \cdot \frac{r^3}{3} = \frac{25}{54\pi} r^3$. Hence $Z_\beta \ge e^{-1/2} \frac{25}{54\pi} \beta^{-3/2}$, and dividing gives (5) ($\frac{54\pi}{25} e^{-3/2} = 1.514\cdots$). ∎

(5) is a crude upper bound; near the antipode ($\theta \approx \pi$, $V_\beta \approx 2\beta$) the probability is smaller still, of order $e^{-2\beta}$. $\beta < 2$ in (i) is sharper than the necessary condition $\beta \le \pi^2/2$ that follows from the Convexity Ceiling Lemma. The role of the Convexity Ceiling Lemma is that it is not limited to the Wilson weight: **any** weight, once convexity is imposed, is confined to the range of (4).

What this section can say: the Convexity Ceiling Lemma, the No Concentration at the Identity Corollary and the One-Link Wilson Weight Proposition are statements with proofs placed. What they speak of is the convexity of one measure on one manifold; about the convexity of the conditional measure on the fibre (a measure on the product of many links) they speak only through the estimate of § 05.

04

The convex and non-convex places are reversed — the wall goes to where the probability is small

For ϕ^4 on flat space (of the type of the one-site $V(\phi) = \lambda(\phi^2 - v^2)^2$), $V''(\phi) = 4\lambda(3\phi^2 - v^2)$ is negative only for $|\phi| < v/\sqrt{3}$. What is not convex is **small fields** (near the summit between the two wells), and at **large fields** V grows like ϕ^4 and is convex. Bauerschmidt–Bodineau wrote "convexity at large fields" as the issue because one needs to show uniformly that the effective potential after renormalisation stays convex at large fields too.

On the group it is the reverse. As in (i) of the One-Link Wilson Weight Proposition, near the identity (small fields, $\theta < \pi/2$) $\mathrm{Hess}\, V_\beta > 0$ and it is close to Gaussian, while on the far hemisphere (large fields) $\mathrm{Hess}\, V_\beta < 0$. This is not peculiar to the Wilson weight. A smooth function on a closed manifold has a maximum point, and at a maximum point $\mathrm{Hess}\, V \le 0$. **The non-convex place at large fields always exists, for topological reasons** Proved here . On the other hand, as in (iii) of the One-Link Wilson Weight Proposition, the probability of being there is of order $e^{-\beta}$.

```
Figure 1  Convex and non-convex places
          (horizontal axis: size of the field; |φ| for φ⁴, angle θ from the identity for

  φ⁴ (flat space):
     |φ| small ———————— |φ| ≈ v ———————————— |φ| large
     non-convex (summit)   bottom of well (convex)   convex (grows like φ⁴)
     → the non-convex place is "small fields".
       Its probability is set by the frequency of crossing between the wells

  SU(2) (closed sphere):
     θ small ———————————— θ = π/2 ———————————— θ = π (antipode)
     convex (near Gaussian)  boundary             non-convex (always, at the maximum)
     → the non-convex place is "large fields".
       Its probability is of order e^(−β) (the One-Link Wilson Weight Proposition)
```

The wall does not vanish; it is pushed into a place of small probability. On flat space, tools that avoid the non-convex summit were conceivable (imposing convexity at large fields, treating small fields separately). On the group the non-convex place cannot be avoided (the Convexity Ceiling Lemma), but in exchange its probability is exponentially small (the One-Link Wilson Weight Proposition). So tools on the group must push with probability, not with convexity Estimate .

An example where the rate of rarity was measured. On the width-2 strip of two-dimensional $U(1)$, the slope of the raw rate of wrapping of a single plaquette (a rare event that crosses a barrier of height 2β) matched the slope $2 - 1/\beta$ of the Kramers rate $\beta e^{-2\beta}$ to 1–3% ($\beta = 3..6$, outer boundary frozen, a post-hoc check, 24-02 § 05) Reading . The relation between this number and renormalisation on the group is an estimate.

The smallest example where rarity cannot be paid with local quantities. For the 0+1-dimensional double well, even for the shortest window (a single time) the local ratio is not 1 but exactly $\omega b/m$ ((7) of 24-03, 24-04 § 07) Proved here (Lean LatticeGauge.LocalHDoubleWell.one_slice_ratio, assumptions: $0 < \varepsilon$, $0 < m$, $0 < \omega$. The bundle guarantees only the algebra). The influence of the non-convex summit remains in the ratio however short the window is made. The implication for the group is an estimate Estimate .

What this section can say: that the non-convex place always exists for topological reasons, and the upper bound (5) on its probability, have proofs. "Must be tools that push with probability" is an estimate.

05

Carrying the hierarchical induction over to the group — applies, changes, does not apply

The model. As a four-dimensional hierarchical gauge model, we consider the lattice on which the recursion of the Migdal–Kadanoff approximation holds exactly (Ito 1984 Cited). Setting the couplings of the vertical plaquettes to 0 or ∞ place by place, the recursion of the plaquette weight g can be written down in the form $g \mapsto (g^{*4})^4$ (a convolution gluing four together, and a power stacking four). It is stated that for four-dimensional $SU(N)$ every coupling flows to strong coupling and confines (Ito 1985 Cited (abstract)). This model lacks translation and rotation invariance, and its theorems are not part of the statement of the four-dimensional Yang–Mills

problem. That the type of relaxation changes with the choice of coordinates to move was seen in 24-02 § 02 (in tree coordinates the gap of the Gaussian approximation is exactly β, independent of the number of steps; in link coordinates it gets smaller in inverse proportion to the square of the side).

Table 1 carries the parts of the Bauerschmidt–Bodineau induction over, row by row, to this model with values in the group $SU(2)$. "Applies" means the form holds as it is, "changes" means there is a corresponding form but its content is replaced, and "does not apply" means it does not hold; apart from the row of the Convexity Ceiling Lemma, these are estimates.

Table 1 Carrying the parts of the hierarchical induction over to $SU(2)$ (verdict labels: Proved here = from the Convexity Ceiling Lemma, Estimate = an estimate)

Part in the original	Carried over to the group	Verdict
The decomposition of the covariance $C = \sum C_j$ and the addition of fields $\phi + \zeta$	Addition is replaced by the group product, and the reference Gaussian by Haar. The role of "the covariance at scale j" is played by the stiffness of the weight (the supremum of the Hessian of $-\ln g$), and there is an inequality of the type in which the inverses of the stiffnesses roughly add under convolution (a paper record; no proof is placed in this book)	Changes Estimate
(A1) uniform convexity at each point	Read as Bakry–Émery for the measure on the fibre, it does not hold at weak-coupling scales by the Convexity Ceiling Lemma	Does not apply Proved here (the Convexity Ceiling Lemma) + the reading is Estimate
Convexity at large fields (the main issue of the original)	On the group, large fields (the far hemisphere) are necessarily non-convex (§ 04). But the probability is $e^{-c\beta}$	Changes (the wall becomes unavoidable, and goes to where the probability is small) Estimate
(A2)(A3) coupling and commuting of scales	In tree (plaquette) coordinates, automatic from the hierarchical structure. In link coordinates the Dirichlet form is not diagonal in the hierarchy, and commuting is expected to break	Tree: applies / link: expected not to apply Estimate
Lemma 2.7 (Brascamp–Lieb for the conditional measure from convexity)	For typical coarse values, the minimal broken line on the fibre is unique and the gap is of order β. When the coarse value is near -1, the geodesics from the identity to -1 form a family of two-dimensional spheres, and the gap in that direction is expected to drop to $O(1)$. Long arcs are expected to be saddle points, not a second well	Changes (convexity cannot be used, but the loss is expected to be polynomial) Estimate
Lemma 2.8 (an identity that turns the derivative in the direction of the coarse field into a covariance by parallel translation of the fluctuation and integration by parts)	Translating the last factor of each copy from the right moves the coarse holonomy by the same amount, and by the invariance of Haar an identity of the same type holds. The difference is that the score is bounded rather than linear in the field	Applies (in form) Estimate
Lemma 2.9 (the Helffer–Sjöstrand representation and an operator lower bound on the Witten Laplacian)	On a manifold, $\mathrm{Ric} + \mathrm{Hess}\, V$ enters the Witten Laplacian on one-forms. What is needed is a lower bound at each point, and for the same reason as (A1) it does not hold at weak coupling	Does not apply Estimate

Part in the original	Carried over to the group	Verdict
Multiscale Bakry–Émery (the Polchinski flow; the coefficient $\dot\lambda_t$ may be negative)	The natural semigroup on the group is convolution with the heat kernel, $V_t = -\ln(e^{-V} * K_t)$. The convolution step of Migdal–Kadanoff is its discrete version. What is needed is $\inf \mathrm{Hess}\, V_t$ (from below), and a formulation on the group was not found within the range searched	Changes (not yet formulated) Estimate

In sum. The decomposition of the variance and identities of the type of Lemma 2.8 hold on the group too. What does not hold is the two places that use convexity **at each point** (Lemmas 2.7 and 2.9), and by the Convexity Ceiling Lemma they do not hold at weak-coupling scales however the constants are arranged. The wall of "convexity at large fields" in the original does not vanish on the group but becomes unavoidable, while the probability on the wall drops to $e^{-c\beta}$ Estimate .

The Polchinski flow on the group. Theorem 3.6 of the review by Bauerschmidt–Bodineau–Dagallier, along a flow C_t of Gaussian covariances, derives from the condition

$$\dot C_t\ \mathrm{Hess}\, V_t(\phi)\, \dot C_t - \tfrac{1}{2}\ddot C_t\ \geq\ \dot\lambda_t\, \dot C_t \quad (\text{for all } \phi), \qquad \frac{1}{\gamma} = \int_0^\infty e^{-2\lambda t}\, dt \ \text{(6)}$$

the log-Sobolev constant $2/\gamma$ Cited . $\dot\lambda_t$ may be negative, and non-convex time intervals are paid for as the swelling $e^{-2\lambda t}$. A version for curved spaces (a form including the flow of the metric and Ric, Theorem 3.20) is also stated, and the original writes that "we currently do not know interesting applications of this generalisation" Cited . It is a candidate home for group-valued fields Estimate . Written on the group, the natural semigroup for this flow is convolution with the heat kernel, $V_t = -\ln(e^{-V} * K_t)$, and what is needed is an estimate of $\inf \mathrm{Hess}\, V_t$ from below. The estimates of the Migdal–Kadanoff recursion so far (the recursion of the stiffness; the paper record that the number of steps until strong coupling is entered is at most $\beta + 4\log\beta + 20$ Assumption (no proof placed in this book)) are all estimates from above ($\sup \mathrm{Hess}$), and the quantity that connects the two is the flow of $\inf \mathrm{Hess}\, V_t$. In weak-coupling time intervals $\inf \mathrm{Hess}\, V_t \approx -\beta$ (the antipode), and how much $e^{-2\lambda t}$ swells has not been estimated Estimate . The first number is one step of the one-link weight (the question "Hessian of the one-link weight", 24-08).

The $\frac{1}{4}$ type does not come back for one link. $e^{(\beta/2)\,\mathrm{tr}\, U}\, d\mathrm{Haar} = e^{\beta\cos\theta}\, d\mathrm{Haar}$ has a single well ($\theta = \pi$ is the minimum of the density; there is no second local minimum), and the gap is expected to approach the Hessian β at the identity for large β, without getting exponentially worse Estimate (general semiclassical theory. The original on uniform log-Sobolev for Boltzmann measures with a field on spheres is known only bibliographically, and has not been checked). The wall of the $\frac{1}{4}$ type at the summit of the double well (two wells) does not appear for one link. On the fibre, the degenerate family where the coarse value is near -1 is expected to produce a polynomial loss (Table 1).

What this section can say: the verdicts of Table 1, apart from the row of the Convexity Ceiling Lemma, are estimates. The results for hierarchical models have no implication for four-dimensional Yang–Mills under any verdict.

> 06

> **Tools that pay with rarity — currency, Lyapunov, field-dependent constants, the example of the action barrier**

Currency. The currency-mix-up type of 23-10 in Part 23 said that what the Poincaré inequality measures is the speed of exit, and that what can pay with rarity is the currency of entropy (23-10 currency-mix-up type). As a formula, when a set B satisfies $\mu(B) \le e^{-s}$,

$$s \int_B g^2 \, d\mu \;\le\; \mathrm{Ent}_\mu(g^2) + \ln 2 \int g^2 \, d\mu \quad (7)$$

Proved here ((3) of 23-09). The ratio of the variance to the Dirichlet form does not change when the function is multiplied by a constant, so if a function supported on a rare set is put in, the rarity cancels between numerator and denominator, and at the Poincaré step rarity has no effect. **A step that pays with rarity needs to pass through an inequality of log-Sobolev (entropy) type**. This is why the candidate tools on the group are not the Poincaré induction (Brascamp–Lieb at discrete scales) but the type that flows Bakry–Émery at each scale in log-Sobolev form ((6) of § 05) Estimate .

The Holley–Stroock perturbation. If $\mu' = e^{-U}\mu/Z$ with U bounded, the Poincaré constant (and the log-Sobolev constant) of μ' is at most $e^{\operatorname{osc} U}$ times that of μ Assumption (the standard form as remembered; the original has not been checked in this chapter). It is a tool that pays for the non-convex place with the "oscillation", and the cost is exponential in the oscillation, independent of rarity. Regarding the one-link Wilson weight as a perturbation of Haar, $\operatorname{osc} U = 2\beta$, and the loss is $e^{2\beta}$. In Part 23, the plan to pay only for the summit band with this perturbation (the detour plan "perturbing only the summit band") put the one-site oscillation $\operatorname{osc}/\hbar = 3.7/11/37$ into the exponent, multiplied by the length along the chain, and came out 2000–4900 times outside the allowance (23-10 § 03, type of the address of 1/ħ) Reading .

Lyapunov conditions. For a generator L, if there are $W \ge 1$ and a good set G with

$$LW \;\le\; -a\,W + b\,\mathbf{1}_G \qquad (a > 0,\ b \ge 0) \quad (8)$$

(a drift that returns from the bad set to the good set), and a local Poincaré inequality (constant C_G) holds on G, then the global Poincaré constant is at most $(1 + bC_G)/a$ Cited (of the type of Bakry–Barthe–Cattiaux–Guillin 2008. The statement was checked through a restatement in a secondary source, 23-14 § 03. The positive control on the one-dimensional Gaussian is row 20 of 23-14 § 04). Convexity is used only on the good set G, and the bad set is paid for by "the speed of coming back". On the group it is natural to take the good set near the identity and the bad set on the far hemisphere, and the loss is expected to be polynomial Estimate . However, (8) is a Poincaré conclusion, not a form that uses rarity itself. To use rarity, a step that moves the type of (8) into log-Sobolev form (the currency of entropy) is needed Estimate .

Field-dependent constants. Bauerschmidt–Bodineau write in Remark 2.4 that ε in (A1) may be made to depend on the coarse field, $\varepsilon = \varepsilon(\phi)$ (but uniformly less than 1), and add that it is "hard to use" Cited . It is a direction that allows ε to be large at bad coarse fields, but as long as it must be uniformly less than 1, it does not get past the ceiling of the Convexity Ceiling Lemma. To get past it, the condition must be replaced by one in the form of an **average weighted by the probability** of bad fields Estimate .

An example where rarity paid — the margin of the action barrier. In the first step of Part 23, when the end of the core on the box side of the Gap-Inside-the-Box Proposition crossed the summit, a second minimum point appeared on the wall of conditioning, and the Poincaré constant of the core grew like $e^{\Delta S/\hbar}$ (23-11 § 06). This is the cost of the non-convex place inside the core. That cost is paid by the rarity $D/(C\xi)^2 \le d e^{-2S_0/\hbar}$ carried by the local term of the Gap-Inside-the-Box Proposition (the rarity of creating a pair of kinks): under the core action-barrier assumption $C_P \le c_* \hbar^{-p} e^{\Delta S_*/\hbar}$ and the reading of ξ, the local term vanishes like $e^{-(2S_0-\Delta S_*-\delta)/\hbar}$ Proved here ((12) of 23-11. Lean LatticeGauge.CoreActionGap.cloc_term_poly, cloc_term_vanishes, assumptions: the core action-barrier assumption, the reading of ξ, $\Delta S_* < 2S_0$). On the $\hbar = 0$ reading, $\Delta S_*^0 \le 1.4 \times 10^{-2}$, its ratio to $2S_0 = 4/3$ is at most 1.05×10^{-2}, and the margin was about 95 times Reading (Lean LatticeGauge.CoreActionGap.measured_ratio, assumption: the measured upper bound $\Delta S^0 \le 0.01401$; the conclusion is in the form of the ratio $\le 1.06 \times 10^{-2}$). Rather than removing the non-convex place by convexity, it is paid by a stronger factor of rarity: this is a small real example of the type of this chapter. However, the core action-barrier assumption itself is an assumption row, supported only by the $\hbar = 0$ reading and the lower bound on $\hbar \ln C_P$.

Table 2 How to pay for the non-convex place (what pays, and what it costs)

Way of paying	What pays	Form of the cost	For one-link $SU(2)$	Label
Convexity (Bakry–Émery, Brascamp–Lieb)	A lower bound on the curvature at every point	The inverse of the lower bound	Usable only for $\beta < 2$ (the One-Link Wilson Weight Proposition). Impossible in principle at weak coupling by the Convexity Ceiling Lemma	Proved here
The Holley–Stroock perturbation	The oscillation of the potential	e^{osc}	$e^{2\beta}$: an exponential loss	Assumption (from memory)
Lyapunov condition (8)	A drift returning from the bad set, and a local constant on the good set	$(1 + bCG)/a$	If the good set is taken near the identity, the loss is expected to be polynomial	Cited (type), Estimate (application to the group)
The currency of entropy (7)	The rarity s of the bad set	Works in the form $1/s$	$s \approx \beta$ ((5) of the One-Link Wilson Weight Proposition). At the confinement scale it becomes $s = O(1)$ and runs out	Proved here (inequality), Estimate (running out)
Paying with a strong factor of rarity (the margin of the action barrier)	A rarity $e^{-2S_0/\hbar}$ stronger than the cost $e^{\Delta S_*/\hbar}$	The margin $\Delta S_* < 2S_0$	The example of the first step (0+1 dimensions). The counterpart on the group is undecided	Proved here (algebra), Reading (margin), Assumption (the core action-barrier assumption)

What this section can say: (7) and the algebra of the action barrier have proofs; the Lyapunov condition is a type whose statement was checked in a secondary source; Holley–Stroock is the standard form from memory. Which of them works on the group, and with what loss, is an estimate.

07

If it were made into rules — the class of measures that pay with rarity

Let us try to rewrite what we have seen in this chapter in the form of rules. It is an attempt that follows the phrasing of the question "if new mathematics is to be made, what should be made the rules of the mathematics?", and the rules written here are **candidates**. Neither consistency nor the ability to restate existing results has been checked. None of them promises a prospect of closing the third step (the continuum limit and the OS axioms) Estimate . Other candidates (axiomatising scale, the algebra of loops, conserved quantities and sectors, an axiom of asymptotic freedom, rules for curvature) and a list of combinations are placed in 24-08 § 02.

Candidate: the class of measures that pay with rarity

Objects. A pair of a probability measure $\mu = e^{-V}\,d\mathrm{vol}/Z$ on a compact Riemannian manifold M (a product of groups) and a good set $G \subset M$. The parameters $(\kappa_{\mathrm{BE}}, s, a, b)$ define the class $\mathcal{C}(\kappa_{\mathrm{BE}}, s, a, b)$.

Candidate rules. Rule of local convexity — locally convex on the good set: $\mathrm{Ric} + \mathrm{Hess}\, V \geq \kappa_{\mathrm{BE}} > 0$ on G. Rule of rarity of bad sets — $\mu(M \setminus G) \leq e^{-s}$. Rule of return drift — a drift returning from the bad set: the type (8), $LW \leq -aW + b\mathbf{1}_G$. Rule of paying for entropy — rarity is paid only through the entropy inequality (7) (the class is defined by quantities of log-Sobolev type, not Poincaré). Rule of closing under coarse-graining — convolution with the heat kernel on the group, $V_t = -\ln(e^{-V} * K_t)$, maps the parameters as $(\kappa_{\mathrm{BE}}, s, a, b) \mapsto (\kappa'_{\mathrm{BE}}, s', a', b')$ by an explicit recursion.

A constraint, not a rule. By the Convexity Ceiling Lemma, a class that places the rule of local convexity on the whole of M is empty for weights whose $\operatorname{osc} V$ exceeds $KD^2/2$ (π^2 for one-link $SU(2)$). For the one-link Wilson weight it is empty for $\beta > \pi^2/2$. **The bad set always exists.**

The rule of paying for entropy makes the currency type of Part 23 into a rule (23-10 currency-mix-up type: Poincaré is the speed of exit, rarity is the currency of entropy).

Candidate first theorems. (a) For one measure: if $\mu \in \mathcal{C}$, the log-Sobolev constant is at most $F(\kappa_{\mathrm{BE}}, s, a, b)$, and F is not exponential in s. On flat space the type that combines a Lyapunov condition with a local inequality corresponds to this (§ 06), and the Holley–Stroock perturbation pays e^{osc}. (b) Closure: applying one step of the heat kernel to the one-link Wilson weight of $SU(2)$ stays in the class, with $s' \geq s - O(1)$. This is the first step of the question "Hessian of the one-link weight" (24-08 § 01). For class functions (functions of the single variable, the angle θ from the identity), convolution with the heat kernel only multiplies the coefficients of the character expansion by exponentials of the Casimir values, so how the lower bound on the curvature on the good set and the weight of the bad set are carried over can be followed by one-variable paper calculation and small numerics Estimate .

Parts that already exist. On flat fields, the weight (regulator) $\tilde{G}(X, \phi)$ of the appendix of the book by Bauerschmidt–Brydges–Slade has four properties — product factorisation (it factorises over disjoint sets), submultiplicativity in sums of fields $\tilde{G}(X, \phi + \phi') \leq \tilde{G}^2(X, \phi)\, \tilde{G}^2(X, \phi')$, closure under the fluctuation expectation $\mathbb{E}_+ \tilde{G}^t(X) \leq 2^{|B(X)|}$, monotonicity to the next step $\tilde{G}^t \leq \tilde{G}_+ -$

and from them the one-step estimate $\|\mathbb{E}_+\theta K(X)\|_{\tilde{G}_+} \le 2^{|B(X)|}\|K(X)\|_{\tilde{G}}$ follows (the One-Step Bound on the Activity Norm (Lemma A.6.1 of BBS)) Cited . It is a real example of **writing the rarity of large fields as a weighted norm and closing it under the expectation of one step of coarse-graining**. What is needed on the group is the group version of this "closing in one step", and the place where submultiplicativity in sums of fields ((ii) of BBS) uses **addition** of fields is replaced by the group product u_1u_2. The multiscale Bakry–Émery of Bauerschmidt–Bodineau–Dagallier ((6) of § 05, $\dot{\lambda}_t$ may be negative) and its version for curved spaces (Theorem 3.20) are also candidate parts Cited . The entropy stability lemma (a form that takes an upper bound on the covariance as its condition instead of the pointwise Hessian, Lemma 3.21) uses a linear tilt $e^{(h,\zeta)}$, so it does not carry over directly to the group Estimate .

Combining with one step of coarse-graining — the coupling window. Combining this class with axiomatising scale (a semigroup of coarse-grainings and a flow on it), one can write a form in which the coarse-graining kernel maps the class at each step, $\mathcal{C}_j = \mathcal{C}(\kappa_j, s_j, a_j, b_j)$, as $\mathcal{C}_j \to \mathcal{C}_{j+1}$. A candidate first theorem is "in a finite box, on the ultraviolet side, as long as the effective coupling β_j is at least β_*, the class closes in the form $s_{j+1} \ge s_j - c$, $\kappa_{j+1} \ge \kappa_j(1 - c/\beta_j)$" Estimate . Where it has closed, the effective measure has a uniform log-Sobolev inequality, and from there it can be handed over to the tools of the strong-coupling side (the type that pays with the Ricci curvature of the group; the result of Shen–Zhu–Zhu giving log-Sobolev and the mass gap at small β Cited (abstract)). But the rate of rarity s_j is proportional to the effective coupling ($s \approx \beta$ by (5) of the One-Link Wilson Weight Proposition), and it runs out at the confinement scale when $\beta_j = O(1)$. The currency of curvature works only in a narrow range. **Between the two, a coupling window remains where neither currency is enough**. This window is a restatement in the language of rules of the second difficulty of the third step — that there is no expansion connecting the ultraviolet and the infrared — and is not a new obstacle (24-07 § 06, 24-07 Table 3) Estimate .

In the hierarchical gauge model (§ 05), the number of steps before the static flow enters strong coupling is finite, and the three — the ultraviolet side, the window and the strong-coupling side — come together within one model. If the candidate rules are to be tried first, it is on this model. However, the static flow there is a one-variable recursion with no many-body remainder, so crossing the window is easy because of the structure of the model, and the results imply nothing for four-dimensional Yang–Mills Estimate .

Relation to the roots Estimate . Of the three roots of the third step (24-07 § 05), the one this class addresses head-on is the third (there is no global gauge fixing, and large fields cannot be controlled by convexity). This is because it places an alternative class where the Convexity Ceiling Lemma says "on the group the convexity class is empty". It addresses the first (uniformity in the number of steps) only when combined with axiomatising scale, and the key is whether the recursion of the rule of closing under coarse-graining gives constants uniform in the number of steps. It does not address the second (connecting the ultraviolet and the infrared) — the coupling window above is the shape of that failure.

What this section can say: the rules are candidates, and the candidate theorems are candidates. The existing parts (the four properties of the weight and the One-Step Bound on the Activity Norm, multiscale Bakry–Émery) hold only within the conditions of their originals (flat fields, hierarchical, flows of Gaussian covariances).

08

The road of stochastic quantisation — subcriticality, and the direction of rebuilding where the objects live

Stochastic quantisation is the road that makes the Yang–Mills measure as the long-time limit of a Langevin dynamics (a stochastic partial differential equation) that has it as its invariant measure (7-09). The dynamics is of the same kind as the Langevin dynamics measured by this book's CP, but the aim is the **construction of the measure**, and the speed of relaxation (the relaxation-time assumption) is not asked about.

The key condition of the solution theory of regularity structures is subcriticality, and it holds only when $d < 4$ (§ 1.2 of Chevyrev's review Cited). In two dimensions, a Polish state space on the space of gauge orbits and a Markov process have been made, and the Yang–Mills measure has been shown to be its invariant measure (Chandra–Chevyrev–Hairer–Shen, Chevyrev–Shen Cited (abstract)). In three dimensions, it has reached a new state space, the space of one-forms smoothed by the heat flow, local-in-time solutions and gauge-covariant renormalisation; the three-dimensional Yang–Mills measure is not yet constructed even on the periodic box $\mathbb{T}^3$ (§ 1 and § 4 of Chevyrev's review Cited).

This road goes not in the direction of extending the lattice renormalisation group, but in the direction of **rebuilding where the objects live (the state space) and the means of construction (stochastic dynamics)** (24-07 § 05) Estimate . However, the condition of subcriticality shows that this new tool too becomes exactly critical in four dimensions. It is one manifestation of the coupling being dimensionless ((c) of 24-07 § 01). This road gives tools neither for the four-dimensional relaxation-time assumption nor for the local relaxation-time assumption.

What this section can say: the condition of subcriticality and the three-dimensional non-construction are statements in the text of the review; the individual two- and three-dimensional results are copies from abstracts. This book does not use regularity structures as a tool.

09

What cannot be said

(a) Hierarchical models. The results for hierarchical models imply nothing for four-dimensional Yang–Mills (they lack translation and rotation invariance). The verdicts of Table 1 are also estimates within the hierarchical model.

(b) The Polchinski flow on the group. No source formulating the flow by convolution with the heat kernel up to the multiscale Bakry–Émery condition was found within the range searched (this is not "there is none").

(c) The fibre. That the gap in the direction of the degenerate family near coarse value -1 drops to $O(1)$, and that long arcs are saddle points, are estimates (by analogy from the Morse index of continuous geodesics).

(d) Dynamics. Statements on the gap or log-Sobolev for Glauber dynamics or Langevin dynamics of hierarchical gauge models were not found within the range searched.

(e) The kind of the original. The induction of Bauerschmidt–Bodineau 2019 is a result of Poincaré type (a spectral gap), not a log-Sobolev result. The form that flows log-Sobolev is later work by the same authors and a theorem of the review.

(f) Candidate rules. The class of § 07 is a candidate, and none of consistency, restating existing results, or the candidate theorems has been checked. "The coupling window is a restatement of the source "no expansion linking scales"" is an estimate, and the width of the window has not been measured in any model.

(g) The example of the action barrier. The margin of 95 times is a $\hbar = 0$ reading in 0+1 dimensions, and the core action-barrier assumption is an assumption row. We say nothing about whether renormalisation on the group has a margin of the same form.

(h) Stochastic quantisation. That four dimensions is critical is not a proof that tools cannot be made in four dimensions. It only copies the statement of the conditions of the original.

10

Table of the five grades and the dependency graph

Table 3 The rows of this chapter ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	Bakry–Émery (1)	Cited	Theorem 3.6 of the review	Lower bound on the curvature at each point	—
2	(A1) of the hierarchical induction, Theorem 2.1 and Corollary 2.2 (2)	Cited	§ 02	Scalar, hierarchical	—
3	The one-site diagonal at the summit $\frac{15}{4}$ and the sum of couplings 4	Proved here	(11) of 23-09	0+1, $\varepsilon = \frac{1}{2}$	—
4	Convexity Ceiling Lemma: $\operatorname{osc} V \le K D^2/2$ (3)	Proved here	Proof in § 03	Compact manifold without boundary	— (the one-dimensional version is a candidate)
5	No Concentration at the Identity Corollary: if convex on $SU(2)$ then $\mu \le e^{\pi^2}$ Haar (4)	Proved here	Proof in § 03	Unit S^3	—
6	One-Link Wilson Weight Proposition: for one link $(2 + \beta \cos\theta) g$, $\beta < 2$, (5)	Proved here	Proof in § 03	$\beta \ge 2$ ((5))	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
7	At a maximum point of a closed manifold $\operatorname{Hess} V \leq 0$	Proved here	§ 04	—	—
8	The raw rate of wrapping on the strip matches the Kramers slope to 1–3%	Reading	24-02 § 05	Two-dimensional $U(1)$, $\beta = 3..6$, post hoc	—
9	The 0+1 one-site ratio ω_b/m	Proved here	(7) of 24-03, 24-04 § 07	0+1	`LatticeGauge.LocalHDoubleWell.one_slice_ratio` (assumption: $0 < \varepsilon, m, \omega$)
10	Read as Bakry–Émery on the fibre, (A1) on the group does not hold at weak coupling	Estimate	§ 02, § 05	Weak-coupling scales	—
11	The verdicts of Table 1	Estimate	Table 1	Hierarchical model	—
12	Multiscale Bakry–Émery (6), the version for curved spaces	Cited	Theorems 3.6 and 3.20 of the review	Flows of Gaussian covariances	—
13	The number of steps until the hierarchical model enters strong coupling $\leq \beta + 4 \log \beta + 20$	Assumption	Paper record (no proof in the book)	Migdal–Kadanoff, $SU(2)$	—
14	A wall of the $\frac{1}{4}$ type does not come back for one link	Estimate	§ 05	One link	—
15	The currency inequality (7)	Proved here	(3) of 23-09	—	—
16	The cost e^{osc} of the Holley–Stroock perturbation	Assumption	Standard form from memory	—	—
17	$(1 + bCG)/a$ from the Lyapunov condition (8)	Cited	Secondary source (23-14 § 03)	—	Positive control `gauss1d_bbcg` (no assumptions, 23-14)
18	Field-dependent $\varepsilon(\phi)$ (uniformly less than 1)	Cited	Remark 2.4 of the original	—	—
19	Core action-barrier assumption	Assumption	23-11 § 06	0+1, the core on the box side	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
20	$\Delta S_*^0 \le 1.4 \times 10^{-2}$, a margin of about 95 times	Reading	23-11 § 06	The $\hbar = 0$ reading	`LatticeGauge.CoreActionGap.measured_ratio` (assumption: the measured upper bound)
21	The local term vanishes like $e^{-(2S_0 - \Delta S_* - \delta)/\hbar}$	Proved here	(12) of 23-11	$\hbar \to 0$	`LatticeGauge.CoreActionGap.cloc_term_poly`, `cloc_term_vanishes` (assumptions: the core action-barrier assumption, the reading of ξ, $\Delta S_* < 2S_0$)

25	Log-Sobolev and the mass gap at strong coupling	Cited	Shen–Zhu–Zhu (abstract)	Small β	—
26	The coupling window is a restatement of the source "no expansion linking scales"	Estimate	§ 07, 24-07 § 06	—	—
27	The solution theory is subcritical for $d < 4$; the three-dimensional measure is also not yet constructed	Cited	Chevyrev's review	—	—
28	The road of stochastic quantisation gives no tools for the four-dimensional relaxation-time assumption	Estimate	§ 08	—	—

What the machine-checking column guarantees is only real algebra and arithmetic; that ΔS is the action barrier of the core, and that CP is the Poincaré constant of the path measure, are outside Lean (23-13). The Convexity Ceiling Lemma, the No Concentration at the Identity Corollary and the One-Link Wilson Weight Proposition have no machine checking.

The way to check is to see by eye that on every "⟸" the numbers on the right are smaller than the number on the left. There are no circles. The nodes with proofs placed are four — the Convexity Ceiling Lemma, the No Concentration at the Identity Corollary, the One-Link Wilson Weight Proposition, and the maximum point on a closed manifold — all statements about one measure on one manifold. The nodes on the conclusion side of this chapter (tools on the group push with probability, the class of measures that pay with rarity, the restatement as the coupling window, the note on stochastic quantisation) are all Estimate, and there is neither a node for the mass gap nor a node for the relaxation-time assumption. The node where the local term vanishes (an example where rarity paid) is algebra on top of the core action-barrier assumption, and does not enter the premises of the nodes on the conclusion side. This is because the 0+1-dimensional example is an example of the type, not grounds for a statement on the group.

What this chapter can say

What is said	What is not said
Proved here The convexity ceiling on closed manifolds (the Convexity Ceiling Lemma); a convex measure on $SU(2)$ does not exceed e^{π^2} times Haar (the No Concentration at the Identity Corollary); the curvature of the one-link Wilson weight, and the upper bound on the probability of the non-convex set (the One-Link Wilson Weight Proposition)	The convexity and gap of the conditional measure on the fibre (a product of many links). The value of the gap in the direction of the degenerate family
Cited Bakry–Émery; the hypotheses and conclusions of the hierarchical induction; multiscale Bakry–Émery; the four properties of the weight and the One-Step Bound on the Activity Norm; the subcriticality of stochastic quantisation	A formulation of the Polchinski flow on the group. The gap of the dynamics of hierarchical gauge models
Proved here + Reading The margin of the action barrier in Part 23 is an example where the non-convex place was paid with rarity (on the core action-barrier assumption and the $\hbar = 0$ reading)	The core action-barrier assumption itself. That the same margin exists on the group
Estimate That tools on the group must push with probability; the verdicts of Table 1; the class of measures that pay with rarity (candidate); that the coupling window is a restatement of the lack of an expansion linking scales	None of these is a theorem. The implication of hierarchical-model results for four dimensions. The consistency of the candidate rules

Terms used in this chapter — the convexity ceiling, the lower bound on the Bakry–Émery curvature κ_{BE}, Brascamp–Lieb, fibre, the reversal of convex and non-convex places, the rate of rarity s, currency (entropy), the Holley–Stroock perturbation, Lyapunov conditions, field-dependent constants, the Polchinski flow on the group, the class of measures that pay with rarity, the coupling window, subcriticality. Their meanings are in A-02 Glossary and 24-09.

Next chapter to read: 24-07 Because it is four dimensions — what works in four dimensions, limited to two points: the dimensionless coupling and topology.

Because it is four dimensions — the dimensionless coupling and topology

> This chapter organises established knowledge. § 03, § 04, § 06 and § 07 are a map of open questions.

What this chapter shows — We state what works in four dimensions, limited to two points: that the coupling is dimensionless (the critical dimension, dimensional transmutation, the opposite directions of asymptotic freedom for ϕ^4_4 and for Yang–Mills), and that there are topological configurations with no scale (instantons and the topological charge). Putting the two points together gives the estimate that the slow quantity and the correlation length split into different origins. Next, for each of the four steps of the staircase of Part 23, we put the hurdle, the known reach, whether the tools of this book reach it, and the kind of cost into one table, and state why the third step (the continuum limit) stayed open so long, through the three sources of difficulty and the descriptions in primary sources (for the existence part of the third step, the committee's assessment is that the construction published on 2026-11-10 has shown it; we read it in Volume 2). On topology, we set the range in which the relaxation-time upper-bound assumption reads as false on a periodic box, and the fact that for this book's group $SU(2)$ it is undecided whether freezing breaks the diffusive-relaxation-time assumption, beside the two-dimensional test bed of 24-02. We add, one line each, why the non-perturbative mechanisms of physics are not proofs.

Prerequisite chapters — 23-03 § 02 (the definition of the four steps) and 23-03 § 06 (the prospect of lifting and the reasons it does not lift), 23-15 § 07 (the distance from the second step on), 23-16 (what is not claimed), 23-01 § 05 (the note on the relaxation-time assumption and topological sectors), 4-07 (dimensional transmutation), 7-07 (Balaban and MRS), 24-01, 24-02. Notation is in 24-09.

Said first — The level is [Y3]. We state the two points not as "things that happen only in four dimensions" but as properties of a theory being at its critical dimension. The reading that puts the two points together is an estimate Estimate . "Does it reach" and the costs in the table of the four steps are estimates and guesses. § 05 is an arrangement of the descriptions in the primary sources read, and the text of Balaban's papers was not obtained (we go through the bibliographic data and the descriptions in other sources). This chapter shows neither the mass gap nor the construction of the continuum limit.

The order of this chapter

1. That the coupling is dimensionless — the critical dimension, dimensional transmutation, asymptotic freedom in the opposite direction ((1)(2), Figure 1)
2. Topological configurations with no scale — instantons, and two ways of counting the weight of dislocations ((3), Table 1)
3. An estimate that puts the two points together — the slow quantity and the correlation length split into different origins
4. The four hurdles — step, hurdle, known reach, does it reach, cost (Table 2)

5. Why the third step stayed open so long — the three sources of difficulty, the object, tools, theory, history (Table 3)
6. A paragraph on candidate rules — the "coupling window" is a restatement of the source "no expansion linking scales"
7. Topology and the box — undecided for $SU(2)$ — the periodic box, open boundaries, correspondence with the two-dimensional test bed
8. Physical mechanisms, and why they are not proofs — Table 4
9. What cannot be said
10. Table of the five grades and the dependency graph — Table 5

01

That the coupling is dimensionless — the critical dimension, dimensional transmutation, asymptotic freedom in the opposite direction

This section summarises existing knowledge (the critical dimension, dimensional transmutation, asymptotic freedom). The introduction is in 4-07 § 02.

Writing the action of d-dimensional Yang–Mills as

$$S = \frac{1}{4g^2}\int d^d x \ \operatorname{tr} F_{\mu\nu}F^{\mu\nu}, \qquad [g^2] = (\text{length})^{\,d-4} \quad (1)$$

the coupling g^2 is exactly dimensionless in four dimensions Cited (dimension counting. On the lattice, by Wilson's heuristic, $\beta \propto \varepsilon^{4-d}$, and in four dimensions β does not depend on the lattice spacing ε; § 3 of Chatterjee's review). In three dimensions or fewer, g^2 has the dimension of a negative power of length, and the interaction weakens like a power at short distances (super-renormalisable). In five dimensions or more it strengthens instead (non-renormalisable). In exactly four dimensions, the correction from each change of scale does not shrink like a power, and remains at the size of g^2. In the language of power counting, a quartic monomial in four dimensions is neither relevant nor irrelevant but marginal (Definition 5.2.1 of the book by Bauerschmidt–Brydges–Slade Cited).

Dimensional transmutation. In the non-abelian case, the sign of that correction points to the side "weaker at shorter distances" (asymptotic freedom, 4-06). The action has no ruler of length, yet on quantisation, at one loop,

$$\Lambda = \mu\,\exp\!\Big(-\frac{1}{2b_0\,g^2(\mu)}\Big), \qquad b_0 = \frac{11N}{48\pi^2} \quad (SU(N)\ \text{pure gauge}) \quad (2)$$

an inverse length is born Cited (the standard one-loop form, 4-07). The mass gap and the confinement scale are expected to be constant multiples of Λ. All derivatives of $\exp(-1/g^2)$ vanish at $g = 0$, so Λ appears at no order of the perturbative expansion in g ("invisible to perturbation theory" in 4-07).

How it shows in the relaxation-time assumption. (a) The correlation length grows exponentially in β ($\xi \propto e^{3\pi^2\beta/11}$ by the one-loop bookkeeping for $SU(2)$, 23-03 Table 2), and quantities measured in ξ

carry a factor $\ln \xi \sim \beta$. This is why Part 23 placed the relaxation-time assumption as a power statement rather than a band statement (23-01 § 07). (b) In the Gaussian approximation the coupling does not flow. In the Gaussian approximation on the hierarchical lattice, the static correlation of plaquettes decayed like the massless R^{-4}, and the correlation length was only cut off by the volume (24-02 § 02). A scale is born only from the non-abelian correction. (c) The solution theory of the equations of stochastic quantisation has subcriticality ($d < 4$) as its key condition, and four dimensions is exactly critical (§ 1.2 of Chevyrev's review Cited , 7-09).

The same marginal, but in the opposite direction. Four-dimensional ϕ^4 also has a dimensionless (marginal) coupling, but under the renormalisation flow the coupling approaches 0 on the side of long distances ("infrared asymptotic freedom", the Infrared Asymptotic-Freedom Proposition (Proposition 6.1.7 of BBS) of Bauerschmidt–Brydges–Slade Cited). In the direction one wants to control (long distances) the theory approaches a Gaussian, so the tools reach, and the limit they reached was trivial (the scaling limit is Gaussian) (Aizenman–Duminil-Copin 2021 Cited (abstract), 7-08). In Yang–Mills the coupling approaches 0 on the side of short distances, and grows towards long distances.

```
Figure 1  Two arrows (the flow of the coupling g;
          left is short distance, right is long distance)

            short distance (UV)                long distance (IR)
  φ⁴₄ :  g toward the large side   ←──────────   g → 0 (approaches a Gaussian)
         → near a Gaussian in the direction to be controlled.
           The tools reach; the limit is trivial

  YM₄ :  g → 0 (approaches a Gaussian)  ────→  g grows (g = O(1) at the scale Λ)
         → near a Gaussian only in the UV.
           No reference for an expansion on the IR side
```

We do not write "only in four dimensions". The two-dimensional $O(N)$ ($N \geq 3$) model and the CP^{N-1} model also have the same pair, a dimensionless coupling and asymptotic freedom, and CP^{N-1} also has instantons with no scale. There too, the construction of the ultraviolet limit is not complete (Rivasseau 2000, Douglas 2004 Cited). Conversely, even at the critical dimension, an abelian ($U(1)$) or non-gauge (ϕ^4_4) theory is equivalent to a free field or trivial. The "because it is four dimensions" of this chapter refers to **being at the critical dimension (a dimensionless coupling) and being non-abelian (the direction of asymptotic freedom, topology, the geometry of gauge orbits) happening at the same time** Estimate .

02

Topological configurations with no scale — instantons and the weight of dislocations

By $\pi_3(SU(N)) = \mathbb{Z}$, four-dimensional gauge fields have an integer topological charge Q, and the action of a self-dual solution (an instanton) is $8\pi^2/g^2$, independent of its size ρ Cited (the abstract of Belavin–Polyakov–Schwartz–Tyupkin 1975; the value of the action from the texts of Lucini–Teper 2001 and Athenodorou–Teper 2021). That the action does not depend on ρ is a manifestation of classical Yang–Mills having no scale in four dimensions.

On the lattice, the smoothed topological charge changes only when a small instanton the size of the lattice spacing passes through the lattice ("disappears into a hypercube") (§ 6.1 of Lucini–Teper 2001

Cited). Its weight is estimated from the one-loop density of small instantons $D(\rho) \propto \rho^{11N/3-5}$, and for the time for the topological charge to move by one unit,

$$\ln \tau_Q = b + \left(\frac{11N}{3} - 5\right) \ln \frac{1}{a\Lambda} \quad (3)$$

a primary source gives this count ((32)(34) of Athenodorou–Teper 2021 Cited). For $SU(2)$ the coefficient is $7/3$, and the original itself writes that it is "rather weak". The comparison with fitted slopes is Table 1.

Table 1 The coefficient of (3) and the fitted slopes (Table 43 of Athenodorou–Teper 2021. Heat bath and overrelaxation, periodic box, normalised to a standard physical volume)

N	**Coefficient of (3) $11N/3-5$**	**Fitted slope**
2	$7/3 \approx 2.33$	Excluded from the table (τ_Q does not become large enough compared with the measurement interval)
3	6.0	6.82(7)
4	9.67	9.27(12)
5	13.3	11.13(20)
6	17.0	13.50(30)
8	24.3	17.58(43)

The label of Table 1 is Cited (numbers from the original). There is one independent route. The figure of the original suggests that the probability that the field smoothed by the Wilson flow is between topological sectors (the probability of exceeding the smoothness threshold $h \geq 0.067$) vanishes in proportion to a^6 on lattices at fixed physical size (§ 4.3 of Lüscher 2010, $SU(3)$, the word "suggests" Cited), and this is the same number as the coefficient 6 of (3) for $SU(3)$. For $SU(2)$, no measurement of the same type was found within the range searched.

Two ways of counting. In the crude count that sets the action of a dislocation to c times the one-loop instanton action, the dynamical exponent is of the type $z = (11N/3)c - 4$ Assumption . It differs by 1 from the counting of (3), in how the volume factor at $\rho \sim a$ and the width $d\rho$ are counted. Fitting c to the numbers for $SU(3)$ (the fitted 6.82, or $z \approx 5$ from another original), **in either counting $SU(2)$ falls near the boundary $z = 2$** Estimate . This book does not judge which of the two counts is right. Nor has it checked that c does not depend on the group.

03

An estimate that puts the two points together — the slow quantity and the correlation length split into different origins

Setting the two points side by side gives the following estimate Estimate . The time of the slow quantity (the topological charge) and the correlation length ξ are both born from the same dimensionless coupling, in the form $e^{(\text{constant})\cdot\beta}$. But the exponents are different numbers. The correlation length is $\xi \propto \Lambda^{-1}$ from (2), and the time of the topological charge is $\tau_Q \propto (a\Lambda)^{-(11N/3-5)}$ from (3); in lattice units τ_Q is of the type $\xi^{11N/3-5}$, and its exponent does not match that of ξ^2, the thing it is compared with.

- For the 0+1-dimensional double well, the slow quantity (the number of kinks) and ξ are born from the same kinks, the exponents match, and only a logarithmic difference remains (24-01 Table 3).
- On the two-dimensional $U(1)$ strip, the static length is linear in β, the length at which conservation breaks is $e^{0.92\beta}$, and the two separate exponentially (24-02 § 03, a reading of a two-dimensional toy).
- For two-dimensional CP^{N-1}, varying N split the strength of freezing and the length at which conservation breaks, while the local ratio did not split (24-02 § 07, a conditional one-point reading).

The reading is that the candidate for the true nature of "even if the mass gap is born, it is not caught in the form of the relaxation-time assumption (the form that ties C_P and ξ^2 with the same power)" is **the slow quantity and the correlation length splitting into different origins**, and that the split comes from two things: the coupling being dimensionless, and topology. On this reading, the form that catches the mass gap is not the whole of the relaxation-time assumption but lies on the side of the part local in time (24-04) and its reverse side, the Poincaré constant of the vacuum measure (24-05).

What this section can say: it is a reading, not a theorem. The numbers for the exponents are fits from the originals and semiclassical counts, and for $SU(2)$ they fall right near the boundary, so whether they "split" for $SU(2)$ is undecided (§ 07). The autocorrelations of the originals are numbers for heat-bath, overrelaxation and HMC dynamics, and rereading them as C_P for the link Langevin dynamics is an assumption (24-01 § 06).

04

The four hurdles

Part 23 split the diffusive-relaxation-time assumption into four steps (23-03 § 02): first step = the path measure of the 0+1-dimensional double well; second step = non-abelian gauge theory on the four-dimensional lattice (with the lattice spacing held fixed); third step = the continuum limit and the OS axioms; fourth step = the mass gap in the limit. Table 2 puts on one sheet, for each step, the hurdle, the known reach, whether the tools of this book reach it, and the kind of cost. There are three kinds of cost. "Weeks" = expected to be reached by accumulating work combining existing tools; "years" = a large extension of existing tools, or a reconstruction of a large body of work, is needed; "new mathematics" = no description of a route in the sources read (this phrase borrows as it is the wording of the question "why is there no mathematics for the third step?").

Table 2 The four hurdles ("does it reach" and "kind of cost" are estimates. The labels for the reach are inside the rows)

Step	Hurdle	Known reach [sources and labels]	Do the tools of this book reach it?	Kind of cost

Step	Hurdle	Known reach [sources and labels]	Do the tools of this book reach it?	Kind of cost
First step: the 0+1-dimensional double well	The double-well relaxation-time power statement uniformly as $\hbar \to 0$. Paying for the lack of curvature at the summit, $\frac{1}{4}$, with rarity	The static side (tunnelling splitting, correlation length) is known semiclassically Cited . The upper side of the relaxation-time assumption goes as far as the Double-Well Relaxation-Time Upper-Bound Proposition (algebra on four conditions), with Proved here, Cited, Computer-assisted and Assumption mixed row by row (23-12)	Partly reached. What remains is the rows for each condition (23-15 Table 1)	Weeks (many rows). But the rows for $\hbar < 0.005$ are "another method", and the one proposition at the summit is "method undecided", with no estimate
Second step: four-dimensional lattice, non-abelian	Exponential decay of correlations (the lattice mass gap) at weak coupling (large β), uniformly in the volume. The upper-bound assumption and the relaxation-time lower-bound assumption	At strong coupling (small β) a theorem (Osterwalder–Seiler 1978 Cited (bibliographic data and secondary sources)). In hierarchical models, confinement at every β (Ito 1985 Cited (abstract)). On the real lattice at weak coupling, unsolved (the lattice correlation-length problem, Chatterjee's Problem 5.1)	Within hierarchical models the static side is known, and the dynamic side (coordinates and conservation, 24-02 § 02) is within reach. Weak coupling on the real lattice is out of reach (it is crossing the confinement scale itself, the source "no expansion linking scales" of § 05)	Weeks (the dynamic side of hierarchical models) / "new mathematics" (weak coupling on the real lattice)

Step	Hurdle	Known reach [sources and labels]	Do the tools of this book reach it?	Kind of cost
Third step: the continuum limit and the OS axioms	Existence and uniqueness of the limit as the lattice spacing $\to 0$, infinite volume, the OS axioms, non-triviality	The construction published on 2026-11-10: a Lean formalisation that builds, for any compact simple group, a theory satisfying the Wightman axioms as a limit of the four-dimensional Wilson lattice (the committee's assessment is that it is proved in Lean Cited). The continuum limit on a periodic cubic box, and an infinite-volume limit along a subsequence of volumes. Convergence and uniqueness of the infinite-volume limit are not shown (6-04). The reach before that: ultraviolet stability of the lattice in finite volume (three and four dimensions, Balaban's 13 papers in Commun. Math. Phys. 1983–89 Cited (bibliographic data and descriptions in the texts of other sources)). Schwinger functions with an infrared cutoff in axial gauge (Magnen–Rivasseau–Sénéor 1993 Cited (introduction in the text)). Even the three-dimensional measure was not yet constructed in a finite box (Chevyrev 2022 Cited)	The tools of this book do not reach it. The existence part is cited from the published construction (Volume 2). The remaining items (convergence and uniqueness of the infinite-volume limit, a probability measure for the continuum theory) are in 6-04	(The existence part is the published construction. The remaining items are expected to need "new mathematics")
Fourth step: the mass gap in the limit	A gap uniform in the volume $\Delta > 0$	None. The problem statement writes that "new ideas are needed for a mass gap uniform in the volume" (§ 6.5 of Jaffe–Witten Cited). Numerically, the lightest glueball of $SU(3)$ is $3.405(21)$ times the square root of the string tension (Athenodorou–Teper 2021 Cited), an extrapolation from finitely many lattice spacings and finite boxes. The published construction has no uniform mass gap either (what it has is polynomial bounds, 6-04)	Does not reach. The one-sided bridge (23-01 § 06) is expected to lift in form only Estimate	"New mathematics"

Before the published construction, the cost of the third step in Table 2 was estimated as "years" for the source "dimensionless coupling" and the source "no global gauge fixing". This estimate depends on descriptions in the sources Estimate : Rivasseau 2000's "simplify and rewrite Balaban's results; since they run to hundreds of pages, this is not a small task", and that Dimock's reconstruction, starting from three-dimensional ϕ^4, reached the stability of the partition function of three-dimensional QED in a little over ten years (abstract). For the source "no expansion linking scales" there are no sources to support an estimate of the cost. The costs of the rows of the first step are as in the estimates of 23-15 § 03, and not a single estimate has been run even for the rows marked "weeks".

What this section can say: the rows of known reach are as their source labels say. "Does it reach" and the kind of cost are estimates, and for the steps marked as not reached we do not say "impossible".

```

Why the third step stayed open so long

This section arranges descriptions in the primary sources read before the construction published on 2026-11-10. On 2026-11-10, a Lean formalisation that builds a theory satisfying the Wightman axioms as a limit of the four-dimensional Wilson lattice, together with the committee's assessment report, was published, and the existence part of the third step reached the level of "the committee's assessment is that it is proved in Lean" (Volume 2, 6-00). What is not shown is convergence and uniqueness of the infinite-volume limit, a probability measure for the continuum theory, a uniform mass gap, Wilson loops and the area law, and one-particle states (6-04). The summary below and Table 3 are kept as the reach before that construction and as a reading of the sources of difficulty.

First a summary in thirteen lines [Y3].

1. The third step is that "there is a single probability measure in the limit of finer and finer lattices, and it satisfies the OS axioms". The theorems in the primary sources before the published construction went only as far as a uniform estimate that, inside a finite box, however fine the lattice is made, the coarse-grained theory does not run wild (Balaban's ultraviolet stability).
2. Beyond that, three things were needed separately — estimates of correlation functions, uniqueness of the limit, and enlarging the box to infinity. The published construction gives the continuum limit on a periodic box and an infinite-volume limit along a subsequence of volumes, but does not show uniqueness of the infinite-volume limit. For three-dimensional non-abelian gauge theory, the measure inside a finite box has not been constructed within the sources read.
3. The first difficulty is that in four dimensions the coupling is dimensionless. In three dimensions or fewer, the interaction weakens like a power as the scale is made finer, and only finitely many divergences had to be dealt with. In four dimensions the correction from each step does not shrink like a power, and the corrections from infinitely many steps must all be controlled in a form independent of the number of steps.
4. The second is that asymptotic freedom works "only at short distances". At short distances the coupling is small and expansions around the free field can be used. At long distances the coupling becomes large, and the confinement scale Λ appears.
5. This Λ appears at no order of the expansion in the coupling, so extending the expansion from short distances does not reach it. The strong-coupling expansion, which converges on the side where the coupling is large, can be used only on the side of large lattice spacing, and does not reach the continuum limit. There is no tool that crosses the scales between the two expansions.
6. The third is non-abelian gauge invariance. No continuous gauge fixing that works for all configurations at once exists (Gribov, Singer), and Balaban chose the gauge afresh scale by scale and place by place.
7. Where the field is large, expansions cannot be used, and the only way to control it is by its being "unlikely". On a group, large fields are necessarily non-convex, so methods that rely on convexity cannot be used, and methods that pay with rarity are needed (24-06).
8. Magnen–Rivasseau–Sénéor (1993) constructed the Schwinger functions in axial gauge, keeping a cutoff at long distances. They wrote in their introduction that the reasons for not removing the cutoff were that the coupling becomes large and enters the non-perturbative effects of confinement, and that there is no easy solvable model around which to expand.
9. In lattice numerics, the mass of the lightest glueball of $SU(3)$ has been extrapolated to the continuum limit as about 3.41 times the square root of the string tension.

10. But the numbers are extrapolations from finitely many lattice spacings and finite boxes, and do not show that the limit exists, that it is unique, or uniformity in the size of the box.
11. Field theories with non-trivial interaction in four dimensions are thought to be limited to asymptotically free ones. The ϕ^4 theory has been shown to be trivial in four dimensions (its scaling limit is Gaussian).
12. As a result, before the published construction there was not a single "interacting theory already constructed" in four dimensions to compare with, and Yang–Mills was sought as its first example.
13. The walls this book met in the first step (the double well) and the second step (the hierarchical gauge model) — paying for the lack of convexity at the summit with rarity, the convexity hypothesis not holding on the group, global quantities not reflected in the gap — are small versions of the third difficulty of the third step. In the third step, that "rarity" ceases to be rare at long distances Estimate .

Three sources of difficulty

Table 3 The sources of difficulty (the column of facts is as its source labels say; "what stops" is an estimate)

Source	Fact (descriptions in primary sources)	What stops	Correspondence with the walls of this book
Source: dimensionless coupling — the coupling is dimensionless, and every scale works with the same weight	In four dimensions g is dimensionless and the quartic term is marginal (§ 01). The models constructed are only super-renormalisable ones in two and three dimensions and the massive Gross–Neveu model in two dimensions (Rivasseau 2000 Cited). $d = 2, 3$ is considerably easier than $d = 4$ (Chevyrev 2022 Cited)	The corrections of infinitely many steps need to be summed uniformly in the number of steps. Asymptotic freedom gives $g_j^2 \sim 1/(bj)$, and the sum converges only logarithmically	Placing the relaxation-time assumption as a power statement (the factor $\ln \xi \sim \beta$)
Source: no expansion linking scales — there is no expansion connecting the ultraviolet and the infrared	The sentence in the introduction of MRS 1993 (below). "The weak-coupling expansion of the ultraviolet limit is to some extent in contradiction with the low-temperature expansion"; "techniques for gluing together different expansions and different regions of the renormalisation group should be developed" (Rivasseau 2000 Cited). The strong-coupling expansion converges only on the side of large lattice spacing (Chatterjee Cited)	The control of Balaban and MRS works only at steps where g_j is small, and there is no theorem usable at the steps that cross the scale Λ^{-1}	In the first step the summit configurations were rare, and there was a currency called rarity. In the infrared, configurations where the Gaussian approximation does not work become typical, and that currency is absent

Source	Fact (descriptions in primary sources)	What stops	Correspondence with the walls of this book
Source: no global gauge fixing — non-abelian gauge invariance	There is no continuous global gauge fixing (Gribov 1978, Singer 1978 Cited (bibliographic data only; the content from memory)). Balaban fixed the gauge locally and scale by scale on regular configurations, and defined averages of group-valued fields separately (titles of the papers). Convexity at large fields is the main issue in going beyond hierarchical models (Bauerschmidt–Bodineau Cited)	Large fields cannot be controlled by convexity, and can only be paid for with rarity	The convexity ceiling on the group (the lemma of 24-06). The convex and non-convex places are the reverse of flat ϕ^4

The relation among the three sources Estimate : the source "dimensionless coupling" is "how many steps there are" (infinitely many, each with the same weight), the source "no expansion linking scales" is "at which step the expansion breaks off" (the confinement scale), and the source "no global gauge fixing" is "what is lacking within one step" (convexity and a global gauge). Balaban handled the lack of global gauge fixing at the ultraviolet steps in finite volume, and handled the source "dimensionless coupling" in the range where g_j is small. None of the sources read has touched the lack of an expansion linking scales.

Where Balaban and MRS stopped

Balaban. The gauge-theory series is 13 papers in Commun. Math. Phys. (1983–1989, including one on estimates of lattice Green's functions), about 426 pages when the pages are added up Cited (counted from the bibliographic data; the texts were not obtained). Combining the descriptions in the texts of other sources, the reach is as follows. In finite volume on the lattice, the effective action on the unit lattice stays bounded after arbitrarily many repetitions of the block-spin transformation (ultraviolet stability). From this it should follow that limits of gauge-invariant quantities such as smoothed Wilson loops exist along **subsequences** by compactness, but **the limit is not necessarily unique** (the summary in the introduction of MRS 1993 Cited). No source includes estimates of correlation functions, uniqueness of the limit, infinite volume, the OS axioms or the mass gap in Balaban's reach.

MRS 1993. What they showed is the construction of the Schwinger functions of pure $SU(2)$ four-dimensional Yang–Mills with a fixed infrared cutoff and no ultraviolet cutoff, in a regularised axial gauge, in the trivial topological sector, and that the Slavnov identities hold non-perturbatively. The authors themselves write that they do not claim to have given the proof of convergence in every detail, and that it is a detailed sketch Cited (introduction checked in the text; the body of the proof not read). The reason they stopped is the following sentence of the introduction (this book's translation).

> We do not investigate invariance under large gauge transformations, or non-trivial topological effects such as instantons. Nor do we try to remove the infrared cutoff, because that leads to large values of the coupling constant, to the so-called non-perturbative effects, which probably correspond to confinement. These problems are for the moment beyond the reach of our constructive methods, in particular because there is no easy solvable model of these phenomena around which to expand.

The "we" of the quotation refers to the authors of MRS. Since the infrared cutoff is not removed, the introduction goes on, the OS axioms as a whole cannot be examined either.

The object, tools, theory, history

The object is undefined. The problem statement is "prove that a non-trivial quantum Yang–Mills theory exists on $\mathbb{R}^4$ and has a mass gap"; for the existence part it requires axioms as strong as Wightman's or OS, and in a footnote it says that weak existence by compactness alone is not counted as a solution (Jaffe–Witten Cited). The construction itself is the content of the problem; it is not in the form of asking about properties of an object already constructed. Douglas's report of 2004 also writes that "there is no satisfactory mathematical definition of quantum Yang–Mills theory" Cited . Moreover, the space on which to place the measure is not fixed. The natural space is the quotient of everything by gauge orbits, which for the non-abelian case is a non-linear space, and even the construction of the state space is not trivial. Chevyrev's review writes that already in three dimensions the Gaussian free field is too singular to be restricted to lines, and the space of holonomies that could be used in two dimensions cannot be used Cited . The objects up to the second step (finite-dimensional probability measures on the lattice) are defined, and there is mathematics that asks about their properties. Before the published construction, for the object of the third step, even on which space and with which topology to place it was undecided. One step before "there are no numbers" there was "there is no object" Estimate . The published construction gives the object as a table of correlations (Schwinger functions) and an OS space, and does not give a probability measure for the continuum theory (6-04).

The tools are perturbation around a Gaussian reference. Most of the models constructed are in the weak-coupling region, made with cluster expansions, Mayer expansions and their multiscale versions (Rivasseau 2000 Cited). The analysis of one step of the renormalisation group relies on perturbation in powers around the field being 0 and on Taylor approximation, which is a good approximation only when the field is small (the book by Bauerschmidt–Brydges–Slade Cited). The solution theory of stochastic quantisation uses the fact that, under subcriticality ($d < 4$), the solution is a perturbation of the stochastic heat equation, which has the Gaussian free field as its invariant measure (Chevyrev Cited). All of them take as input "close to a Gaussian measure at each scale". The asymptotic freedom of Yang–Mills gives this input **only at short distances**. At long distances, the grounds for starting from a Gaussian reference run out. For four-dimensional ϕ^4, on the contrary, it approaches a Gaussian at long distances, so the same tools work, and the conclusion was triviality. **In four dimensions, the theories the tools reach become trivial, and the theory that should be non-trivial gives the tools no input** Estimate .

There is no theory that crosses infinitely many scales with neither a small parameter nor convexity. The multiscale theorems within the range read all place a small parameter or convexity at each step: a small coupling (hierarchical and Euclidean ϕ^4_4), uniform convexity of the conditional measure at each step (Bauerschmidt–Bodineau), a convergent perturbative expansion (two-dimensional Gross–Neveu, bibliographic data only), a small g_j and the rarity of large fields (Balaban, MRS) Cited . For group-valued fields, the convexity hypothesis cannot hold in principle at weak-coupling scales (the lemma of 24-06: on a compact manifold of diameter D, if $\mathrm{Hess}\, V \geq -K$ then $\mathrm{osc}\, V \leq KD^2/2$). **Gauge invariance forbids this control** Estimate : a gauge-invariant function is constant along orbits, so it cannot have convexity ($\mathrm{Hess}\, V > 0$) in the direction of the orbits. If one tries to remove the orbit directions by fixing the gauge, there is no continuous global fixing. Balaban's local fixing and the seam between the two gauges of MRS both work only in the region of small fields. The Riemannian geometry of the orbit space has been described (Singer 1981, bibliographic data only),

but a general theory handling measures on it that are neither Gaussian nor perturbations of one is not in the sources read.

History. The introduction of MRS writes that Balaban's work is "very impressive but hard to access; the results are scattered over many publications, and it is very difficult to check the consistency of all the arguments", and Rivasseau 2000 lists rewriting it among the open problems Cited . Dimock's reconstruction writes that "others have been slow to adopt this method", starts from three-dimensional ϕ^4 (text), and has reached an estimate of the partition function of three-dimensional QED uniform in the lattice spacing (abstract) Cited . A reconstruction for the four-dimensional non-abelian case was not in the sources read before the published construction. Of the intermediate goals, the committee's assessment is that construction on a finite box T^4 was given by the published construction as the continuum limit on a periodic box. The three-dimensional measure is open within the sources read. There are also moves to make different mathematics: the formulation in the language of Wilson loops and probability (Chatterjee), and the road that makes a Markov process on gauge orbits by stochastic quantisation and poses the construction of the invariant measure as an open problem (Chandra–Chevyrev–Hairer–Shen, Chevyrev's review) Cited . Both go in the direction not of extending the lattice renormalisation group but of rebuilding where the objects live (the state space) or the means of construction (stochastic dynamics). However, the key condition $d < 4$ of the latter shows that this new tool too becomes exactly critical in four dimensions.

What this section can say: an arrangement of descriptions in primary sources, and the matching to sources of difficulty (an estimate). Balaban's texts were not obtained, so the description of his reach goes through the texts of other sources. The contents of Gribov and Singer are from memory; only the bibliographic data were checked.

06

A paragraph on candidate rules

The list of candidates for what to place as rules if the "new mathematics" in the table of § 04 were to be made is dealt with in 24-08. Here we write only one Estimate . Combining axiomatising scale (a semigroup of coarse-grainings and a flow on it) with the class of measures that pay with rarity (locally convex on the good set, the bad set rare, a drift returning from the bad set, rarity paid only through the entropy inequality), it seems possible on the ultraviolet side to write a form in which the class closes at each step of coarse-graining. On the strong-coupling side, tools of the type that pay with the curvature of the group work in a narrow range. **Between the two, a "coupling window" remains where neither currency is enough.** It is the range where the rate of rarity, proportional to the effective coupling, runs out at the confinement scale, and the currency of curvature is not yet enough. This window is a restatement in the language of rules of the lack of an expansion linking scales (that there is no expansion connecting the ultraviolet and the infrared), and is not a new obstacle. The hierarchical gauge model is a place where the three — the ultraviolet side, the window, and the strong-coupling side — come together within one model, but the results there imply nothing for four-dimensional Yang–Mills.

07

Topology and the box — undecided for this book's group $SU(2)$

The periodic box. For reversible dynamics $\tau_{\mathrm{int}}(Q) \le C_P$ ((1) of 24-01), so if the autocorrelation of the topological charge grows faster than ξ^2, the upper-bound assumption breaks ((3) of 24-01. Lean

`LatticeGauge.FourDTrial.not_hup_of_fast_tau`, assumptions: $\tau_n \le C_n$, $c\,\xi_n^p \le \tau_n$, $p > 2$, $\xi_n \to \infty$. Negative control `z_two_compatible_with_hup`, no assumptions: $\tau \propto \xi^2$ is compatible with the upper-bound assumption). On the periodic box, originals for $SU(3)$ and above report this, so under the reading that extends the conjecture that HMC and Langevin are in the same dynamic universality class (in the original, a phrase attached to observations with open boundaries) to the topological slowness on the periodic box, **the upper-bound assumption reads as false on the periodic box** Assumption (the note in 23-01 § 05, 24-01 § 06).

Open boundaries rescue only finite boxes. With open boundaries, inside a box with fixed physical side, the growth of the autocorrelation goes back to a^{-2}. But if the spatial side of the box is held fixed and only the length in the time direction is extended, the autocorrelation time of Q^2 grows nearly in proportion to the length: $42.1(2.5)$, $113(6)$, $148(10)$ (lattices with time-direction lengths 24, 48, 80) (§ 5.3 of Lüscher–Schaefer 2011 Cited). This is because the charge enters and leaves only by transport through the boundary, and in this book's order, which takes the volume to infinity first, it is expected not to be a rescue Assumption (24-03 § 05 and Table 2).

For $SU(2)$ there is one primary source, on the a^{-2} side. Within the range searched, there is one primary source that measured the dependence on the lattice spacing of the autocorrelation of the topological charge in pure $SU(2)$ gauge theory (Abe–Morikawa–Suzuki 2025: HMC, periodic, a small box of physical side about $2.2/\sqrt{\sigma}$, three lattice spacings, reporting that it fits a^{-2} fairly well Cited). The heat-bath originals are all observations on the side where freezing in $SU(2)$ does not become strong enough to measure, and $SU(2)$ was excluded in Table 1 as well. Both counts of § 02 place $SU(2)$ near the boundary $z = 2$. **Hence, for this book's group $SU(2)$, it is undecided whether the freezing of the topological charge breaks the relaxation-time assumption.** The primary source leans to the boundary or below it Reading .

Correspondence with the two-dimensional test bed of 24-02 Estimate . For two-dimensional CP^{N-1} at $\xi \approx 4$, freezing split by N (strongly frozen at $N = 21$, not frozen at $N = 2$), while the ratio of local quantities did not split (24-02 § 07, a conditional one-point reading). That the strength of freezing splits with N, which plays the role of the size of the group, can be read as a two-dimensional analogue of $SU(2)$ falling on the boundary in four dimensions while $SU(3)$ and above clearly cross it. The two-dimensional count in the primary source is also of the type "$z \sim N$", and it writes that the same argument applies to four-dimensional $SU(N)$ (Del Debbio–Manca–Vicari 2004 Cited). However, $N = 2$ carries an ultraviolet flag (the two definitions of the topological susceptibility differ by 13–14%), and the reason $N = 2$ does not freeze may be that it is on the side where the lattice scale determines the topological charge. The analogy carries this reservation, and **the two-dimensional results imply nothing for four dimensions**.

What this section can say: "the upper-bound assumption reads as false on the periodic box" is a statement on top of the originals for $SU(3)$ and above and a reading that extends a conjecture; we do not claim that the upper-bound assumption is false. For $SU(2)$ it is undecided.

08

Physical mechanisms, and why they are not proofs

There are many physical mechanisms that explain the mass gap and confinement. This book uses none of them as tools of proof. Table 4 lists, one line each, what each mechanism says and why it is

not a proof. The last row is an estimate that brings the leading-order statement of 24-05 of this book close to the language of physics, and its character differs from the other rows.

Table 4 Physical mechanisms, and why they are not proofs (labels: Cited = statement checked in the text or abstract, Assumption = from memory)

Mechanism	What it says	Why it is not a proof (one line)	Origin and label
The area law at strong coupling	On the strong-coupling lattice, Wilson loops decrease with area, and there are no free quarks	The strong-coupling limit has no rotation (Euclidean) invariance, and does not extend to the side of the continuum limit (weak coupling)	Wilson 1974 Cited (abstract). The strong-coupling theorem (Osterwalder–Seiler 1978) is Assumption (from memory)
Dual superconductivity (abelian projection, condensation of monopoles)	Gauge-fixing the non-abelian part first leaves $N-1$ abelian gauge fields and monopoles, and if the monopoles condense, there is confinement	Condensation has not been shown, and the projection depends on the choice of gauge. The examples where confinement is described by condensation are supersymmetric theories with matter fields plus a perturbation, and do not apply to pure gauge theory	't Hooft 1981, Seiberg–Witten 1994 Cited (abstract), Jaffe–Witten § 6.6 Cited
Centre vortices	Vortices with values in the elements of the centre carry the string tension	Lattice numerics on the maximal centre gauge and projection (the word "suggest"), with neither inequalities nor statements about the limit. The algebra of 't Hooft 1978 classifies phases, but does not decide which phase one is in	Del Debbio–Faber–Greensite–Olejník 1997, 't Hooft 1978 Cited (abstract)
The dilute instanton gas	Approximates the vacuum by a semiclassical sum around the topological solutions of action $8\pi^2/g^2$	Plausible only at small ρ; as ρ grows, (anti-)instantons overlap and the effective action changes. The premise of the approximation breaks down at the scale where the gap is born	BPST 1975, 't Hooft 1976, Callan–Dashen–Gross 1978 Cited (abstract), Lucini–Teper 2001 § 6 Cited (text). The infrared divergence of the integral over sizes is Assumption (from memory)
Large N and duality with strings	Planar diagrams dominate, and $1/N$ plays the role of the string coupling constant	A rearrangement of the perturbation series, or a conjecture, with no way back to finite N. The problem statement too, while saying "for sufficiently large N it may be a starting point", writes that there is no effective road to gauge theories without fermions	't Hooft 1974, Witten 1979 Cited (abstract), Jaffe–Witten § 6.6 Cited
Curvature of the orbit space	From the curvature of the space of gauge orbits and the gauge invariance of the wave functional, excitations have finite energy	Feynman himself writes that it is a qualitative, suggestive argument, and does not discuss 3+1 dimensions. Singer's is a geometric description, with no statement of a lower bound on the Hamiltonian. The language is closest to Bakry–Émery (a gap from a lower bound on curvature) Estimate	Singer 1981, Feynman 1981 Cited (abstract), Jaffe–Witten § 6.6 Cited

Mechanism	What it says	Why it is not a proof (one line)	Origin and label
(This book's estimate) The glueball is the two-particle colour singlet	On the side of the vacuum measure, the lowest gauge-invariant test space for $SU(2)$ is not in one particle but in two particles (the second chaos) (24-05 § 05)	A statement at leading order ($g \to 0$, three independent Gaussian colours), saying nothing about values at finite g. In infinite volume the right-hand side at leading order also goes to 0. The correspondence with glueballs is itself an estimate	(7)(8) of 24-05 Proved here (leading order), the correspondence Estimate

What this section can say: "what it says" in each row is a copy from the abstract or text of the original, and we judge none of the mechanisms right or wrong.

09

What cannot be said

(a) The candidate for the true nature. "The slow quantity and the correlation length split into different origins" of § 03 is an estimate. Neither the value of the ratio c for the action of a dislocation nor its independence of the group has been checked. $SU(2)$ falls near the boundary in either of the two counts.

(b) Mechanisms. This book uses none of the mechanisms of Table 4 as tools of proof.

(c) Two dimensions. We do not say what the results for two-dimensional models (the $U(1)$ strip, CP^{N-1}) imply in four dimensions.

(d) We do not say "only in four dimensions". The two points were stated as properties of being at the critical dimension.

(e) Table 2. "Does it reach" and the kind of cost are estimates and guesses; "new mathematics" refers to the absence of a description of a route in the sources read, and does not mean impossible.

(f) Sources. § 05 is an arrangement within the range of primary sources read, and the texts of Balaban, Gribov, Singer and Osterwalder–Seiler were not obtained. A theory written as "there is none" means "there is none in the sources read", and § 05 is an arrangement of sources from before the publication of 2026-11-10.

(g) $SU(2)$. For this book's group $SU(2)$, it is undecided whether the freezing of the topological charge breaks the relaxation-time assumption. Nor do we claim that the upper-bound assumption is false.

10

Table of the five grades and the dependency graph

Table 5 The rows of this chapter ("—" marks rows without machine checking)

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
1	In four dimensions g^2 is dimensionless and the quartic term is marginal ((1))	Cited	§ 01	—	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
2	Dimensional transmutation (2) (one loop)	Cited	4-07	One loop	—
3	The scaling limit of ϕ^4_4 is Gaussian	Cited	Aizenman–Duminil-Copin (abstract)	Nearest neighbour, lattice cutoff	—
4	Balaban's ultraviolet stability (finite volume, lattice, subsequences)	Cited	Bibliographic data and texts of other sources	Three and four dimensions, finite volume	—
5	The MRS construction (infrared cutoff, axial gauge, $SU(2)$, trivial sector, sketch)	Cited	Introduction in the text	Fixed infrared cutoff	—
6	The three-dimensional measure is also not yet constructed; $d < 4$ is the key for the solution theory	Cited	Chevyrev's review	—	—
7	$8\pi^2/g^2$, $D(\rho) \propto \rho^{11N/3-5}$, (3)	Cited	§ 02	One loop	—
8	The fits of Table 1 ($6.82(7)$ for $SU(3)$)	Cited	Table 1	Heat bath and overrelaxation, periodic	—
9	One primary source for $SU(2)$ (close to a^{-2})	Cited	§ 07	HMC, small box, three points	—
10	With open boundaries the autocorrelation of Q^2 is proportional to the length in the time direction	Cited	§ 07	$SU(3)$, box with fixed physical side	—
11	If $\tau \geq c\xi^p$ ($p > 2$), the upper-bound assumption breaks	Proved here	(3) of 24-01	Sequences with $\xi \to \infty$	`LatticeGauge.FourDTrial.not_hup_of_fast_tau` (assumptions: $\tau_n \leq C_n$, $c\xi_n^p \leq \tau_n$, $p > 2$), negative control `z_two_compatible_with_hup` (no assumptions)
12	A reading that extends the conjecture to topological slowness on the periodic box	Assumption	24-01 § 06	Periodic box	—

Row	Statement (one line)	Grade	Grounds	Scope	Machine checking
13	The upper-bound assumption reads as false on the periodic box ($SU(3)$ and above)	Assumption	§ 07	Periodic box	—
14	In the order that takes the volume to infinity first, open boundaries are no rescue	Assumption	24-03 § 05	Infinite volume	—
15	In the two counts, $SU(2)$ is near the boundary $z = 2$	Estimate	§ 02	Semiclassical	—
16	Whether freezing breaks the relaxation-time assumption for $SU(2)$ is undecided	Estimate	§ 07	—	—
17	The slow quantity and the correlation length split into different origins (the estimate of the two points)	Estimate	§ 03	—	—
18	The two points are properties of the critical dimension (we do not say only in four dimensions)	Estimate	§ 01	—	—
19	The three sources of difficulty and their relation	Estimate	§ 05, Table 3	Within the sources read	—
20	The "coupling window" is a restatement of the lack of an expansion linking scales	Estimate	§ 06	—	—
21	"Does it reach" and the costs in the table of the four steps	Estimate	Table 2	—	—
22	The split in N in two dimensions is an analogue of the boundary for $SU(2)$	Estimate	§ 07	Two dimensions; an ultraviolet flag on $N = 2$	—

What the machine-checking column guarantees is only the algebra of sequences of reals; that τ_n is the autocorrelation time of a reversible dynamics, and that C_n is the Poincaré constant of the Wilson measure, are outside Lean (23-13).

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  CIT  in four dimensions g² is dimensionless, marginal
 2  CIT  dimensional transmutation Λ = μ e^(−1/(2b₀g²))          one loop
 3  CIT  the limit of φ⁴₄ is Gaussian
 4  CIT  Balaban's UV stability (subsequences, no uniqueness)    finite volume
 5  CIT  MRS 1993 (IR cutoff, axial gauge, SU(2), sketch)
 6  CIT  3D measure also not yet constructed, d < 4 is the key
 7  CIT  8π²/g², D(ρ) ∝ ρ^(11N/3−5), (3)
 8  CIT  SU(3) fit 6.82(7)                                      heat bath, periodic
 9  CIT  one primary source for SU(2) (close to a⁻²)            HMC, small box
10  CIT  open boundaries: τ(Q²) proportional to time length     box with fixed physical sid
11  PRV  τ ≥ cξ^p (p > 2) ⇒ the upper-bound assumption breaks   Lean not_hup_of_fast_tau
12  ASM  reading that extends the conjecture to the periodic box
13  ASM  the upper-bound assumption reads as false on the periodic box ⟸ 8, 11, 12   SU(3)
14  ASM  infinite volume first: open boundaries no rescue ⟸ 10
15  EST  SU(2) is near the boundary z = 2 ⟸ 7, 8
16  EST  for SU(2), whether freezing breaks the relaxation-time assumption is undecided ⟸
17  EST  slow quantity and correlation length split into different origins ⟸ 1, 2, 7
18  EST  properties of the critical dimension ⟸ 1, 3

20  EST  the coupling window restates the lack of an expansion linking scales ⟸ 19
21  EST  "does it reach" and costs in the four-step table ⟸ 4, 5, 6, 19
22  EST  the split in N in 2D is an analogue of the SU(2) boundary ⟸ 15, 16
```

The way to check is to see by eye that on every "⟸" the numbers on the right are smaller than the number on the left. There are no circles. The conclusion nodes of this chapter (from "the upper-bound assumption reads as false on the periodic box" onwards) are Assumption or Estimate, and there is neither a node for the mass gap nor a node for the continuum limit. The node for the primary source for $SU(2)$ enters only the node "whether freezing breaks the relaxation-time assumption is undecided", not the premises of the node for the periodic box. This is how the undecided reading for $SU(2)$ looks on the graph (the same form as the dependency graph of 24-01).

What this chapter can say

What is said	What is not said
Cited That the coupling is dimensionless in four dimensions; dimensional transmutation; the triviality of ϕ^4_4; the instanton action and the one-loop density; the fits of the originals	A mathematical proof of the relation between β and the lattice spacing. That a constant multiple of Λ is the mass gap
Cited The reach of the third step (the continuum limit on a periodic box of the construction published on 2026-11-10, at the level of the committee's assessment; before that, Balaban's ultraviolet stability and the MRS construction with an infrared cutoff), and the sentence in the introduction giving why MRS stopped	A check of Balaban's texts. Convergence and uniqueness of the infinite-volume limit, a probability measure for the continuum theory, a uniform mass gap (absent from the published construction too)
Assumption The upper-bound assumption reads as false on the periodic box ($SU(3)$ and above, a reading that extends a conjecture)	That the upper-bound assumption is false. The same reading for $SU(2)$

What is said	What is not said
Estimate The estimate of the two points, the three sources of difficulty, the coupling window, "does it reach" and the costs in the table of the four steps, the two-dimensional analogue	None of these is a theorem. The implication of two-dimensional results for four dimensions

Terms used in this chapter — critical dimension, marginal, dimensional transmutation, infrared asymptotic freedom, instanton, dislocation, the four hurdles, the three sources of difficulty, ultraviolet stability, the coupling window, dual superconductivity, centre vortex. Their meanings are in A-02 Glossary and 24-09.

Next chapter to read: 24-08 Questions, and what is not claimed — questions that can be settled at the size of an undergraduate thesis, the list of candidate rules, and what Part 24 does not claim.

Questions, and what is not claimed

> This chapter is a map of open questions. It marks the boundary between the parts that close and the parts that do not.

What this chapter shows — We put the questions left by the chapters of Part 24 into one table (done, partly done, not yet, new; with what moves if it is settled and what does not move even if it is settled), list candidate rules in answer to the question "if new mathematics is to be made, what should be placed as rules?", and write what Part 24 does not claim as sixteen rows, matching each to the sentence of which chapter of the text supports it.

Prerequisite chapters — None. This chapter can be read from anywhere. The three meanings (not shown, not read strongly, not called false) are used as in 23-16 § 01. Notation is in 24-09.

Said first — The level is [Y2]–[Y3]. This chapter adds no new results. The table of questions is questions, and contains no claims. The candidate rules are candidates, and none of them promises a prospect of closing the third step (the continuum limit and the OS axioms). The "what is not claimed" of Part 23 (23-16) applies to this part as it is.

The order of this chapter

1. The table of questions — nineteen questions, their status, what does not move even if settled (Table 1)
2. The list of candidate rules — six candidates and three combinations, relation to the sources of difficulty (Tables 2 and 3)
3. What is not claimed — sixteen items and the sentences of the text that support them (Table 4)
4. Relation to Part 23

01

The table of questions — questions that can be settled at the size of an undergraduate thesis

Table 1 lists the questions left by the chapters of Part 24. "Size" is the kind of work needed to settle it (paper, reading, computation, Lean), not an estimate of time. In each row we always wrote "what does not move even if it is settled". Even if a question is settled, the mass gap problem does not move. "Done" in the status means that the text of this part has answered the question (with conditions), and the label of the answer is in the chapter on the right.

Table 1 Questions of Part 24 (status: done, partly done, not yet, new [a question added while writing this part])

No.	Question	Size	Status	What moves if settled	What does not move even if settled	From which chapter
1	**Comparing local excitations of the free field**: for the free field, the comparison of excitation energies of observables supported in the box (computing the local-excitation moment assumption)	Paper	Done: in the moment form, it holds for the free field with $\gamma = d\pi^2$	The form of the coefficient of the local bridge	The local-excitation moment assumption for interacting models	24-04 § 05
2	**Monotonicity of the window factor**: monotonicity of the window factor $\varphi(x)/x^2$	Elementary, Lean	Done: strictly decreasing for $x > 0$ (Lean `wr_strictAntiOn`, no assumptions)	The explicit form of the window threshold	Nothing (only the form of the constant)	24-04 § 03
3	**Sign of the Polyakov loop**: whether the static ratio $\mathbf{Var}/\mathcal{E}$ catches the slowness, for the sign of the Polyakov loop on a small periodic box (a quantity of a slow sector whose answer is known)	Small computation	Not yet	A positive control for the method of static test functions	The verdict on the topological charge	24-01 § 02

No.	Question	Size	Status	What moves if settled	What does not move even if settled	From which chapter
4	**U(1) gap on two-dimensional layers**: for compact $U(1)$ on a two-dimensional layer, whether the gap keeps decreasing like M^{-2} or saturates as the strip is lengthened (the non-linear value of the length at which conservation breaks)	Computation	Done: on the width-2 strip, outer boundary frozen, five points $\beta = 2..6$, $\ell_c \propto e^{0.916\beta}$ (a reading)	The non-linear value of the length at which conservation breaks	Four-dimensional ℓ_*	24-02 § 03
5	**Data on topological-charge autocorrelation**: a primary source on the autocorrelation of the topological charge in pure $SU(2)$ gauge theory (if none, a small measurement at fixed physical volume)	Reading, computation	Partly done: one primary source (HMC, small box, close to a^{-2}). The small measurement is not yet done	The label of the $SU(2)$ row (at the boundary, or clearly faster than ξ^2)	The conjecture on the relation between HMC and Langevin	24-07 § 07
6	**Many-family version of the Two-Projection Lemma**: a many-family version of the Two-Projection Lemma (the family of 2^d colours for a d-dimensional box), and its condition on maximal correlation	Paper	Not yet	The node of reduction of the four-dimensional box	An estimate of maximal correlation uniform in β	24-03 § 06
7	**Hessian of the one-link weight**: on $SU(2)$, the flow of $\inf \operatorname{Hess} V_t$ for the one-link Wilson weight convolved with the heat kernel, and of the weight of the bad set (one variable, class functions)	Paper + small computation	Not yet (the first step of the class of measures that pay with rarity)	The first numbers of the Polchinski flow on the group; whether the class closes in one step	Lattices that are not hierarchical; closing uniformly over many steps	24-06 § 07
8	**Time-step comparison for the transfer operator**: for Wilson's transfer operator, show the time-step comparison assumption ((D) in the paper "one-sided bridge": the comparison of increments at neighbouring times with gradients, uniform in β) restricted to functions cut off at low energy	Paper	Not yet	Carrying the finite-volume window bridge to Wilson's lattice with discretised time	Infinite volume	24-04 § 08
9	**Lean for τ_{int} and C_P**: for finite-state reversible Markov chains, close in Lean $\tau_{\mathrm{int}} \le C_P$ and the identity of the ground-state transformation (the algebra of the Gap and Vacuum Measure Proposition), defined from probabilistic objects	Lean	Not yet	An example of formalisation with the objects themselves as types (a check of a different form from 23-13)	Path measures, continuum fields	24-05 § 01
10	**Rereading the modes of $\mathbf{CP^{N-1}}$**: reread the autocorrelations of local modes and topological modes in two-dimensional CP^{N-1} through the eyes of the local diffusive-relaxation-time assumption (index in A-06)	Reading, computation	Partly done: the literature has been read. The test-bed measurement goes only as far as a conditional reading at one volume and one correlation length	Material for the test bed	Four dimensions	24-02 § 07

No.	Question	Size	Status	What moves if settled	What does not move even if settled	From which chapter
11	**Loop families of two-dimensional SU(2)**: for two-dimensional $SU(2)$ (plaquettes independent), find λ_W and Γ of families of loops at finite β	Computation	New	The β-dependence of the threshold for the colour singlet	Four-dimensional values	24-04 § 06
12	**Values of large four-dimensional loops**: on a four-dimensional box, the values for families of loops the size of the span (including non-planar ones and products of lassos)	Computation	New	The four-dimensional value of the colour-singlet reference	The ratio for the target measure	24-04 § 06
13	**Reduction to kink positions**: for the 0+1 double well, sandwich the local ratio by a reduction to one dimension with the position of the kink as coordinate	Paper + small computation	New	The constant of the motion that crosses the window	The four-dimensional ratio	24-04 § 07
14	**The single point β=7 of the band**: add one point $\beta = 7$ for the strip, and see whether the slope of the raw rate keeps matching $2 - 1/\beta$ and whether the slope of ℓ_c settles	Computation	New	The reliability of the slopes for the two-dimensional strip	Four dimensions	24-02 § 05
15	**Mass in the band between the threshold and 1**: for fields whose ratio lies in the band $[K_*, 1)$ between the threshold and 1, whether there is another argument that sees the mass while staying in the ratio form (outside Jensen and Dirichlet test functions)	Paper	New	Handling of the undecided band	Values of the ratio for interacting fields	24-04 § 06
16	**Window bridge on a time-step lattice**: on Wilson's lattice with discretised time, write the window version of the bridge (the In-Window Supremum Proposition and the lower bound in finite volume) under the time-step comparison assumption	Paper	New	The lattice version of the window bridge	Infinite volume	24-04 § 03
17	**Frustration-free sector splitting**: whether the Kogut–Susskind Hamiltonian becomes frustration-free when it is split with terms grouped by sector	Paper	New	Whether local-to-global gap theorems apply	The gap at weak coupling	24-05 § 04
18	**Extending the CP^{N-1} test bed**: on the CP^{N-1} test bed, add other random seeds and the remaining pairs of N, and read the exponent of the slowness of the topological mode at a second correlation length	Computation	New	The reliability of the reading that freezing splits by N	Four dimensions	24-02 § 07

No.	Question	Size	Status	What moves if settled	What does not move even if settled	From which chapter
19	**Conservation length of subregion charge**: measure the definition (2) of the length at which conservation breaks (the smallest R at which the ratio reaches half its saturation value) with the charge of a four-dimensional subregion	Computation	New	The first value of the four-dimensional length at which conservation breaks	Whether the diffusive-relaxation-time assumption is true	24-02 § 01

If any question is settled, the label of one row of one chapter moves. Whether the mass gap, the diffusive-relaxation-time assumption or the relaxation-time upper-bound assumption is true does not move when any question is settled.

02

The list of candidate rules — "if new mathematics is to be made, what should be placed as rules?"

The considerations of Part 24 also ran into the question "if new mathematics is to be made, what should be made the rules of the mathematics?" (24-07 § 06). Like Boolean algebra, which threw away the meaning of propositions and kept only the rules of equality, how could one assemble a system that places properties of renormalisation and the continuum limit as rules? Table 2 is the list of candidates. **Every row is a candidate**, and neither consistency nor the ability to restate existing results has been checked Estimate . The comparison with Boolean algebra is a metaphor for how to assemble, not a mathematical claim.

Every candidate can be written in the same form: remove one assumption of an existing framework, and place a replacement rule instead. We condensed what is removed and what is placed into one line per row, and added one question and what does not move even if that question is settled.

Table 2 Candidate rules (one line each, one question) Estimate

Rule	Candidate rule (one line)	Question (one)	What does not move even if settled
Rule of axiomatising scale	A semigroup of coarse-grainings, locality, gauge covariance, contracting and marginal directions, weights for large fields	On the hierarchical $SU(2)$ model, which of the five rules apply and which do not	Non-hierarchical lattices, the continuum limit
Rule of the loop algebra	Bounded, the Mandelstam identities, positivity and reflection positivity, the loop equations (throw away the connection, keep the values of loops)	On the two-dimensional $SU(2)$ lattice, whether the state satisfying the four rules is determined uniquely at finite β	Definition of continuum loops in three dimensions and above
Rule of conserved quantities and sectors	Decomposition of the variance, the sandwich $C_{\mathrm{trans}} \le CP \le \sup C_P^{\mathrm{sec}} + C_{\mathrm{trans}}$, local windows, two lengths (24-03 § 04)	Whether C_{trans} in the sandwich can be written as a quantity of the reduced chain between sectors	Construction (the third step)
Rule of the rarity class	Local convexity on the good set, rarity of the bad set, a returning drift, the currency of entropy (24-06 § 07)	How the parameters of the class are carried over when the one-link Wilson weight is convolved once with the heat kernel (the question "Hessian of the one-link weight")	Closing uniformly over many steps
Rule of an asymptotic-freedom axiom	Changes of scale, a monotone coupling, a free field in the ultraviolet, dimensional transmutation (nothing is placed in the infrared)	Whether it follows from the rule of approaching a free field in the ultraviolet that the local ratio approaches 1 at short distances	The infrared, the mass gap
Curvature rule	Bakry–Émery on the space of gauge orbits	On the orbit space of one plaquette, whether the curvature term of the quotient widens the range of strong coupling	Weak coupling
Rule of axiomatising scale + rule of the rarity class	A rarity class closed under one step of coarse-graining	On the hierarchical $SU(2)$ model, how wide the coupling window is that remains between how the class closes on the ultraviolet side and the strong-coupling tools	The four-dimensional window
Rule of conserved quantities and sectors + rule of the rarity class	A rarity class with sectors (of Eyring–Kramers type, sandwiching by the larger of the constant within sectors and the rate of transitions between sectors)	On the two-dimensional $U(1)$ strip, whether the upper bound on the gap can be sandwiched by the larger of "within sectors" and "the rate of transitions"	The four-dimensional topological charge
Rule of the loop algebra + rule of conserved quantities and sectors	Putting sectors into the algebra of loops (reading the decomposition of the set of states into extreme points as sectors)	Whether the non-uniqueness of solutions of the loop rules corresponds to there being several phases (sectors)	Uniqueness at weak coupling

Table 3 gives the relation to the three sources of difficulty (24-07 Table 3: controlling infinitely many steps uniformly in the number of steps [source: dimensionless coupling]; that there is no expansion connecting the ultraviolet and the infrared [source: no expansion linking scales]; that there is no global gauge fixing and large fields cannot be controlled by convexity [source: no global gauge fixing]).

Table 3 Candidate rules and the three sources of difficulty ("works" means the language of the rule can handle that source, not that it gets past the source)

Candidate	Source: dimensionless coupling (uniform in the number of steps)	Source: no expansion linking scales (ultraviolet and infrared)	Source: no global gauge fixi
Rule of axiomatising scale	Works (it is the language itself)	Does not work (leaves the region when the coupling is $O(1)$)	Half (the weights on the gr formulated)
Rule of the loop algebra	Does not work (goes back to the definition of continuum loops)	Works in form (the same rules at every β). Whether the solution is unique is undecided	Works best (no gauge fixin
Rule of conserved quantities and sectors	Does not work	Does not work	Only gives a name
Rule of the rarity class	Only when combined with the rule of axiomatising scale	Does not work (the rate of rarity runs out)	Works head-on
Rule of an asymptotic-freedom axiom	Only copies it out	Does not work (leaves the infrared empty)	Does not work
Curvature rule	Does not work	Does not work (only on the strong-coupling side)	Gives a meaning

Reading the table Estimate . There is not a single "works" in the column of the source "no expansion linking scales". Only the rule of the loop algebra has rules of the same form at every coupling, but whether the solution of the rules is unique has been replaced by the very content of the lack of an expansion linking scales. The coupling window that appears with the rule of axiomatising scale + the rule of the rarity class (24-06 § 07) is this lack of an expansion linking scales restated in the language of rules.

Where the Boolean-algebra type is possible Estimate . Replacing continuous objects by discrete rules is already half there at the level of the **algebra** of observables: the lattice (replacing a continuous field by group elements on edges), the Mandelstam identities and loop equations for loops, the integers of sectors, the one-variable recursion of hierarchical models. But the rules that decide the third step are **inequalities**, not equalities: positivity, rarity, convexity, estimates uniform in the number of steps. The loop equations (equalities) do not determine a unique solution; what narrows the solutions is positivity (infinitely many inequalities). Put as a metaphor, what the third step needs is closer to the type of measure theory (rules of inequality such as σ-additivity, and rules of limits) than to Boolean algebra.

What is not claimed about the candidate rules. (i) None of the candidates promises a prospect of closing the third step. (ii) The comparison with Boolean algebra is a metaphor, and "the rules of the third step are inequalities" is also an estimate. We have not shown that the rules of Yang–Mills cannot be written as equalities. (iii) The correspondences between candidates and existing results (for example, between the form of the stable manifold of the rule of axiomatising scale and ultraviolet stability in finite volume) are all restatements not checked in the texts of the originals. (iv) "The hierarchical model is a place where the three — the ultraviolet side, the window and the strong-coupling side — come together" is a way of putting it within the range searched, with no implication for four dimensions. (v) A candidate written as not reaching is not evidence of being false.

03

What is not claimed — sixteen items and the sentences of the text that support them

Table 4 writes, one row each, what Part 24 does not claim, and lists the places in the text that support each row. "Support" means that the sentence of that chapter already writes the conditions, assumptions and scope, and this row merely copies it into one line. The Kind column is the three meanings of 23-16 (not shown, not read strongly, not called false).

Table 4 What Part 24 does not claim, and the sentences of the text that support it

Item	What is not claimed	Kind	Supporting sentence of the text (summary)
1	Solution of the problem of the existence of Yang–Mills and the mass gap. The continuum limit, recovery of rotations, the OS axioms and non-triviality are not touched (for the existence part, the construction published on 2026-11-10 is read in Volume 2)	Not shown	24-00 § 05: what is not dealt with. 24-07 § 04: the third and fourth steps are not reached by the tools of this book
2	That the relaxation-time assumption is false. The statement that the upper-bound assumption does not hold on the four-dimensional periodic box is a statement on top of the numbers of the originals for $SU(3)$ and above, and a reading that extends a conjecture attached to observations with open boundaries (that HMC and Langevin are in the same dynamic universality class) to the topological slowness on the periodic box	Not called false	(a)(b) of 24-01 § 06, 24-07 § 07
3	The sector diffusive-relaxation-time assumption and the local relaxation-time assumption are candidate definitions, not shown at any β. Nor do we claim "the right way to fix" the relaxation-time assumption	Not shown	24-03 § 07
4	The one-sided bridge (including the local version) is an inequality on a lattice with continuous time, and on Wilson's lattice with discretised time the time-step comparison assumption remains. The local version further rests on the local-excitation moment assumption	Not read strongly	24-04 § 08 (Table 4), 24-04 § 09

Item	What is not claimed	Kind	Supporting sentence of the text (summary)
5	"The gap = the Poincaré constant of the vacuum measure" is an identity, and we do not claim it has made the problem easier	Not read strongly	24-05 § 01, 24-05 § 07
6	The definition of the length ℓ_* at which conservation breaks, and the restatement of what to compare with, $CP \asymp \max(\xi^2, \tau_{\mathrm{glob}})$, are candidates, not shown in any model	Not read strongly	24-02 § 06, 24-02 § 08
7	The results for hierarchical models and two-dimensional models imply nothing for four-dimensional Yang–Mills	Not read strongly	(a) of 24-06 § 09, 24-02 § 08
8	The non-perturbative mechanisms of physics (confinement, instantons, centre vortices, duality) are not used as tools of proof in this part	Not shown	24-07 § 08 (Table 4)
9	The two points of "because it is four dimensions" are estimates as properties of the critical dimension, and we do not claim they happen only in four dimensions	Not read strongly	24-07 § 01, (d) of 24-07 § 09
10	The "what is not claimed" of Part 23 applies to this part as it is	—	23-16 § 02
11	The local relaxation-time assumption goes only as far as the definition and the ratio form. At no β has the local relaxation-time assumption been shown for the target gauge theory. What has been shown is properties of the definition and values for the free-field reference	Not shown	24-03 § 03, 24-04 § 04
12	The thresholds of the local bridge (0.342κ, 0.502κ, about 0.62κ) depend on the choice of reference and on the family of test observables. For fields whose ratio lies between the threshold and 1, the bridge says nothing	Not read strongly	24-04 § 06 (Table 2)
13	For the 0+1 double well, the local ratio is not 1 even for the shortest window. Taking "the ratio approaches 1 at short distances" in four dimensions is an assumption depending on asymptotic freedom	Not read strongly	24-04 § 07, (7) of 24-03
14	The length at which conservation breaks was measured only on the width-2 strip of two-dimensional $U(1)$ (outer boundary frozen, $\beta = 2..6$). Nothing is said about four dimensions, the non-abelian case, or the exponent as $\beta \to \infty$	Not read strongly	24-02 § 03 (Table 2)
15	For $SU(2)$, it is undecided whether the freezing of the topological charge breaks the relaxation-time assumption. There is one primary source, and its numbers are on the side close to a^{-2}	Not called false	24-07 § 07, (b) of 24-01 § 06
16	The results of the two-dimensional CP^{N-1} test bed imply nothing for four-dimensional Yang–Mills (the ratio is a ratio of conditional autocorrelations at one fixed volume, a different quantity from the static ratio)	Not read strongly	24-02 § 07

The word "conjecture" in item 2 is, in the original, attached to observations with open boundaries, so its application to the periodic box is written as "an extended reading". What is not claimed about the candidate rules (§ 02) is placed at the end of § 02.

04

Relation to Part 23

The fourteen items of "what is not claimed" of Part 23 (23-16) apply to this part as they are. We do not list them again here. In particular, two of them — that not reaching is not evidence of being false (items 8 and 12 of 23-16), and that conditions fall away in summaries (23-16 § 06) — apply equally when reading the estimate sentences of this part (label "Estimate").

What this chapter can say

What is said	What is not said
The list of questions of Part 24, and what does not move even if each is settled (Table 1)	The answer to any of the questions. The "size" of a question is the kind of work, not an estimate of time
The list of candidate rules, and the estimate of their relation to the three sources of difficulty (Tables 2 and 3)	The consistency of any candidate, or its prospect for the third step
The sixteen items that Part 24 does not claim, and the places in the text that support them (Table 4)	Whether the proposition of each item is true

Sources and reproduction

Item	Kind	Source / tools
Each row of Table 1	This book	The chapter and section in the right-hand column

Item	Kind	Source / tools
The candidates and sources of difficulty of Tables 2 and 3	Estimate	24-06 § 07, 24-07 § 05, § 06. The sources of the existing results the candidates draw on are in the source table of each chapter (the four properties of the weight from the book by Bauerschmidt–Brydges–Slade, the two-dimensional loop equations from the summary in § 6 of Chatterjee's review, log-Sobolev at strong coupling from the abstract of Shen–Zhu–Zhu)
Each row of Table 4	This book	The chapter and section in the right-hand column
The three meanings	This book	23-16 § 01

Terms used in this chapter — the status of a question (done, partly done, not yet, new), what does not move even if settled, candidate rules, combinations, the three sources of difficulty, the coupling window, not shown / not read strongly / not called false. Their meanings are in A-02 Glossary and 24-09.

Next page to read: 24-09 Table of notation for the first road, second half. To go back to the map of Part 24, 24-00.

Table of notation for the first road, second half

This chapter is a guide to notation and terms.

What this page shows — A list of the symbols used in Part 24. For each symbol, its meaning, where it is defined, its unit, and whether it is the same quantity as the symbol with the same letter in Part 23 or a different one.

Prerequisite chapters — None. The notation of Part 23 is in 23-01 § 01 and A-01 Table of notation.

Said first — Quantities are counted in lattice units (the lattice spacing is 1). Langevin time has the dimension of length squared (diffusion), and the value of C_P measured in physical units is $a^2 C_P$. Numbers are values under the conditions of the chapter of definition, and their labels are in that chapter.

01

List of symbols

Table 1 Symbols of Part 24 ("Same" = the same quantity as the same letter in Part 23; "New" = a symbol added in Part 24)

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
ℓ	A ruler of length given from outside (independent of the gap). In four dimensions the bookkeeping length; for the 0+1 double well $1/\omega_b = 1$	24-03 § 02	Length / $a\ell$	New (in four dimensions the same quantity as the bookkeeping length of 23-01 § 07)
ξ	Correlation length $1/m_{\mathrm{lat}}$. In 0+1, $\hbar/\Delta$	(1) and (17) of 23-01	Length / $a\xi$	Same

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
ξ_{RG}	The bookkeeping length (the length fixed by counting the steps that coarsen the lattice) $= 1/a$	23-01 § 07	Length / 1	Same
ξ_{XY}	The static length of the two-dimensional $U(1)$ strip, $-1/\ln(I_1(\beta)/I_0(\beta))$ (the inverse of the string tension)	24-01 § 02, 24-02	Length	New
$R = c\ell$	Side of the local window or box	24-03 § 03	Length	New
c	The ratio of the window length to the ruler	(2) of 24-03	Dimensionless	New
$\mathcal{D}$	The algebra of time-averaged functionals (weights with bounded support)	(1) of 24-03	—	New (fixes the collection over which the supremum in (7) of 23-01 is taken)
$\mathcal{D}_c$	The subfamily of $\mathcal{D}$ whose weights have support in the window $[0, c\ell]$	(2) of 24-03	—	New
$\mathcal{F}_1$	The family of time-integrated single-time functions	24-04	—	A name given to the family of test functions of the One-Sided Bridge Proposition (Theorem 3.1 of the paper) of 23-01
C_P	The Poincaré constant $\sup \mathrm{Var}/\mathcal{E}$ (path measure)	(7) of 23-01. In Part 24 the supremum is taken over $\mathcal{D}$	Length squared (Langevin time) / $a^2 C_P$	Same (the path C_P of 23-01 Table 3)

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
$C_P^{\mathrm{loc}}(c)$	The local Poincaré constant (the supremum over $\mathcal{D}_c$)	(2) of 24-03	Length squared	New
$C_P^{\mathrm{loc},0}(R)$	The value of the massless reference in the same box with the same graduation, $= \Gamma(R)R^2$	(4)(5) of 24-03	Length squared	New
$K(c)$	The constant of the local diffusive-relaxation-time assumption in absolute form, $C_P^{\mathrm{loc}}(c) \le K(c)\ell^2$	(3) of 24-03	Dimensionless	The local version of C in (14) of 23-01 (K in Lean)
K_{rel}	The ratio $C_P^{\mathrm{loc}}/C_P^{\mathrm{loc},0}$	(5) of 24-03	Dimensionless	New
Γ	The coefficient of the value for the reference box, $C_P^{\mathrm{loc},0}(R)/R^2$. $\Gamma_\infty = 0.0740$ for the scalar, $\Gamma_Q = 0.0277$ for the gauge quotient	24-03 § 03, Table 1	Dimensionless	New
λ_W	The Dirichlet value of the box within the test space multiplied by R^2 ($4\pi^2$ for the scalar, 72.0 for the gauge quotient). For a window function W, $\|\nabla W\|^2/\|W\|^2$	(7) of 24-01, 24-03 Table 1	Dimensionless	New

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
κ	The constant comparing the Langevin metric with the metric of the kinetic term (the metric comparison assumption ((A3) in the paper)). A different quantity from the correction κ to the raw rate on the strip in 24-02 § 05 (which is neither κ_BE nor this κ)	The one-sided bridge of 23-01	Dimensionless	Same
κ_{BE}	The lower bound on the Bakry–Émery curvature. A different quantity from the comparison constant κ of the one-sided bridge	24-06 § 01	Inverse length squared	New
s	The rate of rarity (the exponent with which the measure of the bad set B falls, as $\mu(B) \le e^{-s}$). The same quantity as ℓ of Part 23	24-06 § 01 (formulas: (7) of § 06, the rule of rarity of bad sets of § 07)	Dimensionless ($-\ln \mu(B)$; in the 0+1-dimensional example, the order of the action difference divided by $\hbar$; for one link of the group, $s \approx \beta$)	The rarity exponent ℓ of 23-09
K_*	The threshold of the bridge $\kappa/(\lambda_W \Gamma)$	24-04	Dimensionless	New

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
ℓ_c	The length at which conservation breaks on the two-dimensional $U(1)$ strip (the bend in the relaxation of the flux dipole)	24-01 § 02, 24-02	Length	New
ℓ_*	The length at which conservation breaks (the general name. The candidate definition is (2) of 24-02: the smallest R at which the ratio reaches half its saturation value)	24-02	Length	New
R_*	The crossing length $\sqrt{d\lambda_W/\hbar}$ (the boundary between the regimes of transport and of the barrier)	(7) of 24-01	Length	New
λ_Q	The relaxation rate of the topological charge of the strip, $1/\tau_{\mathrm{int}}(Q)$	24-02	Inverse Langevin time	New
τ_{int}	Integrated autocorrelation time	(1) of 24-01, 23-02 § 05	Langevin time (in the originals, numbers of sweeps or molecular-dynamics time)	Same
m	The gap as an inverse time, $m = \Delta/\hbar$. In four dimensions m_{lat}	(1) and (17) of 23-01	Inverse length	Same (m_{lat})

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
m_{phys}	The mass in physical units $m\ell$ ($m_{\mathrm{lat}}\xi_{\mathrm{RG}}$ in four dimensions)	(12)(16) of 23-01	Dimensionless (physical units)	Same
Δ	The gap of the Hamiltonian $E_1 - E_0$	The one-sided bridge of 23-01	Energy	**Restricted to one meaning** (§ 02 below)
ω_b	The angular frequency at the bottom of the double well $\sqrt{V''(\pm 1)} = 1$	(7) of 24-03, 24-04	Inverse time	New (a quantity of the model of 23-04)
S_0	The kink action $2/3$	23-04 § 03	Action	Same
$\varphi(x)$	The window factor $1 - (1 - e^{-x})/x$	The bracket in (17) of 23-01, 24-04	Dimensionless	Same (different from the plaquette angle φ_p)
φ_p	The plaquette angle of the two-dimensional strip	24-01 § 02, 24-02	Angle	New
Q, Q_s	The topological charge, the smoothed topological charge. On the two-dimensional strip $Q = \sum_p [\varphi_p]/2\pi$	24-01 § 02, 24-03 § 04	Integer (Q_s is real)	The same as Q in the note of 23-01 § 05
χ_t, h, d, g	The topological susceptibility, the density of breaking of conservation, the transport coefficient, the coefficient of the boundary layer	(4)(5) of 24-01	Lattice units (h, d, g depend on the graduation of $\mathcal{E}$)	New

Symbol	Meaning	Where defined	Unit (lattice) / physical reading	Correspondence with Part 23
$C_P^{\mathrm{sec}}(n)$, C^{trans}	The Poincaré constant of a sector, the quantity between sectors	(8)(10) of 24-03	Length squared	New

02

Symbols with the same letter but different meanings

Δ. In 23-01 of Part 23, Δ was used in two meanings: $\Delta(\beta) = m_{\mathrm{lat}}/a$ of (1) (the mass in physical units) and $\Delta = E_1 - E_0$ of the one-sided bridge (the gap of the Hamiltonian). In Part 24, Δ is **restricted to the meaning $E_1 - E_0$ of the one-sided bridge**, and the mass in physical units is written m_{phys}.

K. (14) of 23-01 writes the constant of the relaxation-time upper-bound assumption as C, and the Lean theorems write the same constant as K. $K(c)$ in Part 24 is its local version, K_{rel} is the constant of the ratio form, and K_* is the threshold of the bridge. The three are different quantities.

φ. The window factor $\varphi(x)$ carries an argument, and the plaquette angle of the two-dimensional strip is φ_p with a subscript.

Q. The four-dimensional topological charge and the topological charge of the two-dimensional strip are written with the same letter. Both are "global integers that do not show in the gap", examples of the Q of the type of 24-01. The two-dimensional numbers do not imply anything for four dimensions.

Symbols with λ. λ_1 (the Langevin gap $= 1/C_P$, 23-01), λ_W (the Dirichlet value of the box) and λ_Q (the relaxation rate of the topological charge of the strip) are different quantities.

Next chapter to read: 25-00 Entrance — space, not time.

Entrance — space, not time

> This chapter is a guide (the entrance to this part).

This part is a record of this book's study. The theorems that have been machine-checked are in Parts 20–22, and the current list of premises is in 28-04.

What this chapter shows — Part 23 was a road towards the mass gap from the direction of time (the time over which fluctuations are smoothed out, and the transfer matrix). Part 25 is the second road, towards confinement from the direction of space. We shrink two of the four directions to a small twisted two-dimensional torus T^2 and consider the area law of Wilson loops on the remaining plane $\mathbb{R}^2$. In this chapter we state (1) why we go once by way of a small twisted T^2, (2) how the problem then splits in two, (3) which tool works at which scale (Figure 2, "the ladder of scales"), and (4) the map of the ten chapters of Part 25.

Prerequisite chapters — 5-01 (Wilson's lattice), 5-02 (strong coupling), 17-02 centre vortices, 4-06 (asymptotic freedom), 4-07 (dimensional transmutation), 7-07 (what the four-dimensional construction has reached). The entrance of Part 23, 23-00.

Said first — This chapter is a map, and it contains no newly proved statements. "On a small twisted T^2 the coupling stays weak up to the size of the T^2" is a physical estimate made on the assumption of ultraviolet control (a bound, uniform in a, from the lattice spacing a up to the size of the T^2). What the construction published on 2026-11-10 showed is the continuum limit with periodic boundary conditions on a cubic box; construction with twisted boundary conditions or on elongated boxes is not in it (within the range searched). The "ultraviolet control" of this part remains as a still-open condition: "that the same construction holds under twisted boundary conditions". The road of Part 25 heads first for confinement (the area law), not for the mass gap itself. That the two are different statements is as in 17-02 and 16-08.

The order of this chapter

1. The second road — what we look at, and from which direction
2. Two walls — the ultraviolet and the crossover band
3. Why a small twisted T^2 — two reasons

4. The ladder of scales — which tool works at which scale (Figure 2, Table 1)
5. Map of the ten chapters of Part 25 (Table 2)
6. The conventions of notation and words in this part
7. Guide to Part 23 and Part 26
8. What cannot be said
9. The table of five grades and the dependency graph (Table 3)

01

The second road — what we look at, and from which direction

The road of Part 23 regarded one direction of the lattice as "time", and approached the mass gap from the gap of the transfer matrix and from the time over which fluctuations are smoothed out. Where it stopped is summarised in 23-15.

In Part 25 we change direction. Of the four directions of the four-dimensional lattice, we wind two (directions 1 and 2) into a torus T^2 with small period L, and regard the other two (directions 3 and 4) as a large plane. We ask whether a Wilson loop $W(C)$ drawn in the plane decreases as $\langle W(C)\rangle \le e^{-\sigma A}$ in the area A it encloses (the area law). Where the time road looked at "the gap", what this road looks at is "how vortices are counted in the plane".

We put 't Hooft's twist (25-01) on the wound T^2. It is known in the physics literature that if one shrinks to a periodic T^2 without twist, a family of flat connections (zero modes) remains, and there is no prospect of joining the small T^2 to large four dimensions without a phase transition Cited (the title of § 2.1 of Tanizaki–Ünsal 2022 is "compactification to periodic T^2 and the absence of adiabatic continuity"). For a twisted T^2, the same paper states the conjecture that the structure of the weakly coupled vacuum on a small $T^2 \times \mathbb{R}^2$ is joined without a phase transition to the strongly coupled region of $\mathbb{R}^4$ Cited . This conjecture remains a conjecture, and this book also treats it as one.

02

Two walls — the ultraviolet and the crossover band

If one starts from the lattice, builds the four-dimensional theory and tries to show confinement or a mass gap, one hits two walls of different nature.

1. **The ultraviolet wall.** One needs uniform bounds at all scales that do not break down as the lattice spacing a approaches 0. Thanks to asymptotic freedom (4-06) the

coupling becomes weak at short distances, and one can consider a multiscale analysis that controls each scale in perturbative language. For four-dimensional Yang–Mills, on 2026-11-10 a Lean formalisation that builds a theory satisfying the Wightman axioms as a limit of Wilson's lattice was published together with the committee's assessment report, and the committee's assessment is that it is proved in Lean (Volume 2, 6-00). However, what that construction showed is the continuum limit with periodic boundary conditions on a cubic box. Construction on the small T^2 with twisted boundary conditions used in this part, and on elongated boxes (the product of a small T^2 and a large plane), is not in the published construction (within the range searched). In this book we treat the ultraviolet stage of this part as an assumption named "ultraviolet control", and read its content as the open condition "that the same construction holds under twisted boundary conditions" Assumption . The reach before that (Bałaban's series) is in 7-07.

2. **The crossover band.** One must cross, without relying on perturbation theory, the intermediate scale at which the coupling passes from weak (short distances) to strong (long distances), around $1/\Lambda$ in physical length (Λ is the scale born of dimensional transmutation, 4-07). On each side there are tools (perturbation theory and semiclassics on the weak-coupling side, the strong-coupling expansion on the strong-coupling side, 5-02). That no tool works inside the band is where both the road of Part 23 of this book and this road stop (Part 26).

If one heads straight for four dimensions, the two walls appear at the same time. This is because one has to manage, within a single bound, both making the lattice spacing small (the ultraviolet) and looking at long distances in a large box (crossing the band).

03

Why a small twisted T² — two reasons

The skeleton of this road is that going by way of a small twisted T^2 lets us separate the two walls into different stages. There are two reasons.

Reason 1: the twist removes the zero modes, so one can proceed at weak coupling up to the size of the T^2 (an estimate). On a twisted T^2, the configuration with action 0 is fixed to be unique up to gauge (25-01 Uniqueness of the Twisted Vacuum), and the lattice Laplacian of the adjoint fluctuations around it has a positive gap $4\sin^2(\pi/2N)$ (25-01 Twisted Adjoint Gap Lemma, $N = L/a$) Proved here . In physical units, when N is large this gap is of order $(\pi/L)^2$, and all classical fluctuations have masses of order $1/L$. The running of the coupling then stops at the size L of the T^2, and if $L\Lambda \ll 1$ the effective coupling $g^2(L)$ is expected to stay small Reading (a physical estimate, on the assumption of ultraviolet control). The band does not appear in this stage.

Reason 2: the surface of a vortex winding the T^2 closes locally in the plane. A centre vortex (17-02) is a two-dimensional surface in four dimensions, and in four dimensions the vortex surface linked with a Wilson loop in the plane is an extended object whose cost grows with area. In the work of this book, every road that tried to cross the band while staying in four dimensions stopped at one point: "a topological quantity (whether a vortex links a loop) cannot be compared monotonically by local operations" (map in 26-08) Reading . In $\mathbb{R}^2 \times T^2$, the surface $\{p\} \times T^2$ above a point p of the plane is a closed surface of area L^2, and in the plane it behaves like a point. Adding or removing one vortex sheet becomes an operation inside a bounded region of the plane Proved here (that the surface lies in a bounded region is a fact from the definition). This locality supports all of the containers (25-03), slab confinement (25-04) and the insertion identities (25-05).

In this way the problem splits in two.

- **The intermediate goal (on a small T^2):** on $\mathbb{R}^2\times$ a small twisted T^2, show the gap and the area law uniformly in the lattice spacing a. The only wall that remains is the ultraviolet (construction under twisted boundary conditions) (though this is a conditional research plan, placing assumptions named ultraviolet control, uniform acceptance of insertion and frame decorrelation, and not a theorem) Assumption .
- **The last stage (widening the T^2):** that the strength of the area law stays uniform even as L is made larger, beyond $1/\Lambda$. The only wall that remains is the band (25-09) Assumption .

Splitting does not make it easier. The band remains whole in the last stage. What the splitting gains is that all the stages before the band can be arranged in a form that can be checked independently of the band, and that the form of the inequality the band demands can be narrowed to one (Part 26).

04

The ladder of scales — which tool works at which scale

Figure 2 takes the physical length L (the side of the small T^2, or the scale being looked at) vertically, and lays out, from the lattice spacing a at the bottom to infinity at the top, which tool works at which scale. It is a figure for seeing in one picture the shape of the problem: there are tools at the bottom (weak coupling) and at the top (strong coupling), and only the band in the middle is empty. The number and title of the figure match the entrance of Part 26 (Figure 2 "the ladder of scales" of 26-00). Figure 1 (the flow of the logic) is in 16-09.

Figure 2 The ladder of scales. The vertical axis is physical length (shorter towards the bottom). The labels of each stage are in Table 1; the text in the figure summarises the labelled rows and is not itself a claim

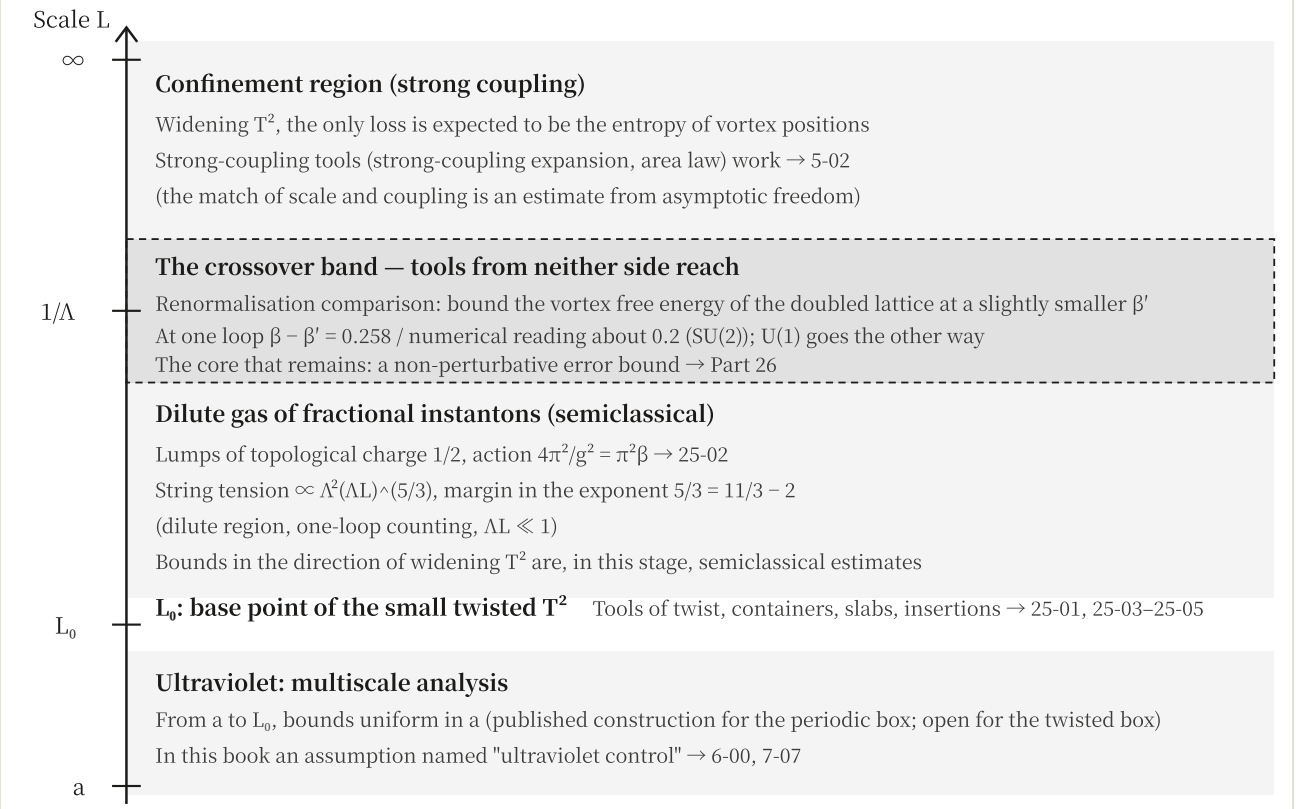

Figure 2 in words is as follows. From the bottom: from the lattice spacing a up to the base-point length L_0 is the ultraviolet stage (construction under twisted boundary conditions; an assumption in this book); L_0 is the base point of the small twisted T^2 (where the tools of Part 25 work directly); from L_0 to $1/\Lambda$ is the stage of the dilute gas of fractional instantons (a semiclassical estimate, with string tension of order $\Lambda^2(\Lambda L)^{5/3}$); around $1/\Lambda$ is the crossover band (where the renormalisation comparison is known only at the one-loop level and numerically); and above that is the confinement region (where strong-coupling tools are expected to work).

Table 1 Content and labels of each stage of Figure 2 (conditions in the same row)

Stage	Content	Label	Conditions, scope	Chapter
$a - L_0$	Multiscale bounds uniform in a (locality of the effective action, rarity of large fields, flow of the coupling)	Assumption	An assumption named ultraviolet control (that the same construction holds under twisted boundary conditions). The published construction covers only the periodic cubic box. In Bałaban's earlier series, stages remain that the original sources call unpublished	6-00, 7-07
L_0	Uniqueness of the vacuum that absorbs the twist, the gap $4\sin^2(\pi/2N)$ of the adjoint Laplacian, positive minimal action in the (1,1) sector	Proved here	SU(2), lattice, N fixed, $n_{12} = 1$	25-01
L_0	With the lattice spacing and the T^2 fixed, an area law at every β	Proved here	N fixed, lattice spacing fixed. In the continuum limit the tension becomes 0. Comparison with earlier work not yet done	25-04

Stage	Content	Label	Conditions, scope	Chapter
L_0	The gap and the area law on a small T^2, uniformly in a	Assumption	A conditional research plan under control of the ultraviolet, uniform acceptance of insertions and frame decorrelation	25-09, 27-01
L_0 – $1/\Lambda$	The lower bound $4\pi^2/g^2$ on the action of a self-dual lump of topological charge $\frac{1}{2}$, and the string tension $\Lambda^2(\Lambda L)^{5/3}$ of the dilute gas	Cited + Reading	The former is the BPS bound (a formula of the original source). The latter is a physical estimate from the dilute region and one-loop counting (equations (2.32) and (2.37) of Tanizaki–Ünsal)	25-02
Around $1/\Lambda$	Renormalisation comparison: at the one-loop level $\beta - \beta' = 0.258$ (per doubling of the lattice)	Proved here	One-loop level, SU(2), $\beta = 4/g^2$. Not a claim outside perturbation theory	26-06
Around $1/\Lambda$	Numerical reading: for SU(2) $\beta - \beta' \approx 0.2$; for U(1) the other way	Reading	Lattices $4^4 \to 8^4$ and others; the number of seeds and the errors are in 26-09	26-06
Around $1/\Lambda$	An inequality that crosses the band without relying on perturbation theory	Assumption	Unsolved. Its form is narrowed to one inequality in Part 26	26-02
$1/\Lambda$ – ∞	Area law on the strong-coupling side	Cited	A lattice statement at small β. The match with the scale of physical length is an estimate from asymptotic freedom	5-02

Of the rows of Table 1 at L_0, the upper two are statements with the lattice spacing fixed, and differ in strength from the third row, "uniform in a". This difference (making things uniform in the lattice spacing) is the ultraviolet wall, and each chapter of Part 25 writes in the same row on which side each statement lies.

05

Map of the ten chapters of Part 25

Part 25 consists of the following ten chapters. The labels are the main labels of the rows in each chapter; the finer division is in each chapter's table of five grades. The "Conditions" column gives the conditions that always attach to the chapter's main statements.

Table 2 The ten chapters of Part 25 (labels and conditions in the same row)

Chapter	Title	Content in one line	Main labels	Conditions

Chapter	Title	Content in one line	Main labels	Conditions
25-00	Entrance — space, not time	This chapter	Reading + Cited	"Stays weakly coupled" is an estimate under the assumption of control of the ultraviolet
25-01	The twisted T^2 and 't Hooft flux	$n_{12} = 1$, sectors, the flux free energy, the twist-summed ensemble. Three elementary facts	Cited (definitions) / Proved here (three facts)	SU(2), lattice, N fixed, $n_{12} = 1$
25-02	Vortices and fractional instantons	Lumps of topological charge $\frac{1}{2}$, action $4\pi^2/g^2$, the dilute gas, string tension $\Lambda^2(\Lambda L)^{5/3}$, and that the lattice action approaches $\pi^2\beta$ from below	Cited / Reading / Computer-assisted / Assumption	Dilute region, one loop, SU(2). The cooled action is an upper bound
25-03	Containers — conditioning on the frame makes things independent	The container identity (Mack–Petkova), nesting in the directions of the plane, limits in four dimensions	Cited / Proved here	The identity is known. Lean covers only the finite algebra
25-04	Slab confinement	With the lattice spacing and the T^2 fixed, an area law at every β	Proved here	N fixed, lattice spacing fixed, tension 0 in the continuum limit. Comparison with earlier work not yet done
25-05	Vortex-insertion identities	Expectation 1 of the insertion ratio, correlation with the sign of the sector, averaged bounds, second moments	Proved here	Finite configuration space, positive weights, a bijection that flips the sector
25-06	Insertion driven by dynamics, and the flow lemma	A Jarzynski-type identity, bounds on simultaneous flips	Proved here / Cited	Bounds on the kernel of one step cannot be used to test the band
25-07	Why fixed maps fail	A map that does not change the shape of fluctuations cannot see the 4 of antiscreening. $11/3 = -1/3 + 4$	Proved here / Reading	One-loop level

Chapter	Title	Content in one line	Main labels	Conditions
25-08	The measured record	Work of driven insertion, vortex free energy, string tension of the slab	Reading	Group, β, lattice size, number of measurements and errors in each row
25-09	Where this road stops	Widening the T^2 = the crossover band	Assumption + Reading	—

We recommend reading in numerical order. A reader in a hurry can follow the skeleton of the road by reading 25-01 § 01– § 02 (the setting), 25-02 § 01– § 03 (fractional instantons and the dilute gas), 25-04 (slab confinement) and 25-09 (where it stops), in that order.

06

The conventions of notation and words in this part

- **Group and coupling.** Throughout Part 25 the group is fixed to $SU(2)$. The Wilson action is $\beta \sum_p (1 - \frac{1}{2} \operatorname{tr} U_p)$ in the convention of 5-01, with $\beta = 4/g^2$.
- **N and M.** The N of Part 25 is not the degree of the group but the number of lattice points along a side of the small T^2 ($L = Na$). We write M for the number of lattice points along a side of the plane. The lattice is $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$.
- **Band and window.** The subject of this part and of Part 26 is "the crossover band" (the band for short). It is a different thing from the "windows" of Parts 23 and 24 (the site window, the window in $\hbar$, the time window), and that the words differ carries no meaning beyond that (note in 26-00).
- **Names of assumptions.** We call assumptions by names, not symbols: control of the ultraviolet, uniform acceptance of insertions, frame decorrelation, the uniform slab tension, the uniform slab gap. The index is collected in A-06.
- **Labels.** The same five as in Part 23: Proved here (a paper proof placed in the text), Cited (known, checked in the original source), Computer-assisted (a computer-assisted bound), Reading (a numerical reading; physical estimates are marked "physical estimate"), Assumption (an assumption, or a row for which only a strand of proof exists; the evidence column says where the strand is). How to read them is in 23-00.

07

Guide to Part 23 and Part 26

To Part 23 (the first road). Part 23 is the road towards the mass gap from the direction of time, and it built the diffusive-relaxation-time assumption in the model of the first step. The entrance is 23-00, where it stopped is 23-15, and the considerations beyond

are in Part 24 (24-00). The two roads aim to show different statements (Part 23 the gap, Part 25 first the area law).

To Part 26 (the band). Both roads stop just before a statement of the type "the same constant at all scales". Part 26 (26-00) treats the correct form of that statement (the correct form of the band, 26-01), its reduction to one inequality (26-02), and the same band seen from the side of time (26-07). The last chapter of Part 25 (25-09) is the bridge to Part 26.

To the table of stages. The table of the stages a proof must contain (the container, the ultraviolet, the gap on a small T^2, confinement on a small T^2, the band, $\mathbb{R}^4$, general groups) is in 16-09. Part 25 fills the two "small T^2" stages of that table and the entrance to the "band" stage.

08

What cannot be said

(a) Weak coupling. "The coupling stays weak up to the size of the T^2" is a physical estimate on the assumption of ultraviolet control, not a theorem. Bounds uniform in the lattice spacing in the setting of this part (the small T^2 with twisted boundary conditions and elongated boxes) appear neither in this book nor in the published construction (the published construction is for the periodic cubic box).

(b) Adiabatic continuity. That the small T^2 and $\mathbb{R}^4$ are joined without a phase transition is a conjecture, and this book does not use it. What it uses is only the form "if they are joined, what must be shown".

(c) Confinement and the gap. The goal of this road is the area law, and there is no known road from the area law to the mass gap. The two are different statements (16-09, 27-01).

(d) Figure 2. Figure 2 is a map of where the tools sit, and the match of scale and coupling (which L corresponds to which β) is an estimate from asymptotic freedom. The numbers in the figure summarise the labelled rows of Table 1.

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
1  CIT  no continuity on a periodic T²                          physical argumen
2  CIT  continuity from twisted T² × R² to R⁴ (conjecture)   conjecture
3  PRV  unique vacuum absorbing the twist, gap 4sin²(π/2N)    SU(2), N fixed,
4  PRV  surface {p} × T² lies in a bounded region of the plane
5  ASM  ultraviolet control (construction under twisted boundary conditions)
6  RDG  weak coupling up to the size of T² ⟸ 3, 5             physical estima
7  RDG  the one point where roads crossing in 4D stopped     within the roads
8  ASM  splits into intermediate goal and last stage ⟸ 4, 6, 7
9  MIX  Figure 2, Table 1 ⟸ 5, 6, 8
```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. The only nodes with proofs placed are the uniqueness of the twisted vacuum and the gap (proved in 25-01) and that the surface lies in a bounded region of the plane (definition). The conjecture of continuity from the twisted T^2 to R^4 enters as a premise of no node. The assumption row (ultraviolet control) does not contain the quantities of the conclusion (gap, area law) and states only the form of a multiscale bound. The nodes on the conclusion side of this chapter (weak coupling persists, the problem splits in two) are "Reading" and "Assumption", and there is neither a node of confinement nor a node of the mass gap.

2026-10-15 · chapter Yang–Mills and the mass gap Part 25 The second road — from the direction of space twist, sectors, the flux free energy · Kiichi, Shiori and Rin

The twisted T² and 't Hooft flux

> In this chapter, § 01 and § 02 are established knowledge and § 03 onward are this book's own investigation.

What this chapter shows — We define the stage of Part 25. To the $SU(2)$ Wilson action on the lattice $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ we add 't Hooft's twist $n_{12} = 1$ in the plane of the small T^2, and set up the two sectors of the flux n_{34} in the directions of the plane, the ratio of their partition functions (the flux free energy), and the twist-summed ensemble that combines the two sectors into one measure. We then state with proofs three elementary facts that form the foundation of this road: (1) uniqueness of the configuration with action 0 (the vacuum that absorbs the twist), (2) the antiperiodicity of the adjoint field around it and the gap $4\sin^2(\pi/2N)$ of the two-dimensional lattice Laplacian, and (3) that the $(1,1)$ sector has no flat configuration and its minimal action is positive.

Prerequisite chapters — 25-00 (the entrance and notation of this part), 5-01 (link variables, plaquettes, the Wilson action), 1-04 ($SU(2)$ and the Pauli matrices), 3-05 (topological charge), 17-02 centre vortices.

Said first — Every statement of this chapter is about the group $SU(2)$, a finite lattice, N fixed and the twist $n_{12} = 1$. It says nothing about the continuum limit, bounds uniform in the lattice spacing, or confinement. Most of the definitions are known ones of the type of 't Hooft (1979, 1981) and Mack–Petkova (1980) Cited ; the three properties are elementary, and their proofs are placed in the text Proved here . All three are lattice versions of things known in the physics literature, and we claim nothing new about them.

The order of this chapter

1. The setting — lattice, action, the sign field z
2. Sectors and the flux free energy — the Moving-Surface Lemma and the definition
3. The twist-summed ensemble — the Parity Representation of the Bias

4. Plaquettes with central values, and holonomy — configurations with action zero, and the commutator of the rounds
5. Uniqueness of the Twisted Vacuum
6. The twisted adjoint gap — antiperiodicity and $4\sin^2(\pi/2N)$
7. Positivity of the Minimal Action in the Twisted Sector — the (1,1) sector has no flat configuration
8. What the three properties of the twisted T^2 say
9. What cannot be said
10. The table of five grades and the dependency graph (Table 1)

01

The setting — lattice, action, the sign field z

This section summarises existing knowledge ('t Hooft's twisted boundary conditions written with a sign field on the lattice). The introduction is in 3-05 § 03.

Let the lattice be $\Lambda = (\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ ($N, M \geq 2$). Directions 1 and 2 form the small T^2, and directions 3 and 4 the plane. On each link (x, μ) we place $U_{x,\mu} \in SU(2)$, and we write the value of a plaquette $p = (x; \mu, \nu)$ ($\mu < \nu$) as

$$U_p = U_{x,\mu}\, U_{x+\hat{\mu},\nu}\, U^{-1}_{x+\hat{\nu},\mu}\, U^{-1}_{x,\nu} \quad (1)$$

(as in 5-01). Given a sign $z_p \in \{+1, -1\}$ for each plaquette, we set the action and the partition function to be

$$S^z(U) = \sum_p \Big(1 - \tfrac{1}{2}\, z_p \operatorname{tr} U_p\Big), \qquad Z[z] = \int e^{-\beta S^z(U)} \prod_\ell dU_\ell, \qquad \beta = \frac{4}{g^2} \quad (2)$$

dU_ℓ is the normalised Haar measure. If $z \equiv +1$, (2) is exactly the Wilson action of 5-01, and each term lies in $[0, 2]$ because $|\operatorname{tr} U| \leq 2$. A plaquette with $z_p = -1$ is "a plaquette with one central element -1 inserted", and there the action is 0 when $U_p = -1$.

The signs of the two sectors. We put the twist of the small T^2 in by placing $z_p = -1$ on exactly one plaquette of each $(1, 2)$ plane (the $N \times N$ plane with x_3, x_4 held fixed), namely the $(1, 2)$ plaquette at $(x_1, x_2) = (N-1, N-1)$. The position is the same for every (x_3, x_4). We write this as $z^{(0)}$ (all others are $+1$). The sign $z^{(1)}$ with one unit of flux added in the directions of the plane is obtained from $z^{(0)}$ by taking, above a unit square $q = (q_3, q_4)$ of the plane, the surface

$$\Pi_q = \{\, ((x_1, x_2, q_3, q_4); 3, 4) \;:\; x_1, x_2 \in \mathbb{Z}/N \,\} \quad (3)$$

and placing $z_p = -1$ on its N^2 $(3,4)$ plaquettes. Π_q is a "surface winding the T^2" standing above the point q of the plane, and in the plane it behaves like a point (reason 2 of 25-00 § 03).

02

Sectors and the flux free energy

Where the surface is placed, q, has no effect on the partition function. The next lemma shows this.

Moving-Surface Lemma Proved here For a link ℓ, write $\delta_\ell z$ for the field in which the signs of all plaquettes containing ℓ are flipped. Then $Z[\delta_\ell z] = Z[z]$. In particular, (a) the surface Π_q can be moved to the surface $\Pi_{q'}$ of a neighbouring square, and the partition function of $z^{(1)}$ does not depend on q. (b) The partition function of the sign $z^{(0)}$ $\prod_{q \in Q}(\text{surface } \Pi_q)$, with surfaces placed over a set Q, is determined only by the parity of $|Q|$.

Proof. The change of variables $U_\ell \mapsto -U_\ell$ preserves the Haar measure. Since -1 is a central element, in a plaquette that contains ℓ exactly once, U_p changes to $-U_p$, and other plaquettes do not change (a plaquette of the lattice contains a given link at most once). Hence $S^{\delta_\ell z}(-U_\ell, \ldots) = S^z(U)$, and the integrals are equal. (a): apply the lemma in turn to all the links in direction 3 above the point $(a, b+1)$ of the plane (the N^2 links obtained by running over x_1, x_2). The only $(3,4)$ plaquettes containing these links are those on $\Pi_{(a,b)}$ and $\Pi_{(a,b+1)}$, each containing exactly one. A $(\mu, 3)$ plaquette ($\mu \le 2$) contains two links in direction 3, both above the same point of the plane, so its sign is flipped twice and returns to what it was. Other plaquettes contain no link in direction 3. So the signs on the two surfaces $\Pi_{(a,b)}$ and $\Pi_{(a,b+1)}$ are flipped, and the surface moves one step over. Direction 4 is the same. (b): moving surfaces so that two overlap makes them cancel, $(-1)^2 = +1$, so this follows from (a) and the connectedness of the squares of the plane. ∎

The Moving-Surface Lemma is a basic property of the lattice version of 't Hooft's twist: it says that it is not the field z itself but only the parity of the number of -1 piercing each plane (the flux $n_{\mu\nu} \in \{0,1\}$) that affects the partition function Cited (the general form is 't Hooft 1979; the form with a lattice $\mathbb{Z}_2$ sign field is Mack–Petkova 1980). In this chapter we use only cases (a) and (b).

Definition of the sector and flux free energies We write $Z(0) = Z[z^{(0)}]$, $Z(1) = Z[z^{(1)}]$, and call the flux pairs $(n_{12}, n_{34}) = (1,0)$ and $(1,1)$ sectors. The flux in the mixed planes ($(1,3)$ and so on) is taken to be 0. We then set

$$\Delta F = \ln \frac{Z(0)}{Z(1)}, \qquad \theta(N, M, \beta) = \frac{Z(0) - Z(1)}{Z(0) + Z(1)} = \tanh \frac{\Delta F}{2} \tag{4}$$

ΔF is the difference of free energy for putting in one unit of flux n_{34} in the directions of the plane ('t Hooft's flux free energy), and θ is the "bias" between the two sectors. The right-hand equality of (4) comes from $(1 - e^{-\Delta F})/(1 + e^{-\Delta F}) = \tanh(\Delta F/2)$. Since $Z(0), Z(1) > 0$, $|\theta| < 1$. $\theta \geq 0$ (that is, $Z(1) \leq Z(0)$) needs a separate argument through the transfer matrix, and is treated in 26-04.

The reason this quantity matters for confinement is that the Tomboulis–Yaffe inequality bounds the expectation of a Wilson loop in the plane from above by a ratio of twisted partition functions Cited . If θ decreases in the size M of the plane as $-\ln \theta \geq cM^2$, the area law follows through that inequality. The exact form of the inequality, and that it is not enough for θ merely to move away from 1, are treated in 26-01.

03 The twist-summed ensemble

Instead of keeping the two sectors as separate measures, we combine them into one measure in which the placement of the surfaces is also a random variable. Let T be the set of all unit squares of the plane (M^2 of them), and for each subset $Q \subset T$ form the sign $z^Q = z^{(0)} \prod_{q \in Q} (\Pi_q \text{: sign } -1)$.

Definition (the twist-summed ensemble) Cited We call the probability measure on pairs (U, Q) of a configuration and a set of surfaces

$$\tilde{\mu}(dU, Q) = \frac{1}{\Xi} e^{-\beta S^{z^Q}(U)} \prod_{\ell} dU_\ell, \qquad \Xi = \sum_{Q \subset T} Z[z^Q] \tag{5}$$

the twist-summed ensemble. The form that sums the $\mathbb{Z}_2$ signs of plaquettes as random variables is of the type of the representation of Mack–Petkova (1980), who sum over all closed sign fields (where the product of the six on each cube is $+1$). Here we use a small form that sums only the surfaces involved in the flux n_{34} of the plane.

Parity Representation of the Bias (the bias as one expectation) Proved here $\theta = \mathbb{E}_{\tilde{\mu}}\left[(-1)^{|Q|}\right]$.

Proof. By the Moving-Surface Lemma (b), $Z[z^Q]$ is $Z(0)$ if $|Q|$ is even and $Z(1)$ if it is odd. Of the 2^{M^2} subsets of T, exactly half have an even number of elements. Hence $\Xi = 2^{M^2-1}(Z(0)+Z(1))$ and $\sum_Q (-1)^{|Q|} Z[z^Q] = 2^{M^2-1}(Z(0)-Z(1))$, and the ratio is the θ of (4). ∎

In the Parity Representation of the Bias, the placement Q of the surfaces is a record of "whether a vortex is there" above the points of the plane, and $(-1)^{|Q|}$ is the parity of the number of vortices in the whole plane. That the bias θ is small means that the parities are mixed almost fairly, that is, vortices well up freely in the plane. In $\mathbb{R}^4$, the vortex surface linked with a loop is an extended surface and cannot be written in this form of "a record above points" (25-00 § 03). This representation is the starting point both for rewriting things as a product of biases per column by dividing the plane into blocks (the Container Identity, 25-03) and for the identities of the map that inserts one vortex (25-05).

04

Plaquettes with central values, and holonomy

The proofs of the three properties reduce to properties of configurations in which every plaquette takes a central value (± 1). First we check that action 0 is the same thing.

Zero-Action Configuration Lemma (configurations with action 0) Proved here A necessary and sufficient condition for $S^z(U) = 0$ is that $U_p = z_p \cdot \mathbf{1}$ for every plaquette.

Proof. An element of $SU(2)$ can be written $U = \cos\alpha\,\mathbf{1} + i\sin\alpha\,(n\cdot\sigma)$ ($|n|=1$), and $\operatorname{tr} U = 2\cos\alpha$ (1-04). Each term $1 - \frac{1}{2} z_p \operatorname{tr} U_p = 1 - z_p \cos\alpha_p$ of (2) is at least 0, and it is 0 only when $z_p \cos\alpha_p = 1$, that is, when $\alpha_p = 0$ ($U_p = \mathbf{1}$) if $z_p = 1$, and $\alpha_p = \pi$ ($U_p = -\mathbf{1}$) if $z_p = -1$. ∎

Next, if all plaquettes take central values, the commutators of the holonomies around a plane are determined by the product of the signs of that plane. We write $P_\mu(x)$ for the product of links along the straight path that goes once around in direction μ from the base point x (of length N if $\mu = 1,2$, of length M if $\mu = 3,4$).

Lemma on the Sign of the Holonomy Commutator (the commutator is the product of the signs of the plane) Proved here If $U_p = z_p \cdot \mathbf{1}$ for every plaquette, then for $\mu \neq \nu$ and a base point x

$$P_\mu(x)\,P_\nu(x)\,P_\mu(x)^{-1}\,P_\nu(x)^{-1} = \varepsilon_{\mu\nu}\,\mathbf{1}, \qquad \varepsilon_{\mu\nu} = \prod_{p \subset (\mu,\nu)\text{ plane } \ni x} z_p \tag{6}$$

holds. The product on the right runs over all plaquettes of the (μ,ν) plane (a two-dimensional torus) through x.

Proof. Cut the (μ,ν) plane through x open into a square R with x at a corner. The path that goes once anticlockwise around the boundary of R from x consists, in this order, of one round in direction μ, one round in direction ν, one round backwards in direction μ and one round backwards in direction ν, and its holonomy is the left-hand side of (6). On the other hand, on a disc of the square lattice, the holonomy of the boundary equals a product, in some order, of the values of the plaquettes conjugated by parallel transport along paths to the base point (the lattice non-abelian Stokes theorem: an induction that peels plaquettes off one at a time and shrinks the boundary path). If all plaquette values are central elements $z_p\mathbf{1}$, conjugation does not change the values and the order does not matter, so the product is $\prod_{p\subset R} z_p$. ∎

For $z^{(0)}$, every $(1,2)$ plane has exactly one -1, so $\varepsilon_{12}=-1$, and the other planes have $\varepsilon=+1$. For $z^{(1)}$, in addition, the $(3,4)$ planes have exactly one -1 (the one meeting the surface Π_q), so $\varepsilon_{34}=-1$. This is the lattice version of the relation, in 't Hooft's twisted boundary conditions of the continuum theory, that the consistency of the gluing in two directions is off by the central element $e^{\pi i n_{\mu\nu}}$ Cited ('t Hooft 1979).

Finally, we state how far the holonomies determine a configuration.

Determination-by-Holonomy Lemma (determined by holonomy) Proved here If two configurations U, U' satisfying $U_p = z_p\mathbf{1}$ (for every p) for the same z have the same four holonomies at the base point 0 ($P_\mu = P'_\mu$, $\mu=1,\dots,4$), then U' is a gauge transform of U.

Proof. For each lattice point x choose a fixed path γ_x from 0 to x (the path that goes in the positive sense in direction 1, direction 2, direction 3 and direction 4, in that order), and write $U(\gamma_x)$ for the product along it. For a link $\ell=(x\to y)$, consider the closed path $c_\ell=\gamma_x\,\ell\,\gamma_y^{-1}$. In the two-dimensional skeleton of the toroidal lattice, a closed path based at 0 can be deformed, by sweeping finitely many plaquettes, into a word in the four straight rounds (the lattice version of $\pi_1(T^4)=\mathbb{Z}^4$, a standard topological fact Cited). The plaquettes swept in the deformation take central values, so the holonomy of c_ℓ is the product of "the product of z over the swept plaquettes" and "a word in the P_μ", both of which are the same for U and U'. Hence $U(\gamma_x)U_\ell U(\gamma_y)^{-1} = U'(\gamma_x)U'_\ell U'(\gamma_y)^{-1}$, that is, setting $g(x)=U'(\gamma_x)^{-1}U(\gamma_x)$ gives $U'_\ell = g(x)\,U_\ell\,g(y)^{-1}$. ∎

05
```

Uniqueness of the Twisted Vacuum

The configuration that absorbs the twist. Set $\Omega_1 = i\sigma_1$, $\Omega_2 = i\sigma_2$, and define the configuration U^0 as follows. Of the links in direction 1, only those at $x_1 = N-1$ (those crossing the seam of the T^2) are Ω_1; of the links in direction 2, only those at $x_2 = N-1$ are Ω_2; all other links (including those in directions 3 and 4) are $\mathbf{1}$.

Lemma on the Configuration that Absorbs the Twist Proved here $\Omega_1\Omega_2\Omega_1^{-1}\Omega_2^{-1} = -\mathbf{1}$. Moreover, among the plaquettes of U^0, only the $(1,2)$ plaquette at $(x_1, x_2) = (N-1, N-1)$ is $-\mathbf{1}$, and all others are $\mathbf{1}$. Hence $S^{z^{(0)}}(U^0) = 0$.

Proof. From $\sigma_1\sigma_2 = i\sigma_3 = -\sigma_2\sigma_1$ we get $\Omega_1\Omega_2 = -\sigma_1\sigma_2 = -i\sigma_3$ and $\Omega_1^{-1}\Omega_2^{-1} = (-i\sigma_1)(-i\sigma_2) = -i\sigma_3$, and the product is $(-i\sigma_3)^2 = -\mathbf{1}$. Looking at the plaquette (1), all $(1,2)$ plaquettes not containing the seam are $\mathbf{1}$. At $x_1 = N-1$, $x_2 \neq N-1$ we get $\Omega_1 \cdot \mathbf{1} \cdot \Omega_1^{-1} \cdot \mathbf{1} = \mathbf{1}$; at $x_2 = N-1$, $x_1 \neq N-1$ we get $\mathbf{1} \cdot \Omega_2 \cdot \mathbf{1} \cdot \Omega_2^{-1} = \mathbf{1}$; at the corner $(N-1, N-1)$ we get $\Omega_1\Omega_2\Omega_1^{-1}\Omega_2^{-1} = -\mathbf{1}$. The links in directions 1 and 2 do not depend on x_3, x_4, so all plaquettes involving directions 3 and 4 are $\mathbf{1}$. By the Zero-Action Configuration Lemma the action is 0. ∎

Rigidity Lemma for Anticommuting Pairs (an anticommuting pair) Proved here If A, $B \in SU(2)$ satisfy $ABA^{-1}B^{-1} = -\mathbf{1}$, then for some $g \in SU(2)$ we have $gAg^{-1} = i\sigma_1$, $gBg^{-1} = i\sigma_2$. Moreover, the only elements of $SU(2)$ that commute with both $i\sigma_1$ and $i\sigma_2$ are $\pm\mathbf{1}$.

Proof. Taking the trace of $ABA^{-1} = -B$ gives $\operatorname{tr} B = -\operatorname{tr} B$, hence $\operatorname{tr} B = 0$ and $B = i\,b \cdot \sigma$ ($|b| = 1$). Likewise $BAB^{-1} = -A$ gives $A = i\,a \cdot \sigma$. Since $(a \cdot \sigma)(b \cdot \sigma) = (a \cdot b)\mathbf{1} + i(a \times b) \cdot \sigma$, $AB = -BA$ is equivalent to $a \cdot b = 0$. A pair (a, b) of orthogonal unit vectors can be moved to (e_1, e_2) by a rotation $R \in SO(3)$ ($(a, b, a \times b)$ is a positively oriented orthonormal basis). $SU(2) \to SO(3)$ is surjective, and taking g with $g(v \cdot \sigma)g^{-1} = (Rv) \cdot \sigma$ gives the first half of the claim. Second half: if $C = c_0\mathbf{1} + i\,c \cdot \sigma$ commutes with σ_1 then $c \times e_1 = 0$, and if it commutes with σ_2 then $c \times e_2 = 0$; hence $c = 0$ and $C = \pm\mathbf{1}$. ∎

Uniqueness of the Twisted Vacuum (uniqueness of the vacuum that absorbs the twist) Proved here In the sector $(1, 0)$, the configuration with action 0 ($S^{z^{(0)}}(U) = 0$) is U^0 alone, up to gauge transformations and central transformations in directions 3 and 4 (the operation of multiplying by -1 all the links in direction 3 of some direction-3 cut $x_3 = c$; likewise for direction 4). On the small T^2 alone (the two-dimensional lattice $(\mathbb{Z}/N)^2$, twist $n_{12} = 1$), it is unique up to gauge transformations only.

Proof. By the Zero-Action Configuration Lemma, $U_p = z_p^{(0)}\mathbf{1}$. By the Lemma on the Sign of the Holonomy Commutator, the holonomies at the base point 0 satisfy $P_1P_2P_1^{-1}P$

$_2^{-1} = -\mathbf{1}$, and the other pairs commute. Re-choosing the gauge at the base point by the Rigidity Lemma for Anticommuting Pairs, $P_1 = i\sigma_1$, $P_2 = i\sigma_2$. P_3, P_4 commute with both, so they are $\pm\mathbf{1}$. The holonomies of U^0 are $(i\sigma_1, i\sigma_2, \mathbf{1}, \mathbf{1})$. If one multiplies the direction-3 links of the cut $x_3 = c$ by -1, every plaquette containing them contains two (the two direction-3 sides of the $(\mu, 3)$ and $(3, 4)$ plaquettes lie at the same x_3), so the action does not change and only P_3 changes sign. Direction 4 is the same. So all four tuples $(i\sigma_1, i\sigma_2, \pm\mathbf{1}, \pm\mathbf{1})$ are obtained from U^0 by central transformations, and by the Determination-by-Holonomy Lemma configurations with action 0 whose holonomies agree are related by gauge transformations. In two dimensions there are no P_3, P_4, so gauge transformations alone suffice. ∎

As the proof of the Rigidity Lemma for Anticommuting Pairs shows, $(-i\sigma_1, i\sigma_2)$ is moved to $(i\sigma_1, i\sigma_2)$ by conjugation with $g = i\sigma_2$. Central transformations in the directions of the small T^2 are absorbed into gauge transformations. Central transformations in the directions of the plane are not absorbed, and there are four configurations with action 0 as gauge classes.

06

The twisted adjoint gap — antiperiodicity and 4sin²(π/2N)

In the quadratic part of the fluctuations around the vacuum U^0, the covariant Laplacian of the adjoint field appears. On the small T^2 (the two-dimensional lattice $(\mathbb{Z}/N)^2$), for a field ϕ with values in $\mathfrak{su}(2)$ we set

$$(-\Delta_U \phi)(x) = \sum_{\mu=1,2} \Big[2\phi(x) - \mathrm{Ad}(U_{x,\mu})\, \phi(x+\hat{\mu}) - \mathrm{Ad}(U_{x-\hat{\mu},\mu})^{-1} \phi(x-\hat{\mu}) \Big], \qquad \mathrm{Ad}(g)X$$

Since Ad is an orthogonal transformation, $-\Delta_U$ is symmetric and non-negative with respect to the inner product of $\mathfrak{su}(2)$.

Twisted Adjoint Gap Lemma Proved here When $U = U^0$, for each component ϕ^1, ϕ^2, ϕ^3 in the basis $i\sigma_1, i\sigma_2, i\sigma_3$ of $\mathfrak{su}(2)$, $-\Delta_{U^0}$ splits into scalar Laplacians under the following signed boundary conditions.

Component	Direction 1	Direction 2	Smallest eigenvalue
ϕ^1 $(i\sigma_1)$	Periodic	Antiperiodic	$4\sin^2(\pi/2N)$
ϕ^2 $(i\sigma_2)$	Antiperiodic	Periodic	$4\sin^2(\pi/2N)$
ϕ^3 $(i\sigma_3)$	Antiperiodic	Antiperiodic	$8\sin^2(\pi/2N)$

Every component is antiperiodic in at least one direction. Hence the smallest eigenvalue of $-\Delta_{U^0}$ is $4\sin^2(\pi/2N) > 0$, and there are no zero modes.

Proof. $\mathrm{Ad}(i\sigma_1)$ preserves $i\sigma_1$ and changes the signs of $i\sigma_2, i\sigma_3$ ($\sigma_1\sigma_2\sigma_1 = -\sigma_2$ and so on), and $\mathrm{Ad}(i\sigma_2)$ preserves $i\sigma_2$ and changes the signs of $i\sigma_1, i\sigma_3$. Only the links of U^0 that cross the seam are Ω_μ, so (7) becomes, component by component, a scalar Laplacian with a sign ± 1 attached only to the bonds crossing the seam. On a ring of length N with a sign s on one bond, the difference operator $2f(x) - f(x+1) - f(x-1)$ has eigenfunctions $f(x) = e^{ikx}$ for k satisfying $e^{ikN} = s$, with eigenvalues $2 - 2\cos k = 4\sin^2(k/2)$. If $s = +1$ then $k \in \frac{2\pi}{N}\mathbb{Z}$ (minimum 0); if $s = -1$ then $k \in \frac{2\pi}{N}(\mathbb{Z} + \frac{1}{2})$ (minimum $4\sin^2(\pi/2N)$, at $k = \pi/N$). In two dimensions it is the sum over the two directions, which gives the values in the table. ∎

For the vacuum $U \equiv \mathbf{1}$ of a periodic T^2 without twist, every component is periodic in both directions, and constant ϕ give three dimensions' worth of zero modes. The role of the twist is to remove these zero modes and give the fluctuations the lower bound $4\sin^2(\pi/2N)$. When N is large, $4\sin^2(\pi/2N) \approx \pi^2/N^2$, and restoring the unit of the lattice spacing a gives $(\pi/L)^2$ ($L = Na$).

Reading the same gap as a mass, the lattice mass m_N is given by $4\sinh^2(m_N/2) = 4\sin^2(\pi/2N)$, that is,

$$m_N = 2\ \mathrm{arsinh}\sin\frac{\pi}{2N} \tag{8}$$

(the relation between the decay rate of the lattice propagator and the gap, $2\cosh m - 2 = 4\sinh^2(m/2)$) Proved here . This m_N appears in 25-02 § 05 as the rate of convergence of the action of a fractional instanton confined to a column.

07

Positivity of the Minimal Action in the Twisted Sector — the (1,1) sector has no flat configuration

Positivity of the Minimal Action in the Twisted Sector Proved here In the sector $(1,1)$ there is no configuration with action 0. Hence the minimal action

$$S_{\min}(N,M) = \min_U S^{z^{(1)}}(U) \tag{9}$$

is positive. Moreover, $S_{\min}(N,M) \le 2N^2$.

Proof. If there were a configuration with action 0, then by the Zero-Action Configuration Lemma and the Lemma on the Sign of the Holonomy Commutator the holonomies at the base point would satisfy $P_1P_2P_1^{-1}P_2^{-1} = -\mathbf{1}$, $P_3P_4P_3^{-1}P_4^{-1} = -\mathbf{1}$ ($\varepsilon_{34} = -1$), with the mixed pairs commuting. By the Rigidity Lemma for

Anticommuting Pairs, P_3 commutes with both P_1, P_2 and so is $\pm\mathbf{1}$, and the same holds for P_4. Then $P_3 P_4 P_3^{-1} P_4^{-1} = \mathbf{1}$, a contradiction. The configuration space $SU(2)^{\#\text{links}}$ is compact and the action is continuous, so the minimum is attained, and since it is not 0 it is positive. Upper bound: evaluating U^0 in the sector $(1,1)$, on the N^2 plaquettes of the surface Π_q we have $U_p = \mathbf{1}$, $z_p = -1$, giving $1 - \frac{1}{2}(-1)(2) = 2$ per plaquette, and 0 elsewhere. ∎

The configuration of the upper bound is a "thin vortex surface", which pays action $2N^2$ on a surface one plaquette thick. The Positivity of the Minimal Action in the Twisted Sector says only that the minimal action is not 0; it does not say how small it is (whether there is a smooth lump far cheaper than the thin surface). That is the story of fractional instantons in the next chapter; lattice numerics read $S_{\min}$ as of order π^2, much smaller than $2N^2$ (25-02 § 05).

In the continuum theory, the topological charge of a bundle with twist $n_{12} = n_{34} = 1$ is restricted to half-integers, and the action is bounded below by $8\pi^2|Q|/g^2 \geq 4\pi^2/g^2$ Cited ('t Hooft 1981, equations (2.24) and (2.25) of Tanizaki–Ünsal). The Positivity of the Minimal Action in the Twisted Sector is the weakest form (positivity) of the lattice version of this lower bound. That $S_{\min}$ is close to π^2 on the lattice has not been shown as a lattice version of the continuum lower bound.

08

What the three properties of the twisted T² say

- **The Uniqueness of the Twisted Vacuum** says that the classical vacuum of the small T^2 is isolated. On a periodic T^2, the whole set of commuting tuples of holonomies (the family of flat connections) is vacuum, and fluctuations move freely over it, so semiclassical counting cannot begin. The twist shrinks it to one point (and its central images).
- **The Twisted Adjoint Gap Lemma** says that fluctuations around the isolated vacuum have the lower bound $4\sin^2(\pi/2N)$. This is the classical side of the grounds for the estimate of 25-00 § 03, "weak coupling up to the size of the T^2". The quantum side (ultraviolet control: that the same construction as the one published on 2026-11-10 stands under twisted boundary conditions) remains an open assumption.
- **The Positivity of the Minimal Action in the Twisted Sector** says that putting in a flux n_{34} in the directions of the plane always costs action, that is, vortices cannot be placed "for free". What moves the bias θ away from 1 is the competition between the cost of vortices and the entropy of their positions, and the Positivity of the Minimal Action in the Twisted Sector is the weakest form of the lower bound on that cost.

All three are statements on a finite lattice with N fixed. None of the statements of this chapter includes increasing N (widening the T^2 as a physical length). That is the problem of the crossover band (25-09).

09

What cannot be said

(a) The continuum limit. None of the three properties says anything about $a \to 0$. The gap of the Twisted Adjoint Gap Lemma is a lower bound on classical fluctuations, not a gap of the quantum effective action.

(b) Confinement. The definition of θ and the Parity Representation of the Bias are where the tools of confinement sit, and they do not say how small θ is. Bounds with the lattice spacing fixed are in 25-04, and the semiclassical rate in 25-02.

(c) Other groups. The proofs rely on computations with the Pauli matrices of $SU(2)$ (the Rigidity Lemma for Anticommuting Pairs). The case of $SU(N)$ is not treated in this chapter.

(d) The value of the minimal action. That $S_{\min}(N, M)$ is close to π^2, and that it approaches π^2 as N grows, are numerical readings and are not shown in this chapter.

10

The table of five grades and the dependency graph

Table 1 The rows of this chapter ("—" is a row without machine checking. The conditions in every row are SU(2), the finite lattice $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, $N, M \geq 2$)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	Only the flux affects the partition function (general form); the twist relation	Cited	't Hooft 1979, Mack–Petkova 1980	—	—

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. This chapter has no assumption rows. There are four cited rows (only the flux matters, Tomboulis–Yaffe, the deformation of closed paths, the continuum lower bound), and the only citation used by the proofs of the three properties is the deformation of closed paths (through the Determination-by-Holonomy Lemma, for the Uniqueness of the Twisted Vacuum only). The Twisted Adjoint Gap Lemma and the Positivity of the Minimal Action in the Twisted Sector close without citations.

The definition of twisted boundary conditions as an object of this book is in 19-02.

What this chapter can say

What is said	What is not said
Proved here The Moving-Surface Lemma, the representation of the bias as an expectation (the Parity Representation of the Bias), uniqueness of the vacuum that absorbs the twist (up to gauge and the centre in the directions of the plane), the gap $4\sin^2(\pi/2N)$ of the adjoint Laplacian, $0 < S_{\min} \leq 2N^2$ in the (1,1) sector. All for SU(2), a finite lattice, N fixed, $n_{12} = 1$	A gap of quantum fluctuations. Bounds uniform in the lattice spacing. The value of $S_{\min}$ and its dependence on N
Cited The general form of "only the flux matters", the Tomboulis–Yaffe inequality, the lower bound on the action in the continuum theory	$\theta \geq 0$ (treated in 26-04). Other groups

Words used in this chapter — 't Hooft's twist, sector, flux $n_{\mu\nu}$, the surface Π_q, the flux free energy ΔF, the bias θ, the twist-summed ensemble, the configuration that absorbs the twist U^0, central transformation, the adjoint Laplacian, antiperiodic, the minimal action $S_{\min}$. Their meanings are in A-02 Glossary.

Next chapter to read: 25-02 Vortices and fractional instantons — what lies inside the minimal action of the $(1,1)$ sector, and the counting of the dilute gas.

Vortices and fractional instantons

This chapter organises established knowledge. § 02 is a map of open questions; § 05 and § 06 are this book's own investigation.

What this chapter shows — The Positivity of the Minimal Action in the Twisted Sector in the previous chapter said that putting in one unit of flux n_{34} in the directions of the plane always costs action. This chapter looks at what that minimal cost consists of. (1) In the continuum theory, the cheapest object carrying the flux on the twisted $T^2 \times \mathbb{R}^2$ is a self-dual lump of topological charge $\frac{1}{2}$ (a fractional instanton), and the lower bound on its action is $4\pi^2/g^2 = \pi^2\beta$. (2) Counting the dilute gas in which such lumps are scattered like points in the plane gives a string tension of order $\Lambda^2(\Lambda L)^{5/3}$ (a physical estimate). The $5/3 = 11/3 - 2$ in the exponent is the difference between the coefficient of asymptotic freedom and the two dimensions of the plane. (3) On the lattice, the minimal action of the sector with flux approaches π^2 from values smaller than π^2 (a numerical reading, and certified upper bounds). (4) We place, as an assumption row, a strand that derives the existence of the lump in the continuum theory by assuming a certain property.

Prerequisite chapters — 25-01 (sectors, θ, the three properties of the twisted T^2), 3-05 (instantons and topological charge, the BPS bound), 17-02 the model of a vortex gas, 4-06 the one-loop coefficient, 4-07 (Λ).

Said first — The counting of the dilute gas is a physical estimate in the dilute region ($\Lambda L \ll 1$), at the one-loop level, for the group $SU(2)$; it is not a theorem. The values of the action obtained by cooling on the lattice are the actions of configurations that were found, so they are **upper bounds** on the minimal action, not lower bounds. The existence of a self-dual solution in the continuum theory is placed in this chapter only as a strand with an assumption.

The order of this chapter

1. The self-dual lump of topological charge 1/2 — the lower bound on the action
2. Does the lump exist — numerics, and a strand with an assumption
3. The dilute gas — counting the string tension (equations (5)–(8))

4. How to read 5/3 = 11/3 − 2
5. The action on the lattice — approaching $\pi^2\beta$ from below (Tables 1 and 2)
6. A statement about the rate on the lattice — from the rate $2N^2$ of the thin surface to the rate of the fractional instanton
7. What cannot be said
8. The table of five grades and the dependency graph (Table 3)

01

The self-dual lump of topological charge 1/2 — the lower bound on the action

The topological charge Q of the continuum theory and the lower bound on the action of an instanton are as in 3-05: the Euclidean action satisfies

$$S_E \;\geq\; \frac{8\pi^2}{g^2}\,|Q| \qquad (1)$$

and equality is attained by solutions of the (anti-)self-duality equation $F = \pm *F$ Cited. On a periodic four-dimensional torus or on $\mathbb{R}^4$, Q is an integer. On a bundle with 't Hooft's twist, however, the fractional part of Q is fixed by the twist: for $SU(N)$ with $n_{12} = n_{34} = 1$, $Q \equiv -1/N \pmod 1$ (when this chapter writes $SU(N)$, the N is the degree of the group, different from the lattice N of this part) Cited (equation (2.24) of Tanizaki–Ünsal; the original source is 't Hooft 1981). For $SU(2)$, $Q \in \frac{1}{2} + \mathbb{Z}$, and from (1)

$$S_E \;\geq\; \frac{4\pi^2}{g^2} = \pi^2\beta \qquad (\beta = 4/g^2) \qquad (2)$$

(ibid., equation (2.25): the lower bound is $1/N$ of the ordinary instanton action $8\pi^2/g^2$) Cited.

A solution attaining this lower bound is a fractional instanton. Tanizaki–Ünsal state that on $\mathbb{R}^2 \times T^2$ (with the twist on T^2) the action density of this solution is localised in the directions of $\mathbb{R}^2$ and takes a vortex-like shape, and that when it lies inside a Wilson loop in the plane it multiplies the loop by the central element -1 ($e^{2\pi i/N}$ for $SU(N)$), that is, it behaves as a centre vortex (17-02) Cited (around equation (2.26)). In the words of the previous chapter, this lump is the cheapest inhabitant of the sector $(1,1)$, carrying the surface Π_q not as a thin surface but as a smooth lump.

A word on size. The action of the lump is fixed by (2) and does not depend on size, but on the twisted T^2 the lump is fixed to an extent of order the size L of the T^2 (a footnote

of the same paper cites earlier numerics in which, for $SU(N)$, the radius of the lump is proportional to the square root of the degree of the group) Cited . Since the size is fixed, no infrared divergence arises in the counting of the dilute gas. This contrasts with the integral over instanton sizes on a periodic $\mathbb{R}^4$, which diverges in the infrared (3-05).

02

Does the lump exist — numerics, and a strand with an assumption

The state of the literature Cited . Tanizaki–Ünsal write that almost no analytic forms of self-dual solutions with fractional topological charge are known (except for abelian constant solutions on tori of particular aspect ratios), and cite reports that numerical searches by lattice cooling have found configurations attaining the lower bound (2) within the discretisation errors of the lattice, and that the limit in which the directions of $\mathbb{R}^2$ are stretched to infinity is also well defined (ibid. § 2.3.1). Analytic existence is not shown in the literature within the range this book checked.

A strand with an assumption Assumption (strand: the "Route to Existence by the Nahm Transform" in the record of this book's study; evidence in the Nahm-transform row of Table 3). We assume the following property.

> **Assumption (equivariance of the Nahm transform).** The Nahm transform between doubly periodic instantons (charge-1 solutions on $T^2 \times \mathbb{R}^2$) and Hitchin-type data on the dual torus is equivariant under translations of physical space and central gauge transformations: translations of physical space correspond to multiplication by flat line bundles on the dual side, and the central twist corresponds to translation by a half period of the dual torus.

The strand has three steps. (i) Map a charge-1 $SU(2)$ doubly periodic instanton on $T^2_{2L\times L} \times \mathbb{R}^2$ by the Nahm transform to data on the dual side (the construction of doubly periodic instantons and the bijectivity of the transform are said to be in the literature; not yet checked). (ii) The composite τ of translation by a half period in the long direction and a central gauge transformation corresponds, by the assumption, to the composite of translation by a half period and a constant shift on the dual side, and if the singular points are placed at a quarter period, data invariant under τ can be chosen. (iii) The corresponding solution is invariant under τ up to gauge, and when brought down to the quotient $T^2_{L\times L} \times \mathbb{R}^2$, since τ contains the central twist, it becomes an anti-self-dual solution of charge $\frac{1}{2}$ on the bundle with $n_{12} = 1$, whose action equals the lower bound (2).

If this strand closes, the lower bound (2) is attained in the continuum theory. What is not closed is the assumption itself (the exact form of equivariance), the check of the literature in (i), and the confirmation that the topology of the bundle (n_{12} and the flux at infinity in the plane) comes out correctly on passing to the quotient. As another strand there is a variational strand combining the Bogomolny bound, exclusion of bubbles by Uhlenbeck compactness, and exclusion of splitting by concentration compactness, but that the minimal value equals the lower bound must itself be shown separately, so it too is Assumption . This book uses neither strand as a premise of the chapters that follow.

03

The dilute gas — counting the string tension

This section summarises existing knowledge (the dilute-gas count). The introduction is in 3-05 § 07.

We assume that the lumps are scattered in the plane far apart from one another (dilute), and count ignoring the interactions between lumps. This is the dilute-gas approximation, and the counting from here on transcribes § 2.3.2 of Tanizaki–Ünsal to $SU(2)$ Cited (a copy of the formulae). The correctness of the approximation itself is a physical estimate Reading .

Note: the original source places the small T^2 in directions 3 and 4 and the plane in directions 1 and 2, so the indices are swapped relative to this book (T^2 in 1 and 2, the plane in 3 and 4). Below we write with this book's indices.

The weight of one lump. The weight of one lump (self-dual, $Q = +\frac{1}{2}$) and of one antilump ($Q = -\frac{1}{2}$) in the plane, with the θ angle set to 0, is

$$K\, e^{-S_I/2}, \qquad S_I = \frac{8\pi^2}{g^2}, \qquad \frac{S_I}{2} = \frac{4\pi^2}{g^2} = \pi^2\beta \tag{3}$$

($N = 2$ in equation (2.27) of the original source). The prefactor K has mass dimension 2 and $K \sim 1/L^2$; its exact value is fixed by an analysis of the fluctuation determinant, which the original source does not give Cited .

Rewriting with asymptotic freedom. Writing the coupling at scale L in terms of Λ with the one-loop running coupling (4-06), for $SU(2)$ we have $8\pi^2/g^2(L) = \frac{22}{3}\ln\frac{1}{\Lambda L}$ (at the one-loop level; for general $SU(N)$, $\frac{11N}{3}$), so

$$e^{-S_I/2} = e^{-4\pi^2/g^2(L)} = (\Lambda L)^{11/3} \quad \text{(one loop)}, \qquad K\, e^{-S_I/2} \sim \frac{1}{L^2}(\Lambda L)^{11/3} = \Lambda^2(\Lambda L)$$

(the last step of equation (2.32) of the original source) Cited . The exponent $11/3$ does not depend on the degree of the group (for $SU(N)$ the action of the lump is S_I/N, and it cancels against the N of the coefficient $11N/3$).

The Wilson loop. If one lump lies inside a loop C of area A, the value of the loop is multiplied by -1 (a centre vortex). If lumps and antilumps are each scattered in the plane as independent Poisson points of density $Ke^{-\pi^2\beta}$, the number n inside follows a Poisson distribution with mean ρA ($\rho = 2Ke^{-\pi^2\beta}$), and

$$\langle W(C)\rangle = \mathbb{E}\big[(-1)^n\big] = e^{-2\rho A} = \exp\!\big(-4Ke^{-\pi^2\beta}\,A\big) \quad (5)$$

This is a one-line computation, $\mathbb{E}[(-1)^n] = e^{-\lambda}\sum_k(-\lambda)^k/k! = e^{-2\lambda}$ for the Poisson distribution Proved here (a computation within the model). The original source obtains the same answer by putting in the constraint on the total charge (the difference between the numbers of lumps and antilumps is a multiple of N) through a Fourier sum: at $\theta = 0$ the string tension of the fundamental representation is

$$T_R \sim \Lambda^2(\Lambda L)^{5/3}\sin^2\frac{\pi|R|}{N} \quad (6)$$

(equation (2.37) of the original source; N is the degree of the group, and $|R|$ is the number of boxes of the Young diagram of the representation modulo N), and for the fundamental representation of $SU(2)$, $\sin^2(\pi/2) = 1$ Cited . Combining (5) and (4),

$$\sigma = 4K\,e^{-\pi^2\beta} \;\sim\; \Lambda^2(\Lambda L)^{5/3} \qquad \text{(dilute region, one loop, } SU(2)) \quad (7)$$

Reading (a physical estimate; $\sim$ is proportionality with the constant of the prefactor omitted).

Relation to the bias θ. Applying the same counting to the parity of the number of lumps in the whole plane (area $A_{\text{plane}} = (Ma)^2$), the $\theta = \mathbb{E}[(-1)^{|Q|}]$ of the Parity Representation of the Bias of 25-01 becomes

$$\theta \approx e^{-2\rho A_{\text{plane}}}, \qquad -\ln\theta \approx 4Ke^{-\pi^2\beta}\,(Ma)^2 \quad (8)$$

and one reads both that $-\ln\theta$ is proportional to the area of the plane (the type of an area law) and that its rate is fixed by the weight $e^{-\pi^2\beta}$ of the fractional instanton Reading (the dilute-gas estimate). The statement, on the lattice, of the part of this form saying "the rate is $e^{-\beta S}$ with S close to π^2" is § 06.

Numerics on the lattice also support the same picture. Bergner–González-Arroyo–Soler (2025) report, for the $SU(2)$ lattice on a four-dimensional torus with two directions far smaller than the others and twisted boundary conditions, that at small sizes of the T^2 the topological charge and the string tension arise from a gas of vortex-like fractional

instantons, and that as the size increases the density increases and the spacing of the structures approaches a constant Cited (checked in the abstract; the numbers in the text not yet checked).

04

How to read 5/3 = 11/3 − 2

The exponent of (4) is the difference of two contributions Reading (a physical estimate).

- $11/3$**: asymptotic freedom.** The smaller the T^2, the weaker the coupling, and lumps become rare at the rate $(\Lambda L)^{11/3}$. The coefficient $11/3$ is exactly the one-loop coefficient ($11/3 = -1/3 + 4$ of 4-06).
- -2**: the two dimensions of the plane.** The size of a lump is L, so the number of places where one can be put per unit area of the plane is $1/L^2$ ($K \sim 1/L^2$). This corresponds to the entropy of the lump positions.

Since the difference $11/3 - 2 = 5/3$ is positive, if one holds Λ fixed and widens the T^2 (increases L), the string tension in physical units increases. It is the direction in which confinement strengthens as one widens, and reaching order Λ^2 at $L \sim 1/\Lambda$ is consistent with dimensional counting. Counting per square of the size of one T^2 (area L^2) gives $\sigma L^2 \sim (\Lambda L)^{11/3}$, which can be restated as: the probability that a lump is in that square increases with L.

The abelian group $U(1)$ has no localised lumps carrying fractional flux. The flux can only spread uniformly over the T^2, and the behaviour in the direction of widening the T^2 is reversed. This difference is treated as "the only place where non-abelianness enters" in 26-03, and there too this counting is an estimate at the one-loop level. Within the scope of this chapter, (4)–(8) are all statements in the dilute region $\Lambda L \ll 1$, and they do not extend into the band $L \sim 1/\Lambda$.

05

The action on the lattice — approaching π²β from below

Matching units. The action $S^z(U) = \sum_p (1 - \frac{1}{2} z_p \operatorname{tr} U_p)$ of 25-01 is the quantity before multiplying by β. In the classical continuum limit of 5-01, for $SU(2)$ and $\beta = 4/g^2$, βS^z approaches the continuum action S_E, so a lump of action $4\pi^2/g^2$ corresponds to $S^z \approx \pi^2$ (that is, $\beta S^z \approx \pi^2 \beta$). All the numbers below are values of S^z divided by π^2.

Cooling numerics Reading . Table 1 gives the result of searching for the minimal action $S_{\min}(N, M)$ of the sector $(1, 1)$ by repeatedly lowering S^z (cooling) through the

operation of replacing each link by the direction of the sum of the remaining sides of the plaquettes containing it (the staple). The action of the configuration at which cooling stopped is an **upper bound** on the minimal action, since that configuration exists (within floating-point computation). The possibility that the true minimum is lower still is set aside only as a reading, on the grounds that different initial configurations arrived at the same value.

Table 1 Cooling values of the minimal action in the sector $(1,1)$ ($S_{\min}/\pi^2$. SU(2), Wilson action, $n_{12}=n_{34}=1$, 3 runs from random initial configurations)

Lattice $T^2_N \times T^2_M$	$N \times M$	$S_{\min}$	$S_{\min}/\pi^2$
Symmetric	2×2	7.841	0.794
Symmetric	3×3	9.661	0.979
Symmetric	4×4	9.799	0.993
Symmetric	6×6	–	0.998
Elongated	2×4	–	0.683
Elongated	2×6	–	0.677
Elongated	3×6	–	0.921
Elongated	4×8	–	0.960

How to read it Reading : (i) every value is smaller than π^2 and approaches π^2 as N grows (the lattice values approach the continuum value from below; a physical reading consistent with the discretisation correction of the Wilson action being negative). (ii) On elongated lattices ($M > N$), at $N=2$ the value hardly changes when the plane is widened, $M = 4 \to 6$. The lump is localised in the directions of the plane and its action does not depend on the size of the plane; that is, the lattice supports the premise of the dilute gas (that a lump is a single localised object). (iii) That the values on symmetric lattices are larger than on elongated ones can be read as the lump being squeezed to order N in the directions of the plane as well on a symmetric lattice. In a separate cooling that measured the distribution of the action on a slab of size 16 in the directions of the plane ($4\times4\times16\times16$), $S^z/\pi^2 \approx 0.96$, about 91% of the action lay within radius 2 of the centre of the lump in the directions of the plane, and about 99.6% within radius 4 ($=N$) Reading .

A lump confined to a column, and certified upper bounds Computer-assisted . The paper on lattice fractional instantons (one of the papers that came out of this book, a draft; A-07) divides the plane into square blocks of side ℓ, puts flux into the column $T^2_N \times [0,\ell]^2$ above one block, and defines the minimal action when the outer frame of the column is fixed to the vacuum that absorbs the twist U^0 (25-01 § 05) as

$$S_*(N,\ell) = \min\{\ \text{action of the column with frame fixed to } U^0 \ :\ \text{one flux } n_{34} \text{ in the column}\ \}$$

The values obtained by normalising the saved configurations exactly, checking that the outer frame agrees with the vacuum, and re-evaluating the action in 40-digit arithmetic are upper bounds on each S_*:

$$S_*(2,12) \le 6.67348665542 \le 0.6762\,\pi^2, \quad S_*(3,12) \le 9.07284242009 \le 0.9193\,\pi^2, \quad S_*(4,8)$$

($N=4$ is a value at which cooling had not converged). Conditions: the group $SU(2)$, the Wilson action, an evaluation of the action of concrete configurations, and only in the direction of upper bounds. The label "Computer-assisted" attaches only to these upper bounds (actions of concrete configurations evaluated with guaranteed digits), not to the minimal values themselves. All are smaller than π^2, so "the minimal cost on the lattice is smaller than the continuum value π^2" can be said directly from the upper bounds for $N=2,3,4$.

Dependence on the width of the column Reading . A table from the same paper (cooling values):

Table 2 Dependence of $S_*(N,\ell)/\pi^2$ on ℓ (cooling. SU(2), outer frame fixed to the vacuum)

ℓ	3	4	5	6	7	8	10	12
$N=2$	0.7082	0.6924	0.6779	0.6771	0.6763	0.6762	0.67617	0.67617
$N=3$	1.1524	1.0185	0.9493	0.9347	0.9230	0.9213	0.9195	0.9193

Elementary properties of S_* Proved here : (a) the minimum is attained (compactness). (b) $S_*(N,\ell) \le 2N^2$ (place one thin surface in the column). (c) It does not increase in ℓ (embed the minimal configuration of a smaller column into a larger column, filling the rest with vacuum; the plaquettes on the border are vacuum against vacuum, with action 0). (d) Relation to the minimal action on a periodic lattice: $S_*(N,\ell) \ge S_{\min}(N, k\ell)$ ($k \ge 1$; extend the configuration of the column to the periodic lattice, filling the outside with vacuum). Hence $\lim_\ell S_*(N,\ell)$ exists.

The values on periodic lattices (cooling) are $S_{\min}(2,M) = 6.740117,\ 6.677345,\ 6.673724,\ 6.673486,\ 6.673485$ ($M=4,6,8,12,16$) and $S_{\min}(3,16) = 9.072494$, and $S_*(N,\ell)$ approaches them from above as ℓ grows. The difference $S_*(N,\ell) - S_{\min}(N,\infty)$ is read as decreasing like $e^{-m_N \ell}/\ell$ in terms of the twist mass $m_N = 2\,\mathrm{arsinh}\,\sin(\pi/2N)$ of (8) of 25-01 ($m_2 \approx 1.317$, $m_3 \approx 0.962$) Reading (the draft of the paper on lattice fractional instantons sets the observed slopes 1.41, 1.02 beside the predicted values 1.45, 1.06; how the predicted values are obtained has not been checked in this book). The reading is that the tail of the lump is cut off by the mass of the adjoint fluctuations on the twisted T^2.

In summary, the minimal cost on the lattice is roughly $0.68\pi^2,\ 0.92\pi^2,\ 0.96\pi^2$ for $N=2,3,4$ (values on periodic lattices; $N=4$ is cooling on the elongated lattice 4×8), and

approaches π^2 from below as N grows. "$S_{\min}(N,\infty) \to \pi^2$ as $N \to \infty$" is numerical only, with no proof Reading .

06

A statement about the rate on the lattice — from the rate 2N² of the thin surface to the rate of the fractional instanton

With N and the lattice spacing fixed, a bound of area-law type $-\ln\theta \geq c\,M^2$ follows elementarily at every β (25-04). The rate c there is fixed by the cost of the thin surface, $c \approx e^{-2\beta N^2}$ (the configuration of the upper bound $2N^2$ in the Positivity of the Minimal Action in the Twisted Sector of 25-01). $2N^2$ grows with N and has nothing to do with fractional instantons.

The main theorem of the paper on lattice fractional instantons (the Confinement Lower Bound by Fractional Instantons, Theorem A of that paper) is a statement that replaces this rate by $S_*(N,\ell)$. We transcribe the form of the draft with its conditions Assumption (this book has not yet placed the proof in the text; the evidence column is § 3– § 6 of the draft of the paper on lattice fractional instantons. The proof uses the Chessboard Estimate and a Morse–Bott lemma by citation, and only the existence of the rigidity constants is shown, with their values not made explicit).

Confinement Lower Bound by Fractional Instantons (the statement of the draft). For all $N \geq 2$, $\ell \geq 2$, $\beta \geq 1$, $M \in 2\ell\mathbb{N}$, there exist $c(N,\ell) > 0$, $a > 0$ and $\varepsilon(\beta) = O\big(\sqrt{\ln\beta/\beta}\big)$ such that

$$-\ln\theta(N,M,\beta) \;\geq\; c(N,\ell)\,\beta^{-a}\,e^{-\beta\,(S_*(N,\ell)+\varepsilon(\beta))}\,M^2. \quad (11)$$

Combined with the upper bounds of (10), the rate drops from $2N^2 = 8, 18, 32$ to about $\leq 0.68\pi^2$, $0.92\pi^2$, $0.98\pi^2$ ($N = 2, 3, 4$). However, the terms of the prefactor β^{-a} and $\varepsilon(\beta)$ are crude, so (11) beats the thin-surface bound only from some large, non-explicit β onwards. (11) is not uniform in N, and says nothing about the continuum limit or the mass gap. The bound in the reverse direction (an upper bound from the dilute gas, uniform in M) is open. Where these stand is treated in 27-01 and 27-02.

Setting the estimate (8) beside (11), the position is that, of the part of the estimate saying "the rate is the action of the fractional instanton", only the direction of confinement (the bound from below), on a lattice with fixed N, has the form of a statement.

07

What cannot be said

(a) The dilute gas. (5)–(8) are counting that ignores interactions, a physical estimate in the dilute region $\Lambda L \ll 1$ at the one-loop level. The value of the prefactor K is not known.

(b) Cooling values. The values of Tables 1 and 2 are upper bounds on the minimal action, not lower bounds. Of "approaches π^2 from below", "below π^2" can be said for $N = 2, 3, 4$ from the upper bounds of (10), and "approaches" is a numerical reading.

(c) Continuum existence. The existence of a solution attaining the lower bound (2) on the twisted $T^2 \times \mathbb{R}^2$ is a strand with an assumption in this book, and is not shown.

(d) The band. Every statement of this chapter is a statement with $\Lambda L \ll 1$ or with N fixed, and says nothing about widening the T^2 beyond $1/\Lambda$ (25-09).

(e) The paper on lattice fractional instantons. The Confinement Lower Bound by Fractional Instantons is a statement of a draft, and this book's label is "Assumption". It is not raised until the proof of the draft has been checked line by line and placed in the text.

08

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. The only nodes with proofs placed in the text are the one line of the Poisson model and the properties of S_*, both one-line arguments within a model or on a finite lattice. The "Assumption" of the Route to Existence by the Nahm Transform and of the Confinement Lower Bound by Fractional Instantons enters as a premise of no node. The nodes on the conclusion side of this chapter (the string tension, the reading of θ, the reading of 5/3, approaching π^2 from below) are all "Reading", and there is neither a node of confinement nor a node of the mass gap.

Containers — conditioning on the frame makes things independent

> This chapter organises established knowledge. § 04, § 05 and § 07 are this book's own investigation.

What this chapter shows — The most naive tool for bounding a Wilson loop in the direction of confinement is to divide the surface spanned by the loop into small regions (containers) and to consider things with the outside of the containers (the frame) held fixed. With a nearest-neighbour action, fixing the frame makes the containers independent of each other, and the expectation of the Wilson loop is bounded from above by the average of the product of "the biases of the sectors of each container" (the Container Identity). This is the vortex-container identity of Mack–Petkova (1980), rewritten in the sector-summed ensemble, and this book claims nothing new about it. In this chapter we look in turn at (1) the Container Identity and its tanh form, (2) the form of "inner and outer regions" needed to pass to a fixed sector, (3) an inequality nesting containers in the directions of the plane (the directions of R^2), (4) the point made by Kovács–Tomboulis that in four dimensions, placing containers of fixed length independently gives only up to $V(R) \gtrsim R/\ln R$, and (5) that in a solvable two-dimensional model the bound of the Container Identity is sharp in its exponent.

Prerequisite chapters — 25-01 (the twisted T^2 and 't Hooft flux, sectors), 25-02 (vortices). From Part 5, 5-01 (the Wilson action and Wilson loops) and 5-08 (string tension); from Part 17, 17-02 (the picture of centre vortices).

Said first — The group is $SU(2)$, the action is the Wilson action, the lattice is finite and the lattice spacing is fixed. All statements of this chapter are statements "on the lattice, at some fixed β", and say nothing about the continuum limit. The Container Identity is known (Cited). What this book places on paper are three things: the rewriting in the sector-summed ensemble, the form of the correction when passing to a fixed sector, and the nesting inequality (Proved here). What the Lean column guarantees is only the algebra of finite sums; the Haar measure and the topology of sectors rest on the argument in the text.

01

Summary — fixing the frame makes things independent

This section is a summary for [Y3] readers. The formulae and proofs are from § 02 on.

1. The Wilson action on the lattice is an action that couples only neighbouring links (nearest-neighbour). So the links inside a region and the links outside it talk only through the links on the border. If all of the border is held fixed, the insides of separate regions become independent of each other. This is exactly the Markov property of statistical mechanics.
2. The Wilson loop $W(C)$ can be rewritten as a product of "signs of the sector" $\sigma_j = \pm 1$ per small region (container) on the surface spanned by the loop (in the sector-summed ensemble, § 02). If the frame (the outside of the containers) is held fixed, the σ_j are independent of each other, so the expectation becomes a product, and taking absolute values and averaging gives $|\langle W \rangle| \le \mathbb{E}[\prod_j \theta_j]$, with $\theta_j = |\mathbb{E}[\sigma_j \,|\, \mathbf{frame}]|$. This is the Container Identity Cited .
3. θ_j can be written $\tanh(|\Delta F_j|/2)$. ΔF_j is the difference in free energy, inside a container with the frame fixed, between the sector with one vortex and the sector without. The more cheaply a vortex enters a container (the smaller ΔF_j), the smaller θ_j, and the smaller the bound on the Wilson loop.
4. This identity is the "vortex container" identity of Mack–Petkova (1980), written as it stands in equations (18)–(22) of Kovács–Tomboulis (2001). The only differences are that we wrote it with the sectors summed, and that we took the average over frames rather than the maximum. This book claims no novelty.

5. To pass to the Wilson loop in a fixed sector (one twisted sector), containers are needed not only inside the loop but also outside it (the Inner and Outer Container Proposition of § 04) Proved here .
6. If containers are nested in the directions of the plane, the bias of a large container is bounded by the average of the product of the biases of small containers (the Nesting Inequality in the Plane Directions of § 05) Proved here . But this concerns a slab with the size of the T^2 held fixed, and cannot be used for widening together with the T^2 (the crossover band).
7. In four-dimensional space (R^4), the length of the containers through points inside the loop grows with the loop. To keep the cost of a container constant its thickness must grow to order $\sqrt{\ln R}$, and independent containers give only up to $V(R) \gtrsim R/\ln R$ (Kovács–Tomboulis) Cited . In a slab with a small T^2, the length of a container stops at the area of the T^2, so this obstruction does not appear.
8. Two-dimensional $SU(2)$ is solvable, so one can see in numbers how sharp the bound of the Container Identity is. Tiling with containers of side ℓ, the string tension coming from the bound approaches the true value in the form $\sigma - \ln(16/(3\pi))/\ell^2$ (§ 07) Proved here + Reading .

02

The setting — the sector-summed ensemble, frame and containers

The lattice Λ is a finite hypercubic lattice, and the link variables are $U = (U_b) \in SU(2)^{\text{links}}$. On each plaquette p we place a sign $z_p \in \{\pm 1\}$, and impose $\prod_{p \in \partial c} z_p = 1$ (coclosed) on every 3-dimensional cube c. We set the weight and the measure to be

$$w(U,z) = \exp\Big(\frac{\beta}{2}\sum_p z_p \operatorname{tr} U_p\Big), \qquad d\mu \;\propto\; w(U,z)\prod_b dU_b \;\times\; (\text{counting of coclosed } z) \tag{1}$$

(dU_b is the Haar measure). z in the same cohomology class are related by central gauge transformations $U_b \mapsto \omega U_b$ ($\omega \in \{\pm 1\}$), so the sum (1) equals, up to a constant factor, the sum of the $SU(2)$ partition functions of all of 't Hooft's twisted sectors (25-01) (the summed ensemble of Mack–Petkova) Cited . Which sector one is in is fixed by the cohomology class of z, and the indicator function of a sector is a function of z. In this chapter we call (1) the **sector-summed ensemble**, and write its expectation $\mathbb{E}$.

Taking a loop C and one surface $S(C)$ spanning C (a collection of plaquettes whose boundary is C),

$$W(C) = \tfrac{1}{2}\operatorname{tr} U_C \prod_{p \in S(C)} z_p \tag{2}$$

is unchanged by central gauge transformations, and $|W(C)| \le 1$. The Wilson loop with the sector fixed to one is (2) multiplied by the indicator function of the sector, i.e. conditioned (§ 04).

Frame and containers. We take regions $R_1, \dots, R_n$ (containers) in the lattice, separated from each other, call the variables inside a container (the inner links and the z of the inner plaquettes) x_j, and call all other variables the **frame** Φ. The links on the border of a container belong to the frame. Since the action is nearest-neighbour, each plaquette term and each cube constraint depends only on the inside of at most one container and on the frame. Hence the weight splits when the frame is fixed.

$$w(\Phi, x) = a(\Phi) \prod_{j=1}^{n} f_j(\Phi, x_j), \qquad a > 0,\ f_j > 0 \tag{3}$$

If the loop C runs inside the frame, and we write $\sigma_j(x_j) \in \{\pm 1\}$ (the **sign of the sector** of the container) for the product of the z on the part of $S(C)$ inside the container R_j, then (2) splits as well.

$$W(C) = c(\Phi) \prod_{j=1}^{n} \sigma_j(x_j), \qquad |c(\Phi)| \le 1 \tag{4}$$

($c(\Phi)$ is $\frac{1}{2}\mathrm{tr}\, U_C$ times the product of the z on the part of $S(C)$ in the frame.) σ_j is unchanged by central gauge transformations inside the container (the boundary C of $S(C)$ lies in the frame), so it is well defined as a quantity on the conditional distribution with the frame fixed. Moreover, fixing the frame does not determine σ_j. This is because, in the small-T² slab $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, if a container is taken as "a disc of the plane $\times$ T²", then the surface $S_p = \{p\} \times T^2$ above a plaquette p of the plane inside the disc (N^2 plaquettes of type (3,4)) is coclosed and lies inside the container, and flipping all the z on it flips only σ_j without changing the frame Proved here (the check that it is coclosed is step 2 of 25-04 § 03).

03

The Container Identity and its tanh form

This section summarises existing knowledge (the container identity of Mack–Petkova). The introduction (independent vortex signs and the area law) is in 17-02 § 06.

With the frame Φ fixed, we write $q_j^{\pm}(\Phi) = \mathbb{P}(\sigma_j = \pm 1 \mid \Phi)$ for the probabilities of the sectors of container j, and $Z_j^{\pm}(\Phi) = \sum_{x_j : \sigma_j = \pm 1} f_j(\Phi, x_j)$ for the partition functions of the two sectors inside the container (Haar integrals for continuous variables), and set

$$\theta_j(\Phi) := \big|\mathbb{E}[\sigma_j \,|\, \Phi]\big| = |q_j^{+} - q_j^{-}|, \qquad \Delta F_j(\Phi) := \ln \frac{Z_j^{+}(\Phi)}{Z_j^{-}(\Phi)} = \ln \frac{q_j^{+}}{q_j^{-}} \tag{5}$$

We call θ_j the **bias** of container j, and ΔF_j the **vortex free energy** with the frame fixed.

Container Identity

Under (3)(4),

$$\mathbb{E}[W(C) \,|\, \Phi] = c(\Phi) \prod_{j=1}^{n} \mathbb{E}[\sigma_j \,|\, \Phi], \qquad |\langle W(C) \rangle| \;\le\; \mathbb{E}_{\Phi}\Big[\, |c(\Phi)| \prod_{j=1}^{n} \theta_j(\Phi) \Big] \;\le\; \mathbb{E}_{\Phi}\Big[\prod_{j=1}^{n} \theta$$

Moreover, $\theta_j(\Phi) = \tanh\big(|\Delta F_j(\Phi)|/2\big)$.

Cited (the identity) + Proved here (the rewriting in the summed ensemble). Proof. By (3), the conditional distribution with the frame fixed is the product of the distributions $f_j(\Phi, \cdot)/(Z_j^{+} + Z_j^{-})$ per container, and each σ_j is a function of the variables of a different container, so the conditional expectation splits into a product. Substituting (4) gives the first formula. Taking absolute values, using $|c| \le 1$ and averaging over the frame gives the second. Finally, from $q^{+} + q^{-} = 1$ and $q^{\pm} > 0$,

$$\frac{q^{+} - q^{-}}{q^{+} + q^{-}} = \frac{e^{\Delta F/2} - e^{-\Delta F/2}}{e^{\Delta F/2} + e^{-\Delta F/2}} = \tanh \frac{\Delta F}{2}, \qquad \Delta F = \ln \frac{q^{+}}{q^{-}} \tag{7}$$

∎

Lean FrameLemma (`FrameLemma.frame_bound`) (hypotheses: the space of frames, the number of containers and the space inside each container are finite, the inside of each container is non-empty, $a(\varphi) > 0$, $f_j(\varphi, y) > 0$. Conclusion: $|\sum_{\varphi} \sum_{x} a \prod_j f_j \cdot c \prod_j \sigma_j| \le \sum_{\varphi} a \prod_j Z_j \cdot |c| \prod_j |\sum_y f_j \sigma_j| / Z_j$, $Z_j = \sum_y f_j$), FrameLemma (`FrameLemma.sign_mean_le_one`) (hypotheses: $f > 0$, $\sigma = \pm 1$. Conclusion: the absolute value of the normalised conditional mean is at most 1), FrameLemma (`FrameLemma.ratio_eq_tanh`) (hypotheses: $q^{+}, q^{-} > 0$. Conclusion: (7)), Containers (`Containers.container_bound`) (hypotheses: finite, $a \ge 0$, $|s| \le 1$. Conclusion: $|\sum_{\varphi} \sum_{x} a\, s \prod_i f_i \sigma_i| \le \sum_{\varphi} a \prod_i |\sum_y f_i \sigma_i|$). All are algebra of finite sums; that (3)(4) follow from the Haar integral, a coclosed z, the topology of sectors and the nearest-neighbour action is outside Lean.

Correspondence with the original source. Kovács–Tomboulis (hep-lat/0108017, Phys. Rev. D 65 (2002) 074501), in a fixed sector, fix the links on the border of a container Λ_i and integrate the inside, and from the partition functions $z_{\Lambda_i}^{(\mp)}$ with the signs of the couplings on a coclosed surface V_i flipped (their equation (19)) write

$$f_{\Lambda_i}(U_{\partial\Lambda_i}) = \frac{1}{2}\Big(1 - \frac{z_{\Lambda_i}^{(-)}}{z_{\Lambda_i}^{(+)}}\Big) \;\; (18), \qquad W[C] = \Big\langle \tfrac{1}{2}\mathrm{tr}\, U[C] \prod_i f_{\Lambda_i}(U_{\partial\Lambda_i}) \Big\rangle \;\; (20), \qquad W[C] \le$$

and attribute (20) to Mack–Petkova (Ann. Phys. 125 (1980) 117, their reference [3]) Cited (the formulae of the original source checked in the text of hep-lat/0108017; the text of Mack–Petkova has not been checked in this book). There are only two differences from the Container Identity. (i) Since we wrote it with (1), with the sectors summed, the factor is $(Z^{+}-Z^{-})/(Z^{+}+Z^{-}) = \tanh(\Delta F/2)$ rather than $\tfrac{1}{2}(1-z^{-}/z^{+})$ (a difference in the normalisation of the measure). (ii) (22) takes the maximum over frames, while (6) takes the average. (ii) leaves room to use the rarity of bad frames. In the two-dimensional test of § 07, the averaged form approaches the true value faster.

04

To a fixed sector — inner and outer containers

The Container Identity is a statement about the sector-summed ensemble. What one wants to see in physics is the Wilson loop with the twisted sector fixed to one. In the slab $(\mathbb{Z}/N)^{2}\times(\mathbb{Z}/M)^{2}$, let the loop C lie in the (3,4) plane at a point y_{0} of the T^{2}. Writing $(-1)^{n_{34}}$ for the parity of the (3,4) flux among the labels of the sector (the product of z over the whole (3,4) plane at y_{0}), and $\mathbf{1}_{O}$ for the indicator function of the other labels (n_{12} and so on), the expectation with the sector fixed to $s\in\{\pm 1\}$ is

$$\langle W(C)\rangle_{s} = \frac{\mathbb{E}\big[W\cdot\tfrac{1}{2}\big(1+s(-1)^{n_{34}}\big)\mathbf{1}_{O}\big]}{\mathbb{E}\big[\tfrac{1}{2}\big(1+s(-1)^{n_{34}}\big)\mathbf{1}_{O}\big]} \tag{8}$$

If containers are placed only inside the loop, the second term of the numerator, $\mathbb{E}[W(-1)^{n_{34}}\mathbf{1}_{O}]$, is a problem. $W(-1)^{n_{34}}$ is $\tfrac{1}{2}\operatorname{tr}U_{C}$ multiplied by the product of the z **outside $S(C)$ in the plane**; it contains no signs of the inner containers, so the Container Identity does not make it small. The remedy is to place containers outside as well.

Inner and Outer Container Proposition (inner and outer regions)

In the (3,4) plane, arrange containers $R_{1},\dots,R_{n}$ inside the loop and containers $R'_{1},\dots,R'_{m}$ outside it in a grid, with the frame made of straight strips, so that in each direction there is a straight line passing only through the frame. Then $\mathbf{1}_{O}$ is a function of the frame, and one can write $(-1)^{n_{34}} = c''(\Phi)\prod_{j}\sigma_{j}\prod_{k}\sigma'_{k}$ ($|c''|=1$). Let θ_{j},θ'_{k} be the biases of (5) and set $\mathbb{E}_{O}[\,\cdot\,] := \mathbb{E}[\,\cdot\,\mathbf{1}_{O}]/\mathbb{E}[\mathbf{1}_{O}]$; then, when $\mathbb{E}_{O}[\prod_{j}\theta_{j}\prod_{k}\theta'_{k}]<1$,

$$|\langle W(C)\rangle_{s}| \;\le\; \frac{\mathbb{E}_{O}\big[\prod_{j}\theta_{j}\big]+\mathbb{E}_{O}\big[\prod_{k}\theta'_{k}\big]}{1-\mathbb{E}_{O}\big[\prod_{j}\theta_{j}\prod_{k}\theta'_{k}\big]} \tag{9}$$

Proved here Proof. $n_{12}, n_{13}, n_{14}, n_{23}, n_{24}$ are each the product of z over the respective plane, and that plane can be retaken on a straight strip passing only through the frame (since z is coclosed, the product does not depend on the position of the plane), so they are functions of the frame. Hence $\mathbf{1}_O$ is a function of the frame. The (3,4) plane splits into $S(C)$ and its complement, each of which splits into a frame part and container parts, so $W = c(\Phi)\prod_j \sigma_j$, $W(-1)^{n34} = c'(\Phi)\prod_k \sigma'_k$, $(-1)^{n34} = c''(\Phi)\prod_j \sigma_j \prod_k \sigma'_k$ ($|c|$, $|c'| \le 1$, $|c''| = 1$). Multiplying the first formula of the Container Identity by $\mathbf{1}_O$ and averaging over the frame gives $|\mathbb{E}[W\mathbf{1}_O]| \le \mathbb{E}[\mathbf{1}_O \prod_j \theta_j]$, $|\mathbb{E}[W(-1)^{n34}\mathbf{1}_O]| \le \mathbb{E}[\mathbf{1}_O \prod_k \theta'_k]$, $|\mathbb{E}[(-1)^{n34}\mathbf{1}_O]| \le \mathbb{E}[\mathbf{1}_O \prod_j \theta_j \prod_k \theta'_k]$. The numerator of (8) is at most half the sum of the first two, and the denominator is at least $\frac{1}{2}(\mathbb{E}[\mathbf{1}_O] - \mathbb{E}[\mathbf{1}_O \prod \theta \prod \theta'])$. Dividing both by $\mathbb{E}[\mathbf{1}_O]$ gives (9). ∎

The second term of (9) goes to 0 as the size of the plane $M \to \infty$ when the biases are typically smaller than 1 in the outer containers too (when the rarity of bad frames can be used outside as well). This book does not show that Assumption . In the theorem of slab confinement (25-04), the group of flips acts on all plaquettes of the plane, so the outer term automatically becomes small, $t^{M^2 - A}$, and this problem does not arise.

05

Nesting in the directions of the plane

We divide a large container R (a disc of the plane $\times$ T^2) into small containers $R_1, \dots, R_k$ separated by an inner frame Φ_{int}. The product of z over the surface spanned by R is $\sigma_R = s(\Phi_{\mathrm{int}})\prod_i \sigma_i$ ($|s| = 1$, the product of z over the part in the frame).

Nesting Inequality in the Plane Directions

Writing Φ_R for the frame outside R,

$$\left|\mathbb{E}[\sigma_R \mid \Phi_R]\right| \;\le\; \mathbb{E}\Big[\prod_{i=1}^{k} \left|\mathbb{E}[\sigma_i \mid \Phi_R, \Phi_{\mathrm{int}}]\right| \;\Big|\; \Phi_R\Big] \tag{10}$$

Proved here Proof. Apply the Container Identity with Φ_R and Φ_{int} together as the frame ($c = s$), and average over Φ_{int} with Φ_R held fixed. ∎ Lean Containers (`Containers.container_bound`) (hypotheses: finite, $a \ge 0$, $|s| \le 1$) is the finite-sum version of this algebra, the form whose description in the Lean file says it "contains the Mack–Petkova container identity and the planar doubling inequality".

How to read it. If, for containers of some size, the bias is $\theta_0 < 1$ for typical frames, one can expect that each doubling of the containers in the directions of the plane lowers

the bias to order θ_0^4 Reading (a physical estimate: the right-hand side of (10) is the average of a product, not the product of averages, so this does not follow directly from the inequality). Disorder propagates to large scales in the directions of the plane.

However, (10) concerns **a slab with the size of the T^2 held fixed**. What is needed when widening the T^2 (approaching four-dimensional space) is the behaviour of the bias $\theta(L, L)$ when the T^2 and the containers are doubled together, and (10) says nothing about that (when the T^2 changes, the very surface around which the vortex sheet winds changes). That the form needed there cannot be "$\theta(L, L)$ stays uniformly away from 1" but must be $\ln(1/\theta(L, L)) \geq cL^2$ (the contrast with $U(1)$) is treated in the chapter on the crossover band, 26-01.

06

Limits in four dimensions — independent containers reach only $R/\ln R$

The Container Identity is an identity that depends neither on the size of the lattice nor on the dimension. So, if one lines up many containers in four-dimensional space (the lattice of R^4), does an area law follow? Kovács–Tomboulis (hep-lat/0108017 § 3) show by the following counting that **independent containers do not reach it** Cited ((23)–(27) below are the equation numbers of the original source; checked in its text).

1. Let d_i be the width in the two directions transverse to the coclosed surface V_i of a container Λ_i, and $|V_i|$ its longitudinal length. **Assume** that a sufficiently thick container is in the regime where $-\ln(z^{(-)}/z^{(+)}) \sim |V_i| \exp(-c\, d_i^2)$ for all boundary values ((23) of the original source; c is the ρ of the original source).
2. To keep the free-energy cost of one container below a constant f, one needs $d_i^2 \geq c^{-1} \ln(|V_i|/f)$ ((24)). Then $\max |f_{\Lambda_i}| < \frac{1}{2}(1 - e^{-f})$ is constant.
3. For a rectangular loop with sides $T \times R$ ($T > R$), the length of the containers through points away from the perimeter is $|V_i| \sim R^{d-2}$ (R^2 in four dimensions). So a thickness of order $\sqrt{\ln R}$ is needed, and $\sim RT/\ln R$ containers fit inside the loop. From (22)

$$V(R) \;\geq\; \text{const} \cdot \frac{R}{\ln R} \qquad \text{((25) of the original source)} \quad (11)$$

is all that follows, which is not a purely linear potential (an area law). The original source goes on to state that if the boundary values of neighbouring containers are also integrated, grouping containers as thick as possible, and containers with transverse area $\sim R^2$ are used, one gets $V(R) \geq \text{const}\, R - \frac{\text{const}}{R}(\ln R + \text{const})$ ((27)), that is, **the linear potential comes from thick vortex fluctuations of the size of the loop**. It also states that the form (22) is crude, and that the inequalities coming from reflection

positivity (their (11)(13), the global form of Tomboulis–Yaffe) give an area law directly, with bounds uniform in the size of the lattice Cited .

Restated in the words of this chapter: in R^4 the length of the containers grows with the loop, so the road of placing containers of fixed length independently does not reach the area law. In a small-T^2 slab, the length of the container $\{\mathrm{disc}\} \times T^2$ (the area of the vortex sheet) stops at the area of the T^2, so this obstruction does not appear Proved here (a rereading of the fact that $|V_i| = N^2$ becomes a constant in (24) of the original counting). The obstruction returns when the T^2 is widened, and that is the crossover band (26-01, 25-09).

07

A test in a solvable two-dimensional model

Two-dimensional $SU(2)$ (a planar lattice, Wilson action $\frac{\beta}{2}\mathrm{tr}\, U_p$) is solvable because the plaquettes behave independently of each other. Here we see how close the bound of the Container Identity is to the true value. Two dimensions has no problem of "the length of containers", so this test says nothing about the four-dimensional obstruction of § 06.

Setting. Tile the inside of the loop with square containers of side ℓ, and take the links on the borders of the containers as the frame (container area $A = \ell^2$). With the frame fixed, container j sees only the holonomy $V_j \in SU(2)$ of its border. Using the characters $\chi_n(V) = \sin((n+1)\vartheta)/\sin\vartheta$ ($e^{\pm i\vartheta}$ are the eigenvalues of V, and $n = 0, 1, 2, \ldots$ is $2\times$ the spin of the representation) and $a_n = I_{n+1}(\beta)/I_1(\beta)$ (I is the modified Bessel function), the heat-kernel expansion gives

$$\mathbb{E}[\sigma_j \,|\, \mathrm{frame}] = \frac{\sum_{n\ \mathrm{odd}} (n+1)\, a_n^A\, \chi_n(V_j)}{\sum_{n\ \mathrm{even}} (n+1)\, a_n^A\, \chi_n(V_j)} \quad (12)$$

and the holonomies of the containers are independent of each other, distributed with the denominator as density. So the bound of the Container Identity becomes a product of factors per container,

$$|\langle W\rangle| \;\le\; B(A)^{\#\mathrm{containers}}, \qquad B(A) = \int_{SU(2)} dV \,\Big|\sum_{n\ \mathrm{odd}} (n+1)\, a_n^A\, \chi_n(V)\Big| \quad (13)$$

The true value is $\langle W\rangle = a_1^{\mathrm{area}}$, and the true string tension is $\sigma = -\ln a_1$. We write $\sigma_{\mathrm{L5}}(\ell) := -\ln B(\ell^2)/\ell^2$ for the string tension coming from (13), and $\sigma_{\max}(\ell) := -\ln\big(\max_V |(12)|\big)/\ell^2$ for that coming from the form of (22) of Kovács–Tomboulis (maximum over frames).

The subscript L5 is a letter for the form that comes from the Container Identity (the average over frames), used as the counterpart of the maximum form $\sigma_{\max}$.

The limit of large containers. As $A \to \infty$, the odd sum is dominated by the $n = 1$ term $2a_1^A \chi_1(V) = 4a_1^A \cos\vartheta$ and the even sum by the $n = 0$ term 1, so with the Haar distribution $\frac{2}{\pi}\sin^2\vartheta\, d\vartheta$

$$\frac{B(A)}{a_1^A} \longrightarrow \frac{2}{\pi}\int_0^{\pi} 4|\cos\vartheta|\sin^2\vartheta\, d\vartheta = \frac{16}{3\pi} \approx 1.6977, \qquad \sigma_{\mathrm{L5}}(\ell) \;=\; \sigma - \frac{\ln(16/(3\pi))}{\ell^2} + (A\text{-e}$$

Proved here . The bound of the Container Identity is **sharp in its exponent**, and the loss vanishes as $1/\ell^2$.

Table 1 The string tension $\sigma_{\mathrm{L5}}(\ell)$ from the Container Identity and the maximum form $\sigma_{\max}(\ell)$ for two-dimensional $SU(2)$. Floating point, trapezoidal rule in ϑ with 4×10^5 points, representations truncated at $n \le 200$, the check of the normalisation of the denominator is 1.000000 in every row. The numbers are numerics from this book's study (Reading)

β	True σ	$\ell = 1$	$\ell = 2$	$\ell = 4$	$\ell = 8$	$\ell = 16$	$\sigma_{\max}$: $\ell = 1, 4, 16$
1	1.4263	0.9132	1.2940	1.3932	1.4180	1.4242	0.2723, 1.3397, 1.4209
2	0.8367	0.3663	0.7044	0.8036	0.8285	0.8347	0.0366, 0.7501, 0.8313
4	0.4185	0.0624	0.2866	0.3854	0.4102	0.4164	0.00067, 0.3318, 0.4131
8	0.1994	0.0016	0.0761	0.1663	0.1911	0.1973	$< 10^{-6}$, 0.1128, 0.1940

How to read it Reading . (i) The $\ell = 16$ column agrees with the right-hand side of (14) to the fourth decimal place (for example, at $\beta = 1$, $1.426309 - \ln(1.69765)/256 = 1.424242$). (ii) For thin containers ($\ell = 1$), the bound becomes exponentially worse when β is large (at $\beta = 8$, 0.0016 against 0.1994). This is the two-dimensional form of the need for thick containers. (iii) The maximum form approaches the same limit, but lags behind. The Container Identity, which takes the average, is always closer to the true value at the same ℓ.

The maximum form for $\ell = 1$ in (ii) can be written in closed form. A container of side 1 is a single plaquette, and all four of its links belong to the frame, so $\mathbb{E}[z_p \mid V] = \tanh\!\left(\frac{\beta}{2}\operatorname{tr} V\right)$, and the maximum is $\tanh\beta$ at $\operatorname{tr} V = \pm 2$ Proved here . The $\sigma_{\max}(1)$ of the table agrees with $-\ln\tanh\beta$ (0.27234, 0.036635, 0.000671 at $\beta = 1, 2, 4$). This is the same formula as the case $N = 1$ of the slab-confinement bound $\sigma \ge -\ln\tanh(\beta N^2)$ of the next chapter (25-04 § 05).

08
```

What cannot be said

(a) Novelty. The Container Identity is the container identity of Mack–Petkova, written in (18)–(22) of Kovács–Tomboulis. The rewriting in the sector-summed ensemble, the Inner and Outer Container Proposition and the Nesting Inequality in the Plane Directions are elementary, and have not been compared with literature other than Kovács–Tomboulis. No novelty is claimed for the results of this chapter.

(b) The second term of the Inner and Outer Container Proposition. That the biases of the outer containers are typically small (that the second term goes to 0 as $M \to \infty$) is not shown.

(c) The reading of the Nesting Inequality in the Plane Directions. "θ_0^4 at each doubling" is an estimate and does not follow directly from (10). (10) says nothing about widening together with the T^2.

(d) The four-dimensional counting. The $R/\ln R$ of § 06 is counting on top of the assumption on the form of the thick-container free energy in the original source ((23) of Kovács–Tomboulis: that the free energy of a thick container has the form $|V_i| e^{-c d_i^2}$ uniformly in the boundary values), and is not a four-dimensional theorem. This book shows neither (23) nor its negation.

(e) Uniform bounds on the free energy of containers. Bounding ΔF_j uniformly over good frames and uniformly in the lattice spacing is not shown anywhere in this book. That needs a multiscale analysis of the conditional measure with the frame fixed, and the variational principle alone (which gives only lower bounds on partition functions) points the wrong way.

(f) Lean. The machine-checking column is only the algebra of finite sums. That (3)(4) follow from the Haar measure, a coclosed z, the topology of sectors and the nearest-neighbour action is outside Lean.

(g) The two-dimensional test. Table 1 is two-dimensional numerics and says nothing about the problem of the length of containers in four dimensions.

```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. The row of rarity outside (second term of (9) $\to$ 0) is an assumption row and enters as a premise of no row. The inequality (9) of the Inner and Outer Container Proposition holds without this row; the row is needed only when reading (9) as an area law. This chapter has neither a node of the continuum limit nor a node of the four-dimensional area law.

The machine-checked theorems on the vortex side are in Part 21.

Words used in this chapter — the sector-summed ensemble, frame, container, the sign of the sector, the bias θ, the vortex free energy with the frame fixed ΔF, the Container Identity, inner and outer containers, nesting, the length and thickness of containers. Their meanings are in A-02 Glossary (the words of Part 25 are to be added).

Next chapter to read: 25-04 Slab confinement — letting the group of flips act on all plaquettes of the plane gives, in a slab with the lattice spacing and the T^2 fixed, an area law at every β.

2026-10-15 · chapter Yang–Mills and the mass gap Part 25 The second road — from the direction of space the Slab Confinement Theorem, group averaging, thin vortices · Kiichi, Shiori and Rin

Slab confinement

> This chapter is this book's own investigation. The established knowledge it builds on is in 25-03 and 5-01.

What this chapter shows — Consider a "slab" lattice in which two directions are wound into a small T^2 (a lattice of side N) and the remaining two directions (the plane) are wide. With the lattice spacing and the size of the T^2 fixed, the $SU(2)$ Wilson loop obeys an area law **at every** β, with string tension $\sigma \geq -\ln\tanh(\beta N^2) \geq 2e^{-2\beta N^2} > 0$ (the slab-confinement theorem). The proof is elementary: one just averages over the group that flips at once the signs on the vortex sheets $\{p\} \times T^2$ standing directly above the plaquettes of the plane. In this chapter we place the statement of the theorem (§ 02), a proof in five steps (§ 03), the container form $\sup\theta \leq \tanh(\beta N^2)^{\ell^2}$ and why this lower bound becomes 0 in the continuum limit (§ 04), a test in two dimensions (§ 05), and where it stands relative to earlier literature (§ 06).

Prerequisite chapters — 25-03 (the sector-summed ensemble, frame and containers, the Container Identity), 25-01 (twisted sectors and flux). From Part 5, 5-01 (the Wilson action) and 5-02 (the area law at strong coupling); from Part 7, 7-02 (two dimensions).

Said first — The theorem is a statement on the lattice, with the lattice spacing and the side N of the T^2 fixed. In the continuum limit ($N \to \infty$, $\beta \to \infty$) this lower bound vanishes to 0. That the theorem holds at every β without using the strong-coupling expansion is because the slab is in effect a two-dimensional system, and it says nothing about confinement in four-dimensional space. Comparison with earlier literature is not done (comparison with arguments of Tomboulis–Yaffe type and with Borgs 1985 remains).

The order of this chapter

1. Summary — flip the vortex sheets all at once and average
2. Setting and the Slab Confinement Theorem
3. Proof — five moves
4. The container form and the cost of thin vortices — in the continuum limit the lower bound on the tension is 0

5. A test in two dimensions
6. Where it stands relative to earlier literature
7. What cannot be said
8. The table of five grades and the dependency graph — Table 1

01

Summary — flip the vortex sheets all at once and average

1. Two-dimensional lattice gauge theory confines at every coupling (Wilson loops decrease exponentially in the area). This is because the plaquettes behave independently of each other (7-02).
2. Seen from afar, the lattice of a slab $T^2 \times \mathbb{R}^2$ with two small closed directions is a two-dimensional system. So, with the size of the T^2 held fixed, one can expect it too to confine at every coupling. This chapter states that on the lattice, with a proof Proved here .
3. The tool is the sector-summed ensemble of 25-03. For each plaquette p of the plane, consider the sheet S_p of the N^2 (3,4) plaquettes at all points of the T^2 standing directly above it. Flipping the signs z on S_p all at once preserves the coclosedness condition and leaves the links unchanged. Flipping at a p inside the loop changes the sign of the Wilson loop, and the weight changes by at most a factor $e^{\pm 2\beta N^2}$.
4. Averaging over all combinations of flips (2^{M^2} of them), the Wilson loop is bounded by a product of factors $(1 - r_p)/(1 + r_p)$ over the inner plaquettes, and each factor is at most $\tanh(\beta N^2)$. Hence $|\langle W \rangle| \le \tanh(\beta N^2)^A$ (A is the area of the loop).
5. This lower bound is superexponentially weak in N (at $\beta = 2.5$, $N = 4$, $\sigma \ge 2e^{-80}$), and becomes 0 in the continuum limit. This is because the cost $2\beta N^2$ of flipping a thin vortex sheet at once grows with the number of points of the T^2 lattice. The cost of a physical vortex (a fractional instanton) is of order $\pi^2\beta$ and does not depend on N, so the road of doing the same thing with thick vortices is the next two chapters (25-05, 25-06).

02

Setting and the Slab Confinement Theorem

The lattice is $\Lambda = (\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$. Directions 1 and 2 form the T^2 (side N), and directions 3 and 4 the plane (cut off with period M). The group is $SU(2)$, the action is

the Wilson action $\frac{\beta}{2}\sum_p \operatorname{tr} U_p$, and the twist of the T^2 (n_{12} and so on) is fixed arbitrarily. The loop C lies in the (3,4) plane at a point y_0 of the T^2, and encloses a region $S(C)$ of area A (number of plaquettes) in the plane.

Slab Confinement Theorem

Set $t := \tanh(\beta N^2)$. For every $\beta > 0$, every M, and any fixed twisted sector,

$$\left|\langle \tfrac{1}{2}\operatorname{tr} U_C\rangle\right| \;\le\; \frac{t^{A} + t^{M^2 - A}}{1 - t^{M^2}} \quad (1)$$

In particular, at any limit point as $M \to \infty$, $|\langle \frac{1}{2}\operatorname{tr} U_C\rangle| \le t^{A}$, and uniformly in the area of the loop,

$$\sigma \;\ge\; -\ln\tanh(\beta N^2) \;\ge\; 2e^{-2\beta N^2} \;>\; 0. \quad (2)$$

Proved here (proof in § 03). The σ of (2) is the string tension in lattice units, and the conditions are "$SU(2)$, Wilson action, N fixed, lattice spacing fixed, every β". The right-hand inequality of (2) follows from setting $u = e^{-2x}$ and $-\ln\tanh x = \ln(1+u) - \ln(1-u) = 2(u + u^3/3 + \cdots) \ge 2u$.

03

Proof — five moves

Step 1 (the sector-summed ensemble). (1) of 25-03 § 02: for coclosed $z \in \{\pm 1\}^{\text{plaquettes}}$ and U the weight is $w(U,z) = \exp(\frac{\beta}{2}\sum_p z_p \operatorname{tr} U_p)$, and the measure is Haar $\times$ counting. Every z that can be written $z = z_0 \cdot \delta\omega$ ($\omega \in \{\pm 1\}^{\text{links}}$, $(\delta\omega)_p = \prod_{b\in\partial p}\omega_b$) gives the same integral as z_0 by the invariance $U_b \mapsto \omega_b U_b$ of the Haar measure, so the sum over z in one cohomology class is a constant multiple of the $SU(2)$ partition function of the twisted sector that the class represents Proved here. The sector is fixed by the class of z, and the indicator function of a sector is a function of z. The gauge-invariant Wilson loop is $W(C) = \frac{1}{2}\operatorname{tr} U_C \prod_{p\in S(C)} z_p$; under the same substitution $\prod_{p\in S(C)}(\delta\omega)_p = \prod_{b\in C}\omega_b$ cancels against the sign on the side of $\operatorname{tr} U_C$, so within a sector it has the same expectation as $\frac{1}{2}\operatorname{tr} U_C$ (up to a sign depending on the choice of representative of the sector).

Step 2 (vortex sheets are coclosed). For each plaquette p of the plane set $S_p := \{$ p's overlying (3,4) plaquettes $\} \times T^2$ (N^2 plaquettes). Among three-dimensional cubes, only those of orientation (1,3,4) and (2,3,4) have (3,4) faces; for example, the (3,4) faces

of the (1,3,4) cube that extends in direction 1 from a point y of the T^2 and spans the plaquette p' of the plane are the two copies of p' at y and $y+e1$. If $p'=p$ both lie in S_p; if $p' \neq p$ neither does. Cubes of type (1,2,3) and (1,2,4) have no (3,4) faces. Hence every cube contains 0 or 2 faces of S_p, and flipping the z on S_p preserves the coclosedness condition Proved here . If $p \neq q$, S_p and S_q have no plaquette in common.

Step 3 (the group action). Let P be the set of all plaquettes of the plane ($|P| = M^2$), and assign to a subset $g \subseteq P$ the map $z \mapsto z \cdot \chi_{S_g}$ (flipping on $S_g = \bigcup_{p\in g} S_p$). This is an action of the group $G = \{\pm 1\}^P$, a bijection on coclosed z, and since it does not change U it preserves the Haar $\times$ counting measure.

- The Wilson loop: $S(C)$ consists of A plaquettes in the plane at y_0, and S_p contains exactly one plaquette of the plane at y_0, the one at the position of p. Hence $W(g\cdot x) = W(x)\prod_{p\in g}\varepsilon_p$, with $\varepsilon_p = -1$ ($p \in S(C)$) and $+1$ (otherwise).
- The weight: flipping the z on S_p changes the action by $-\beta\sum_{q\in S_p} z_q \operatorname{tr} U_q$, so setting $r_p(x) := \exp(-\beta\sum_{q\in S_p} z_q \operatorname{tr} U_q)$, from $|\operatorname{tr} U_q| \le 2$ we get $r_p \in [e^{-2\beta N^2}, e^{2\beta N^2}]$. r_p is determined only by the values on S_p, and the sheets do not meet, so $w(g\cdot x) = w(x)$ $\prod_{p\in g} r_p(x)$.

Step 4 (averaging). Let $\mathbb{E}$ be the expectation of the sector-summed ensemble, and $\sum_x$ the sum over z together with the Haar integral over U. For each g, relabelling the variables gives $\sum_x W(x)w(x) = \sum_x W(g\cdot x)w(g\cdot x) = \sum_x W(x)w(x)\prod_{p\in g}\varepsilon_p r_p(x)$. Averaging over g and using $\sum_{g\subseteq P}\prod_{p\in g}\varepsilon_p r_p = \prod_{p\in P}(1+\varepsilon_p r_p)$,

$$2^{M^2}\sum_x Ww = \sum_x W(x)w(x)\prod_{p\in S(C)}(1-r_p(x))\prod_{p\in\complement S(C)}(1+r_p(x)), \qquad 2^{M^2}\sum_x w = \sum_x$$

The one-sheet inequality $|1-r| \le \tanh(a)\,(1+r)$ ($r\in[e^{-2a}, e^{2a}]$, here $a=\beta N^2$) follows from $(1-r)/(1+r) = -\tanh(\tfrac12 \ln r)$ and $|\tfrac12 \ln r| \le a$. Together with $|W|\le 1$, the absolute value of the right-hand side of the left formula of (3) is at most $t^A\sum_x w\prod_P(1+r_p) = t^A\,2^{M^2}\sum_x w$. Hence

$$|\mathbb{E}[W(C)]| \;\le\; t^A. \quad (4)$$

At this step there is no need to split into orbits. We use only the relabelling (a bijection) for each g, and the exchange of the sum over g with the sum over x.

Step 5 (projection to a fixed sector). The group G changes only the parity of the (3,4) flux. S_p contains one plaquette of the (3,4) plane at y_0, so it flips $(-1)^{n34}$ (the product of z over the whole (3,4) plane at y_0); it contains no plaquettes of other orientations, so

it does not change the indicator function $\mathbf{1}_O$ of the other labels such as n_{12}. The expectation with the sector fixed to s is, as in (8) of 25-03,

$$\langle W\rangle_s = \frac{\mathbb{E}[W\mathbf{1}_O] + s\,\mathbb{E}[W(-1)^{n_{34}}\mathbf{1}_O]}{\mathbb{E}[\mathbf{1}_O] + s\,\mathbb{E}[(-1)^{n_{34}}\mathbf{1}_O]} \tag{5}$$

$W(-1)^{n_{34}} = \frac{1}{2}\mathrm{tr}\,U_C \prod_{p\in/\,S(C)} z_p$ (the complement in the plane at y_0, of area $M^2 - A$) changes sign under flips at $p \in/\ S(C)$ and does not change under flips at $p \in S(C)$. $(-1)^{n_{34}}$ changes sign under flips at every p. $\mathbf{1}_O$ is invariant under G, so by the same averaging as in step 4 (with the roles of ε_p exchanged)

$$|\mathbb{E}[W\mathbf{1}_O]| \le t^{A}\,\mathbb{E}[\mathbf{1}_O], \qquad |\mathbb{E}[W(-1)^{n_{34}}\mathbf{1}_O]| \le t^{M^2-A}\,\mathbb{E}[\mathbf{1}_O], \qquad |\mathbb{E}[(-1)^{n_{34}}\mathbf{1}_O]| \le t^{M^2}\,\mathbb{E}$$

Bounding the numerator and denominator of (5) by (6) gives (1). As $M \to \infty$, $t^{M^2-A} \to 0$ and $t^{M^2} \to 0$ ($t < 1$), so at limit points $|\langle W\rangle| \le t^{A}$, and (2) follows. ∎

Here the group acts on all plaquettes of the plane, so the problem of 25-03 § 04, "the outer term does not become small", does not arise. The outer term automatically becomes small, t^{M^2-A}.

Lean SlabConfine (`SlabConfine.group_average`) (no hypotheses: $\sum_{g\subseteq P}\prod_{p\in g}\varepsilon_p r_p = \prod_{p\in P}(1+\varepsilon_p r_p)$), SlabConfine (`SlabConfine.factor_split`) (no hypotheses: the splitting into inner and outer), SlabConfine (`SlabConfine.tanh_bound`) (hypotheses: $t \ge 0$, $r_p > 0$, $|1-r_p| \le t(1+r_p)$), SlabConfine (`SlabConfine.one_sheet`) (hypotheses: $a \ge 0$, $e^{-2a} \le r \le e^{2a}$. Conclusion: $|1-r| \le \tanh a \cdot (1+r)$), SlabAverage (`SlabAverage.average_bound`) (hypotheses: the set of configurations is finite, $w > 0$, $|W| \le 1$, the action of each $g \subseteq P$ is a bijection, $r_p > 0$, $|1-r_p| \le t(1+r_p)$, $W(gx)w(gx) = W(x)w(x)\prod_{p\in g}\varepsilon_p r_p(x)$, $w(gx) = w(x)\prod_{p\in g} r_p(x)$. Conclusion: $|\sum Ww| \le t^{|P\cap A|}\sum w$). These are the finite-sum version of step 4. Replacing the sums by Haar integrals, and the coclosed z and the topology of sectors (steps 1, 2 and 5), are outside Lean and rest on the argument in the text.

04

The container form and the cost of thin vortices

Carrying out the same averaging only inside one container, it can be written in the language of the biases of 25-03. Take as container the product of a square Q of side ℓ in the plane (ℓ^2 plaquettes) with the T^2, and let σ_Q be the product of z over the surface spanned by Q. Flips by $g \subseteq Q$ change only the z inside the container, so they do not change the frame Φ, and they multiply σ_Q by $\prod_{p\in g}(-1)$. On the orbit $\{g\cdot x : g \subseteq Q\}$ of one x, the weight has the product form $w(x)\prod_{p\in g} r_p(x)$, so conditioning on the orbit makes the components of g independent, and

$$\mathbb{E}[\sigma_Q \mid \mathrm{orbit}] = \sigma_Q(x)\prod_{p\in Q}\frac{1-r_p(x)}{1+r_p(x)} = \pm\prod_{p\in Q}\tanh X_p, \qquad X_p = -\tfrac{1}{2}\ln r_p \in [-\beta N^2, \beta N^2]$$

Proved here . Conditioning on the orbit is finer than conditioning on the frame, so

$$\sup_{\Phi}\ \theta_Q(\Phi) = \sup_{\Phi}\big|\mathbb{E}[\sigma_Q \mid \Phi]\big| \ \le\ \tanh(\beta N^2)^{\ell^2} \qquad (8)$$

Proved here . That it can be bounded by the **maximum** over frames is because the cost of flipping a thin sheet, $|\ln r_p| \le 2\beta N^2$, is uniform and independent of the frame.

Extremely weak. The lower bound of (2) becomes superexponentially small in N. At $\beta = 2.5$, $N = 4$, $2\beta N^2 = 80$ and $\sigma \ge 2e^{-80} \approx 3.6 \times 10^{-35}$. The lower bound $2e^{-2\beta N^2}/a^2$ on the physical string tension $\sigma_{\text{phys}} = \sigma/a^2$ goes to 0 if the physical size $L = Na$ of the T^2 is held fixed and $a \to 0$ ($N = L/a \to \infty$, and β increases by asymptotic freedom) Proved here . **In the continuum limit, the lower bound on the tension in this theorem is 0.**

The reason is the cost of thin vortices. The cost of a flip, $2\beta N^2$, is the action of turning over at once the N^2 plaquettes of the lattice sheet S_p, one lattice unit thick, and it grows with the number of points of the T^2 lattice. On the other hand, what physics regards as the cost of a vortex is of the order of the action $4\pi^2/g^2 = \pi^2\beta$ ($\beta = 4/g^2$) of a smooth fractional instanton winding the T^2, which does not depend on N (25-02) Reading (physics). The same group-averaging argument goes through with $t = \tanh(F/2)$ whenever the ratio of weights r_p of a flip lies in $[e^{-F}, e^{F}]$, so if the flip of a thin sheet is replaced by "a measure-preserving map that inserts a thick vortex" and F can be bounded by a quantity independent of N, a lower bound uniform in the lattice spacing can be expected Assumption (where the evidence is: the form (7) of this chapter, the insertion identities of 25-05, and the insertion driven by dynamics of 25-06). That needs a uniform bound on the cost of insertion (ultraviolet control; in the setting of this part, that the same construction as the one published on 2026-11-10 stands under twisted boundary conditions), and this book does not show it. The published construction is on a periodic cubic box and does not reach here.

(8) also shows that arguments using $\sup_\Phi$ get superexponentially worse in N. To get uniformity in the problem of widening the T^2 (the crossover band), only the averaged form over frames can be used, not the maximum (one of the reasons why the Container Identity of 25-03 takes the average).

05

A test in two dimensions

Applying the five moves of the proof directly to the two-dimensional lattice $(\mathbb{Z}/M)^2$, there are no cubes, so the coclosedness condition is empty, and the vortex sheet is $S_p = \{p\}$ (a single plaquette, the formula of the Slab Confinement Theorem with $N = 1$).

So the same proof gives $|\langle W\rangle| \le \tanh(\beta)^A$ for two-dimensional $SU(2)$. The true value in two dimensions is $\langle W\rangle = a_1^A$, $a_1 = I_2(\beta)/I_1(\beta)$, so the theorem contains $I_2(\beta)/I_1(\beta) \le \tanh\beta$ for every β.

- Leading terms at large β: from $I_\nu(\beta) \sim e^\beta(2\pi\beta)^{-1/2}(1 - \frac{4\nu^2-1}{8\beta})$ we get $a_1 \approx 1 - \frac{3}{2\beta}$, while $\tanh\beta \approx 1 - 2e^{-2\beta}$. The lower bound is exponentially smaller than the true tension $\approx \frac{3}{2\beta}$, and there is no contradiction Proved here .
- In numbers: the true $\sigma = -\ln a_1$ is $1.4263,\ 0.8367,\ 0.4185,\ 0.1994$ at $\beta = 1, 2, 4, 8$, and the lower bound of the theorem $-\ln\tanh\beta$ is $0.2723,\ 0.0366,\ 0.00067,\ 2.25\times10^{-7}$ Reading (floating point).
- This lower bound agrees exactly with "the maximum form for containers of side 1", $\sigma_{\max}(1)$, in Table 1 of 25-03. This is because in a container of side 1 only the z of one plaquette is inside, $\mathbb{E}[z_p \mid V] = \tanh(\frac{\beta}{2}\operatorname{tr} V)$, and its maximum is $\tanh\beta$ Proved here (25-03 § 07). The slab theorem has the same form as the bound "containers one unit thick, bounded by the maximum over frames".

Measurements of Wilson loops on four-dimensional slabs (Creutz ratios, comparison with and without twist) are placed in the chapter of the measured record, 25-08.

06

Where it stands relative to earlier literature

The method of the Slab Confinement Theorem (averaging, as a group, the signs on central sheets winding the compact directions) is of the same lineage as the vortex free-energy arguments of Mack–Petkova and Tomboulis–Yaffe, and amounts to bounding directly by the action the free energy of a container $\{p\}\times T^2$ one unit thick Cited (the correspondence of lineage is by comparison with the framework of Kovács–Tomboulis hep-lat/0108017 § 2– § 3). Since the idea is classical, the same bound may already exist in the literature, or as folklore. Two comparisons remain.

- Arguments of Tomboulis–Yaffe type (Commun. Math. Phys. 100 (1985) 313): inequalities that bound a Wilson loop by a ratio of twisted partition functions (as restated in Kanazawa arXiv:0808.3442). We have not checked whether a bound of the same form on a slab is written out explicitly.
- Borgs (Nucl. Phys. B 261 (1985), the area law of spatial Wilson loops in lattice gauge theory at high temperature): recorded as work that showed, by a cluster expansion, an area law for spatial Wilson loops at sufficiently high temperature. This book has not checked the text of the original source (bibliographic data from secondary records). The expected differences from the Slab Confinement Theorem are three —

non-abelian $SU(2)$, every β with N fixed, and an explicit and elementary bound — but the comparison is not done.

Within this book, the Slab Confinement Theorem reappears in the next chapter as a special case (thin insertion) of the insertion identities (25-05 § 06).

07

What cannot be said

(a) The continuum limit. The lower bound of (2) becomes 0 as $a \to 0$. The Slab Confinement Theorem says nothing about a tension uniform in the lattice spacing.

(b) Four-dimensional space. The Slab Confinement Theorem is a statement with the size N of the T^2 fixed, and the lower bound vanishes as $N \to \infty$ (approaching four-dimensional space). It says nothing about confinement in four dimensions. The stage of widening the T^2 is the crossover band (25-09, 26-01).

(c) Improvement to thick vortices. "Bounding F independently of N with a map of thick vortices" in § 04 is a provisional strand; there is no proof, including of the uniform bound on the cost of insertion.

(d) Earlier literature. The comparison with the two items of § 06 is not done. No novelty is claimed for the results of this chapter.

(e) Lean. The machine-checking column is only the algebra of finite sums (the group-average identity, the tanh bound, the one-sheet inequality). The Haar measure of $SU(2)$, the coclosed z, and the topology of sectors and the projection (steps 1, 2 and 5) are outside Lean.

(f) Existence of the limit. The existence of the limiting measure as $M \to \infty$ is not treated in this chapter; the statement is an upper bound at all limit points.

08

The table of five grades and the dependency graph

Table 1 The rows of this chapter ("—" is a row without machine checking)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	The sector-summed ensemble is the sum of the sector partition functions; the correspondence of Wilson loops (move 1)	Proved here	§ 03	$SU(2)$, finite lattice	—
2	The vortex sheets S_p are coclosed and do not meet each other (move 2)	Proved here	§ 03	Slab $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$	—
3	Under a flip W is multiplied by ε_p and the weight by $r_p \in [e^{-2\beta N^2}, e^{2\beta N^2}]$ (move 3)	Proved here	§ 03	Wilson action	—
4	Group average (3) and $\lvert\mathbb{E}[W]\rvert \le t^A$ (4)	Proved here	§ 03 move 4	Sector-summed ensemble	SlabAverage (`SlabAverage.average_bound`), SlabConfine (`SlabConfine.group_average`, `SlabConfine.tanh_bound`, `SlabConfine.one_sheet`) (hypotheses as at the end of § 03)
5	Projection to a fixed sector (5)(6)	Proved here	§ 03 move 5	The group acts on all plaquettes of the plane	—
6	Slab Confinement Theorem: (1) and $\sigma \ge -\ln\tanh(\beta N^2) \ge 2e^{-2\beta N^2}$	Proved here	§ 02, § 03	$SU(2)$, Wilson action, N fixed, lattice spacing fixed, every β	— (only the finite-sum core, row 4)
7	Container form (7), $\sup_\Phi \theta_Q \le \tanh(\beta N^2)^{\ell^2}$ (8)	Proved here	§ 04	Container of side $\ell \times \mathrm{T}^2$	—
8	In the continuum limit ($L = Na$ fixed, $a \to 0$) the lower bound is 0	Proved here	§ 04	That β does not decrease as $a \to 0$	—

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
9	The cost of a physical vortex is of order $\pi^2\beta$, independent of N	Reading (physics)	25-02	Dilute region, semiclassical	—
10	A map inserting thick vortices gives a lower bound uniform in the lattice spacing	Assumption	Strand: the form (7) of § 04, and 25-05, 25-06	Under ultraviolet control	—
11	Applied to two dimensions, $I_2(\beta)/I_1(\beta) \le \tanh\beta$; agrees with the maximum form for containers of side 1	Proved here	§ 05	Two-dimensional $SU(2)$	—
12	The numbers of § 05	Reading	§ 05	Floating point	—
13	The method is of the lineage of the vortex free energy of Mack–Petkova and Tomboulis–Yaffe	Cited	Comparison with Kovács–Tomboulis § 2– § 3	—	—

The bundles in the machine-checking column are those confirmed, by re-checking on this book's side, to contain no `sorry` and to use axioms forming a subset of the three standard ones. What is guaranteed is the algebra of sums over a finite set of configurations; moves 1, 2 and 5 and the Haar integral are outside Lean (23-13).

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  PRV  summed = sum of sector partition fns; W matches   SU(2), finite latti
 2  PRV  vortex sheets S_p coclosed, disjoint              slab
 3  PRV  W times ε_p, weight times r_p, |ln r_p| ≤ 2βN²
 4  PRV  group average (3)(4) ⟸ 2, 3                       Lean average_bound
 5  PRV  to a fixed sector (5)(6) ⟸ 1, 4
 6  PRV  Slab Confinement Theorem (1)(2) ⟸ 5                N fixed, a fixed,
 7  PRV  container form (7)(8) ⟸ 3
 8  PRV  lower bound 0 in continuum limit ⟸ 6              L = Na fixed
 9  RDG  cost of physical vortex π²β (physics)             dilute, semiclassic
10  ASM  uniform bound with thick vortices ⟸ 7, 9           under ultraviolet
11  PRV  to two dimensions; matches maximum form ⟸ 6
12  RDG  numbers of §05 ⟸ 11                                floating point
13  CIT  lineage of vortex free energy
```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. The premises of the Slab Confinement Theorem are only the rows of the five moves of § 03, and the assumption row (uniform bound with thick vortices) enters as a premise of no row. Its conclusion is "a lower bound uniform in the lattice spacing", and does not contain the quantity of the Slab Confinement Theorem (a lower bound with N fixed).

The machine-checked theorems on the vortex side are in Part 21.

What this chapter can say

What is said	What is not said
Proved here For the $SU(2)$ Wilson action on the slab $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, with N and the lattice spacing fixed, $\sigma \geq -\ln \tanh(\beta N^2) \geq 2e^{-2\beta N^2}$ at every β and in every twisted sector (the Slab Confinement Theorem)	A tension uniform in the lattice spacing. The tension when the T^2 is widened (the crossover band). Novelty (comparison not done)
Proved here The container form $\sup_\Phi \theta Q \leq \tanh(\beta N^2)^{\ell^2}$; that the lower bound becomes 0 in the continuum limit	A uniform bound on the cost of inserting a thick vortex (the thick-vortex row is an assumption)
Proved here + Reading Consistency in two dimensions ($I_2/I_1 \leq \tanh\beta$, agreement with the maximum form for containers of side 1)	Measurements on four-dimensional slabs (25-08)

Words used in this chapter — slab, the vortex sheet S_p, the group of flips, group averaging, the cost of thin vortices, the bias of a container θ_Q, the Slab Confinement Theorem. Their meanings are in A-02 Glossary (the words of Part 25 are to be added).

Next chapter to read: 25-05 Vortex-insertion identities — if the flip of a thin sheet is replaced by a general "bijection that flips the sector", what can be said unconditionally.

Vortex-insertion identities

This chapter is this book's own investigation. The established knowledge it builds on is in 25-03 and 1-08.

What this chapter shows — In 25-04 we obtained slab confinement by averaging over maps that flip thin vortex sheets. In this chapter we list what can be said **unconditionally** when that map is replaced by a general "bijection that flips the sector" T (a map that inserts one vortex). We use only three things: a finite configuration space, positive weights, and a bijection that flips the sign of the sector. From these follow (1) the mean of the insertion ratio ρ is 1, and $\mathbb{E}[\rho\sigma] = -\mathbb{E}[\sigma]$; (2) the bias of the sector is bounded by the fluctuation of the insertion ratio: $4\mathbb{E}[\sigma]^2 \le \mathbf{Var}(\bar{\rho})$; (3) passing to an involution, a bounded form $\mathbb{E}[H] = \mathbb{E}[H\,\tanh(\Delta S/2)]$ and a form averaged over positions; (4) the second-moment form and the Paley–Zygmund form that follow from $\mathbb{E}[H\sqrt{\bar{\rho}}] = 0$. All are elementary identities and Cauchy–Schwarz, and their finite-sum versions are checked in Lean.

Prerequisite chapters — 25-03 (the sector-summed ensemble, the sign of the sector, the bias), 25-04 (slab confinement). From Part 1, 1-08 (probability and measure, Cauchy–Schwarz).

Said first — Every theorem of this chapter is a statement under three conditions — a finite configuration space, positive weights, and a bijection that flips the sector (a finite version of a Haar-preserving map) — and the row of each theorem states those conditions. To pass to the continuous configuration space of $SU(2)$ one must replace the sums by Haar integrals and have the map preserve the measure (or put the Jacobian into the weight), and that part is outside Lean. The results are elementary, and comparison with earlier literature is not done. Nothing about confinement follows from these identities alone. What is missing is written in § 07 and § 08.

The order of this chapter

1. Summary — the balance of a map that inserts one vortex
2. The setting — three conditions
3. The Mean Insertion-Ratio Identity, and the bias estimate by fluctuation

4. Bounded forms — the Bounded Insertion Identity, the fluctuation relation, the average over positions
5. Second-moment forms — the square-root identity, the Paley–Zygmund form, many cells
6. Rederiving slab confinement
7. What it means, and what is missing — Table 1
8. What cannot be said
9. The table of five grades and the dependency graph — Table 2

01

Summary — the balance of a map that inserts one vortex

1. In the sector-summed ensemble (25-03), whether a vortex passes through a region is expressed by a sign $\sigma = \pm 1$. A map T that inserts (or removes) one vortex flips σ.
2. We call the ratio of weights when a vortex is inserted in a configuration x the insertion ratio $\rho(x)$. The smaller ρ is than 1, the more expensive it is to insert a vortex.
3. The mean of the insertion ratio is always exactly 1 (the Mean Insertion-Ratio Identity). This is nothing but a balance equation: "relabelling configurations by a map does not change the total sum of weights". From the same balance also follows $\mathbb{E}[\rho\sigma] = -\mathbb{E}[\sigma]$ Proved here .
4. Combining the two, the bias of the sector $|\mathbb{E}[\sigma]|$ is at most half the square root of the fluctuation (variance) of the insertion ratio (the Bias Estimate by Insertion-Ratio Fluctuation). If one inserts at many positions and averages the insertion ratio, the fluctuation can become small. Averaging over positions plays the role of entropy Proved here .
5. The insertion ratio can take large values (heavy tails), so we also prepare a bounded form that is easy to handle. $\tanh(\Delta S/2)$ always lies in $[-1, 1]$, and $\mathbb{E}[H] = \mathbb{E}[H \tanh(\Delta S/2)]$ holds (the Bounded Insertion Identity). $1 - \mathbb{E}[\tanh]$ is twice the mean acceptance rate of a Monte Carlo move that inserts a vortex (the Insertion Fluctuation Relation Lemma) Proved here .
6. The form using $\sqrt{\rho}$ has a second moment that is always at most 1, so there is no worry about tails (the Square-Root Insertion Identity, the Paley–Zygmund-Type Bias Estimate) Proved here .
7. Taking the flip of a thin vortex sheet (25-04) as the insertion, the slab-confinement theorem comes out as a special case of this chapter (§ 06).

8. These are not a proof of confinement. An area law needs the bias to be small in many regions at once (large deviations) and a bound on the cost of insertion uniform in the lattice spacing (the ultraviolet), and both are outside this chapter.

02

The setting — three conditions

Throughout this chapter we place the following three.

- **Finite configuration-space condition** X (a finite set).
- **Positive-weight condition** $w : X \to (0, \infty)$. The expectation is $\mathbb{E}[f] = \sum_x w(x) f(x) / \sum_x w(x)$.
- **Sector-flipping bijection condition**: a sign of the sector $\sigma : X \to \{\pm 1\}$ and a bijection $T : X \to X$ with $\sigma(Tx) = -\sigma(x)$.

The sector-flipping bijection condition is a finite version of "a map that preserves the Haar measure and flips the sign of the sector of some region" in the sector-summed ensemble (for example, the composite of flipping the z of a vortex sheet with a smooth left multiplication supported inside the region). Being an involution, commuting with one another, and worst-case bounds are not used in § 03. To pass from the finite configuration-space condition to the continuous configuration space $(SU(2)^{\text{links}}$ and coclosed z), one must replace the sums by Haar and counting integrals, and T must preserve the measure (if not, the Jacobian must be put into the weight). The proofs go through with the same relabelling of variables, but that version is outside Lean.

We set the insertion ratio to be

$$\rho(x) = \begin{cases} w(Tx)/w(x) & (\sigma(x) = +1) \\ w(T^{-1}x)/w(x) & (\sigma(x) = -1) \end{cases} \quad (1)$$

The orientation is chosen so that a vortex is inserted by T into configurations with $\sigma = +1$, and configurations with $\sigma = -1$ are taken back by T^{-1}. In terms of the action $S = -\ln w$, $\rho = e^{-\Delta S}$.

03

The Mean Insertion-Ratio Identity, and the bias estimate by fluctuation

Mean Insertion-Ratio Identity

Under the finite configuration-space condition, the positive-weight condition and the sector-flipping bijection condition,

$$\mathbb{E}[\rho] = 1, \qquad \mathbb{E}[\rho\,\sigma] = -\mathbb{E}[\sigma]. \tag{2}$$

Proved here Proof. Set $X_\pm = \{\sigma = \pm 1\}$. T maps X_+ to X_- and X_- to X_+, and since it is a bijection, $T(X_+) = X_-$ and $T^{-1}(X_-) = X_+$. Hence

$$\sum_{x \in X_+} w(x)\rho(x) = \sum_{x \in X_+} w(Tx) = \sum_{y \in X_-} w(y), \qquad \sum_{x \in X_-} w(x)\rho(x) = \sum_{x \in X_-} w(T^{-1}x) =$$

Adding gives $\sum w\rho = \sum w$, and multiplying by σ and adding gives $\sum w\rho\sigma = \sum_{X_-} w - \sum_{X_+} w = -\sum w\sigma$. ∎

Lean InsertionIdentity (`Insertion.mean_one`, `Insertion.mean_rho_sigma`) (hypotheses: X is finite, $w > 0$, T is a bijection of X, $\sigma(Tx) = -\sigma(x)$, $\sigma = \pm 1$. Conclusion: $\sum w\rho = \sum w$, $\sum w\rho\sigma = -\sum w\sigma$). No involution, commutativity or measure structure is used.

Bias Estimate by Insertion-Ratio Fluctuation (the bias of the sector is bounded by the fluctuation of the insertion ratio)

Under the finite configuration-space condition and the positive-weight condition, take a sign of the sector σ and a non-empty finite family $T_1, \dots, T_n$ of bijections that flip it (each T_k satisfying the sector-flipping bijection condition), and let $\bar\rho = \frac{1}{n}\sum_k \rho_k$ be the mean insertion ratio. Then

$$4\,\mathbb{E}[\sigma]^2 \;\le\; \mathbb{E}\big[(\bar\rho - 1)^2\big] = \mathrm{Var}(\bar\rho), \qquad \text{that is} \quad |\mathbb{E}[\sigma]| \le \tfrac{1}{2}\sqrt{\mathrm{Var}(\bar\rho)}. \tag{3}$$

Proved here Proof. Applying the Mean Insertion-Ratio Identity to each T_k and averaging gives $\mathbb{E}[\bar\rho] = 1$, $\mathbb{E}[\bar\rho\sigma] = -\mathbb{E}[\sigma]$. Hence $\mathbb{E}[(\bar\rho - 1)\sigma] = -2\mathbb{E}[\sigma]$. From Cauchy–Schwarz and $\sigma^2 = 1$, $4\mathbb{E}[\sigma]^2 \le \mathbb{E}[(\bar\rho - 1)^2]\mathbb{E}[\sigma^2] = \mathrm{Var}(\bar\rho)$. ∎

Lean InsertionIdentity (`Insertion.sector_bias_le`) (hypotheses: X is finite, the index set of the family is finite and non-empty, $w > 0$, each T_k is a bijection with $\sigma(T_k x) = -\sigma(x)$, $\sigma = \pm 1$. Conclusion: $4(\sum w\sigma)^2 \le (\sum w)\sum w(\bar\rho - 1)^2$).

To apply it to containers (25-03), use the Bias Estimate by Insertion-Ratio Fluctuation on the conditional measure with the frame fixed. A bijection that moves only the inside of a container does not change the frame, so $\theta_j(\Phi) = |\mathbb{E}[\sigma_j \mid \Phi]| \le \frac{1}{2}\sqrt{\mathrm{Var}(\bar\rho \mid \Phi)}$ Proved here . The reading is that the factor $\tanh(|\Delta F_j|/2)$ of the Container Identity is bounded from above by the fluctuation of the mean insertion ratio of insertions at many positions inside the container.

04

Bounded forms — tanh and the average over positions

The insertion ratio $\rho = e^{-\Delta S}$ can take large values, so $\mathrm{Var}(\bar{\rho})$ can be large. We therefore switch to a bounded factor. From the T of the sector-flipping bijection condition we build the map oriented by the sector

$$\tau(x) = \begin{cases} Tx & (\sigma(x) = +1) \\ T^{-1}x & (\sigma(x) = -1) \end{cases} \quad (4)$$

and τ is an **involution** ($\tau \circ \tau = \mathrm{id}$) (if $\sigma(x) = +1$, then $\tau x = Tx \in X_-$, so $\tau(\tau x) = T^{-1}Tx = x$; the converse is the same) Proved here . We set $\Delta S = S \circ \tau - S$, $\rho = w \circ \tau / w = e^{-\Delta S}$, and

$$t(x) := \frac{w(x) - w(\tau x)}{w(x) + w(\tau x)} = \tanh \frac{\Delta S(x)}{2} \quad \in (-1, 1) \quad (5)$$

with these definitions.

Bounded Insertion Identity

Under the finite configuration-space condition and the positive-weight condition, if τ is an involution of X and H is a function odd under τ ($H \circ \tau = -H$), then $\mathbb{E}[H] = \mathbb{E}[H\, t]$.

Proved here Proof. Since $1 - t = 2w \circ \tau / (w + w \circ \tau)$, $\mathbb{E}[H] - \mathbb{E}[Ht]$ is proportional to $2 \sum_x g(x) / \sum w$ with $g(x) = w(x)H(x)w(\tau x)/(w(x) + w(\tau x))$. $g(\tau x) = -g(x)$ (H is odd and the rest is symmetric under $x \leftrightarrow \tau x$), so relabelling the sum by τ gives $\sum g = -\sum g$, hence 0. ∎

Lean BoundedInsertion (`Bounded.single`) (hypotheses: X is finite, τ is a bijection with $\tau \circ \tau = \mathrm{id}$, $w > 0$, $H \circ \tau = -H$. Conclusion: $\sum wHt = \sum wH$).

Insertion Fluctuation Relation Lemma (the fluctuation relation and the acceptance rate)

In the setting of the Bounded Insertion Identity, for every real s, $\mathbb{P}(\Delta S = s) = e^{s}\, \mathbb{P}(\Delta S = -s)$. In particular $\mathbb{E}[t] \geq 0$, and

$$1 - \mathbb{E}[t] = 2\,\mathbb{E}\Big[\frac{1}{1 + e^{\Delta S}}\Big] = 2 \times (\text{mean Barker acceptance rate of an insertion move}). \quad (6$$

Proved here Proof. Relabelling gives $\mathbb{E}[g] = \mathbb{E}[(g \circ \tau)\, \rho]$ for any g. Since $\Delta S \circ \tau = -\Delta S$, taking $g = \mathbf{1}\{\Delta S = s\}$ gives $g \circ \tau = \mathbf{1}\{\Delta S = -s\}$, and on the set $\{\Delta S = -s\}$ we have $\rho =$

$e^{-\Delta S} = e^{s}$, which gives the first formula. Pairing s with $-s$ gives $\mathbb{P}(s)\tanh\frac{s}{2} + \mathbb{P}(-s)\tanh\frac{-s}{2} = \mathbb{P}(-s)(e^{s}-1)\tanh\frac{s}{2} \geq 0$, so $\mathbb{E}[t] \geq 0$. Finally $1 - \tanh(\Delta S/2) = 2/(1+e^{\Delta S})$. ∎ This lemma has no Lean check.

How to read (6). A Barker-type move is a Monte Carlo move that "accepts the configuration with a vortex inserted with probability $w(\tau x)/(w(x)+w(\tau x))$". If insertions are almost always refused (the cost is high), $\mathbb{E}[t] \approx 1$; if they pass often, $\mathbb{E}[t]$ moves away from 1. The first formula has the same form as what non-equilibrium statistical mechanics calls Crooks' fluctuation relation (comparison with the original source, and the version driven by dynamics, are in 25-06).

Many cells and the average over positions. For each of mutually separated cells c, take insertion involutions $\tau_{c,p}$ at positions $p \in P$ in the cell (P a non-empty finite set), build $t_{c,p}$ by (5), and set $\bar{t}_c = \frac{1}{|P|}\sum_p t_{c,p}$.

Position-Averaged Insertion Estimate (a bounded estimate averaged over positions)

Under the finite configuration-space condition and the positive-weight condition, assume that each $\tau_{c,p}$ is an involution, H is odd under every $\tau_{c,p}$, and the factors of other cells do not move ($t_{d,q}\circ\tau_{c,p} = t_{d,q}$ if $c \neq d$). Then

$$\mathbb{E}[H] = \mathbb{E}\Big[H\prod_c \bar{t}_c\Big], \qquad |H| \leq 1 \text{ implies } |\mathbb{E}[H]| \leq \mathbb{E}\Big[\prod_c |\bar{t}_c|\Big]. \tag{7}$$

Proved here Proof. First, for $\prod_c t_{c,p_c}$ with one position chosen from each cell, an induction adding cells one at a time gives $\mathbb{E}[H\prod_c t_{c,p_c}] = \mathbb{E}[H]$: at the step adding cell d, the product so far $G = \prod_{c\neq d} t_{c,p_c}$ does not move under τ_{d,p_d}, so HG is odd and the Bounded Insertion Identity applies. Expanding $\prod_c \bar{t}_c$ gives the average over the $|P|^{\#\text{cells}}$ choices, hence the first formula. Taking absolute values with $|H| \leq 1$ gives the second. ∎ Each factor lies in $[-1,1]$, and no moment assumptions are needed.

Lean BoundedInsertion (`Bounded.averaged`, `Bounded.averaged_bound`) (hypotheses: X, the set of cells and the set of positions P are finite, P is non-empty, every $\tau_{c,p}$ is an involution, $w > 0$, H is odd under every $\tau_{c,p}$, $t_{d,q}\circ\tau_{c,p} = t_{d,q}$ if $c \neq d$, and for the latter also $|H| \leq 1$. Conclusion: (7)). One step of the induction is BoundedInsertion (`Bounded.multi`).

05

Second-moment forms

The tanh form is bounded, but it does not capture the exponential average (the free energy) as it is. Another bounded form is $\sqrt{\rho}$.

Square-Root Insertion Identity (the Bhattacharyya form)

Under the finite configuration-space condition and the positive-weight condition, if τ is an involution, $H \circ \tau = -H$ and $\rho = w \circ \tau / w$, then $\mathbb{E}[H\sqrt{\rho}] = 0$.

Proved here Proof. $w\sqrt{\rho} = \sqrt{w \cdot w \circ \tau}$ is symmetric under $x \leftrightarrow \tau x$ and H is antisymmetric, so $\sum_x w(x)H(x)\sqrt{\rho(x)}$ changes sign when relabelled by τ, and is 0. ∎

Lean SecondMoment (`SecondMoment.sqrt_identity`) (hypotheses: X is finite, τ is a bijection with $\tau \circ \tau = \mathrm{id}$, $w > 0$, $H \circ \tau = -H$. Conclusion: $\sum wH\sqrt{w \circ \tau / w} = 0$).

Paley–Zygmund-Type Bias Estimate

Under the finite configuration-space condition and the positive-weight condition, take an involution τ_p for each p of a non-empty finite set P, and let H be odd under every τ_p with $|H| \le 1$. Setting $Y := \frac{1}{|P|}\sum_p \sqrt{\rho_p}$ (a weighted count of insertions that flip the sector),

$$\mathbb{E}[H]^2\,\mathbb{E}[Y^2] \;\le\; \mathbb{E}[Y^2] - \mathbb{E}[Y]^2, \qquad \text{that is} \quad \mathbb{E}[H]^2 \le 1 - \frac{\mathbb{E}[Y]^2}{\mathbb{E}[Y^2]}, \qquad \text{and} \;\; \mathbb{E}[Y^2] \le 1.$$

Proved here Proof. Averaging the Square-Root Insertion Identity gives $\mathbb{E}[HY] = 0$. Setting $C = \mathbb{E}[Y^2]$, $B = \mathbb{E}[Y]$ gives $\mathbb{E}[H(C - BY)] = C\,\mathbb{E}[H]$. From Cauchy–Schwarz and $H^2 \le 1$, $C^2\mathbb{E}[H]^2 \le \mathbb{E}[(C - BY)^2] = C^2 - 2CB^2 + B^2C = C(C - B^2)$. Dividing by $C > 0$ ($\rho_p > 0$) gives the first formula. The last inequality follows from $Y^2 \le \frac{1}{|P|}\sum_p \rho_p$ (Cauchy–Schwarz) and, for involutions, $\mathbb{E}[\rho_p] = \sum_x w(\tau_p x)/\sum w = 1$. ∎

Lean SecondMoment (`SecondMoment.pz_bound`) (hypotheses: X and P are finite, P is non-empty, every τ_p is an involution, $w > 0$, H is odd under every τ_p, $|H| \le 1$. Conclusion: $(\sum wH)^2(\sum wY^2) \le (\sum w)\big((\sum wY^2)(\sum w) - (\sum wY)^2\big)$, which normalised is the first formula of (8)). $\mathbb{E}[Y^2] \le 1$ has no Lean check.

(8) says that the more concentrated Y is in the sense of second moments (the closer $\mathbb{E}[Y^2]$ is to $\mathbb{E}[Y]^2$), the smaller the bias. The second moment is always at most 1, so there is no worry about heavy tails as in the variance form of ρ.

Many cells. We also place a form that handles products of insertion ratios over cells.

Many-Cell Second-Moment Estimate

Under the finite configuration-space condition and the positive-weight condition, with $|H| \le 1$, take a function $r_c : X \to \mathbb{R}$ (an averaged insertion ratio) for each c of

a finite set of cells C, and assume **oddness under insertion** — for every $S \subseteq C$, $\mathbb{E}[H \prod_{c \in S} r_c] = (-1)^{|S|}\mathbb{E}[H]$. Then

$$\mathbb{E}\Big[H \prod_{c \in C}(1 - r_c)\Big] = 2^{|C|}\,\mathbb{E}[H], \qquad 4^{|C|}\,\mathbb{E}[H]^2 \;\le\; \mathbb{E}\Big[\prod_{c \in C}(1 - r_c)^2\Big]. \tag{9}$$

Proved here Proof. Expand $\prod_c(1 - r_c) = \sum_{S \subseteq C}(-1)^{|S|}\prod_{c \in S} r_c$; using the assumption each term becomes $\mathbb{E}[H]$, and there are $2^{|C|}$ terms. Cauchy–Schwarz and $H^2 \le 1$ give the second formula. ∎

Lean MultiCell (`MultiCell.bound`) (hypotheses: X and C are finite, $w > 0$, $|H| \le 1$, the equalities of "oddness under insertion" above for every $S \subseteq C$. Conclusion: the second formula of (9)) and MultiCell (`MultiCell.expand_identity`) (the first formula). Within Lean, "oddness under insertion" is **an equality placed as a hypothesis**. For a single bijection it follows from the pushforward equality $\sum w\,(w \circ T/w)\,F = \sum w\,F \circ T^{-1}$ (MultiCell (`MultiCell.pushforward`), hypotheses: finite, $w > 0$), but that the equality holds when insertions in separate cells are composed depends on the commutativity of the maps and the invariance of the ratios, and is outside Lean.

06

Rederiving slab confinement

Take the thin insertion of 25-04. Let the cells be the plaquettes $p \in S(C)$ of the plane inside the loop, with one position ($|P| = 1$), and let τ_p be the flip of z on the vortex sheet S_p. τ_p is itself an involution, and since it does not change the links it preserves the Haar $\times$ counting measure. $H = W(C)$ is odd under each τ_p, and $t_p = (1 - r_p)/(1 + r_p)$ is determined only by the values on S_p, so it does not move under τ_q for $q \neq p$. From the Position-Averaged Insertion Estimate,

$$|\mathbb{E}[W(C)]| \;\le\; \mathbb{E}\Big[\prod_{p \in S(C)} |t_p|\Big] \;\le\; \tanh(\beta N^2)^A \tag{10}$$

($|t_p| \le \tanh(\beta N^2)$ is the one-sheet inequality of 25-04) Proved here . This is exactly (4) of move 4 of 25-04, and the projection to a fixed sector is the same as move 5 of 25-04. The Slab Confinement Theorem is the special case "thin insertion, one position" of the Position-Averaged Insertion Estimate. (10) on the continuous configuration space is the same argument with sums replaced by integrals, and is outside Lean.

07

What it means, and what is missing

The average over positions is entropy. The $\mathrm{Var}(\bar{\rho})$ of the Bias Estimate by Insertion-Ratio Fluctuation is expected to be of order $\approx VK/n$, where K is the number of

positions, among the n, within reach of each other's correlations and V is the variance of one insertion ratio Reading (physics). Increasing the number of positions n plays the role of entropy, and the decay of correlations between positions (the mass gap) plays the role of keeping K small. For insertions of the smooth fractional-instanton type, $V \sim e^{S_{\text{inst}}}$ is expected, the area of the region needed is proportional to V, and the string tension is of order $\sigma \sim e^{-S_{\text{inst}}}/L^2$, the same form as the formula for a dilute vortex gas Reading (physics, a semiclassical estimate; not a proof).

Table 1 Comparison of the three forms (factor per cell)

Form	Factor	Strengths	Weaknesses
Variance of the insertion ratio (Bias Estimate by Insertion-Ratio Fluctuation)	$1-\bar{\rho}$	Captures the free energy (the exponential average) as it is	Heavy tails. The second moment can be large
tanh (Position-Averaged Insertion Estimate)	$\bar{t}_c$	Bounded. Meaning as an acceptance rate (Insertion Fluctuation Relation Lemma)	Not an exponential average, so it captures the entropy of vortex shapes poorly
$\sqrt{\rho}$ (Paley–Zygmund-Type Bias Estimate)	Y	Second moment always at most 1, and it can capture the entropy of shapes too	Needs bounds on the overlaps between positions and shapes

Collapsing onto a chessboard. If there is reflection positivity in the directions of the plane, chessboard estimates collapse things into a single translation-invariant quantity, $\mathbb{E}[\prod_{c\in\text{inside}} |\bar{t}_c|] \le \Lambda^n$ with $\Lambda := (\mathbb{E}[\prod_{\text{all cells}} |\bar{t}_c|])^{1/\#\text{cells}}$, and if $\Lambda < 1$ an area law follows; this is a strand Assumption (where the evidence is: the treatment of reflection positivity is in 26-04 and 26-05. The same structure is in (13)(21) of Kovács–Tomboulis Cited).

What is missing. (i) The large-deviation stage: $\Lambda < 1$ needs the event that insertions are often refused in all cells at once to be exponentially rare in the number of cells. (ii) The ultraviolet stage: the lower bound on the acceptance rate must be uniform in the lattice spacing, and with thin flips (25-04) it gets worse with N. With smooth insertions, it is known that fixed maps pay an extra cost in the ultraviolet (25-07). (iii) An upper bound on second moments: an upper bound on the V of the Bias Estimate by Insertion-Ratio Fluctuation. This book shows none of the three.

A negative control. Four-dimensional $U(1)$ does not confine at weak coupling, so if the bounds of this chapter are applied there, they must stop working somewhere (for example, V becoming large). This check has not yet been done in this book.

> 08

What cannot be said

(a) Confinement. None of the identities and inequalities of this chapter implies confinement. (i)–(iii) of § 07 remain.

(b) The continuous configuration space. All the theorems are finite versions under the finite configuration-space condition, the positive-weight condition and the sector-flipping bijection condition; the version on the Haar measure of $SU(2)$ is the same argument with the measure preservation of the maps (or the Jacobian) added, but it is outside Lean.

(c) The hypothesis of the Many-Cell Second-Moment Estimate. The equalities of "oddness under insertion" are not shown in this chapter for maps composed of insertions in separate cells (in Lean too they are hypotheses).

(d) Novelty. All are elementary combinations of relabelling of variables and Cauchy–Schwarz, and comparison with earlier literature is not done. The summed ensemble and the container identity lie within the framework of Mack–Petkova, the form bounding Wilson loops by twisted partition functions within Tomboulis–Yaffe, and products on a chessboard within Kovács–Tomboulis. The combination of insertion averaged over positions with Cauchy–Schwarz is recorded as a standard technique in proofs of Mermin–Wagner type, and is said to appear in gauge theory in Chatterjee (arXiv:2602.00436) as well (not yet checked). No novelty is claimed for the results of this chapter.

(e) The estimates of § 07. $\mathrm{Var}(\bar{\rho}) \approx VK/n$, $V \sim e^{S_{\mathrm{inst}}}$ and $\sigma \sim e^{-S_{\mathrm{inst}}}/L^2$ are physical estimates, and none is a proof.

(f) The negative control. That the bounds stop working for four-dimensional $U(1)$ has not yet been checked.

09

The table of five grades and the dependency graph

Table 2 The rows of this chapter (conditions: the finite configuration-space condition, the positive-weight condition, the sector-flipping bijection condition)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	Mean Insertion-Ratio Identity: $\mathbb{E}[\rho] = 1$, $\mathbb{E}[\rho\sigma] = -\mathbb{E}[\sigma]$	Proved here	§ 03	The finite configuration-space, positive-weight and sector-flipping bijection conditions. Uses neither involution nor commutativity	InsertionIdentity (`Insertion.mean_one`, `Insertion.mean_rho_sigma`) (hypotheses: the finite configuration-space, positive-weight and sector-flipping bijection conditions, $\sigma = \pm 1$)
2	Bias Estimate by Insertion-Ratio Fluctuation: $4\mathbb{E}[\sigma]^2 \le \mathrm{Var}(\bar{\rho})$	Proved here	§ 03	The finite configuration-space and positive-weight conditions, each T_k satisfies the sector-flipping bijection condition, the family is finite and non-empty	InsertionIdentity (`Insertion.sector_bias_le`) (hypotheses: as left)

The bundles in the machine-checking column are those confirmed, by re-checking on this book's side, to contain no `sorry` and to use axioms forming a subset of the three standard ones. What is guaranteed is only the algebra of sums over finite sets (23-13). In every chapter Lean names are written in the form "file (namespace.theorem)". The theorems of the namespace Insertion are in the file InsertionIdentity, and those of Bounded in the file BoundedInsertion.

```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. The only assumption row is the chessboard row (collapse to Λ; area law if $\Lambda < 1$), and it enters as a premise of no row. The "oddness under insertion" of the many-cell estimate is a hypothesis within the statement of the theorem, and does not come from another row. This chapter has neither a node of confinement nor a node of the mass gap.

What this chapter can say

What is said	What is not said
Proved here Under the finite configuration-space, positive-weight and sector-flipping bijection conditions, $\mathbb{E}[\rho] = 1$, $\mathbb{E}[\rho\sigma] = -\mathbb{E}[\sigma]$, $4\mathbb{E}[\sigma]^2 \leq \mathrm{Var}(\bar{\rho})$	An upper bound on $\mathrm{Var}(\bar{\rho})$ (a bound on the second moment V)
Proved here For involutions and odd H: the tanh form, the fluctuation relation, the average over positions, the $\sqrt{\rho}$ form, the Paley–Zygmund form	The large-deviation stage (rarity of the event of simultaneous refusal in all cells). The ultraviolet stage (a lower bound on the acceptance rate uniform in the lattice spacing)
Proved here The slab-confinement theorem is a special case of thin insertion	Confinement when the T^2 is widened. The negative control of four-dimensional $U(1)$
Assumption The strand of collapsing onto a single quantity Λ by the chessboard	A proof of $\Lambda < 1$

Words used in this chapter — insertion map, the insertion ratio ρ, the involution oriented by the sector τ, the tanh factor t, acceptance rate, the average over positions, the $\sqrt{\rho}$ form, the Paley–Zygmund form, oddness under insertion. Their meanings are in A-02 Glossary (the words of Part 25 are to be added).

Next chapter to read: 25-06 Driven insertion and the flow lemma — if, instead of applying the map at once, the vortex is inserted slowly by heat-bath dynamics, the Bounded Insertion Identity takes the form of the work W.

Driven insertion and the flow lemma

This chapter is this book's own investigation. The established knowledge it builds on is in 25-03 and 2-08.

What this chapter shows — In 25-05 we obtained $\mathbb{E}[H] = \mathbb{E}[H \tanh(\Delta S/2)]$ from a map τ that inserts a vortex at once. For thin vortices the cost of insertion ΔS is large, proportional to the area, and the bound is almost useless. In this chapter, instead of inserting at once, we consider "driven insertion", which updates only the inside of the container by heat bath while flipping the couplings of the vortex sheet little by little, and show (1) that on the space of paths the combination of time reversal and sector flip is an involution, with weight ratio e^{-W} (W is the work along the path) (the Crooks relation); (2) that from this follow $\mathbb{E}[H] = \mathbb{E}[H \tanh(W/2)]$ (the driven identity) and the Jarzynski equality; (3) for the probability a that one step of a stationary kernel flips the sector, $\theta \le 1 - a$ (the flow lemma), and flip probability $\le 1 - \theta^2$; and (4) that moving containers simultaneously gives $\mathbb{E}\prod \theta \le \mathbb{P}(\text{none flips})$. Finally we record that for a one-step kernel this guarantee reaches only $\theta_0 \sim \frac{1}{2}$, and cannot be used to test the crossover band (26-01).

Prerequisite chapters — 25-03 (containers, frame, the bias of the sector θ, the Container Identity), 25-05 (the Bounded Insertion Identity, the Insertion Fluctuation Relation Lemma, the Position-Averaged Insertion Estimate), 26-01 (the correct form of the band $\ln(1/\theta(L,L)) \ge cL^2$). From Part 2, 2-08 (Gibbs measures, free energy), and from Part 5, 5-07 (heat bath, detailed balance).

Said first — All theorems are statements under "a finite configuration space, positive weights, and kernels that move only the inside of the container", and each row states those conditions. Passing to the continuous configuration space of $SU(2)$ is the same as in 25-05 § 02 (replace the sums by Haar integrals) and is outside Lean. The Crooks relation and the Jarzynski equality are known results of non-equilibrium statistical mechanics; here we write out their proofs in order to apply them to the sector-summed ensemble of the lattice. Confinement follows from none of the inequalities of this chapter.

1. Summary — inserting a vortex slowly
2. The setting — the driving procedure and the space of paths
3. The Crooks involution and the driven identity — the Jarzynski Equality, the acceptance rate, many cells
4. Two limits — inserting at once, inserting quasi-statically
5. The Cut-Measure Formula
6. The Flip-Probability Lemma and the Flow Lemma
7. The Simultaneous-Flip Estimate, and the limits of this guarantee (Table 1)
8. What cannot be said
9. The table of five grades and the dependency graph — Table 2

01

Summary — inserting a vortex slowly

1. The insertion of 25-05 was an operation that flips at once the signs of the couplings on a vortex sheet. Its cost ΔS is, for a thin vortex sheet, proportional to the number of plaquettes on the sheet (the area N_T^2 of the T^2), and the factor of the bound $\tanh(\Delta S/2)$ is almost 1.
2. So we split the coupling into m steps and flip it little by little, updating only the inside of the container by heat bath at each step. The surrounding fluctuations relax to fit the new coupling, so the work paid W goes down.
3. On the space of paths, the map "follow time backwards and flip the sector" is an involution, and the weight ratio is e^{-W} (the Crooks Relation) Cited . Applying the Bounded Insertion Identity of 25-05 to this involution gives $\mathbb{E}[H] = \mathbb{E}[H\,\tanh(W/2)]$ Proved here .
4. From the same relation, independently of the number of steps m of the procedure, $\mathbb{E}[e^{-W}\,|\,\text{frame}] = Z_-/Z_+$ (the Jarzynski equality) Cited . With 0 steps, $W = \Delta S$ and we are back to 25-05.
5. For any stationary kernel that flips the sector, the probability a that the sector flips in one step is at most $1-\theta$. In other words $\theta \le 1-a$ (the flow lemma) Proved here . There is also a weaker form, $a \le 1-\theta^2$ Proved here .
6. With the frame fixed the containers are independent, so running kernels in all containers simultaneously gives $\mathbb{E}\prod_t \theta_t \le \mathbb{P}(\text{no container flips})$ Proved here . The right-hand side is a quantity measurable by Monte Carlo, and it estimates an upper bound on the Wilson loop in the correct direction.

7. However, the form of the band needs $a \geq 1 - e^{-cL^{\not 2}}$, that is, a kernel that brings the overlap of the forward and reverse paths to 1 exponentially in the area; the a of the one-step kernels measured is about 0.6–0.73 (acceptance $\min(1, e^{-W})$), and what this guarantee can say goes only up to $\theta \leq \theta_0$ (a constant less than 1) Reading . It cannot be used to test the form of the band, $\theta \leq e^{-cL^2}$. Its proper use is a lower bound on the slab tension with the T^2 fixed.

02

The setting — the driving procedure and the space of paths

We use the sector-summed ensemble of 25-03 and 25-04. The weight on the $SU(2)$ link variables U and the ± 1 plaquette variables z (coclosed) is $w(U, z) = \exp\left(\frac{\beta}{2} \sum_p z_p \operatorname{tr} U_p\right)$. For a plaquette p of the $(3,4)$ plane of the slab $T^2_{N_T} \times (\mathbb{Z}/M)^2$, flipping all the z of the vortex sheet $S_p = \{p\} \times T^2$ flips the sign of the sector seen by a Wilson loop enclosing p (25-04). We take a container $D_p \times T^2$ around p (D_p is a disc in the $(3,4)$ plane), and call the variables outside the container the **frame** Φ.

Throughout this chapter we place the following three.

- **Finite configuration-space condition** X. The continuous case is as noted in 25-05 § 02.
- **Positive-weight condition** $w = e^{-S} > 0$.
- **Kernel moving only inside the container**: the kernels K below update only the variables inside the container and do not change the frame.

Interpolating the coupling. For $\lambda \in [0,1]$, let S_λ be the action in which only the couplings of the plaquettes on S_p are multiplied by $1 - 2\lambda$. $S_0 = S$, and $S_1(x) = S(Rx)$ (R is the flip of z on S_p). S_λ is gauge invariant.

Kernels. Let K_λ be a heat-bath transition kernel that moves only the links inside the container and is reversible (detailed balance) with respect to e^{-S_λ}:

$$e^{-S_\lambda(x)} K_\lambda(x, y) = e^{-S_\lambda(y)} K_\lambda(y, x). \quad (1)$$

The forward procedure. $\lambda_k = k/m$ ($k = 0, \dots, m$). Starting from a configuration x_0 in sector $+$, at each step $k = 1, \dots, m$: "change the coupling $\lambda_{k-1} \to \lambda_k$, add the resulting change of action to the work, then update $x_{k-1} \to x_k$ by K_{λ_k}". The work is

$$W = \sum_{k=1}^{m} \left[S_{\lambda_k}(x_{k-1}) - S_{\lambda_{k-1}}(x_{k-1}) \right]. \quad (2)$$

Rx_m, obtained by finally applying R, is a configuration in sector $-$. From configurations in sector $-$, the same is done by the reverse procedure mapped by R (λ going $1 \to 0$). If $m = 0$ there is no update, and $W = S_1(x_0) - S_0(x_0) = \Delta S$, the single insertion of 25-05.

The space of paths. Let $\Omega = \{(s, x_0, \dots, x_m)\}$ ($s = \pm$ is the sector of the starting point), and set the weight of a path starting in sector $+$ to be

$$\hat{W}(+, x_0, \dots, x_m) = e^{-S_0(x_0)} \prod_{k=1}^{m} K_{\lambda_k}(x_{k-1}, x_k), \tag{3}$$

The weight of a path starting in sector $-$ is defined by the product of the same form for the reverse procedure. The rows of the kernels sum to 1, so projecting the measure on Ω to the starting point gives back the original measure. Hence the expectation of a quantity determined by the starting point alone does not change when computed on Ω Proved here .

The involution. $\iota(+, x_0, \dots, x_m) = (-, Rx_m, \dots, Rx_0)$: follow the path backwards and flip the sector (and conversely for paths starting at $-$). $\iota \circ \iota = \mathrm{id}$. By (1), paths of positive weight are mapped to paths of positive weight.

03

The Crooks involution and the driven identity

Crooks Relation

Under the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container and (1), for every path ω of positive weight,

$$\frac{\hat{W}(\iota\omega)}{\hat{W}(\omega)} = e^{-W(\omega)}, \qquad W \circ \iota = -W. \tag{4}$$

Cited A relation of this form is due to Crooks (source table); here we write out the standard computation adapted to the lattice procedure. Proof. Let $\omega = (+, x_0, \dots, x_m)$. The weight of the reversed path, brought back to the coordinates of $+$ using that $S\lambda$ maps to $S_{1-\lambda}$ under R, is $e^{-S_1(x_m)} \prod_{k=1}^{m} K_{\lambda_k}(x_k, x_{k-1})$. Replacing each factor by $K_{\lambda_k}(x_{k-1}, x_k)\, e^{S_{\lambda_k}(x_k) - S_{\lambda_k}(x_{k-1})}$ using (1), the exponent of the ratio is

$$S_0(x_0) - S_1(x_m) + \sum_{k=1}^{m} \left[S_{\lambda_k}(x_k) - S_{\lambda_k}(x_{k-1}) \right] = \sum_{k=1}^{m} S_{\lambda_{k-1}}(x_{k-1}) - \sum_{k=1}^{m} S_{\lambda_k}(x_{k-1}) =$$

(shift the summation index by one, and let $S_0(x_0)$ cancel against the $k = 1$ term and $-S_1(x_m)$ against the $k = m$ term). Computing (2) along the reversed path, the same terms appear with opposite signs, so $W \circ \iota = -W$. ∎

The Crooks Relation says that "the involution with weight ratio $e^{-\Delta S}$" of (5) of 25-05 has been replaced, on the space of paths, by "an involution with weight ratio e^{-W}". So the Bounded Insertion Identity of 25-05 can be used as it is.

Driven Insertion Identity (the driven identity)

Under the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container and (1), if $H = h(\Phi)\,\sigma$ (h is a function of the frame alone, σ is the sign of the sector of the container), then

$$\mathbb{E}[H] = \mathbb{E}_\Omega\big[H \tanh(W/2)\big]. \quad (5)$$

Proved here Proof. Regard H as a function on Ω evaluated at the starting point. The kernels and R do not change the frame, so h is invariant under ι and σ flips, giving $H \circ \iota = -H$. For the weight $\hat{W}$ and the involution ι on Ω, the factor of (5) of 25-05 is $(\hat{W} - \hat{W} \circ \iota)/(\hat{W} + \hat{W} \circ \iota) = (1 - e^{-W})/(1 + e^{-W}) = \tanh(W/2)$ by (4). From the Bounded Insertion Identity of 25-05, $\mathbb{E}_\Omega[H] = \mathbb{E}_\Omega[H \tanh(W/2)]$. The left-hand side is determined by the starting point alone, so it equals $\mathbb{E}[H]$ (§ 02). ∎

Lean: the core is BoundedInsertion (`Bounded.single`) (hypotheses: a finite set, an involution, $w > 0$, H odd. Conclusion: $\sum wHt = \sum wH$) applied to the finite space of paths Ω (restricted to paths of positive weight). The construction of the space of paths and the Crooks Relation are outside Lean.

Jarzynski Equality

Under the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container and (1), independently of the number of steps m,

$$\mathbb{E}\big[e^{-W} \,\big|\, \Phi,\ \sigma = +\big] = \frac{Z_-(\Phi)}{Z_+(\Phi)}, \quad (6)$$

Here $Z_\pm(\Phi)$ is the partition function of sector $\pm$ with the frame Φ fixed.

Cited Due to Jarzynski (source table). Proof. From (4), $\sum_\omega \hat{W}(\omega) e^{-W(\omega)} = \sum_\omega \hat{W}(\iota\omega)$. The right-hand side is the total weight of the paths starting in sector $-$, which is $Z_-(\Phi)$ since the rows of the kernels sum to 1. Dividing the left-hand side by the total weight $Z_+(\Phi)$ of paths in sector $+$ gives (6). ∎

(6) is a quantity that does not depend on the speed of the procedure (the number of steps m), and can be used as a numerical check. On the other hand, the average of e^{-W} is dominated by rare small W, so with few samples the estimate fluctuates strongly (that is why some rows of the table in 25-08 have negative $-\ln\langle e^{-W}\rangle$).

Driven Insertion Acceptance-Rate Corollary (the acceptance rate)

In the setting of the Driven Insertion Identity, $1-\mathbb{E}_\Omega[\tanh(W/2)] = 2\,\mathbb{E}_\Omega\big[1/(1+e^{W})\big]$. The right-hand side is twice the mean acceptance rate of a move that accepts the endpoint of a driven path by the Barker-type rule.

Proved here One just takes the expectation of $1-\tanh(W/2) = 2/(1+e^{W})$. It is the Insertion Fluctuation Relation Lemma of 25-05 with ΔS replaced by W.

Many cells. For each of mutually separated cells c (containers $D_c \times T^2$), choose a position P_c uniformly and independently from a set of positions P (a non-empty finite set), and perform driven insertion at the chosen position. The path of each cell reads only its own container and its surroundings in the starting configuration.

Many-Cell Driven Estimate

Under the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container and (1), if the containers are separated from each other (no plaquette straddles the insides of two containers), $H = h(\Phi)\prod_c \sigma_c$ and $|H|\le 1$, then

$$|\mathbb{E}[H]| \;\le\; \mathbb{E}\Big[\prod_c \frac{1}{|P|}\sum_{p\in P}\mathbb{E}\big[\,|\tanh(W_{c,p}/2)|\;\big|\;x_0\big]\Big]. \tag{7}$$

Proved here Proof. Build the enlarged space consisting of the starting point x_0, the choice of positions (P_c) and the path of each cell. The involution ι_d of cell d follows the path of cell d backwards and replaces the inside of container d of the starting point by the flip of the endpoint of the path. Since the containers are separated, the weight with the frame fixed splits into a product over containers, and ι_d does not change the path weights or works of other cells. So the weight ratio of ι_d is e^{-W_d}, and the factors $\tanh(W_c/2)$ of the other cells ($c \neq d$) do not move under ι_d. The proof of the Position-Averaged Insertion Estimate of 25-05 (the induction adding cells one at a time) goes through as it is, giving $\mathbb{E}[H] = \mathbb{E}[H\prod_c \tanh(W_{c,P_c}/2)]$. Taking absolute values, and using that with the starting point fixed the paths of the cells and the choices of positions are independent, gives (7). ∎

Unlike the Position-Averaged Insertion Estimate of 25-05, (7) has the absolute value inside the average over positions. It is weaker by the amount that it does not use cancellation of signs between positions.

04

Two limits — inserting at once, inserting quasi-statically

Zero steps. At $m = 0$, $W = \Delta S$, and the Driven Insertion Identity is the Bounded Insertion Identity of 25-05 Proved here . For thin vortices ΔS is proportional to the area of the T^2, and $\tanh(W/2)$ is almost 1.

The quasi-static limit. As $m \to \infty$ (driving slowly), W is expected to approach the conditional free energy of the container with the frame fixed, $\Delta F_D(\Phi) = \ln\big(Z_+(\Phi)/Z_-(\Phi)\big)$ Reading (physics; the standard estimate of thermodynamic integration, which requires the kernel to mix well enough at each λ. Not proved in this book). The factor of the Driven Insertion Identity then becomes $\tanh(\Delta F_D/2) = \theta_D(\Phi)$, and we return to the Container Identity of 25-03 (the Mack–Petkova identity). The reading is that the length m of the procedure connects the crude bound of inserting at once with the exact conditional free energy.

The numerical picture. For $SU(2)$, $\beta = 2.3$, the slab $2 \times 2 \times 8 \times 8$, twist $n_{12} = 1$, disc radius 2, 6 configurations $\times$ 4 positions, the mean work at $m = 0, 4, 16$ steps was 10.7, 6.5, 2.9, and the mean of $\tanh(W/2)$ was 0.990, 0.968, 0.688 Reading . Increasing the number of steps lowers the work and moves the factor away from 1. The records for other β, N_T and container radii are collected in 25-08. If the container is smaller than the vortex, the work does not come down fully even as the number of steps increases (same table).

05

The formula of the cut measure

Inside the container $D \times T^2$, let μ_{cut} be the measure (with the frame Φ fixed) in which only the plaquette terms on the flip sheet $S = \{p_0\} \times T^2$ are removed from the action, and set $X := \sum_{p \in S} z_p \operatorname{tr} U_p$ (z is the representative of sector $+$). The weight on the sheet is $e^{(\beta/2) z_p \operatorname{tr} U_p}$, and in sector $-$ the z on S are flipped, so

Cut-Measure Formula

$$\frac{Z_{\pm}(\Phi)}{Z_{\mathrm{cut}}(\Phi)} = \mathbb{E}_{\mathrm{cut}}\left[e^{\pm\beta X/2}\right], \qquad \theta(\Phi) = \frac{\left|\mathbb{E}_{\mathrm{cut}}[\sinh(\beta X/2)]\right|}{\mathbb{E}_{\mathrm{cut}}[\cosh(\beta X/2)]}. \tag{8}$$

Proved here The first formula is from the definition; the second just puts the first into $\theta = |Z_+ - Z_-|/(Z_+ + Z_-)$ and uses $e^a \mp e^{-a} = 2\sinh a,\ 2\cosh a$.

Lean FlipLemma (`FlipLemma.cut_formula`) (hypotheses: real-valued weights v on a finite set (non-negativity not used either), real-valued X, a real b. Conclusion: $\sum v e^{bX/2} - \sum v e^{-bX/2} = 2\sum v \sinh(bX/2)$, and the equality in sum form for cosh). What is guaranteed is only the algebra of sums.

μ_{cut} has no sectors. $\theta(\Phi)$ can be read as "the strength with which the information of the frame reaches the sheet, crossing the cut measure over the size of the container". Driven insertion can also be set up in the symmetric form $+ \to \text{cut measure} \leftarrow -$ (compatible with the involution of the Crooks Relation).

06

The flip-probability lemma and the flow lemma

Let μ_Φ be the conditional measure with the frame Φ fixed, $\sigma \in \{\pm 1\}$ the sign of the sector of the container, $m_\Phi = \mathbb{E}[\sigma \mid \Phi]$, $\theta(\Phi) = |m_\Phi|$. Let K be a Markov kernel that moves only the inside of the container, and $(X, X') \sim \mu_\Phi \otimes K$ (X drawn from μ_Φ and advanced one step by K gives X').

Flip-Probability Lemma

If K is **stationary** with respect to μ_Φ ($\sum_x \mu_\Phi(x)K(x,y) = \mu_\Phi(y)$), then

$$\mathbb{P}\big(\sigma(X') \neq \sigma(X)\big) \ \le\ 1 - m_\Phi^2 = 1 - \theta(\Phi)^2. \tag{9}$$

Proved here Proof. Since $\sigma = \pm 1$, $\mathbb{P}(\sigma(X') \neq \sigma(X)) = \sum_{x,y} \mu_\Phi(x)K(x,y)(\sigma(x) - \sigma(y))^2/4$. Bound it above by $(a-b)^2 \le 2(a-m)^2 + 2(b-m)^2$, and use that the rows sum to 1 and stationarity to turn both sums into $\sum_x \mu_\Phi(x)(\sigma(x) - m)^2 = 1 - m^2$, giving $\frac{1}{2}(1-m^2) + \frac{1}{2}(1-m^2)$. ∎ Reversibility is not used.

Lean FlipLemma (`FlipLemma.flip_le`) (hypotheses: a finite set, $w \ge 0$, $\sum w = 1$, $K \ge 0$, rows sum to 1, stationarity $\sum_x w_x K_{xy} = w_y$, $\sigma^2 = 1$. Conclusion: $\sum_{x,y} w_x K_{xy}(\sigma_x - \sigma_y)^2/4 \le 1 - (\sum w\sigma)^2$).

Flip-Probability Corollary for Positive Kernels

If K is reversible with respect to μ_Φ and positive as an operator on $L^2(\mu_\Phi)$ ($\langle f, Kf\rangle \geq 0$), the right-hand side of (9) drops to $(1-\theta^2)/2$.

Proved here Proof. $\mathbb{P}(\text{flip}) = (1 - \langle\sigma, K\sigma\rangle)/2$ (inner product in μ_Φ). Setting $\tilde\sigma = \sigma - m$, since the rows of K sum to 1 and it is reversible, $\langle\sigma, K\sigma\rangle = \langle\tilde\sigma, K\tilde\sigma\rangle + m^2 \geq m^2$. ∎ This corollary has no Lean check.

The next form is sharper, and is the one mainly used in this chapter.

Flow Lemma

In the setting of the Flip-Probability Lemma (stationary K), letting $a(\Phi)$ be the probability that the sector flips in one step,

$$a(\Phi) \;\leq\; 1 - \theta(\Phi), \qquad \text{that is} \qquad \theta(\Phi) \;\leq\; 1 - a(\Phi). \tag{10}$$

Proved here Proof. Take the flow $A = \mathbb{P}(\sigma(X) = +, \sigma(X') = -)$ from $+ \to -$ and the flow B from $- \to +$. By stationarity the distribution of the sector of X' is the same as that of X, so $A = B$. Also $A \leq \mathbb{P}(\sigma(X) = +) = (1+m)/2$, $B \leq (1-m)/2$. Hence $a = A + B = 2A \leq 2\min\big((1+m)/2, (1-m)/2\big) = 1 - |m|$. ∎ Since $\theta \leq 1$, $1 - \theta \leq 1 - \theta^2$, and (10) is a sharper form than (9).

Lean FluxLemma (`FluxLemma.flip_le_one_sub_abs`) (hypotheses: a finite set, $w \geq 0$, $\sum w = 1$, $K \geq 0$, rows sum to 1, stationarity, the values of σ are 1 or -1. Conclusion: $\sum_{x,y} w_x K_{xy} (\sigma_x - \sigma_y)^2/4 \leq 1 - |\sum w\sigma|$).

How to use it. If one can build a stationary kernel that flips the sector with flip probability at least c, then $\theta \leq 1 - c$. A kernel that proposes a driven insertion and accepts the endpoint with probability $\min(1, e^{-W})$ is reversible (hence stationary) with respect to μ_Φ by the Crooks Relation, and its flip probability is the acceptance rate. The acceptance rate is at least $\mathbb{P}(W \leq w_0)\, e^{-w_0}$, so there is no need to control the average of e^{-W}; it is enough that "cheap work occurs with positive probability" Proved here .

07

Simultaneous flips, and the limits of this guarantee

Take a finite set S of mutually separated containers, and let $\theta_t(\Phi)$ be the bias of the sector of each container $t \in S$ (the frame Φ is the variables outside all containers).

Simultaneous-Flip Estimate

Under the finite configuration-space condition and the positive-weight condition, if the containers are separated from each other, and for each container t one takes a stationary kernel K_t that moves only the inside of that container and moves all containers one step simultaneously, then

$$\mathbb{E}\Big[\prod_{t\in S}\theta_t(\Phi)\Big] \;\le\; \mathbb{P}\big(S:\text{no container flips}\big). \tag{11}$$

Proved here Proof. With the frame fixed, the insides of the containers are conditionally independent (the conditional independence of 25-03), and the kernels also move independently per container, so $\mathbb{P}(\text{none flips}\,|\,\Phi)=\prod_t(1-a_t(\Phi))$. By the Flow Lemma each factor is at least $\theta_t(\Phi)$. Take expectations. ∎

The container identity of 25-03 had the form $|\langle W(C)\rangle|\le\mathbb{E}\prod_t\theta_t$ (for the containers inside C). Together with (11), an upper bound on the Wilson loop is bounded **in the correct direction** by a quantity measurable by Monte Carlo, $\mathbb{P}(\text{none flips})$ Proved here .

Limits (an important caution). What (10) gives is $\theta\le 1-a$. The flip probability a of a one-step kernel (a kernel that proposes one driven insertion and decides whether to accept it) is about 0.6–0.73 in the range measured with kernels of acceptance $\min(1,e^{-W})$ Computed (values recomputed from the raw W of Tables 1 and 2 of 25-08. The acceptance-rate columns of the tables are means of the Barker-type $1/(1+e^{W})$, and their ceiling $1/(1+e^{\Delta F})\le\frac12$ belongs to the acceptance rule, not to the kernel Paper Lean). So what can be said for containers of size L is $\theta\le\theta_0$ (with θ_0 a constant less than 1) at best. Even if this held uniformly in L, all that follows is

$$\sigma \;\ge\; \frac{\ln(1/\theta_0)}{L^2} \;\longrightarrow\; 0 \qquad (L\to\infty) \tag{12}$$

and this is exactly the "weak form" of 26-01 (a form that $U(1)$ also satisfies) Proved here . To show the correct form of the band $\theta(L,L)\le e^{-cL^2}$ by (10), one needs a kernel with $a\ge 1-e^{-cL^2}$, that is, a kernel that flips the sector almost surely Proved here (a rewriting of (10)). The acceptance rate is sandwiched by the overlap O of the measures of the forward and reverse paths ($e^{-\Delta F}O\le a_F\le\min(e^{-\Delta F},O)$, and for the mixed kernel $(1-\theta)O\le a\le 1-\theta$) Paper Lean (LatticeGaugeAcceptanceSandwich (overlap_sandwich, mixture_sandwich); the assumption is the Crooks-type relation $P_F e^{-W}=e^{-\Delta F}P_R$), and $a\ge 1-e^{-cL^2}$ demands $O\ge 1-e^{-cL^2}$, in terms of dissipation of the order $D\lesssim e^{-2cL^2}$ Reading (Pinsker's inequality read in reverse). There is no prospect of building that with a one-step kernel.

Therefore, **the guarantee from simultaneous flips cannot be used as a numerical test of the crossover band.** The record measured with this tool (25-08 § 06) cannot be read as a numerical picture of the band either. Its proper uses are a lower bound on the slab tension with the size L of the T^2 fixed, and an estimate from above of the chessboard density κ_{cb} (26-05).

Table 1 What the bounds of this chapter can and cannot say (conditions: the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container)

Bound	Form	What can be said	What cannot be said
Driven identity (the Driven Insertion Identity, the Many-Cell Driven Estimate)	$\mathbb{E}[H] = \mathbb{E}[H \tanh(W/2)]$	Increasing the number of steps can move the factor away from 1 (numerics)	That the upper bound on the factor is uniform in L
Jarzynski Equality	$\mathbb{E}[e^{-W}] = Z_-/Z_+$	A numerical check	Precision with few samples (dominated by rare events)
Flip probability (the Flip-Probability Lemma)	$a \le 1 - \theta^2$	$\theta \le \sqrt{1-a}$	— (weaker than the Flow Lemma)
Flow Lemma	$\theta \le 1 - a$	A lower bound on the slab tension with the T^2 fixed	For a one-step kernel only up to $\theta_0 \sim \frac{1}{2}$. The form of the band e^{-cL^2} does not follow
Simultaneous-Flip Estimate	$\mathbb{E}\prod\theta \le \mathbb{P}(\text{no flip})$	An estimator in the correct direction for an upper bound on the Wilson loop	A numerical test of the band

08

What cannot be said

(a) Confinement. None of the identities and inequalities of this chapter implies confinement. One would need the factors of the Driven Insertion Identity and the Many-Cell Driven Estimate to stay away from 1 uniformly in L and the lattice spacing, or a kernel with a close to 1, and this book shows neither.

(b) The quasi-static limit. That $W \to \Delta F_D$ as $m \to \infty$ is the estimate of § 04; this book has no proof of it, including bounds on how the kernels mix.

(c) The continuous configuration space. All theorems are finite versions under the finite configuration-space condition. The version on the Haar measure of $SU(2)$ needs the reversibility of the heat-bath kernels and the measure on the space of paths to be rewritten for the continuous case, and is outside Lean.

(d) The limit of one-step kernels. The a of the kernels measured (0.6–0.73 with acceptance $\min(1, e^{-W})$) is a reading of measurements, not a theorem. The conclusion that the form of the band is not reached rests not on this reading but on the rewriting

of (10) that $a \geq 1 - e^{-cL^{\angle}}$ is needed (the row "only the weak form follows" of Table 2). That the acceptance rates of the tables of 25-08 stay below $\frac{1}{2}$ is the ceiling of the Barker-type rule. Conversely, if there were a kernel with a close to 1, (10) could be used as it is, but no construction of one is known.

(e) Novelty. The Crooks Relation and the Jarzynski Equality are known, and the application to the sector-summed ensemble, the Flip-Probability Lemma, the Flow Lemma and the Simultaneous-Flip Estimate are elementary. Techniques that raise the acceptance rate with non-equilibrium proposals that flip a sector are known in the Monte Carlo literature as tempered transitions and non-equilibrium candidate methods (not yet checked). No novelty is claimed for the results of this chapter.

The table of five grades and the dependency graph

Table 2 The rows of this chapter (conditions: the finite configuration-space condition, the positive-weight condition, the kernel moving only inside the container)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	The marginal of the starting point on the space of paths is the original measure	Proved here	§ 02	The finite configuration-space and positive-weight conditions, the kernel moving only inside the container, rows of the kernels sum to 1	—
2	Crooks Relation: $\hat{W} \circ \iota / \hat{W} = e^{-W}$, $W \circ \iota = -W$	Cited	§ 03, Crooks	The finite configuration-space and positive-weight conditions, the kernel moving only inside the container, detailed balance (1)	—

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
3	Driven Insertion Identity: $\mathbb{E}[H] = \mathbb{E}_\Omega[H \tanh(W/2)]$	Proved here	§ 03	The finite configuration-space and positive-weight conditions, the kernel moving only inside the container, (1), $H = h(\Phi)\sigma$	BoundedInsertion (`Bounded.single`) applied to Ω (hypotheses: finite, involution, $w > 0$, H odd. The construction of Ω is outside Lean)
4	Jarzynski Equality (independent of the number of steps)	Cited	§ 03, Jarzynski	The finite configuration-space and positive-weight conditions, the kernel moving only inside the container, (1), frame fixed	—
5	Driven Insertion Acceptance-Rate Corollary: $1 - \mathbb{E}[\tanh(W/2)] = 2\times$ acceptance rate	Proved here	§ 03	The setting of row 3	—
6	Many-Cell Driven Estimate: (7)	Proved here	§ 03	Containers separated, $\lvert H\rvert \le 1$, positions chosen independently and uniformly	— (the type of induction is BoundedInsertion (`Bounded.averaged`) of 25-05)
7	$W \to \Delta F_D(\Phi)$ as $m \to \infty$	Reading (physics)	§ 04	The kernels mix well enough at each λ	—
8	The work goes down with the number of steps ($\beta = 2.3$, $2 \times 2 \times 8 \times 8$)	Reading	§ 04, 25-08	$SU(2)$, 6 configurations $\times$ 4 positions	—
9	Cut-Measure Formula (8)	Proved here	§ 05	Frame fixed, terms of the flip sheet removed	FlipLemma (`FlipLemma.cut_formula`) (hypotheses: a finite set, real-valued v, X, b)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
10	Flip-Probability Lemma: flip probability $\leq \frac{1-\theta}{2}$	Proved here	§ 06	Stationary kernels (reversibility not needed)	FlipLemma (`FlipLemma.flip_le`) (hypotheses: $w \geq 0$, $\sum w = 1$, $K \geq 0$, rows sum to 1, stationary, $\sigma^2 = 1$)
11	Flip-Probability Corollary for Positive Kernels: $(1 - \theta^2)/2$ for positive kernels	Proved here	§ 06	Reversible and a positive operator	—
12	Flow Lemma: $\theta \leq 1 - a$	Proved here	§ 06	Stationary kernels (reversibility not needed)	FluxLemma (`FluxLemma.flip_le_one_sub_abs`) (hypotheses: $w \geq 0$, $\sum w = 1$, $K \geq 0$, rows sum to 1, stationary, $\sigma = \pm 1$)
13	The kernel with acceptance $\min(1, e^{-W})$ is stationary, acceptance rate $\geq \mathbb{P}(W \leq w_0) e^{-w_0}$	Proved here	§ 06	The setting of row 2	—
14	Simultaneous-Flip Estimate: $\mathbb{E}\prod \theta_t \leq \mathbb{P}(\text{no flip})$	Proved here	§ 07	Containers separated, a stationary kernel per container	— (the core is row 12)
15	The a of a one-step kernel is 0.6–0.73 in the range measured (acceptance $\min(1, e^{-W})$; the Barker-type columns of the tables are below the ceiling $\frac{1}{2}$ of the rule)	Reading	§ 07, 25-08	The range of β, N_T and containers measured	—
16	What follows from (10) is $\sigma \geq \ln(1/\theta_0)/L^2$ (the weak form). The form of the band needs $a \geq 1 - e^{-cL^2}$	Proved here	§ 07	When only $\theta \leq 1 - a$ is used	—

The bundles in the machine-checking column are those confirmed, by re-checking on this book's side, to contain no `sorry` and to use axioms forming a subset of the three standard ones. What is guaranteed is only the algebra of sums over finite sets (23-13).

`flip_le` and `cut_formula` are in the file FlipLemma, and `flip_le_one_sub_abs` is in the file FluxLemma.

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  PRV  marginal of start on paths = original measure   rows sum to 1

16  PRV  only the weak form; band needs a ≥ 1 − e^(−cL²) ⟸ 12
```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. This chapter has no assumption (Assumption) rows. The reading of the acceptance of one-step kernels is not made a premise of the row "only the weak form follows" (that row is a rewriting that follows from $\theta \le 1 - a$ alone, and the reading of the acceptance is a judgement of how far it can be used). There is neither a node of confinement nor a node of the mass gap.

What this chapter can say

What is said	What is not said
Proved here Under the finite configuration-space condition, the positive-weight condition and the kernel moving only inside the container, the driven identity $\mathbb{E}[H] = \mathbb{E}[H \tanh(W/2)]$ and its form for many cells	An upper bound on the factor $\tanh(W/2)$ uniform in L and the lattice spacing
Cited The Crooks relation and the Jarzynski equality (written out for the lattice procedure)	A proof of the quasi-static limit $W \to \Delta F_D$
Proved here For stationary kernels, $a \le 1 - \theta^2$, $\theta \le 1 - a$, and simultaneous flips $\mathbb{E}\prod\theta \le \mathbb{P}(\text{no flip})$	A construction of a kernel with a close to 1. The form of the band $\theta \le e^{-cL^2}$

What is said	What is not said
Reading The one-step kernels measured are far from $a \geq 1 - e^{-cL^2}$ (cannot be used to test the band)	The same theorems on the continuous configuration space (outside Lean)

Words used in this chapter — driven insertion, the number of steps m, the work W, the space of paths Ω, the Crooks involution ι, quasi-static, the cut measure, the flip probability, the flow lemma, simultaneous flips. Their meanings are in A-02 Glossary (the words of Part 25 are to be added).

Next chapter to read: 25-07 Why fixed maps fail — why driven insertion is cheap and a fixed map applied at once is expensive, explained at the one-loop level as the difference of "whether the shape of the fluctuations is changed".

Why fixed maps fail

This chapter is this book's own investigation. The established knowledge it builds on is in 4-06 and 4-04.

What this chapter shows — As seen in 25-05 and 25-06, a fixed map that inserts a vortex at once is expensive, and driven insertion that inserts it slowly by heat bath is cheap. In this chapter we explain the difference in the form of a principle. (1) Bounds from below on the sector ratio Z_-/Z_+ (from above on the sector free energy ΔF) are obtained by the Gibbs variational principle with a map, and the gap is exactly a relative entropy (the principle of direction). (2) In a Gaussian model, the loss of a map that does not change the shape of the fluctuations (an isometric map) does not decrease as the number of degrees of freedom grows, while reshaping the fluctuations with a map of determinant 1 brings the loss down to $\Delta F^2/n$. (3) In the one-loop count $\frac{11}{3} = -\frac{1}{3} + 4$ for gluons in a background magnetic field, the $+4$ of antiscreening comes from a spin term that is traceless in the polarisations, so **at the one-loop level** a comparison by isometric maps can give only the direction opposite to asymptotic freedom, $\beta' \geq \beta + 0.023$, while a map that reshapes the fluctuations reproduces $\beta - \beta' = 0.258$. (4) We set side by side that fixed pointwise maps pay an extra cost in the ultraviolet (numerics in a two-dimensional model), and that if the residual relative entropy grows with the area, no area law follows.

Prerequisite chapters — 25-05 (insertion identities), 25-06 (driven insertion), 26-01 (the correct form of the band). From Part 4, 4-06 (asymptotic freedom, the one-loop coefficient) and 4-04 (renormalisation); from Part 2, 2-08 (free energy, relative entropy).

Said first — All claims of § 03– § 05 are statements **at the one-loop (Gaussian) level**. This chapter makes no non-perturbative claims. Bounding the error of maps that reshape fluctuations at intermediate coupling and large fields is an open problem, and that is where the core of the crossover band (Part 26) lies. The extra ultraviolet cost of § 06 is a numerical reading in a two-dimensional model.

The order of this chapter

1. Summary — whether the shape of the fluctuations is changed

2. The principle of direction — upper bounds come from variation (the Transport Identity)
3. The Gaussian model — the loss of isometric maps, and shaping the fluctuations (Table 1)
4. The one-loop table 11/3 = −1/3 + 4 — the spin term does not appear in first-order traces (Table 2)
5. Consequences for the renormalisation comparison — isometric versus shaping comparison (Table 3)
6. The extra ultraviolet cost of fixed maps — Table 4
7. Deterministic squeezing and the area law — the relative-entropy obstruction of the residual, and additivity
8. What cannot be said
9. The table of five grades and the dependency graph — Table 5

01

Summary — whether the shape of the fluctuations is changed

1. Confinement needs the sector with a vortex not to be too expensive compared with the sector without, that is, a bound **from above** on the sector free energy $\Delta F = \ln(Z_+/Z_-)$ (to make $\theta = \tanh(\Delta F/2)$ small).
2. What gives a bound in that direction is the Gibbs variational principle with a map T that carries the measure of sector $+$ to sector $-$: $\Delta F = \mathbb{E}_+[S \circ T - S - \ln J_T] - \mathrm{KL}$. Discarding the KL (relative entropy) gives an upper bound Proved here .
3. The discarded KL is the loss of the bound. Computing in a Gaussian model, the loss of maps that do not change the shape of the fluctuations (the identity map, group translations, gauge transformations, decimation) does not decrease as degrees of freedom are added. A map that stretches and shrinks the fluctuations while keeping volume brings the loss down to $\Delta F^2/n$ (n is the number of degrees of freedom) Proved here .
4. The coefficient of asymptotic freedom $\frac{11}{3}$ splits at the one-loop level into an orbital part $-\frac{1}{3}$ and a spin term $+4$. The spin term is traceless in the polarisations, so it does not appear in bounds from maps that do not change the shape of the fluctuations (first-order traces) Proved here (at the one-loop level).
5. As a result, at the one-loop level, a renormalisation comparison built with isometric maps can give only $\beta' \geq \beta + 0.023$ per doubling (the same direction as $U(1)$), while a

map that reshapes the fluctuations reproduces the $\beta - \beta' = 0.258$ of asymptotic freedom Proved here (at the one-loop level).

6. In a two-dimensional model, fixed pointwise maps paid an extra cost growing faster than linearly in the lattice size N_T in the twisted direction. In trials that redraw the fluctuations around the new background, this growth disappears Reading .
7. If the residual KL of a deterministic map grows with the area of the sheet, no area law follows from the variational bound Proved here (under that assumption). The role of the transport road lies in a qualitative target weaker than the form of the band itself.

02

The principle of direction — upper bounds come from variation

Let X_+, X_- be the sets of configurations of sectors $+$ and $-$, $\mu_\pm = e^{-S}/Z_\pm$ the Gibbs measures on each, and set the sector free energy to be $\Delta F = \ln(Z_+/Z_-)$ (the same orientation as ΔF_D of 25-06). The bias of the sector is $\theta = \tanh(|\Delta F|/2)$, so what is needed in the direction of confinement is an **upper bound** on ΔF, in other words a **lower bound** on Z_-/Z_+.

Transport Identity (the transport identity, the Gibbs variational principle)

If $T : X_+ \to X_-$ is a measurable bijection with Jacobian J_T relative to the reference measure (Haar $\times$ counting; Lebesgue in the Gaussian model), and $T_\# \mu_+$ is the pushforward of μ_+ by T, then

$$\Delta F = \mathbb{E}_+\left[S \circ T - S - \ln J_T\right] - \mathrm{KL}\left(T_\# \mu_+ \,\|\, \mu_-\right). \quad (1)$$

In particular $\Delta F \le \mathbb{E}_+[S \circ T - S - \ln J_T]$, with equality only when $T_\# \mu_+ = \mu_-$ (T carries μ_+ exactly to μ_-).

Proved here A standard computation. Proof. The density of $\nu = T_\# \mu_+$ is $\nu(y) = \mu_+(x)/J_T(x)$ at $y = Tx$. Hence

$$\mathrm{KL}(\nu \| \mu_-) = \mathbb{E}_+\left[\ln \mu_+(x) - \ln J_T(x) - \ln \mu_-(Tx)\right] = \mathbb{E}_+\left[S(Tx) - S(x) - \ln J_T(x)\right] - \ln Z$$

Rearranging gives (1). The inequality follows from $\mathrm{KL} \ge 0$. ∎ On a finite configuration space (the finite configuration-space condition of 25-05), if T is a bijection then $J_T = 1$, and the first term of the right-hand side of (1) is the $\mathbb{E}_+[\Delta S]$ of 25-05.

The other direction. The structural tools used in this book do not bound ΔF from above. Reflection positivity gives $Z_- \le Z_+$ ($\theta \ge 0$, $\Delta F \ge 0$), but that is a **lower bound** on ΔF, the direction opposite to confinement (26-04) Proved here . Chessboard estimates replace $\mathbb{E}\prod\theta$ by a single density κ_{cb}, but saying $\kappa_{cb} < 1$ still needs an upper bound on ΔF (26-05). The Tomboulis–Yaffe inequality carries a bound on θ to the Wilson loop, and does not bound θ itself (26-01). Within the range of this book's tools, upper bounds on ΔF have come only from variation of the type (1) (trial maps, trial measures) and from explicit constructions Reading (a judgement arranging the list of tools, not a theorem). We call this the **principle of direction**. A candidate tool for crossing the band must first of all give a bound in this direction.

03

The Gaussian model — isometric maps and reshaping maps

We look at how large the KL of (1) is in a Gaussian model where everything can be computed. Take two Gaussian measures on $\mathbb{R}^n$, $\mu_0 = N(0, \Delta_0^{-1})$ and $\mu_B = N(0, \Delta_B^{-1})$ (actions $S_0 = \frac{1}{2}x^{\mathsf{T}}\Delta_0 x$, $S_B = \frac{1}{2}x^{\mathsf{T}}\Delta_B x$; Δ_0, Δ_B positive definite). μ_0 plays the role of "the fluctuations of sector $+$ (no background)", and μ_B that of "the fluctuations of sector $-$ (around the vortex background B)". The exact value is

$$\Delta F = -\ln\frac{Z_B}{Z_0} = \tfrac{1}{2}\ln\det(\Delta_B\Delta_0^{-1}) = \tfrac{1}{2}\sum_k \ln\lambda_k, \quad (2)$$

λ_k are the eigenvalues of $\Delta_0^{-1/2}\Delta_B\Delta_0^{-1/2}$. Putting a linear map T into (1), the bound, using $M := \Delta_0^{-1/2}T^{\mathsf{T}}\Delta_B T\Delta_0^{-1/2}$, is

$$\mathbb{E}_0\big[S_B\circ T - S_0\big] - \ln|\det T| = \tfrac{1}{2}(\operatorname{tr} M - n) - \ln|\det T| \quad (3)$$

(from $\mathbb{E}_0[x^{\mathsf{T}}Ax] = \operatorname{tr}(A\Delta_0^{-1})$).

A **map isometric for the fluctuations** is a linear map with $T^{\mathsf{T}}\Delta_0 T = \Delta_0$ (it does not change the shape of the fluctuations of μ_0, i.e. it preserves μ_0). The identity map, linearisations of group translations and gauge transformations, and the linearisation of decimation (the operation of discarding some of the fine degrees of freedom and taking the rest as they are as degrees of freedom of the coarse lattice) belong to this class (for the treatment of decimation, see § 08 (b)).

Isometric-Map Loss Proposition (the loss of isometric maps is not diluted by degrees of freedom)

If T is isometric for the fluctuations, the bound (3) is $\frac{1}{2}\sum_k(\lambda_k - 1)$ independently of T, and its difference from the exact value (2) is

$$\tfrac{1}{2}\sum_k \big(\lambda_k - 1 - \ln\lambda_k\big) \;\geq\; 0. \tag{4}$$

Proved here Proof. $O := \Delta_0^{1/2} T \Delta_0^{-1/2}$ is an orthogonal matrix satisfying $O^{\mathsf{T}} O = 1$, and $M = O^{\mathsf{T}} (\Delta_0^{-1/2} \Delta_B \Delta_0^{-1/2}) O$. Hence $\operatorname{tr} M = \sum_k \lambda_k$ and $|\det T| = 1$. The difference is the sum of $t - 1 - \ln t \geq 0$. ∎ (4) is exactly the relative entropy $\mathbf{KL}(\mu_0 \| \mu_B)$ of the two Gaussian measures. If the background changes the fluctuations in only a few directions (finitely many λ_k different from 1), (4) does not decrease as n is made large.

Fluctuation-Shaping Proposition (shaping with a map of determinant 1 gives loss $\Delta F^2/n$)

Taking the infimum of the bound (3) over all linear maps with $\det T = 1$, with $r := \det(\Delta_B \Delta_0^{-1}) = e^{2\Delta F}$,

$$\inf_{\det T = 1} \Big(\tfrac{1}{2}(\operatorname{tr} M - n) \Big) = \tfrac{n}{2}\big(r^{1/n} - 1\big), \qquad 0 \;\leq\; \tfrac{n}{2}\big(e^{2\Delta F/n} - 1\big) - \Delta F \;\leq\; \frac{\Delta F^2}{n}\, e^{2|\Delta}$$

Proved here Proof. If $\det T = 1$ then $\det M = r$, and conversely any positive definite M with $\det M = r$ is realised by $T = \Delta_B^{-1/2} M^{1/2} \Delta_0^{1/2}$ (times an orthogonal matrix; $\det T = r^{-1/2} r^{1/2} = 1$). By the arithmetic–geometric mean inequality $\operatorname{tr} M \geq n (\det M)^{1/n} = n r^{1/n}$, with equality at $M = r^{1/n} \cdot 1$. The bound on the difference follows, with $u = 2\Delta F/n$, from $e^u - 1 - u \leq \frac{u^2}{2} e^{|u|}$. ∎

The map of the Fluctuation-Shaping Proposition preserves volume ($\ln J_T = 0$), stretches and shrinks the fluctuations in the few directions the background changes, and spreads that change of volume thinly over the many remaining directions, $\Delta F/n$ each. **What is needed is not having a Jacobian (entropy), but changing the shape of the fluctuations.**

Table 1 An example in the Gaussian model: eigenvalues 0.2, 0.3, 3, 4 (all the rest 1)

Bound	$n = 10$	$n = 100$	$n = 10^4$
Exact value (2)	-0.16425	-0.16425	-0.16425
Isometric map (Isometric-Map Loss Proposition)	$+1.75$	$+1.75$	$+1.75$
Optimal map of determinant 1 (Fluctuation-Shaping Proposition)	-0.1616	-0.1640	-0.16425

Proved here (values of the closed formulae (2), (4), (5)). When small and large eigenvalues are mixed, the first-order trace $\frac{1}{2}\sum(\lambda_k - 1)$ and $\frac{1}{2}\sum \ln \lambda_k$ can have opposite signs. In this example the change of sector is exactly **cheap** ($\Delta F < 0$), yet the bound of the isometric map says it is expensive ($+1.75$). The spin term of the next section has exactly this form.

04

The one-loop table 11/3 = −1/3 + 4

Place a constant abelian magnetic field B in the (1,2) plane as background, and consider the fluctuations of the $SU(2)$ gluons around it in Feynman gauge. The operator of the quadratic action of the fluctuations is

$$M_B = -D^2\,\delta_{\mu\nu} - 2iF_{\mu\nu} \quad (6)$$

where the first term is the orbital part (the square of the covariant derivative) and the second term is the spin term. The ghost operator is $-D^2$. The heat-kernel traces (per volume, omitting the common factor $1/(16\pi^2 s^2)$ and the group factor $C_A = 2$ = the number of charged components), as functions of the proper time s, are

$$\text{vector (4 polarisations)}: \ \frac{Bs}{\sinh Bs}\big(2 + 2\cosh 2Bs\big), \qquad \text{ghosts}: \ -2\,\frac{Bs}{\sinh Bs} \quad (7)$$

With $x = Bs$, using $x/\sinh x = 1 - x^2/6 + O(x^4)$ and $\cosh 2x = 1 + 2x^2 + O(x^4)$ and picking out the coefficient of x^2 gives the following table.

Table 2 Breakdown of the coefficient of $B^2 s^2$ (at the one-loop level)

Part	Form of the heat-kernel trace	Coefficient of $B^2 s^2$	Meaning
Orbital (4 orbital degrees of freedom of the vector − 2 of the ghosts)	$\frac{Bs}{\sinh Bs}\,(4-2)$	$-\frac{1}{3}$	Diamagnetic (screening). The same type as a charged particle of $U(1)$
Spin term	$\frac{Bs}{\sinh Bs}\,2(\cosh 2Bs - 1)$	$+4$	Paramagnetic (antiscreening). Peculiar to the non-abelian case
Total	Sum of (7)	$+\frac{11}{3}$	The one-loop coefficient of asymptotic freedom (the $\frac{11}{3}$ of 4-06)

Proved here (at the one-loop level. The expansion is a two-line computation: orbital $2(1 - x^2/6) = 2 - x^2/3$, spin $(1 - x^2/6)\cdot 4x^2 = 4x^2 + O(x^4)$.) In the conventions of this count, the coefficient $+\frac{11}{3}$ is the direction of asymptotic freedom and $-\frac{1}{3}$ the opposite direction.

First-Order Vanishing of the Spin Term (the spin term does not appear in first-order traces — at the one-loop level)

At the Gaussian level, when comparing the operator without background $M_0 = -\partial^2\delta_{\mu\nu}$ with the M_B of (6), the bound (1) from a map isometric for the fluctuations is the first-order trace $\frac{1}{2}\mathrm{tr}\big((M_B - M_0)M_0^{-1}\big)$, and the contribution of the spin term is

exactly 0. This bound is at least the exact value for the orbital part alone, $\frac{1}{2}\ln \det(M_{\mathrm{orb}} M_0^{-1})$.

Proved here (at the one-loop level) Proof. M_0^{-1} is proportional to $\delta_{\mu\nu}$ in the polarisation indices, and $F_{\mu\nu}$ is antisymmetric, so $\mathrm{tr}_{\mu\nu}(F_{\mu\nu}) = 0$. Hence the first-order trace of the spin term is 0, the bound equals $\frac{1}{2}\mathrm{tr}((M_{\mathrm{orb}} - M_0)M_0^{-1})$, and by the inequality $t - 1 \geq \ln t$ of the Isometric-Map Loss Proposition it is at least $\frac{1}{2}\ln\det(M_{\mathrm{orb}} M_0^{-1})$. ∎ The spin term takes effect at second order ($\cosh 2Bs - 1 = O(B^2)$ in Table 2) and gives the $+4$ of antiscreening. A bound that looks only at first-order traces loses it completely. (Traces and determinants of infinite-dimensional operators are statements under the regularisation usually done in one-loop computations.)

05

Consequences for the renormalisation comparison

The renormalisation comparison of Part 26 (26-06) aims to bound from above the vortex free energy of $(2N, \beta)$, with the whole lattice doubled, by that of the original size (N, β'), and to say $\beta' < \beta$ (the direction in which the coupling becomes stronger, asymptotic freedom). At the one-loop level, the coefficient c around the vortex background fixes the shift of the coupling per doubling, and with $\beta = 4/g^2$ and $b_0 = c\,C_A/(16\pi^2)$, $\beta - \beta' = 8b_0 \ln 2$.

Isometric versus Shaping Comparison Proposition (comparison of the two maps — at the one-loop level)

(a) If the bound (1) is built with maps isometric for the fluctuations, the coefficient that can be captured at the one-loop level is at most $c = -\frac{1}{3}$, and only $\beta' \geq \beta + 0.023$ per doubling can be given (the same as $U(1)$, the direction opposite to asymptotic freedom).
(b) A map that shapes the fluctuations while preserving volume (the Fluctuation-Shaping Proposition) reproduces the exact $\frac{1}{2}\ln\det$ with error $O(\Delta F^2/n)$, and gives $c = \frac{11}{3}$, $b_0 = 22/(48\pi^2)$, and $\beta - \beta' = 0.258$ per doubling.

Proved here (at the one-loop level) Proof. (a) follows from the First-Order Vanishing of the Spin Term and the fact that the bound is an upper bound (the Transport Identity). The number is $8 \cdot \frac{-1/3 \cdot 2}{16\pi^2}\ln 2 = -\frac{0.2575}{11} \approx -0.0234$. (b) applies the Fluctuation-Shaping Proposition to the fluctuations shell by shell, and the number is $8 \cdot \frac{22}{48\pi^2}\ln 2 \approx 0.2575$.

∎

Table 3 Shift of the coupling per doubling $\beta - \beta'$ ($SU(2)$, $\beta = 4/g^2$)

From what	$\beta - \beta'$	Grade	Conditions written in the same row
The exact one-loop coefficient $\frac{11}{3}$	0.258	Proved here	One-loop level
Bound from a map shaping the fluctuations (Isometric versus Shaping Comparison Proposition (b))	0.258 (error $O(\Delta F^2/n)$)	Proved here	One-loop level, Gaussian bound
Bound from an isometric map (Isometric versus Shaping Comparison Proposition (a))	≤ -0.023	Proved here	One-loop level. The same direction as $U(1)$
Test doubling the whole lattice ($4^4 \to 8^4$, 1–3 seeds per β)	$+0.16$ to $+0.25$	Reading	$\beta = 2.5$ to 3.0. The range at each β is as in 26-06 Table 4 (for example $+0.13$ to $+0.19$ at $\beta = 2.7$, $+0.19$ to $+0.5$ at $\beta = 2.5$). At $\beta = 2.3$, $\gtrsim 0.1$. Small lattices
The same test for $U(1)$ ($(N, M) = (4, 8) \to (8, 16)$, $\beta = 1.5$)	< -0.2	Reading	Opposite direction ($\beta' > 1.7$, off the curve). 48 replicas, minimum exchange acceptance 0.37. One seed (26-06 Table 2)

The attempt to build a renormalisation comparison with Migdal–Kadanoff-type decimation (Tomboulis 2007) was criticised on the point that the same argument also flows to strong coupling for $U(1)$ Cited (Ito–Seiler, Kanazawa; source table).

Decimation belongs on the side that does not change the shape of the fluctuations, so the Isometric versus Shaping Comparison Proposition (a) can be read as giving a one-loop-level explanation of this criticism Reading (physics; an interpretation in which a one-loop computation pins down the gap in a non-perturbative argument, not a proof of the criticism itself).

A screening criterion. A candidate method for crossing the band must have **a linearisation of the trial map that is non-isometric for the fluctuations** — this is a necessary condition at the one-loop level Proved here (a restatement of the Isometric versus Shaping Comparison Proposition (a); at the one-loop level). The view that the same condition is needed at the non-perturbative level is Reading (physics). The driven insertion of 25-06 is cheap because the heat bath relaxes the shape of the fluctuations to fit the new coupling, which is consistent with this criterion Reading (physics).

> 06

The extra ultraviolet cost of fixed maps

The Isometric-Map Loss Proposition said that "the loss of isometric maps is not diluted by degrees of freedom". Numerics show that with fixed pointwise maps on the lattice, the loss moreover **grows** as the lattice spacing is made finer.

A two-dimensional model. Place the two-dimensional $O(3)$ model (spins $s_x \in S^2$, action $-\beta \sum s_x \cdot s_y$) on the strip $\mathbb{Z} \times (\mathbb{Z}/N_T)$, with a twist of a π rotation about the z axis in the periodic direction. The classical vacua are the north and south poles, and the action of the kink joining them (the two-dimensional version of the fractional instanton) approaches $2\pi\beta$ from below. It is a light test bed for the small twisted T^2 in four dimensions.

Table 4 The cost of kink insertion on the twisted two-dimensional strip (action in units with β removed; the extra cost is $\beta \times (\mathbb{E}[\Delta S] - \text{classical value})$)

Trial	β	$N_T = 2$	$N_T = 4$	$N_T = 8$	Conditions
Extra cost of the fixed pointwise rotation (the minimal rotation from vacuum to kink at each point)	2	-2.1	$+4.1$	$+14.7$	Standard deviations at $N_T = 8$ are 4.6 ($\beta = 2$) and 2.6 ($\beta = 4$). The number of configurations is not in the record
Same as above	4	-2.0	$+4.6$	$+16.2$	

Reading The extra cost hardly depends on β and grows faster than linearly in N_T. This is the opposite of the expected "decrease by $\ln N_T$ due to the running coupling".

On the other hand, in trials that do not carry the fluctuations over on the old background but **redraw them from the Gaussian measure around the new background (the kink)**, the difference of the bound becomes the ratio of one-loop determinants $\frac{1}{2} \ln[\det' H_{\text{kink}} / \det H_{\text{vac}}]$. Its value (with the two collective coordinates removed) changes only logarithmically, $-3.68, -2.94, -2.43, -2.11, -1.88$ at $N_T = 3, 4, 6, 8, 10$, and the quantity including the measure of the rotational and translational collective coordinates was almost constant, -4.91 to -4.85 for $N_T = 4$ to 12 Reading (numerical computation of eigenvalues; no error estimate). The faster-than-linear growth has disappeared.

A four-dimensional slab. For $SU(2)$, $\beta = 2.3$, the slab $2 \times 2 \times 8 \times 8$, an insertion that spreads the flux smoothly in a fixed colour direction (σ_3) raised the cost instead of lowering it: the mean of ΔS was 21.9 at spreading radius 1 and 36.0 at radius 2 Reading . This can be read as being because, in configurations without gauge fixing, the field in a fixed direction does not line up with the colour direction at each point Reading (physics). On the same slab, driven insertion (25-06) brought the mean work down to 2.9 with 16 steps.

How to read it. Fixed pointwise maps move the fluctuations "on a fixed background", so they fail to capture the difference of entropy of the fluctuations on the new background. The picture is that the loss of the Isometric-Map Loss Proposition piles up for each fine degree of freedom of the lattice Reading (physics; whether it is proportional to N_T is a reading from three numerical points, and there is no general bound). The average of insertions (25-05), driven insertion (25-06) and redrawing the fluctuations are all tools for avoiding this cost.

07

Deterministic squeezing and the area law

The correct form of the band was $\theta(L,L) \le e^{-cL^2}$ (26-01). Since $\theta = \tanh(\Delta F/2) \le \Delta F/2$, showing this variationally requires the upper bound on $\Delta F(L,L)$ to be as small as order $2e^{-cL^2}$.

Relative-Entropy Obstruction to the Area Law (if the residual KL grows with the area, no area law follows)

If, for a map T, the residual $\mathrm{KL}(T_{\#}\mu_+ \| \mu_-)$ of (1) is $\ge c'A$ ($c' > 0$) in the area A of the vortex sheet, then the bound $\mathbb{E}_+[S \circ T - S - \ln J_T]$ from (1) is at least $c'A$, and the upper bound on θ derived from it is at least $\tanh(c'A/2)$, approaching 1 as $A \to \infty$. In particular no bound of the form $\theta \le e^{-\sigma A}$ follows.

Proved here Proof. From (1), $\mathbb{E}_+[\cdots] = \Delta F + \mathrm{KL} \ge \mathrm{KL} \ge c'A$ (taking the orientation of the sectors so that $\Delta F \ge 0$). $\tanh$ is monotone. ∎ This is a statement under an assumption, and whether the assumption holds must be checked map by map.

Additivity of Relative Entropy over Containers (for independent containers the residual KL adds up)

If, with the frame fixed, the insides of containers $D_1, \dots, D_k$ are conditionally independent (25-03) and the map is a product over containers $T = T_1 \times \cdots \times T_k$, then $\mathrm{KL}(T_{\#}\mu_+ \| \mu_- \mid \Phi) = \sum_j \mathrm{KL}(T_{j\#}\mu_{+,j} \| \mu_{-,j} \mid \Phi)$. If each term is at least $c_0 > 0$, the residual is proportional to the number of containers, that is, to the area.

Proved here The standard fact that the relative entropy of a product measure is the sum of the relative entropies of the factors. ∎

That for fixed maps (not adapted to the fluctuations) the residual of each container is bounded below by $c_0 > 0$, so that the assumption of the Relative-Entropy Obstruction to the Area Law holds, is the shared judgement of the study from two viewpoints,

constructive field theory and probability Reading (physics, an estimate; the same goes for the judgement that the ceiling of triangular maps is of perimeter type). Under this judgement the transport road is not a tool for showing the form of the band itself, but a tool for a weaker qualitative target — $\Delta F(L, L) \to 0$ (at any speed). $\Delta F(L, L) \to 0$ is enough to rule out the Coulomb phase of $U(1)$ (where $\Delta F(L, L)$ approaches a positive constant) and the deconfined phase of $\mathbb{Z}_2$, but it yields neither confinement nor a mass gap Reading (physics; numerics in 26-06).

08

What cannot be said

(a) The non-perturbative level. The First-Order Vanishing of the Spin Term, the Isometric versus Shaping Comparison Proposition and the top three rows of Table 3 are all statements at the one-loop (Gaussian) level. Bounding the error of maps that shape the fluctuations at intermediate coupling and large fields (local relative entropy near the vortex sheet, and higher loops) is an open problem, and this book does not show it.

(b) The classification of isometric maps. The identity map and the linearisations of group translations and gauge transformations are isometric by definition. Putting decimation on the isometric side is a classification in the sense that it carries the fluctuations of the kept degrees of freedom over as they are; decimation is not a bijection, so this is not a literal application of the Isometric-Map Loss Proposition.

(c) The principle of direction. "Upper bounds on ΔF come only from variation and explicit constructions" is a judgement about the list of this book's tools, not a theorem.

(d) The extra ultraviolet cost. Table 4 is three numerical points in a two-dimensional model, and does not show that four-dimensional gauge theory grows in the same way. In four dimensions cancellations through Ward identities are said to be possible, and whether they occur depends on gauge fixing and the covariance of the map.

(e) The assumption of the Relative-Entropy Obstruction to the Area Law. That the residual KL of fixed maps is proportional to the area can be said only in the product case of the Additivity of Relative Entropy over Containers, assuming that the residual of each container is bounded below; for general maps it is an estimate.

(f) Novelty. The Gibbs variational principle, the relative entropy of Gaussian measures and the one-loop computation of the background field are all standard. No novelty is claimed for the view that lines them up as a screening criterion of "whether the shape of the fluctuations is changed". For scalar fields, Polchinski-type transport maps are known (Bauerschmidt–Bodineau–Dagallier); no example for gauge fields was found in the range searched (not yet checked).

09

The table of five grades and the dependency graph

Table 5 The rows of this chapter (§ 03– § 05 are all at the one-loop (Gaussian) level)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	Transport Identity: $\Delta F = \mathbb{E}_+[S \circ T - S - \ln J_T] - \mathrm{KL}$	Proved here	§ 02 (standard)	Measurable bijection, Jacobian defined	—
2	Reflection positivity gives only $\Delta F \geq 0$ (the direction opposite to confinement)	Proved here	§ 02, 26-04	Reflection directions with the twist fixed	—
3	The principle of direction: upper bounds on ΔF only from variation and explicit constructions	Reading	§ 02	A judgement about the list of this book's tools	—
4	Isometric-Map Loss Proposition: $\frac{1}{2}\sum(\lambda_k - 1 - \ln \lambda_k)$ (not diluted in n)	Proved here	§ 03	Gaussian model, $T^{\mathsf{T}}\Delta_0 T = \Delta_0$	—
5	Fluctuation-Shaping Proposition: the optimum over maps of determinant 1, and loss $\leq (\Delta F^2/n)e^{2\lvert\Delta F\rvert/n}$	Proved here	§ 03	Gaussian model, linear maps	—
6	Values of the example of Table 1	Proved here	§ 03	Eigenvalues 0.2, 0.3, 3, 4	—
7	Table 2: $\frac{11}{3} = -\frac{1}{3} + 4$ ($+4$ is the spin term)	Proved here	§ 04	One-loop level, constant abelian background, Feynman gauge	—
8	First-Order Vanishing of the Spin Term: the spin term does not appear in first-order traces	Proved here	§ 04	One-loop level	—
9	Isometric versus Shaping Comparison Proposition (a): isometric comparison gives $\beta' \geq \beta + 0.023$	Proved here	§ 05	One-loop level, per doubling	—
10	Isometric versus Shaping Comparison Proposition (b): shaping comparison gives $\beta - \beta' = 0.258$	Proved here	§ 05	One-loop level, per doubling	—

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
11	$\beta - \beta'$ of the doubling test (positive for $SU(2)$, negative for $U(1)$)	Reading	§ 05, 26-06	Small lattices, a few values of β, 1–3 seeds	—
12	Migdal–Kadanoff interpolation does not distinguish $U(1)$ (criticism)	Cited	Ito–Seiler, Kanazawa	On the argument of Tomboulis 2007	—
13	A one-loop-level explanation of row 12	Reading (physics)	§ 05	One-loop level	—
14	Screening criterion: the linearisation must be non-isometric for the fluctuations	Proved here	§ 05	A necessary condition at the one-loop level (Reading non-perturbatively)	—
15	The extra cost of fixed pointwise maps is at least linear in N_T	Reading	§ 06	Two-dimensional $O(3)$, twisted strip, $N_T = 2, 4, 8$	—
16	Redrawing the fluctuations makes the growth disappear	Reading	§ 06	Same, $N_T = 3$ to 12, no error estimate	—
17	In four dimensions, insertion spread in a fixed direction raises the cost	Reading	§ 06	$SU(2)$, $\beta = 2.3$, $2 \times 2 \times 8 \times 8$	—
18	Relative-Entropy Obstruction to the Area Law: if the residual KL is $\geq c' A$, no area law follows	Proved here	§ 07	Assuming a lower bound on the residual KL	—
19	Additivity of Relative Entropy over Containers: for independent containers the KL adds up	Proved here	§ 07	With the frame fixed the containers are independent, and the map is a product	—
20	For fixed maps the residual of each container is bounded below	Reading (physics)	§ 07	Estimate	—
21	$\Delta F(L, L) \to 0$ rules out the Coulomb phase and the deconfined $\mathbb{Z}_2$ phase	Reading (physics)	§ 07, 26-06	Yields neither confinement nor a gap	—

This chapter has no machine-checked bundles.

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

```

The way to check is to see by eye that every number to the right of "⟸" is smaller than the number on the left. There are no circles. There are no assumption (Assumption) rows. The conclusion of the Relative-Entropy Obstruction to the Area Law applies to fixed maps only when the estimate "for fixed maps the residual of each container is bounded below" is correct, and that distinction is expressed by the grade (Reading) of the last row (the role of $\Delta F(L,L) \to 0$). This chapter has no node of confinement, no node of the mass gap, and no non-perturbative node.

What this chapter can say

What is said	What is not said
Proved here The transport identity (the Gibbs variational principle), and that the loss of its bound is a relative entropy	Bounds on the error of maps reshaping the fluctuations at the non-perturbative level
Proved here In the Gaussian model, the loss of isometric maps is not diluted, and the loss of reshaping maps is $\Delta F^2/n$	Literal extension to operations that are not bijections, such as decimation

What is said	What is not said
Proved here At the one-loop level $\frac{11}{3} = -\frac{1}{3} + 4$, the isometric comparison gives $\beta' \geq \beta + 0.023$, the reshaping comparison $\beta - \beta' = 0.258$	The renormalisation comparison at intermediate coupling (the core of the band in Part 26)
Reading Fixed pointwise maps pay an extra cost in the ultraviolet (three points in a two-dimensional model)	The same growth in four-dimensional gauge theory
Proved here If the residual KL is proportional to the area, no area law follows (with an assumption)	That the assumption holds for fixed maps in general

The four-dimensional slab numerics of § 06	Reading	The same measurement as the numerical section of the paper on vortex-insertion identities in A-07

Words used in this chapter — the transport identity, the Gibbs variational principle, the principle of direction, maps isometric for the fluctuations, reshaping the fluctuations, the spin term, antiscreening, the residual relative entropy, the screening criterion. Their meanings are in A-02 Glossary (the words of Part 25 are to be added).

Next chapter to read: 25-08 The measured record — the numerics of Part 25 (the work of driven insertion, the vortex free energy when the T^2 is widened, the string tension of slabs) gathered in one place, with conditions.

The measured record

> This chapter is this book's own investigation. The established knowledge it builds on is in 25-03 and 5-07.

What this chapter shows — We collect the numerical record of Part 25 in one place. There are three series: (1) the work and acceptance rate of driven insertion (25-06), (2) the vortex free energy of the global flux when the twisted T^2 is widened (with a $U(1)$ control), and (3) the string tension of slabs (Creutz ratios). Finally we annotate the measurement of simultaneous flips, and why it cannot be used as a test of the band.

Prerequisite chapters — 25-06 (driven insertion, the flow lemma), 25-03 (containers, the bias of the sector θ), 26-02 (the lateral-widening inequality, monotonicity of the string tension). From Part 5, 5-07 (Monte Carlo) and 5-08 (string tension, Creutz ratios).

Said first — The numbers of this chapter are **all numerical readings** (label "Reading"), and none is a proof. Each row states the group, β, the size of the T^2 N_T, the size of the plane M, the number of measurements and the error. Where the error is not in the record, we write "not in the record". The lattices are small, and β takes a few values. The rows with $N_T = 2$ are a region where the T^2 is only 2 in lattice units and lattice artefacts are large.

The order of this chapter

1. Summary — three series
2. Common setting and how to read it
3. The work of driven insertion — Tables 1 and 2
4. The vortex free energy when the T^2 is widened — Tables 3, 4 and 5
5. The string tension of slabs — Tables 6 and 7
6. The measurement of simultaneous flips, and why it cannot be used as a test of the band — Tables 8 and 9
7. What cannot be said
8. The table of five grades and the dependency graph — Table 10

01

Summary — three series

1. **Driven insertion.** On $SU(2)$ slabs, the cost of inserting a vortex in one go (0 steps) is large and proportional to the area of T^2, at 11.8, 24.2 and 44.9 ($N_T = 2, 3, 4$, $\beta = 2.3$), but driving it over 256 steps brought it down to 0.50–0.63 Reading (rows A, B and C of Table 1. In rows G and H, under different conditions, the work over 256 steps stays high, at 3.64 and 6.67). When the container (a disc) is smaller than the size of the vortex, increasing the number of steps does not bring it all the way down.
2. Fixing the container radius at 4 and widening to $N_T = 4, 6, 8$ ($\beta = 2.5$, 1024 steps), the work was 1.1–1.6, with no clear increase in N_T Reading (10 configurations $\times$ 3 positions).
3. **The vortex free energy.** The free energy ΔF of the global flux sector increased as T^2 was widened for $U(1)$ ($\beta = 1.5$), and did not increase, or decreased, for $SU(2)$ ($\beta = 2.4, 2.5$) Reading ($M = 8$ and 12; the errors are 0.04–0.78 for $U(1)$ and 0.1–0.36 for $SU(2)$).
4. **String tension of slabs.** For $SU(2)$, $\beta = 2.5$, $M = 16$, the Creutz ratio $\chi(4)$ increased for $N_T = 4 \to 8$ and was nearly saturated at $N_T = 10$. No significant overshoot is seen Reading (2000 measurements).
5. **Simultaneous flips.** The measurement driving containers simultaneously cannot be used as a numerical picture of the crossover band (25-06 § 07). It remains only as a tool for lower bounds on the slab tension with the T^2 fixed.

02

Common setting and how to read it

- **Lattice.** The slab $(\mathbb{Z}/N_T)^2 \times (\mathbb{Z}/M)^2$. Directions 1 and 2 form the twisted T^2 (twist $n_{12} = 1$), and directions 3 and 4 the plane. $SU(2)$ uses the Wilson action, and $U(1)$, as a control, an action of the same form.
- **Driven insertion.** The work W (equation (2) of 25-06) when only the inside of a container, a disc of the plane (radius r) $\times$ T^2, is updated by heat bath and the couplings of the vortex sheet are changed $1 \to -1$ in m steps. The acceptance rate is the mean of $1/(1 + e^W)$ (Barker-type; the acceptance rate of the Driven Insertion Acceptance-Rate Corollary of 25-06, equal to $\frac{1}{2}(1 - \mathbb{E}\tanh(W/2))$). Only the simultaneous flips of Tables 8 and 9 use the mean of $\min(1, e^{-W})$ (Metropolis-type).
- **Vortex free energy.** The $\Delta F = \ln(Z(1,0)/Z(1,1))$ of the two sectors of the flux $n_{34} \in \{0, 1\}$ through the whole $(3, 4)$ torus of the plane, estimated by replica exchange interpolating the coupling and Bennett's acceptance ratio (BAR). The bias is $\theta = \tanh(\Delta F/2)$. The errors are the record's estimates.
- **String tension.** The Creutz ratio $\chi(R)$ built from $R \times R$ Wilson loops in the plane. At small R it contains the Coulomb term and overestimates the tension.
- **Physical size.** In the record, $N_T = 8$ at $\beta = 2.5$ is estimated as $L\sqrt{\sigma} \approx 1.5$, $N_T = 8$ at $\beta = 2.4$ as $L\sqrt{\sigma} \approx 2.2$, and $N_T = 4$ at $\beta = 2.7$ as $L\sqrt{\sigma} \approx 0.4$ Reading (converted from known values of $a\sqrt{\sigma}$). Only the last is in the semiclassical region of a small T^2.

- $N_T = 2$. The rows where the T^2 is 2 in lattice units are a region of large lattice artefacts. They are excluded when reading trends.

03

The work of driven insertion

All are $SU(2)$, twist $n_{12} = 1$. The number of samples is "number of configurations × number of insertion positions per configuration". The figures in brackets for W are the standard deviations of the samples (from the records of the run outputs), not the errors of the means. Samples at different positions in the same configuration are not independent, so the error of the mean should be taken as larger than the standard deviation divided by the square root of the number of samples.

Table 1 Driven insertion (comparison of 0 steps with the slowest driving. Left and right of the slash are the two values of the number of steps or of the radius)

Run	β	N_T	M	r	Steps m	Samples	Mean of W (s.d.)	Mean of $\tanh(W/2)$	Acceptance rate
P	2.3	2	8	2	0 / 4 / 16	6 × 4	10.7 / 6.5 / 2.9 (not in the record)	0.990 / 0.968 / 0.688	0.005 / 0.016 / 0.156
A	2.3	2	8	2	0 / 256	12 × 4	11.8 (2.5) / 0.50 (0.71)	1.00 / 0.22	0.000 / 0.39
B	2.3	3	8	2	0 / 256	12 × 4	24.2 (4.6) / 0.52 (0.84)	1.00 / 0.21	0.000 / 0.39
C	2.3	4	8	2	0 / 256	8 × 4	44.9 (6.8) / 0.63 (1.19)	1.00 / 0.24	0.000 / 0.38
D	2.3	2	10	3	256	12 × 4	0.19 (0.74)	0.09	0.46
E	2.5	4	10	2 / 4	1024	8 × 3	2.40 (2.11) / 0.44 (1.21)	0.67 / 0.17	0.17 / 0.41
F	2.7	4	12	2 / 4	1024	6 × 3	6.00 (1.34) / 3.77 (1.18)	0.99 / 0.92	0.006 / 0.04
G	2.7	4	18	8	256 / 1024	4–6 × 3	3.64 (3.98) / 2.72 (2.53)	0.54 / 0.59	0.23 / 0.20
H	2.5	8	12	4	256 / 1024	4–6 × 3	6.67 (2.63) / 0.51 (1.64)	0.98 / 0.17	0.012 / 0.42

Row P is the measurement cited in 25-06 § 04. Rows P, A and D are $N_T = 2$ (the region of lattice artefacts).

Reading Reading : (i) The cost at 0 steps is roughly proportional to N_T^2 (11.8, 24.2, 44.9 for A, B, C). (ii) If the container is large enough, the work of driven insertion comes down to near 0. (iii) The container radius needed appears to roughly double each time the lattice spacing halves (2 at $\beta = 2.3$, 4 at 2.5; at 2.7, 4 is not enough and even 8 does not reach near 0). This is consistent with the thickness of the vortex being fixed by a physical length. (iv) The work 0.51 at 1024 steps for H ($N_T = 8$) is almost the same as 0.44 for E ($N_T = 4$), but at 256 steps it is high, 6.67, depending strongly on the speed of driving.

Table 2 Driven insertion with more statistics ($SU(2)$, twist $n_{12} = 1$)

Run	β	N_T	M	r	Steps m	Samples	Mean of W (s.d.)	$-\ln\langle e^{-W}\rangle$	Mean of $\tanh(W/2)$	Acceptance rate

Run	β	N_T	M	r	Steps m	Samples	Mean of W (s.d.)	$-\ln\langle e^{-W}\rangle$	Mean of $\tanh(W/2)$	Acceptance rate
I4	2.5	4	12	4	1024	10×3	1.32 (1.12)	0.72	0.48	0.26
I6	2.5	6	12	4	1024	10×3	1.14 (1.03)	0.59	0.44	0.28
I8	2.5	8	12	4	1024	10×3	1.64 (1.59)	0.22	0.52	0.24
J	2.7	4	18	8	4096	Not in the record	2.84 (0.84)	2.44	0.85	0.07

Reading Reading : (i) I: fixing the container radius at 4 and widening to $N_T = 4, 6, 8$, the work is 1.1–1.6, with no clear increase in N_T (the error of the mean is the standard deviation $/\sqrt{30}$, about 0.2–0.3). The 0.44 and 0.51 of E and H in Table 1 were fluctuations from little statistics. (ii) J: at $\beta = 2.7$, $r = 8$, driving four times more slowly than G still gives $W \approx 2.8$ (2.7 with 1024 steps for G), and the Jarzynski estimate is 2.4. Most of the work can be read not as dissipation due to the speed of driving but as a genuine free energy. $N_T = 4$ at $\beta = 2.7$ is a physically small T^2 ($L\sqrt{\sigma} \approx 0.4$), on the side of the dilute region, so the reading is that the vortex really is expensive (physics).

On the Jarzynski estimate. $-\ln\langle e^{-W}\rangle$ is an estimate of the sector free energy by the Jarzynski Equality of 25-06, but it is dominated by rare small W, so with few samples it fluctuates strongly. It is a column not shown in Table 1, but negative values have occurred (for example -0.30 for E at radius 4 with 1024 steps, -0.085 for A with 64 steps). This column is a guide for checking, and the values themselves are not reliable.

The acceptance rule. The acceptance-rate columns of Tables 1 and 2 are means of the Barker-type $1/(1+e^{W})$. Recomputing the mean of the Metropolis-type $\min(1, e^{-W})$ from the raw W of the same record gives, in the slowest-driving rows, A 0.641, B 0.647, C 0.595, D 0.729 and E ($r = 4$, 1024 steps) 0.607, all above $\frac{1}{2}$ Computed . Pointwise $\frac{1}{2}\min(1, e^{-x}) \le 1/(1+e^{x}) \le \min(1, e^{-x})$, and under a Crooks-type relation the Barker-type mean is at most $1/(1+e^{\Delta F})$ (at most $\frac{1}{2}$ if $\Delta F \ge 0$) Paper Lean (LatticeGaugeAcceptanceSandwich (half_metro_le_fermi, fermi_le_metro, barker_le_of_crooks)). That the acceptance rates of the tables stay below $\frac{1}{2}$ is the ceiling of this rule, not a physical limit of the kernel.

The limits of this series. What confinement on R^4 needs is that the bias becomes small exponentially in the area as L grows (26-01), and that is not visible in this measurement. β takes a few values between 2.3 and 2.7, and the error estimates are still rough.

04

The vortex free energy when the T² is widened

The container is the whole plane ($M \times M$), and the $T^2 = N_T \times N_T$ is widened. It is a test of the sign of the lateral-widening inequality (26-02). All by replica exchange + BAR, twist $n_{12} = 1$, 24 replicas (unless otherwise stated). The number of iterations is not in the record.

Table 3 ΔF, plane $M = 8$

Theory	β	$N_T = 2$	$N_T = 4$	$N_T = 6$	$N_T = 8$

Theory	β	$N_T = 2$	$N_T = 4$	$N_T = 6$	$N_T = 8$
$U(1)$ (control)	1.5	-0.03 ± 0.04	0.83 ± 0.11	2.10 ± 0.47	5.14 ± 0.78
$SU(2)$	2.5	-0.01 ± 0.12	0.63 ± 0.18	0.33 ± 0.22	1.51 ± 0.29

Table 4 ΔF, plane $M = 12$ (remeasurement with a larger container)

Theory	β	$N_T = 4$	$N_T = 6$	$N_T = 8$
$U(1)$ (control)	1.5	0.20 ± 0.21	1.35 ± 0.30	1.72 ± 0.47 (40 replicas; with 24, 0.54 ± 0.53, with poor mixing)
$SU(2)$	2.5	0.57 ± 0.22	0.42 ± 0.24	-0.15 ± 0.36

Table 5 ΔF, $SU(2)$, $\beta = 2.4$, plane $M = 8$

N_T	**4**	**8**
ΔF	0.31 ± 0.10	0.11 ± 0.25

Reading Reading : (i) For $U(1)$, ΔF increases as the T^2 is widened (at $M = 8$, θ goes $0 \to 0.39 \to 0.78 \to 0.99$; at $M = 12$, $0.20 \to 1.35 \to 1.72$). (ii) For $SU(2)$, in three settings ($M = 8$ and 12 at $\beta = 2.5$, $M = 8$ at $\beta = 2.4$), it does not increase or decreases when widened. The exception is 1.51 at $N_T = 8 = M$ (the symmetric torus T^4_8) for $\beta = 2.5$, $M = 8$. (iii) For $N_T = 4 \to 8$, $\ln(1/\theta)$ goes 0.93 $\to$ 0.012 for $U(1)$ (about 1/80) and 1.18 $\to$ 0.45 for $SU(2)$ (about 1/2.6) ($M = 8$). This can be read as a numerical sign of the sign of the lateral-widening inequality. (iv) That $N_T = 8$ at $\beta = 2.4$ is smaller than at $\beta = 2.5$ is consistent with the same lattice being physically larger ($L\sqrt{\sigma} \approx 2.2$ against 1.5).

Limits. This is a regime where θ is not close to 1 (it is $O(1)$), so the $U(1)$ ratio is also held down because $\theta \leq 1$, and in this geometry the lateral-widening inequality has little power to discriminate. The errors are large, 0.04–0.78 for $U(1)$ and 0.1–0.36 for $SU(2)$, and β is one or two points. $\beta = 1.5$ for $U(1)$ and $\beta = 2.5$ for $SU(2)$ are not matched to "the same physics". The $N_T = 2$ column is in the region of lattice artefacts.

05

The string tension of slabs

$SU(2)$, $\beta = 2.5$, plane $M = 16$, twist $n_{12} = 1$. We measured the Creutz ratio $\chi(R)$ of Wilson loops in the plane for each size N_T of the T^2. It is a test of "monotonicity of the reduced two-dimensional string tension $\sigma_{\text{eff}}(N_T)$" contained in the lateral-widening inequality (strong form) of 26-02, and of an "overshoot" in which the tension once becomes large at $L \sim 1/\Lambda$. In the record, the four-dimensional value at $\beta = 2.5$ is given as $\sigma a^2 \approx 0.036$ Reading .

Table 6 Creutz ratios, 400 measurements

N_T	$\chi(3)$	$\chi(4)$	$\chi(5)$
2	0.098 ± 0.006	0.034 ± 0.029	-0.02 ± 0.14
4	0.113 ± 0.007	0.070 ± 0.018	0.07 ± 0.06
6	0.108 ± 0.003	0.089 ± 0.013	0.11 ± 0.05
8	0.113 ± 0.003	0.051 ± 0.010	0.07 ± 0.04

Table 7 Creutz ratios, 2000 measurements (5 times the statistics) and $N_T = 10$

N_T	$\chi(3)$	$\chi(4)$	$\chi(5)$
4	0.103 ± 0.002	0.059 ± 0.009	0.03 ± 0.04
6	0.115 ± 0.001	0.061 ± 0.004	0.084 ± 0.019
8	0.116 ± 0.002	0.076 ± 0.002	0.070 ± 0.022
10	0.112 ± 0.002	0.071 ± 0.002	0.076 ± 0.009

Reading Reading : (i) With 400 measurements $\chi(4)$ was largest at $N_T = 6$ (0.089), and its difference from $N_T = 8$ was about 2.3 standard deviations. It looked like a sign of overshoot, but with 2000 measurements $N_T = 6$ gives 0.061 ± 0.004, so it was **a statistical fluctuation**. (ii) With 2000 measurements $\chi(4)$ increases for $N_T = 4 \to 8$, and at $N_T = 10$ it is 0.071 (1.7 standard deviations from $N_T = 8$), almost saturated. No significant overshoot is seen. This is consistent with monotonicity of the tension (a necessary condition of 26-02). (iii) $\chi(4)$ contains the Coulomb term, so it comes out larger than the four-dimensional $\sigma a^2 \approx 0.036$. We read only the trend in N_T, not the absolute value. (iv) The $N_T = 2$ row (Table 6) is in the region of lattice artefacts, with only 400 measurements.

Limits. β is the single value 2.5, and the plane the single size $M = 16$. From $\chi(5)$ on the errors are large, and the value of the tension itself is not determined. $N_T = 10$ is about 2 in $L\sqrt{\sigma}$, and the trend as $L \to \infty$ is an extrapolation.

06

The measurement of simultaneous flips, and why it cannot be used as a test of the band

A measurement that uses the Simultaneous-Flip Estimate of 25-06 ($\mathbb{E}\prod\theta \le \mathbb{P}(\text{no container flips})$) numerically. $SU(2)$, $\beta = 2.5$, containers placed with spacing B, and driven insertions (512 steps) with acceptance $\min(1, e^{-W})$ performed simultaneously in 4 containers per configuration. We write $\bar{a}$ for the mean acceptance rate.

Table 8 Container radius fixed at $r = 4$ ($B = 10$, $M = 20$, 512 steps)

N_T	Configurations	$\bar{a}$	Mean of W	W/N_T^2
4	30	0.36 ± 0.03	1.6	0.10
6	20	0.25 ± 0.04	2.6	0.07
8	10	0.12 ± 0.03	4.5	0.07
10	6	0.02 ± 0.01	8.2	0.08

Table 9 Remeasurement with container radius proportional to N_T ($r = N_T$, $B = 2r + 2$, $M = 2B$, 512 steps)

N_T	r	Configurations	$\bar{a}$	Mean of W
4	4	30	0.35 ± 0.03	1.6
6	6	11	0.34 ± 0.05	2.0
8	8	3	0.16 ± 0.08	4.5

Reading Reading : (i) Table 8: widening the T^2 with the radius fixed, the work increases roughly in proportion to N_T^2, and the acceptance rate falls. The size of the vortex is fixed by the size of the T^2, so the reading is that a container of radius $r < L$ cannot hold the vortex, which then pays a cost proportional to the area as a sheet inside a thin tube. The lateral-widening inequality is a claim about containers of size at least L, so this is not a counterexample. The guaranteed tension ($-\ln \mathbb{P}(\text{no flip})$ divided by the number of containers and B^2) was about 0.005 at $N_T = 4$. (ii) Table 9: if the containers are enlarged together with L, the acceptance rate is almost constant for $N_T = 4 \to 6$ ($N_T = 8$ cannot be judged from 3 configurations).

Why it cannot be used as a test of the band. This measurement **cannot be read** as "a numerical picture of the uniform slab tension (the crossover band)". The reason is as in 25-06 § 07: the guarantee of the Flow Lemma is $\theta \le 1 - a$, and obtaining the form of the band $\theta \le e^{-cL^2}$ needs a kernel with $a \ge 1 - e^{-cL^2}$, which requires bringing the overlap O of the measures of the forward and reverse paths to 1 exponentially in the area (in terms of dissipation, $D \lesssim e^{-2cL^2}$) (25-06 § 07). The kernels measured are far from that, so all that can be said is "for containers of size L, $\theta \le \theta_0$ (with θ_0 a constant less than 1)", and the resulting $\sigma \ge \ln(1/\theta_0)/L^2$ is the weak form that $U(1)$ also satisfies (26-01). **This measurement can be used only as a tool for measuring lower bounds on the slab tension with the T^2 fixed.** The continuation of Table 9 at $N_T = 6, 8$ has been stopped.

07

What cannot be said

(a) Proof. None of the numbers of this chapter is a proof, and the hypotheses of no inequality have been checked.

(b) The band. The trends of Table 2, Tables 3–5 and Table 7 do not show the crossover band ($\theta \le e^{-cL^2}$ uniform in L) numerically. The T^2 measured go only up to about $L\sqrt{\sigma} \approx 2$, and $L \to \infty$ is an extrapolation.

(c) Errors. The error estimates of driven insertion are still rough (sample standard deviations only), the errors of replica exchange are the record's estimates, and the treatment of autocorrelation is not in the record.

(d) Lattice artefacts. The rows with $N_T = 2$ are the region of lattice artefacts. Even at $N_T = 4$, small-lattice corrections remain.

(e) Balance of the control. $\beta = 1.5$ for $U(1)$ and $\beta = 2.5$ for $SU(2)$ are not a comparison with matched physical sizes.

(f) Simultaneous flips. Tables 8 and 9 cannot be read as a numerical picture of the band.

08

The table of five grades and the dependency graph

Table 10 The rows of this chapter (all numerical readings. Conditions in the scope column of each row)

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
1	The cost of insertion at 0 steps is roughly proportional to N_T^2	Reading	Table 1 (A, B, C)	$SU(2)$, $\beta = 2.3$, $M = 8$, $r = 2$, 8–12 configurations $\times$ 4	—
2	If the container is large enough, the driven work comes down to near 0	Reading	Table 1	$\beta = 2.3$ to 2.5, 256–1024 steps, includes $N_T = 2$ rows	—
3	The container radius needed roughly doubles each time the lattice spacing halves	Reading	Table 1 (E, F, G)	$\beta = 2.3, 2.5, 2.7$, little statistics	—
4	With radius 4 fixed, the work does not clearly increase for $N_T = 4 \to 8$	Reading	Table 2 (I)	$\beta = 2.5$, $M = 12$, 1024 steps, 10 configurations $\times$ 3, error 0.2–0.3	—
5	The work at $\beta = 2.7$, $r = 8$ is free energy, not dissipation	Reading (physics)	Table 1 (G), Table 2 (J)	$N_T = 4$, $M = 18$, the Jarzynski estimate fluctuates strongly	—
6	Widening the T^2 increases the ΔF of $U(1)$	Reading	Tables 3 and 4	$\beta = 1.5$, $M = 8$, 12, errors 0.04–0.78	—
7	Widening the T^2 does not increase, or decreases, the ΔF of $SU(2)$ (except $N_T = M = 8$)	Reading	Tables 3–5	$\beta = 2.4, 2.5$, $M = 8, 12$, errors 0.1–0.36	—
8	Rows 6 and 7 are a sign of the sign of the lateral-widening inequality	Reading (physics)	§ 04 ⟸ 6, 7	Weak discriminating power in the region where θ is $O(1)$	—
9	The overshoot at $N_T = 6$ is a statistical fluctuation	Reading	Tables 6 and 7	$\beta = 2.5$, $M = 16$, 400 and 2000 measurements	—
10	$\chi(4)$ increases for $N_T = 4 \to 8$ and nearly saturates at $N_T = 10$	Reading	Table 7	$\beta = 2.5$, $M = 16$, 2000 measurements, includes the Coulomb term	—

Row	Statement (one line)	Grade	Evidence	Scope	Machine checking
11	With the radius fixed, the work of simultaneous flips grows in proportion to N_T^2	Reading	Table 8	$\beta = 2.5$, $r = 4$, 6–30 configurations × 4 containers	—
12	The acceptance rate of one-step kernels is, in the range measured, at most 0.46 Barker-type and at most 0.73 Metropolis-type (Tables 8 and 9 at most 0.36 Metropolis-type)	Reading	Tables 1, 2, 8 and 9	The range of β, N_T and containers measured	—
13	The measurement of simultaneous flips cannot be used to test the band	Proved here	§ 06, 25-06 § 07 ⟸ 12	When only the Flow Lemma $\theta \leq 1 - a$ is used	— (the core is FluxLemma (`FluxLemma.flip_le_one_sub_abs`) of 25-06)

Only the row "the measurement of simultaneous flips cannot be used to test the band" is a row of logic rather than numerics: it is an application of the row "only the weak form follows" of 25-06, that only the weak form follows from $\theta \leq 1 - a$; the reading of the acceptance-rate row shows how far that takes effect.

Dependency graph (the numbers of premises are smaller than the number of the conclusion):

Words used in this chapter — driven insertion, number of steps, work, acceptance rate, the free energy of the global flux, replica exchange, BAR, Creutz ratio, overshoot, simultaneous flips, guaranteed tension. Their meanings are in A-02 Glossary (the words of Part 25 are to be added). The numerics of Part 26 (the test doubling the whole lattice, step functions, column biases) are in 26-09.

Next chapter to read: 25-09 Where this road stops — confirms that widening the T^2 is exactly the crossover band, and summarises what the road from the direction of space has reached.

2026-10-15 · chapter Yang–Mills and the mass gap Part 25 The second road — from the direction of space the band, lateral widening, the end of the road · Kiichi, Shiori and Rin

Where this road stops — widening the T² is the band

> This chapter is a map of open questions. It marks the boundary between the parts that close and the parts that do not.

What this chapter shows — At which stage the road from the direction of space, starting from a small twisted T^2, stops. It stops at the stage of widening the side L of the T^2 beyond the correlation-length scale $1/\Lambda$, and this is the crossover band (the band for short). At the two ends of the band — the region of dilute fractional instantons where L is small, and the confinement region where L is large — there is a prospect that the needed inequality holds, and all that remains is to pass non-perturbatively through the middle, $L \sim 1/\Lambda$.

Prerequisite chapters — 25-00 (the entrance of this part), 25-02 (vortices and fractional instantons), 25-04 (slab confinement), 16-09 (the band stage in the table of the seven stages a proof must contain).

Said first — This is a short guiding chapter, and it places no new proofs. Every statement crossing the band is an assumption, and the prospects at the two ends are physical estimates resting on one-loop and dilute-gas counting, or on the picture of confinement.

The order of this chapter

1. The stage where it stops — what is in hand on a small T^2, and the stage of widening
2. The two ends and the middle of the band — the dilute region, the confinement region, and between them (Table 1)
3. The statement to show in the band — the correct form of the band, and intermediate goals
4. To Part 26

01

The stage where it stops — what is in hand on a small T^2, and the stage of widening

The road of this part went by way of a small twisted T^2 in order to split the four-dimensional problem in two (25-00). Since the twist removes the zero modes, the theory stays weakly coupled at scales up to the size L of the T^2, and the vortex sheets winding the T^2 close locally as fractional instantons. In this way the problem splits into an intermediate goal where only the ultraviolet wall remains (the gap and confinement on a small T^2; among the seven stages a

proof must contain, the small-T^2 gap stage and the small-T^2 confinement stage) and a stage where all other walls gather (widening the T^2, the band stage).

What is in hand on the side of the small T^2 is all either conditional or stated with the lattice spacing fixed. With the lattice spacing and the T^2 fixed, the area law holds at every β, but the tension is fixed by the cost of thin vortices and becomes 0 in the continuum limit Proved here (25-04). The insertion identities and averaged bounds reduce confinement to a single local quantity Proved here (25-05). Confinement and the gap on a small T^2 with the lattice spacing sent to 0 are a strand resting on assumptions such as ultraviolet control Assumption . Ultraviolet control in this part is "that the same construction as the one published on 2026-11-10 stands under twisted boundary conditions"; the published construction is only for a periodic cubic box, so this is an open condition (the arrow of the small-T^2 gap and the arrow of the small-T^2 area law in 27-01).

What the problem statement asks for is the theory on $\mathbb{R}^4$, so $L \to \infty$ is needed. One must widen L from well below the correlation length $1/\Lambda$ to well above it, keeping a bound with the same constant at every L. This stage is where this road stops, and in this book we call it **the crossover band** (the band for short) Assumption . It is a different word from the "windows" of Parts 23 and 24 (the site window, the window in $\hbar$, the time window) (note in 26-00).

02

The two ends and the middle of the band

The statement to show in the band, in the language of the bias of the sector of a container $\theta(R; T^2_L)$ (container side R, side L of the transverse T^2, 25-03), has the form that the bias does not grow when the transverse T^2 is widened (the lateral-widening inequality, 26-02). The situation differs at the two ends and in the middle.

Table 1 The two ends and the middle of the band (Λ is the dynamical scale, L the side of the transverse T^2)

Region	Picture	When the transverse T^2 is widened	Label	Conditions written in the same row
$L \ll 1/\Lambda$ (dilute region)	Vortices are self-dual lumps of charge $\frac{1}{2}$ (fractional instantons), and the action $4\pi^2/g^2$ does not depend on the shape of the T^2. In the dilute gas $\ln(1/\theta) \propto A_D\, L^{5/3}$ (A_D is the area of the container)	$\ln(1/\theta)$ grows and the bias becomes smaller. The exponent $5/3 = 11/3 - 2$ is the margin by which the coefficient of asymptotic freedom beats the entropy of the two transverse dimensions	Reading (physics: one-loop and dilute-gas counting). The formula of the tension $\Lambda^2 (\Lambda L)^{5/3}$ is Cited	Dilute region, one loop, SU(2). For U(1) the same counting gives exponent -2

Region	Picture	When the transverse T^2 is widened	Label	Conditions written in the same row
$L \gg 1/\Lambda$ (confinement region)	The free energy of the vortex sheet in a container is tension $\times$ area, and the dependence on the area of the T^2 is only the entropy of the position of the vortex sheet (logarithmic)	The ratio of biases stays of order s^2	Reading (physics: on the picture of confinement)	A picture that assumes confinement. Not shown
$L \sim 1/\Lambda$ (middle)	Neither the weak-coupling picture nor the strong-coupling picture can be used	The statement to be shown itself	Assumption	Needs non-perturbative input. Structural inputs (reflection positivity, duality, the transfer matrix) alone do not give it (26-04)

Putting U(1) beside it as a control: the flux of $U(1)$ can only spread uniformly, and $U(1)$ on a slab becomes at long distances a two-dimensional $U(1)$ with coupling e^2/A_T (A_T is the area of the T^2), so $\ln(1/\theta) \propto A_D/A_T$, and the ratio of biases when the T^2 is widened (after over before) becomes arbitrarily large Reading (physics: the estimate counting of the paper on the reduction of the band). Weakly coupled four-dimensional $\mathbb{Z}_2$ breaks it in the same way. What separates SU(2) from U(1) is that non-abelian flux can localise into lumps of finite action independent of scale (26-03). The measured record (the vortex free energy when the T^2 is widened goes up for U(1) and not for SU(2); the slab tension grows and saturates) is in 25-08 and 26-09 Reading .

03

The statement to show in the band — the correct form of the band, and intermediate goals

The goal of the band is not "the bias stays uniformly away from 1" ($\sup_L \theta(L;T_L^2) \le \theta_0 < 1$). This form is satisfied by four-dimensional $U(1)$ too, and the tension it gives is $\ln(1/\theta_0)/L^2 \to 0$ (26-01). The correct form of the band is that the vortex free energy of the container becomes small exponentially in the area,

$$\ln \frac{1}{\theta(L;T_L^2)} \;\ge\; c\,L^2 \qquad \text{(in physical units, uniform in the lattice spacing } a\text{)} \quad (1)$$

a local version, conditioned on the frame, of 't Hooft's criterion for confinement Assumption . (1) follows by iterating doubling, given the base point, frame decorrelation and the lateral-widening inequality (the Doubling-Iteration Theorem of 27-01 § 03 and its premises). In the language of the chessboard, the content of (1) becomes two uniformities: the uniform slab tension and the uniform slab gap (26-05).

As intermediate goals before reaching (1), two weaker statements have been named Assumption . (a) That the vortex free energy of the container approaches 0 as $L \to \infty$ (a restatement of there being no deconfined phase). (b) $\ln(1/\theta) \geq cL^2/\ln L$ (an almost-area law). Neither has been shown.

04

To Part 26

This road came as far as just before the band and stopped. What is needed in the band can be narrowed in form with the tools of this part: the correct form of the band (1), the reduction to one inequality, where non-abelianness enters, and that structure alone cannot cross, in that order. The road from the direction of time (Parts 23 and 24) also arrives at a uniformity of the same type when its four-dimensional goal is written in the form "a constant uniform in $\beta \to \infty$" (23-15 § 08). That the two roads meet at this band is treated in the entrance of Part 26.

What this chapter can say

What is said	What is not said
That the stage at which the road from the direction of space stops is the stage of widening the transverse T^2 beyond the correlation-length scale (the band). The correct form of the band (1), and the naming of the exclusion of a deconfined phase (a)	Each of (1), (a) and (b) is Assumption
The prospects at the two ends: $5/3 = 11/3 - 2$ in the dilute region, logarithmic entropy in the confinement region Reading (physics)	Passing non-perturbatively through the middle $L \sim 1/\Lambda$. Proofs of the prospects at the two ends

Words used in this chapter — the crossover band (the band), the lateral-widening inequality, the bias of the sector $\theta(R;T_L^2)$, the dilute region, the confinement region, intermediate goals. Their meanings are in A-02 Glossary.

Next chapter to read: 26-00 Entrance — confluence — that the two roads arrive at a statement of one type, "the same constant at all scales".

Entrance — confluence

> This chapter is a guide. § 03 and § 05 are a map of open questions.

This part is a record of the study. The theorems that have been machine-checked are in Parts 20–22, and the current list of premises is in 28-04.

What this chapter shows — That the road entering from the direction of time (Parts 23 and 24) and the road entering from the direction of space (Part 25) both arrive at a statement of one type: "it holds at every scale with the same constant". In this part we call the interval of scales that this statement has to cross **the crossover band** (**the band** for short). In the figure of the ladder of scales (Figure 2) we see how far the weak-coupling tools and the strong-coupling tools each reach, and where the gap is. We put the breakdown of the band (the goal, the reduction, the negative lemmas, the electric flux, the place of the non-abelian, β-monotonicity, the renormalisation comparison, the chessboard) into one table, and give a map of the thirteen chapters of Part 26.

Prerequisite chapters — 23-15 § 07, 23-15 § 08 (the one line on uniformity), 24-07 § 01 (the dimensionless coupling), 4-07 (dimensional transmutation), 25-00 (the entrance to the road from the direction of space), 16-09 (the seven stages a proof must contain).

Said first — This page is a map and sets out no new theorem. Figure 2 is a figure of physical estimates, and each row carries a label. "The two roads meet" is a statement at **the level of the goal**. It is not a statement that the **walls at which the roads now stop** are the same (§ 05). No chapter of this part shows the mass gap, or confinement in the continuum limit.

The order of this chapter

1. One type that the two roads reach — "the same constant at every scale"
2. A note on words — the "band" of this part and the "window" of Parts 23 and 24 are different things
3. The ladder of scales — which tool works at which scale (Figure 2)
4. The breakdown of the band — eight components and their labels (Table 1)
5. Confluence at the level of the goal, difference at the level of the wall (Table 2)
6. The map of Part 26 — thirteen chapters, and the one line of 24-07 (Table 3)
7. The table of the five grades and the dependency graph

01

One type that the two roads reach — "the same constant at every scale"

From Part 23 onwards, this book has approached the problem of the mass gap from two directions.

The first is the road from the direction of time (Parts 23 and 24). Around **the diffusive-relaxation-time assumption** — that the time over which fluctuations are smoothed out grows as the square of the correlation length (the upper side is the relaxation-time upper-bound assumption, the lower side the relaxation-time lower-bound assumption; 23-01 § 05) — we compared the relaxation time on the lattice with the correlation length. The statement aimed at on the four-dimensional lattice is the physical-unit target level of Table 5 in 23-15 § 07: the mass in physical units of the lattice, $m_{\mathrm{lat}}(\beta)/a(\beta)$, tends to a positive finite value. To get there by combining the one-sided bridge (23-01 § 06) with the upper-bound assumption, the constant K of the upper-bound assumption must be uniform as $\beta \to \infty$.

The second is the road from the direction of space (Part 25). We wrap two directions of space on a small torus T^2_L with the 't Hooft twist $n_{12} = 1$, and look at confinement on the remaining plane $\mathbb{R}^2$. If T^2_L is small enough, the twist removes the zero modes, the theory stays weakly coupled up to the scale L, and the vortices can be treated as fractional instantons (25-00, 25-02). The goal of this road is that the string tension $\sigma_{\mathrm{eff}}(L)$ of the two-dimensional theory obtained by shrinking the transverse directions to T^2_L is **positive uniformly in** L, that is,

$$\inf_{L \geq L_0} \sigma_{\mathrm{eff}}(L) \;>\; 0 \qquad \text{(physical units, uniform in the lattice spacing } a\text{)} \tag{1}$$

(the uniform slab tension; the definition is in 26-02).

The two goals have the same form. Neither is "it holds at some scale"; both are statements that "**it holds at every scale, with the same constant**". They ask that the constant does not break down at any intermediate scale, from the lattice spacing a across the physical length $1/\Lambda$ up to large scales. The one line of 23-15 § 08 — what is missing is not the number of steps but uniformity, holding at every scale with the same constant — was a statement of this type written from the side of the first road. We also saw at the end of 23-15 § 07 that it appears in changed form: uniform as $\hbar \to 0$ at the first step (0+1 dimensions), uniform as $\beta \to \infty$ on the four-dimensional lattice.

In four dimensions, between the weak-coupling scales and the strong-coupling scales, there is a scale $L \sim 1/\Lambda$ at which the size of the coupling is of order 1. Λ is a scale born quantum mechanically through dimensional transmutation (4-07), and measured in lattice units it diverges as $a \to 0$. Neither of the two goal statements holds unless it passes through this scale with a uniform constant. In this part we call the interval of scales around $L \sim 1/\Lambda$ **the crossover band**, and we call the statement the two roads reach "a statement that crosses the band".

This confluence also agrees with an arrangement made outside our study. In the division of the continuum tasks (the task of a uniform gap in 16-07), the uniform gap $\inf_L \Delta_L > 0$ is set as one task, and the two roads attack it in two languages. In the table of the seven stages a proof must contain in 16-09, the band corresponds to the "band stage".

02

A note on words — the "band" of this part and the "window" of Parts 23 and 24 are different things

Parts 23 and 24 used the word "window" in at least three senses. **The "band" of this part is different from all of them.** If the words were the same, the two roads would read as if they stopped at the same place, so we separate them here.

Table 0 The "window" and the "band" compared, and notes on other words and symbols

Word	Meaning	Chapters	Relation to the band
The window of sites (the window of A_W, the window mark σ_W, the marginal log-Sobolev input for the window)	An interval of finitely many sites on the path in 0+1 dimensions	23-09	Of finite length in lattice units. Not the band
The window in $\hbar$	The range of $\hbar$ that can be checked with computer assistance	23-07, 23-08, 23-15	An interval of a parameter. Not an interval of scales
The time window (the window factor φ, the In-Window Supremum Proposition)	Test functions restricted to an interval of time	24-04, 24-05	The name of a tool. Not the band
The crossover band (the band)	The interval around the scale $L \sim 1/\Lambda$ at which weak coupling gives way to strong coupling	Part 26	—
The "band" of Parts 23 and 24	The "band statement" of 23-01 § 05 and 23-15 (5) (the statement that a quantity lies in a band of width a constant multiple of the square of a length), ℓ_{band} of 23-09 (a length concerning the summit band), and the "two-dimensional strip" of 24-02 § 03, § 05 and 24-09 (a narrow strip-shaped lattice). The "twisted strip" of the two-dimensional model in 25-07 § 06 also means a strip-shaped lattice	23-01, 23-09, 23-15, 24-02, 24-09, 25-07	A word with another meaning. Not the band of this part (an interval of scales)
Three meanings of θ	The threshold θ of 23-09 (θ_B, θ_σ and others, values that divide configurations into the valley side and the summit side), the sector bias $\theta(R; T_L^2)$ of this part ((4) of 25-01), and the vacuum angle θ of Tanizaki–Ünsal (set to $\theta = 0$ in 25-02)	23-09, 25-01, 25-02	Only the sector bias is a quantity of this part. The other two are different quantities

Word	Meaning	Chapters	Relation to the band
L and L_0	In 26-11, L is the blocking factor and L_0 is the side of the box (as in 7-05)	7-05, 26-11	Different from the L of Parts 25 and 26 (the size of T^2)

There are other clashes of symbols, so in this part we write by the following conventions.

- We call by name the property that the vortex free energy increases monotonically in β — "**β-monotonicity**" — and the inequality comparing the vortex free energy of the doubled lattice with that of the coarse lattice — "**the renormalisation comparison**".
- We call the assumptions only by name: **the base point at small T^2**, **frame decorrelation**, **the lateral-widening inequality** (strong form, weak form), **the uniform slab tension**, **the uniform slab gap**.
- We write the chessboard density as κ_{cb} (to distinguish it from κ of Part 23).

03

The ladder of scales — which tool works at which scale

Figure 2 sets out, in the language of the road from the direction of space, the scale L (the size of the small torus T^2_L, or the size of the box being compared) vertically. The bottom is short distance (the lattice spacing a), the top is long distance. Each row carries a label at its right end. Figure 1 (the flow of the logic) is in 16-09. The number and title of Figure 2 are the same as those of Figure 2 in 25-00.

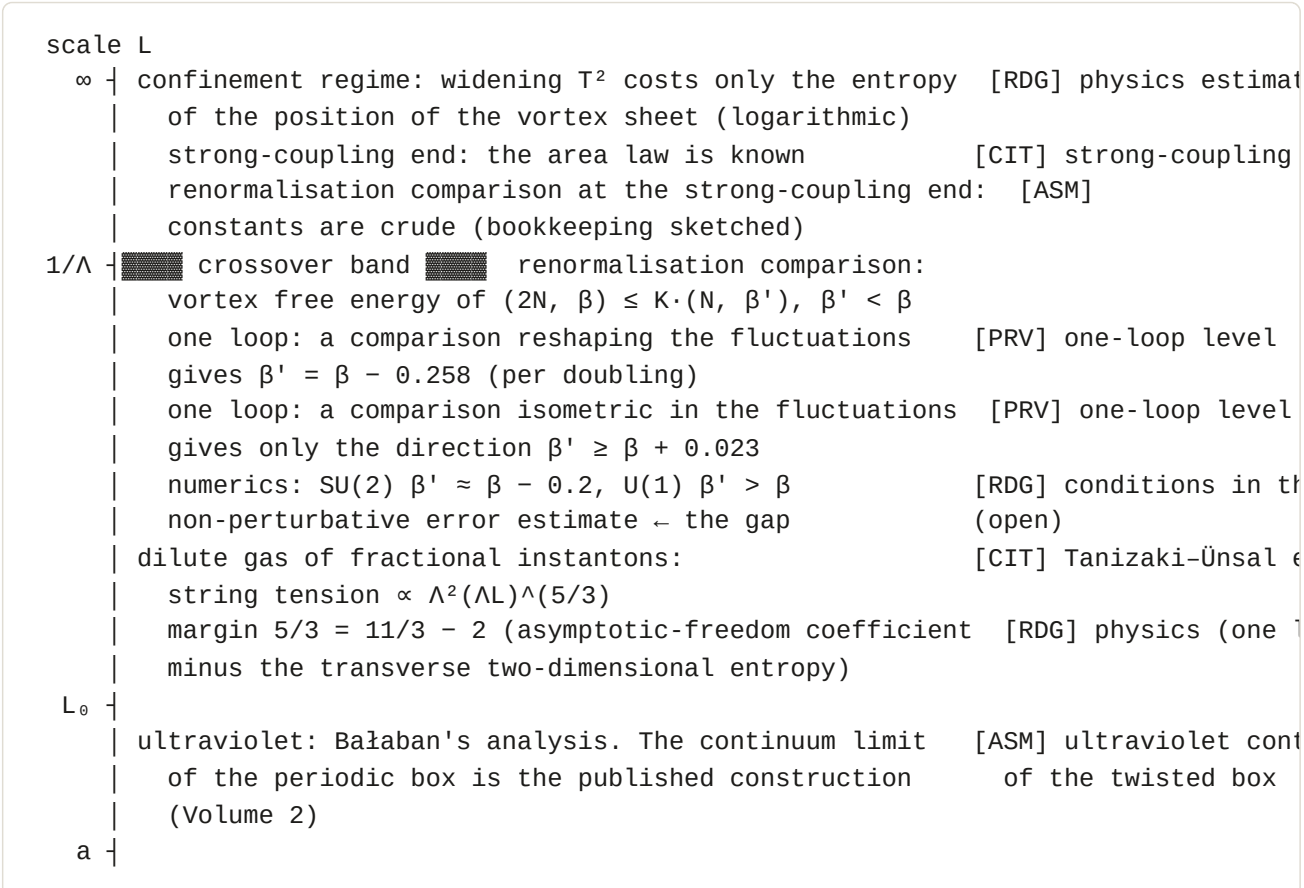

Figure 2 The ladder of scales. The weak-coupling tools (bottom) and the strong-coupling tools (top) each work at their own end; only the non-perturbative estimate in the band (L ~ 1/Λ) is missing. Labels are per row.

Just three points on how to read the figure.

(i) The shift of β per doubling. "β′ = β − 0.258" is the value coming from the coefficient $11/3 = -1/3 + 4$ of the one-loop heat kernel of fluctuations in a background magnetic field; in the convention $\beta = 4/g^2$ it is $\beta - \beta' = 8b_0 \ln 2$, with $b_0 = 22/(48\pi^2)$. A comparison that reshapes the fluctuations reproduces this value. In a comparison isometric in the fluctuations (the identity map, translation, gauge transformation, Migdal–Kadanoff-type decimation), the spin term $+4$ does not contribute to the first-order estimate, and only $\beta' \geq \beta + 0.023$ on the $-1/3$ side (the same direction as U(1)) comes out. Both are **statements at the one-loop level**, not non-perturbative comparisons. The breakdown into tables and the computation are in 25-07; the comparison itself is treated in 26-06.

(ii) The conditions of the numerical "β′ ≈ β − 0.2". This is a value read from measurements of the vortex free energy ΔF for $SU(2)$ with twist $n_{12} = 1$, by replica exchange and Bennett's acceptance-ratio method: the whole lattice was doubled ($N_T \times M = 4 \times 8 \to 8 \times 16$ and $4^4 \to 8^4$), and the value on the large lattice was fitted to the β' curve of the small lattice. For $\beta = 2.5$–3.0, with 1–3 seeds, the $\beta - \beta'$ read off is $+0.13$–$+0.25$ (the width of the reading is of order ± 0.05–0.1; judging from the differences between seeds, the errors are rather underestimated). For $U(1)$ at $\beta = 1.5$, $4 \times 8 \to 8 \times 16$, $\beta - \beta' < -0.2$ (the opposite direction). The lattices are small and the statistics few, so this is a reading of the direction, not a determination of the value [Reading]. The table is in 26-09.

(iii) The gap. The strong-coupling end and the one-loop end are each held by a different tool. In the band in the middle, there is no tool that estimates the error of the comparison non-perturbatively (at intermediate coupling, large fields included). The "▒" row of the figure is the subject of this whole part.

04

The breakdown of the band — eight components and their labels

Table 1 lists, in the language of the road from the direction of space, the components involved in the statement that crosses the band. Labels are per row, and conditions are written in the same row. The labels mean what they mean in the five grades of Part 23: [Proved here] a proof set out on paper; [Cited] known, checked in the original source; [Computer-assisted]; [Reading] a numerical reading (physical estimates are noted "physics"); [Assumption]. The Lean column is outside the labels and lists names and assumptions.

Table 1 The breakdown of the band (labels per row; "—" marks a row with no machine checking)

Component	Content in one line	Label	Conditions in the same row	Lean	Chapter

Component	Content in one line	Label	Conditions in the same row	Lean	Chapter
Goal	"The sector bias θ stays away from 1 uniformly in the scale" is not enough. What is needed is $\ln(1/\theta(L,L)) \geq cL^2$ (an area exponent). To the area law by the Tomboulis–Yaffe inequality	Proved here (the logic of insufficiency), Cited (Tomboulis–Yaffe), Reading (the U(1) count, physics)	The U(1) row: Coulomb phase, two-dimensional U(1) at long distance, an estimate	—	26-01
Reduction	Under the three of the base point, frame decorrelation and the lateral-widening inequality, the goal follows from the doubling iteration $\theta(2R) \leq K\theta(R)^4$	Proved here (conditional)	Under the three assumptions. $L \geq L_{\min}(a)$, with no lattice artefacts. On a dyadic sequence of scales	`Doubling.iterate`, `decay` (only the algebra of the iteration)	26-02
Negative lemma	Reflection positivity, the centre and duality identities, and the positivity of the transfer matrix hold in the same way for $\mathbb{Z}_2$ and U(1), so the lateral-widening inequality does not follow from them alone	Proved here	In the form "from this set of inputs alone"	—	26-04
Electric flux	$\theta = Y(1)/Y(0) \geq 0$ (the ratio of the partition functions with electric flux 1 and 0; a lattice version of 't Hooft duality)	Proved here	For $\theta \leq 1$, the positivity of the twisted partition function is used as an assumption	`FluxDuality` (the algebra of the spectral form)	26-04
The place of the non-abelian	In the dilute regime $\ln(1/\theta) \propto A_D L^{5/3}$, with the exponent margin $5/3 = 11/3 - 2$. For U(1), -2	Reading (physics), Cited (Tanizaki–Ünsal)	Dilute regime, one loop. The place where the non-abelian works "within this reduction"	—	26-03

Component	Content in one line	Label	Conditions in the same row	Lean	Chapter
β-monotonicity	The vortex free energy increases in β. A problem of the same weight as the β-monotonicity of the string tension in lattice units	Assumption (unproved for SU(2))	Proofs exist only in limited cases (small two-dimensional lattices; near $\beta \to 0$ and $\beta \to \infty$ on a fixed lattice), and the book does not set them out	—	26-06
Renormalisation comparison	The vortex free energy of $(2N, \beta) \leq K \cdot (N, \beta')$, $\beta' < \beta$. The only place asymptotic freedom enters	Proved here (one-loop level), Reading (the doubling test), Assumption (the non-perturbative comparison)	On the strong-coupling side, crude bookkeeping of constants; on the weak-coupling side, the one-loop level. U(1) goes the other way	—	26-06
Chessboard	Under reflection positivity in z, frame decorrelation is replaced by a single density κ_{cb}. The band is concentrated into the uniform slab tension and the uniform slab gap	Proved here (the chessboard at fixed L), Assumption (the uniform slab tension, the uniform slab gap)	If L is fixed. Making it uniform in L is open	`ReflPos` (the algebra of the kernel)	26-05

What the Lean column guarantees is only the algebra of finite sums and real numbers. That θ is the sector bias, the Haar measure and the positivity of the transfer matrix lie outside Lean. Names and assumptions are written in the classification table of each chapter.

Of the rows of Table 1, **non-abelian dynamics enters only the rows concerned with "the lateral-widening inequality" and "the uniform slab tension"** (the third assumption of the reduction, the place of the non-abelian, the renormalisation comparison). These have a form that fails for U(1) and $\mathbb{Z}_2$. The other rows are structural facts that hold for any group, or arrangements of logic.

05

Confluence at the level of the goal, difference at the level of the wall

The phrase "the two roads reach the same wall" is **correct at the level of the goal, and not accurate at the level of the walls at which they now stop**.

The correct part is as in § 01. The four-dimensional goal of Part 23 (the physical-unit target level of 23-15: the upper-bound assumption and the one-sided bridge with the same constant

as $\beta \to \infty$) and the goal (1) of the road from the direction of space are both statements that must cross the band.

The inaccurate part is the **present wall** of Part 23. The "summit-curvature shortfall wall" of 23-09 § 06 (that the diagonal $15/4$ of one site at the summit does not balance the sum of couplings 4) was the wall of the first step of the staircase, on the double well in 0+1 dimensions. The length at which things cross over there is a **classical** length fixed by the first conjugate point of the Jacobi equation at the summit; it does not depend on $\hbar$ and is finite in lattice units. The length $1/\Lambda$ at which things cross over in the band is born quantum mechanically and diverges in lattice units. Table 2 sets out the differences.

Table 2 The wall of the first step and the band (details in 26-07)

	The wall of the first step (Part 23)	**The crossover band (Part 26)**
Place	0+1 dimensions, double well, the lattice with $\varepsilon = \frac{1}{2}$	Four-dimensional lattice, $SU(2)$
Crossover length	The first conjugate point at the top (classical, independent of $\hbar$)	$1/\Lambda$ (born quantum mechanically through dimensional transmutation)
Size in lattice units	Finite	Diverges as $a \to 0$
Tools at the two ends	Convexity for short chains, mixing for long chains	One loop and ultraviolet analysis at weak coupling, expansion at strong coupling
Type	The same: there are different tools at the two ends, the estimate of the worst configuration stops in the middle, and there is a prospect that uniformity comes out on moving to averaging tools	

So the wall of the first step is **a miniature** of the band, but it is not the band itself. At the first step one can think of a road that crosses with a finite block longer than the crossover length and strong mixing (labelled [Assumption]), but in four dimensions there is no "finite block longer than the crossover length". This difference, and what the two have in common in type, are written from the side of time in 26-07. The reason for the difference — that the four-dimensional coupling is dimensionless and has no classical length — is in 24-07 § 01.

06

The map of Part 26 — thirteen chapters, and the one line of 24-07

Table 3 The chapters of Part 26 (labels are those of the main rows of each chapter; conditions in the same row)

Chapter	Title	One line	Main labels and conditions
26-00	Entrance — confluence	This page	Map (physics figure + the label of each row)
26-01	The correct form of the band	θ moving away from 1 is not enough; $\ln(1/\theta(L,L)) \geq cL^2$ is needed	[Proved here] the logic of the shortfall; [Cited] Tomboulis–Yaffe; [Reading] the U(1) count (physics)

Chapter	Title	One line	Main labels and conditions
26-02	Reduction to a single inequality	The lateral-widening inequality (strong form, weak form) and iterated doubling. The Conditional Reduction Theorem	[Proved here] under the three assumptions of the base point, frame decorrelation and lateral widening
26-03	The only place where non-abelian enters	$5/3 = 11/3 - 2$; the contrast with U(1) and $\mathbb{Z}_2$	[Reading] physics (dilute regime, one loop; "within this reduction")
26-04	Structure alone cannot cross	Reflection positivity, duality and the transfer matrix are the same for $\mathbb{Z}_2$ and U(1). $\theta = Y(1)/Y(0) \geq 0$	[Proved here] "with this set of inputs alone"
26-05	The chessboard and simultaneous flips	Frame decorrelation turned into the density κ_{cb}. The band is concentrated into the uniform slab tension and the uniform slab gap	[Proved here] for fixed L; [Assumption] uniformity
26-06	Renormalisation comparison — a comparison that distinguishes groups	Band = β-monotonicity + renormalisation comparison. Asymptotic freedom enters only through $\beta' < \beta$	[Proved here] one-loop level; [Reading] doubling test; [Assumption] non-perturbative
26-07	The band seen from the side of time	The form of the statement that corresponds to the band on the road of Part 23. The wall of the first step is a miniature of the band but not the band	[Proved here] the computation of the first conjugate point; [Assumption] the statement that crosses the band itself
24-07	Precisely because it is four-dimensional	Kept in Part 24. The dimensionless coupling and topology — why the length of the band is born quantum mechanically	The label of each row as in 24-07
26-08	A map of the roads tried and stopped	The roads tried and why they stopped. Tomboulis's (2007) claim, and the criticism that it does not distinguish U(1)	[Cited] only literature that has been checked; unchecked items are marked
26-09	The measured record	Widening T^2 makes the U(1) vortex costlier, but not the SU(2) one. The slab tension increases and saturates. The test of doubling the lattice	[Reading] lattice size, β, number of seeds and error on each row
26-10	Candidate new viewpoints	Four faces of the middle band. Including viewpoints that the study found negative	[Reading] physics estimate

Chapter	Title	One line	Main labels and conditions
26-11	Ultraviolet control — what it means to close at infinitely many steps	The foundation under both roads. What closing at one step means, three difficulties, the five steps of the series and where it stopped, a proposed statement	[Proved here] Background–Fluctuation Decomposition Lemma, Coupling-Smallness Induction Lemma (the one-step remainder = the net one-step bracket of the coupling is unproved); [Cited] the five steps of Bałaban's series; [Reading] the class of one-link heat kernels (one link, registered range); [Assumption] the ultraviolet statement for a small twisted four-dimensional torus (proposal, unproved)
26-12	A sieve for arguments about the band — seven test models	Six models besides U(1), listing for each type of argument which models it fails. A table sorting this book's theorems and the candidate statements for the band into true, false or undefined for each model	[Cited], [Reading], [Proved here], [Assumption] (only what was checked in the literature is Cited; computations on small lattices are conditional)

We recommend reading in numerical order. In 26-01 and 26-02 we narrow the band down to a single inequality, in 26-03 to 26-05 we see what enters where in that inequality, and in 26-06 and 26-07 we look at the band itself from two directions. 26-08 to 26-10 are records and candidates. 26-11 is the foundation under the two roads (ultraviolet control), the content of the "ultraviolet control" row of the ledger of conditions. 26-12 is a list of models against which to test arguments about the band. The conditional statement as a whole is gathered in Part 27 (27-01).

07

The table of the five grades and the dependency graph

The labels of the rows of Tables 1 and 3 are fixed in the classification table of each chapter. The rows this page sets out itself are the following twelve.

Table 4 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	Λ is born through dimensional transmutation and, in lattice units, diverges as $a \to 0$	Cited	4-07	One- and two-loop flow	—
2	A comparison that reshapes the fluctuations gives $\beta - \beta' = 8b_0 \ln 2 = 0.258$	Proved here	25-07	One-loop level, per doubling	—
3	A comparison isometric in the fluctuations gives only the direction $\beta' \geq \beta + 0.023$	Proved here	25-07	One-loop level	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
4	The doubling test: $\beta - \beta' \approx +0.13$–$+0.25$ for SU(2), the opposite direction for U(1)	Reading	§ 03 (ii), 26-09	$4 \times 8 \to 8 \times 16$, $4^4 \to 8^4$, $\beta = 2.5$–3.0, 1–3 seeds	—
5	The string tension on a small T^2, $\propto \Lambda^2 (\Lambda L)^{5/3}$	Cited	Tanizaki–Ünsal eq. (2.37)	Dilute regime, one loop	—
6	The margin $5/3 = 11/3 - 2$ (the coefficient of asymptotic freedom beats the transverse entropy)	Reading (physics)	26-03	Dilute regime, one loop	—
7	The area law at strong coupling	Cited	5-02	Small β	—
8	The renormalisation comparison at the strong-coupling end	Assumption	26-06 (bookkeeping sketched)	Very small β	—
9	Ultraviolet control (the twisted small-T^2 box; the continuum limit in the periodic cubic box was shown by the published construction, Volume 2)	Assumption	7-07, 27-02	From a to L_0	—
10	The goals of the two roads are both statements of "the same constant at every scale", and cross the band	Reading (physics)	§ 01	The level of the goal	—
11	The crossover length at the wall of the first step is classical and finite in lattice units	Proved here	26-07 § 02	0+1 dimensions, $\varepsilon = \frac{1}{2}$	—
12	The wall of the first step is a miniature of the band, not the band	Reading (physics)	§ 05	A comparison of types	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  CIT  dimensional transmutation: Λ is quantum, diverges in lattice units  4-07

12  RDG  the first-step wall is a miniature of the band, not the band ⟸ 1, 10, 11
```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The rows of Figure 2 are a rearrangement of the rows of Table 4 from the reshaping comparison to ultraviolet control, and the figure itself creates no new node. The conclusion-side nodes (that the goals of the two roads are of the same type, and that the wall of the first step is a miniature of the band) are "Reading (physics)", and this page has no node for the statement that crosses the band itself (the uniform slab tension, the uniformity of the upper-bound assumption). That is placed as an assumption in the ledger of conditions of Part 27.

What this chapter can say

What is said	What is not said
Reading (physics) That the goals of the two roads are of the same type (the same constant at every scale), and that both cross the band	Crossing the band. The goal of either road
Proved here The direction of the comparison in the band at the one-loop level (the difference between the reshaping comparison and the isometric comparison)	The non-perturbative comparison. Estimating the error at the intermediate couplings of the band
Reading That in the doubling test on small lattices the directions for SU(2) and U(1) separate	Determining the value. Behaviour on large lattices
Reading (physics) That the wall of the first step is a miniature of the band, not the band	Getting past the wall of the first step. Whether the tools of the first step cross the band

Terms used in this chapter — the crossover band (the band), the ladder of scales, the uniform slab tension, the lateral-widening inequality, frame decorrelation, the base point at small T^2, β-monotonicity, the renormalisation comparison, the chessboard density κ_{cb}, the diffusive-relaxation-time assumption. Their meanings are in A-02 Glossary and A-06 Index of names.

Next chapter: 26-01 The correct form of the band — why "θ moves away from 1" is not enough.

2026-10-15 · chapter Yang–Mills and the mass gap Part 26 The crossover band the sector bias, the area exponent, Tomboulis–Yaffe · Kiichi, Shiori and Rin

The correct form of the band

> This chapter is this book's own investigation. § 06 is a map of open questions.

What this chapter shows — How the statement that crosses the band should be written in the language of the sector bias θ. The naive form "θ stays away from 1 uniformly in the scale" is not enough: the lower bound on the string tension that the container estimate gives from that form is $\ln(1/\theta_0)/L^2$, which goes to 0 as $L \to \infty$, and weakly coupled four-dimensional U(1) can be estimated to satisfy that form. What is needed is the form in which the bias becomes small with an area exponent, $\ln(1/\theta(L, L)) \geq cL^2$; this is the local form of 't Hooft's criterion for confinement, conditioned on the frame. We also see how the Tomboulis–Yaffe inequality connects decay of the vortex free energy with an area exponent to the area law.

Prerequisite chapters — 26-00 (the band), 25-01 (the twist and 't Hooft flux), 25-03 (containers and the sector bias), 25-04 (slab confinement), 5-06 (U(1) and the non-abelian case).

Said first — The proofs in this chapter are only manipulations of elementary inequalities. The count for the Coulomb phase of U(1) is an estimate by an effective theory ([Reading], physics), not a theorem. Of the conclusion "the naive form is not enough", the part that can be said on paper is "the lower bound that the container estimate gives from that form goes to 0"; the part "from that form, confinement does not follow by any road" stands on the U(1) estimate. This chapter shows neither confinement nor the correct form (7).

The order of this chapter

1. The naive form — θ stays away from 1 uniformly in the scale
2. What follows from the naive form — the lower bound on the tension goes to 0 as L→∞
3. The count for the Coulomb phase of U(1) — it satisfies the naive form and does not confine
4. The correct form — an area exponent and the Tomboulis–Yaffe inequality
5. The touchstone — the behaviour for U(1), $\mathbb{Z}_2$ and SU(2) (Table 1)

6. What this form imposes on the band
7. The table of the five grades and the dependency graph

01

The naive form of the band — θ stays away from 1 uniformly in the scale

We take the notation from 25-03. We write the Wilson action of $SU(2)$ on the lattice $(\mathbb{Z}/L)^2 \times (\mathbb{Z}/M)^2$ as the ensemble summed over Mack–Petkova twists (links U and closed ± 1 variables z_p, with weight $\exp(\frac{\beta}{2}\sum_p z_p \operatorname{tr} U_p)$), and fix the background twist $n_{12} = 1$ in the two transverse directions 1 and 2. For a disc or square D in the plane (directions 3 and 4), we call $D \times T^2_L$ the **container**, the $\mathbb{Z}_2$ flux $\sigma_D = \prod_{p \in D \times \{y_0\}} z_p$ through D its **sector**, and define the **sector bias**, conditioned on all the variables outside the container (the **frame**) Φ, as

$$\theta_D(\Phi) \;:=\; \big|\, \mathbb{E}[\sigma_D \mid \Phi] \,\big| \;\in [0,1] \quad (1)$$

We write $\theta(R; T^2_L)$ for its value at a typical frame for a container of size R with transverse T^2_L, and in particular $\theta(L,L) := \theta(L; T^2_L)$. Given the frame, the insides of the containers are conditionally independent, and for disjoint containers D_j inside a loop C in the plane

$$|\langle W(C)\rangle| \;\le\; \mathbb{E} \prod_j \theta_{D_j}(\Phi) \quad (2)$$

holds (the Mack–Petkova container estimate Cited , 25-03).

The line of the road from the direction of space was this: confinement is visible on a small T^2_L (25-04), and carrying it to $L \to \infty$ gives confinement on $\mathbb{R}^4$. So the first statement of the band that comes to mind is the following **naive form of the band** (the naive form, below).

(naive form) $\qquad \sup_{L \ge L_0} \theta(L,L) \;\le\; \theta_0 \;<\; 1 \qquad$ (at a typical frame, uniform in the lattice sp

It is the statement that "even if the container and the transverse torus are enlarged together, the sector bias does not stick to 1" — disorder remains at every scale.

02

What follows from the naive form — the lower bound on the tension goes to 0 as L → ∞

Tension Lower Bound from the Naive Form Proved here Suppose that, for some L, when the plane is tiled with square containers of side L, the product on the right-hand side of (2) splits into the product of the individual factors up to a constant $C_{\mathrm{D}} \geq 1$ (frame decorrelation Assumption), and that each factor is at most θ_0. Then for a square loop C of area A (with side a multiple of L)

$$|\langle W(C)\rangle| \;\leq\; C_{\mathrm{D}}\,\theta_0^{A/L^2} \;=\; C_{\mathrm{D}}\,e^{-\sigma_L A}, \qquad \sigma_L := \frac{\ln(1/\theta_0)}{L^2}. \tag{4}$$

Proof Place A/L^2 square containers of side L inside C and use (2) and the assumption: $|\langle W(C)\rangle| \leq C_{\mathrm{D}} \prod_j \theta_0 = C_{\mathrm{D}}\theta_0^{A/L^2}$. Rewriting the exponent gives (4). ∎

The tension σ_L in (4) is positive for each L. But the naive form (3) gives only *one* constant θ_0, so the lower bound on the tension obtained by this road is $\ln(1/\theta_0)/L^2$, which goes to 0 in the four-dimensional limit ($L \to \infty$, where the slab $T^2_L \times \mathbb{R}^2$ approaches $\mathbb{R}^4$). In physical units, whatever multiple of $1/\Lambda$ we take L to be, the lower bound is $\Lambda^2 \ln(1/\theta_0)/(L\Lambda)^2$, and it gives no uniform tension.

What is said here is that "the lower bound that follows from (3) **by the container estimate** goes to 0". That a theory satisfying (3) does not confine does not follow from the Tension Lower Bound from the Naive Form. The U(1) estimate in the next section fills that step.

03

The count for the Coulomb phase of U(1) — it satisfies the naive form and does not confine

We apply the same language of containers to compact $U(1)$ in four dimensions (the twist enters in the same way, as a centre flux with values ± 1). What follows is an estimate by an effective theory Reading (physics).

Weakly coupled $U(1)$ is in the Coulomb phase, and on the slab $T^2_L \times \mathbb{R}^2$, after integrating over the transverse directions at long distance, it becomes two-dimensional $U(1)$ with coupling e^2/A_T ($A_T = L^2$ is the area of T^2). In two-dimensional $U(1)$, the partition function for flux Φ through a region of area A_D can be written as a Poisson sum over the wrapping k:

$$Z(\Phi) \;\propto\; \sum_{k\in\mathbb{Z}} e^{ik\Phi}\, e^{-e^2 A_D k^2/(2A_T)} \tag{5}$$

The sectors $\sigma_D = \pm 1$ correspond to $\Phi = 0$ and $\Phi = \pi$, so when $q := e^{-e^2 A_D/(2A_T)}$ is small

$$\theta(R; T_L^2) \;=\; \frac{Z(0) - Z(\pi)}{Z(0) + Z(\pi)} \;\approx\; 2q \;=\; 2\exp\Big(-\frac{e^2 A_D}{2A_T}\Big). \quad (6)$$

Taking the container size $R = L$, A_D/A_T is a number independent of L (1 for a square), so $\theta(L, L)$ is a constant independent of L and satisfies the naive form (3). On the other hand, that weakly coupled four-dimensional $U(1)$ does not confine is a theorem (Guth 1980, Fröhlich–Spencer 1982, Villain-type action Cited , 5-06). Together, the two give the conclusion that **(3) cannot lead to confinement**. But (6) is an estimate, so this conclusion carries the same label, [Reading] (physics).

(6) is consistent with the string tension $\sigma \sim e^2/(2L^2)$ of U(1) reduced to two dimensions. U(1) on the slab confines, but its tension goes to 0 as $1/L^2$. The $\ln(1/\theta_0)/L^2$ of the Tension Lower Bound from the Naive Form has exactly the same form as this behaviour.

Note The classical energy count we tried first (the energy $(\beta/2)(\pi/L^2)^2 L^4 = \beta\pi^2/2$ of the flux π spread uniformly over a container of radius L does not depend on L) gives the same conclusion, but it drops the sum over the wrapping k, so we put the forms (5) and (6) in the text.

04

The correct form of the band — an area exponent

To get a uniform tension, the bias must become small with an exponent in the area of the container. In physical units,

$$\text{(correct form)} \qquad \ln\frac{1}{\theta(L,L)} \;\geq\; c\,L^2 \qquad (L \geq L_0, \text{ at a typical frame, uniform in } a) \quad (7)$$

This is the correct form of the band. Seen from the side of the container estimate, (7) turns directly into a tension independent of L.

Area Law from the Area Exponent Proved here Under the same frame-decorrelation assumption as the Tension Lower Bound from the Naive Form, if $\theta \leq e^{-cL^2}$ for containers of side L, then for square loops with side a multiple of L, $|\langle W(C)\rangle| \leq C_{\mathrm{D}}\, e^{-cA}$.

Proof Replacing θ_0 by e^{-cL^2} in the proof of the Tension Lower Bound from the Naive Form gives $C_{\mathrm{D}}(e^{-cL^2})^{A/L^2} = C_{\mathrm{D}} e^{-cA}$. ∎

(7) is 't Hooft's criterion for confinement — that the free energy of a vortex (a centre flux) becomes small with an exponent in the area of the cross-section — put in a local

form conditioned on the frame. The global form can be written with partition functions with twisted boundary conditions. On the torus, define the vortex free energy by $e^{-F_v} := Z_-/Z_+$ as the ratio of the partition function Z_- with twist flux in the plane $\mu\nu$ of the loop to the one Z_+ without; then the global version of the sector bias is

$$\theta \;=\; \frac{Z_+ - Z_-}{Z_+ + Z_-} \;=\; \tanh\frac{F_v}{2} \tag{8}$$

(from the definition, Proved here). Since $\tanh x \le x$, and $\operatorname{artanh}\theta \le \theta/(1-\theta^2) \le 2\theta$ for $0 \le \theta \le 1/\sqrt{2}$, give $\theta \le F_v/2 \le 2\theta$, the conditions $\ln(1/\theta) \ge cL^2$ and $F_v \lesssim e^{-cL^2}$ are the same up to constants.

It is the Tomboulis–Yaffe inequality that connects the global form to the area law Cited . In $SU(2)$ lattice gauge theory, for a rectangle C (area A_C) in the plane of the directions with periods L_μ, L_ν,

$$\langle W(C)\rangle \;\le\; 2\Big\{\tfrac{1}{2}\big(1-e^{-F_v}\big)\Big\}^{A_C/(L_\mu L_\nu)} \tag{9}$$

holds. Here F_v is the free energy of the twist flux in the same plane as C; the vortex sheet wraps the remaining two directions and winds once around C (this is a different twist from the background twist n_{12} of the slab). T. Kanazawa extended this inequality to $SU(N)$ and to general classical spin systems, using reflection positivity Cited .

Tension Lower Bound from Tomboulis–Yaffe Proved here Under (9), if $F_v \le e^{-\rho L_\mu L_\nu}$ (with $\rho > 0$ independent of the size of the torus), then $\langle W(C)\rangle \le 2e^{-\rho A_C}$; that is, the string tension is at least ρ.

Proof From $1-e^{-F} \le F$, $\tfrac{1}{2}(1-e^{-F_v}) \le \tfrac{1}{2}e^{-\rho L_\mu L_\nu}$. Raising to the power $A_C/(L_\mu L_\nu)$ gives $2^{-A_C/(L_\mu L_\nu)}e^{-\rho A_C} \le e^{-\rho A_C}$. ∎

ρ is called the 't Hooft string tension. The assumption of the Tension Lower Bound from Tomboulis–Yaffe and (7) are conditions of the same type — the former a ratio of global partition functions, the latter the bias of a container conditioned on the frame. The global form does not need frame decorrelation; in exchange, the base point (the estimate on a small T^2) must also be shown for the global partition functions (the note in 26-02).

```
05
```

The touchstone — the behaviour for U(1), $\mathbb{Z}_2$ and SU(2)

An argument that crosses the band must fail for a theory that does not confine. The naive form (3) does not pass this touchstone; the correct form (7) is expected to pass. All the behaviour in Table 1 is estimated Reading (physics).

Table 1 The behaviour of $\theta(L, L)$ (estimates; four dimensions, weak coupling)

Theory	$\theta(L, L)$ as L grows	Naive form (3)	Correct form (7)	Confinement
$U(1)$ (Coulomb phase)	Constant ((6))	Satisfied	Not satisfied	No Cited
$\mathbb{Z}_2$ (weak coupling)	Tends to 1 (the flux makes a wall of the area of T^2)	Not satisfied	Not satisfied	No
$SU(2)$	Tends to 0 (expected)	Satisfied (expected)	Satisfied (expected)	Yes (physical expectation)

Satisfying the naive form is not a touchstone for confinement, because U(1) satisfies it. The right way to impose "failing for U(1)" is as "θ does not become small with an area exponent as L grows".

06

What this form imposes on the band

(7) is a statement that joins the two sides of the band. At small L (the regime of a dilute gas of fractional instantons), $\ln(1/\theta)$ is expected to grow as the product of the string tension $\propto \Lambda^2(\Lambda L)^{5/3}$ and the area of the container (26-03); at large L (the confinement regime) it is expected to take the form σL^2 minus the logarithm of the entropy of the position of the vortex sheet Reading (physics). (7) asks that the region in between — $L \sim 1/\Lambda$ — be passed with a single constant c.

Two intermediate goals weaker than (7) can also be named.

- (a) $F_v(L, L) \to 0$: excluding a non-confining phase. Stronger than the naive form, but gives no uniform lower bound on the tension.
- (b) $\ln(1/\theta(L, L)) \geq cL^2/\ln L$: almost area law. In the form of the Tension Lower Bound from the Naive Form, the lower bound on the tension is $c/\ln L$, still not uniform.

Both are unsolved.

The conclusion of this chapter also changes the standing of the tools of Part 25. The flow lemma $\theta \leq 1 - a$ (25-06) gives only an estimate of the form $\theta_0 \sim \frac{1}{2}$ — the naive

form (3) — because the flip probability a of a one-step kernel can be at most of order $\frac{1}{2}$. So that tool cannot be used to test the band; its use is limited to supporting a lower bound on the slab tension at fixed L Proved here .

In the next chapter, 26-02, we reduce (7) to a single inequality that fixes the container and widens only the transverse torus.

07

The table of the five grades and the dependency graph

Table 2 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	The container estimate (2)	Cited	Mack–Petkova, 25-03	The ensemble summed over twists	—
2	Frame decorrelation (the product in (2) splits up to a constant C_{D})	Assumption	A-06	—	—
3	Tension Lower Bound from the Naive Form: the lower bound on the tension that the container estimate gives from the naive form is $\ln(1/\theta_0)/L^2 \to 0$	Proved here	Proof in § 02	Under frame decorrelation, loops with side a multiple of L	—
4	Weakly coupled four-dimensional U(1) does not confine	Cited	Guth, Fröhlich–Spencer (5-06)	Villain-type action	—

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. Of the conclusion nodes of this chapter, the ones that stand on paper are four: the Tension Lower Bound from the Naive Form, the Tension Lower Bound from Tomboulis–Yaffe, the Area Law from the Area Exponent,

and the Flow Lemma's estimate; all are elementary manipulations on an assumption row (frame decorrelation) or a literature row (the Tomboulis–Yaffe inequality). The whole of "the naive form is not enough" has an estimate row (the count for the Coulomb phase of U(1)) as a premise, so it is "Reading (physics)". There is no node for the correct form (7) itself. That is the statement of the band, and this chapter does not show it.

What this chapter can say

What is said	What is not said
Proved here The lower bound on the tension that the container estimate gives from the naive form is $\ln(1/\theta_0)/L^2$ and goes to 0 (under frame decorrelation). With the area-exponent form the tension is uniform (under the same assumption)	Frame decorrelation itself. The correct form (7)

Terms used in this chapter — container, sector, frame, the sector bias θ, the naive form, the correct form (an area exponent), the vortex free energy F_v, the 't Hooft string tension, frame decorrelation, touchstone. Their meanings are in A-02 Glossary and A-06 Index of names.

Next chapter: 26-02 Reduction to a single inequality — the correct form, as a single inequality that widens the transverse directions.

Reduction to a single inequality

> This chapter is this book's own investigation. § 08 is a map of open questions.

What this chapter shows — The conditional reduction theorem, which derives the correct form of the band $\ln(1/\theta(L,L)) \geq cL^2$ (26-01) under three assumptions — the small-T² base point, frame decorrelation and the lateral-widening inequality — and its proof. Alternating between nesting, which widens the container in the directions of the plane, and an inequality that fixes the container and widens the transverse T^2, we obtain decay with an area exponent from the fact that the sequence of biases t_k satisfies $t_{k+1} \leq Kt_k^4$ (the doubling iteration). We also look at the strong and weak forms of the lateral-widening inequality, at the fact that the strong form is stronger than confinement (it includes monotonicity of the slab tension), and at why we state things restricted to scales $L \geq L_{\min}(a)$ free of lattice artefacts.

Prerequisite chapters — 26-01 (notation, the container estimate, the Area Law from the Area Exponent), 25-03 (nesting of containers), 25-04 (slab confinement), A-04 (Lean).

Said first — The Conditional Reduction Theorem and the Reduction Theorem in the Weak Form are conditional, and none of the three assumptions has been shown. In particular the lateral-widening inequality is the only place in this reduction where non-abelian dynamics enters, and the difficulty of the band has only moved there. The conclusion is a statement on the dyadic sequence of scales $R_k = 2^k R_0$, and whether the constants are uniform in the lattice spacing a is decided by whether the constants of the assumptions are uniform. What was checked in Lean is only the real-number algebra of the iteration.

The order of this chapter

1. Two moves — nesting in the directions of the plane, and widening the transverse T^2
2. Three assumptions — the base point, frame decorrelation, the lateral-widening inequality (strong form, weak form)
3. The Conditional Reduction Theorem and its proof
4. The Reduction Theorem in the Weak Form, and what replaces the jump step

5. The strong form of the lateral-widening inequality is stronger than confinement — monotonicity of the slab tension
6. Lattice artefacts and $L_{\min}(a)$
7. Reading the Lean statements — Doubling (`Doubling.iterate`, `Doubling.decay`)
8. What remains
9. The table of the five grades and the dependency graph

01

Two moves — nesting in the directions of the plane, and widening the transverse T^2

The notation is as in 26-01 § 01. $\theta(R;T^2_L)$ is the sector bias at a typical frame of the container $D_R \times T^2_L$ of size R in the directions of the plane, and we write $\theta(R,R) := \theta(R;T^2_R)$. The goal is, for some $c>0$ uniform in physical units,

$$\ln \frac{1}{\theta(R,R)} \;\geq\; c\,R^2 \qquad (1)$$

There are two moves that change $\theta(R;T^2_L)$.

Nesting in the directions of the plane. Keeping T^2_L fixed, split a large container R by an interior frame Φ_{int} into small containers $R_1,\dots,R_k$; conditioned on the frame, the small containers are independent, so

$$\big|\mathbb{E}[\sigma_R \mid \Phi_R]\big| \;\leq\; \mathbb{E}\Big[\prod_i \theta_{R_i} \;\Big|\; \Phi_R\Big] \qquad (2)$$

holds (the nested form of the Mack–Petkova container identity Cited , 25-03). If the container is enlarged s times, the right-hand side is a product of s^2 factors. If the factors are close to their typical value and nearly independent of each other, $\theta(sR;T^2_L) \approx \theta(R;T^2_L)^{s^2}$, and the disorder propagates to large scales. But this is a matter inside a slab with T^2 fixed, and it has the same content as slab confinement (25-04).

Widening the transverse T^2. (1) asks that the container and the transverse torus be enlarged *together*. Nesting does not change T^2, so it alone does not reach (1). Replacing T^2_L by $T^2_{L'}$ changes the very surface that the vortex sheet wraps, and a relation connecting containers at the two scales does not come out of structure (26-04). Setting this relation as an assumption is the lateral-widening inequality of the next section.

02

Three assumptions

We call the assumptions by name. All lengths are in physical units and at least $L_{\min}(a)$, where lattice artefacts can be neglected (§ 06).

The base point at small T^2 Assumption For some physical $L_0 \geq L_{\min}(a)$ and $\varepsilon_0 \in (0,1)$,

$$\theta(L_0; T^2_{L_0}) \;\leq\; 1-\varepsilon_0. \tag{3}$$

In the estimate of a dilute gas of fractional instantons, $\varepsilon_0 \propto (L_0\Lambda)^{11/3}$ (25-02). A line of showing it under ultraviolet control and uniform acceptance of insertions has been considered, but it has not been shown.

Frame decorrelation Assumption There is a constant $C_{\mathrm{D}} \geq 1$ such that for all R, L and integers $s \geq 1$,

$$\theta(sR; T^2_L) \;\leq\; C_{\mathrm{D}}\, \theta(R; T^2_L)^{s^2}. \tag{4}$$

The right-hand side of (2) is the average of a product of factors that share a frame, and Hölder's inequality alone loses the power (only the form $\mathbb{E}\theta^4_{2R} \leq \mathbb{E}\theta^4_R$ comes out). (4) is the assumption that this product splits, up to a constant, into the product of typical values. If L is fixed, it can be replaced, under reflection positivity of z, by the chessboard density κ_{cb} (26-05). Read in terms of κ_{cb}, the power in the nesting holds with constant 1 for all L (the Nested Supermultiplicativity Lemma of 26-05, and the Reduction Read in the Chessboard Density in § 03). The form uniform in L with θ as it is remains open.

The lateral-widening inequality (strong form) Assumption There is a constant C such that for $L_{\min}(a) \leq L \leq L' \leq R$,

$$\theta(R; T^2_{L'}) \;\leq\; C\Big(\frac{L'}{L}\Big)^2\, \theta(R; T^2_L). \tag{5}$$

It is the statement that, even if the container is fixed and the transverse T^2 is widened by a factor $s = L'/L$, the bias grows by at most a factor Cs^2. The factor s^2 is the entropy of the transverse position of the vortex sheet. Setting $L' = L$, we need $C \geq 1$ (if $\theta > 0$).

The lateral-widening inequality (weak form) Assumption For the dyadic scales $R_k = 2^k R_0$, there are $0 \leq \varepsilon_k < 1$ with $\sum_k \varepsilon_k < \infty$ and a constant $C' \geq 0$ such that

$$\ln \frac{1}{\theta(R_{k+1}; T^2_{R_{k+1}})} \;\geq\; (1-\varepsilon_k)\, \ln \frac{1}{\theta(R_{k+1}; T^2_{R_k})} \;-\; C'. \tag{6}$$

It is the statement that at each step of doubling the transverse directions one may lose a fraction ε_k of $\ln(1/\theta)$ and a constant C', provided the sum of the fractions lost is finite. The strong form (5) at $s = 2$ loses only the constant $\ln(4C)$ from $\ln(1/\theta)$, so it is the case $\varepsilon_k = 0$ of (6).

03

The conditional reduction theorem

Conditional Reduction Theorem Proved here Assume the base point at small T^2, frame decorrelation and the lateral-widening inequality (strong form). Set $K := 4C\,C_{\mathrm{D}}$ (≥ 1), and choose an integer $s \geq 1$ so that

$$t_0 \;:=\; C\,C_{\mathrm{D}}\,s^2(1-\varepsilon_0)^{s^2} \;<\; K^{-1/3} \quad (7)$$

(this is possible because $s^2(1-\varepsilon_0)^{s^2} \to 0$). Setting $R_0 := sL_0$ and $R_k := 2^k R_0$, for all $k \geq 0$

$$\theta(R_k, R_k) \;\leq\; K^{-1/3}\big(K^{1/3}t_0\big)^{4^k}, \qquad \text{in particular} \qquad \ln\frac{1}{\theta(R_k,R_k)} \;\geq\; \gamma\,R_k^2, \quad \gamma := \frac{\ln(1}$$

Moreover, under frame decorrelation, by the Area Law from the Area Exponent in 26-01, for square loops on the slab $T^2_{R_k} \times \mathbb{R}^2$ with side a multiple of R_k, $|\langle W(C)\rangle| \leq C_{\mathrm{D}} e^{-\gamma A}$. The lower bound γ on the tension does not depend on k.

Proof In three steps.

Step 1 (jump). Using frame decorrelation with $R = L = L_0$ and s, and putting in the base point at small T^2, gives $\theta(sL_0; T^2_{L_0}) \leq C_{\mathrm{D}}(1-\varepsilon_0)^{s^2}$. Next, using the lateral-widening inequality (strong form) with $L = L_0$ and $L' = R = sL_0$,

$$t_0' \;:=\; \theta(R_0,R_0) \;=\; \theta(sL_0; T^2_{sL_0}) \;\leq\; C\,s^2 \cdot C_{\mathrm{D}}(1-\varepsilon_0)^{s^2} \;=\; t_0.$$

Step 2 (one doubling). Set $t_k := \theta(R_k, R_k)$. Using frame decorrelation with $R = L = R_k$ and $s = 2$ gives $\theta(2R_k; T^2_{R_k}) \leq C_{\mathrm{D}} t_k^4$. Using the lateral-widening inequality (strong form) with $L = R_k$ and $L' = R = 2R_k$,

$$t_{k+1} \;=\; \theta(2R_k; T^2_{2R_k}) \;\leq\; 4C \cdot C_{\mathrm{D}}\,t_k^4 \;=\; K\,t_k^4. \quad (9)$$

Step 3 (iteration). Setting $c := K^{1/3} \geq 1$, (9) becomes $t_{k+1} \leq c^3 t_k^4$. Multiplying both sides by c gives $ct_{k+1} \leq (ct_k)^4$, so by induction $ct_k \leq (ct_0')^{4^k} \leq (ct_0)^{4^k}$ (using $0 \leq ct_0' \leq ct_0$). Hence $t_k \leq c^{-1}(ct_0)^{4^k}$. From $4^k = R_k^2/R_0^2$, $ct_0 < 1$ and $c \geq 1$,

$$\ln\frac{1}{t_k} \;\geq\; 4^k \ln\frac{1}{ct_0} + \ln c \;\geq\; \frac{\ln(1/(ct_0))}{R_0^2}\, R_k^2 \;=\; \gamma R_k^2.$$

For the last claim, take $L = R_k$ in the Area Law from the Area Exponent and replace e^{-cL^2} by $e^{-\gamma R_k^2}$. ∎

The algebra of the iteration in step 3 — from $t_{k+1} \leq c^3 t_k^4$ to $ct_k \leq (ct_0)^{4^k}$ and $t_k \leq (ct_0)^{4^k}/c$ — is checked in Lean (§ 07).

What the Conditional Reduction Theorem does not say.

- The conclusion is a statement on the dyadic sequence R_k. Extending it to the scales in between, $R_k < R < R_{k+1}$, needs an additional property such as monotonicity of $\theta(R, R)$ in R, which we do not assume here.
- The constant γ is uniform in the lattice spacing a only when the constants $\varepsilon_0, C_{\mathrm{D}}, C$ of the base point at small T^2, frame decorrelation and the lateral-widening inequality (strong form), and L_0, are uniform in a.
- Frame decorrelation is used in two places — the power in the nesting (steps 1 and 2) and the bridge from the bias to the Wilson loop (the Area Law from the Area Exponent).
- The meaning of "typical frame" is put inside frame decorrelation. We have not used a form that treats the tail of the distribution of frames (the rarity of bad frames) separately.

Note (the global version). If the same chain is written with the ratio of twisted partition functions on the torus $T_L^2 \times T_M^2$ ((8) of 26-01) instead of θ conditioned on the frame, the bridge to the area law is carried by the Tomboulis–Yaffe inequality (the Tension Lower Bound from Tomboulis–Yaffe in 26-01), and frame decorrelation is not needed. In exchange, the base point at small T^2 must also be shown for the global partition functions — as a lower bound saying that vortices are *cheap*. This is also open.

Reduction Read in the Chessboard Density (the reduction read in terms of κ_{cb}) Proved here For the $\kappa_{\mathrm{cb}}(R; L)$ of 26-05 (the density with the container taken to be the whole interior of the block; M fixed to a multiple of all the $2R_k$ of the steps considered), assume

$$\begin{aligned}
&(\mathrm{A_{cb}}) \quad \kappa_{\mathrm{cb}}(L_0; L_0) \leq 1 - \varepsilon_0, \\
&(\mathrm{C_{cb}}) \quad \kappa_{\mathrm{cb}}(R; L') \leq C\,(L'/L)^2\, \kappa_{\mathrm{cb}}(R; L) \quad (L_{\min}(a) \leq L \leq L' \leq R)
\end{aligned}$$

The formula label $(\mathrm{A_{cb}})$ is the chessboard-density base point, $(\mathrm{C_{cb}})$ is the lateral comparison of the chessboard density, and $(\mathrm{B_0})$ below is the base-point translation

inequality (names as in A-06). If the Nested Supermultiplicativity Lemma of 26-05 ($\kappa_{\mathrm{cb}}(sR;L) \le \kappa_{\mathrm{cb}}(R;L)^{s^2}$, constant 1, all L) is used in place of frame decorrelation, the proof of the Conditional Reduction Theorem goes through as it is with $C_{\mathrm{D}} = 1$, $K = 4C$, $t_0 = C\,s^2(1-\varepsilon_0)^{s^2} < K^{-1/3}$, and $t_k := \kappa_{\mathrm{cb}}(R_k;R_k) \le K^{-1/3}(K^{1/3}t_0)^{4^k}$. The step down to loops is made directly by (5) of 26-05, so the C_{D} of the Area Law from the Area Exponent is not needed either. Step 3 is the same algebra as Doubling.iterate, and the doubling form is Lean: LatticeGaugeNestedBlocks (doubling_iterate, doubling_bound). In this form frame decorrelation does not remain as an independent assumption, and the content uniform in L goes into $(\mathrm{C}_{\mathrm{cb}})$. If the base point at small T^2 is kept with θ as it is, adding the single-scale line

$$(\mathrm{B}_0)\quad 1-\kappa_{\mathrm{cb}}(L_0;L_0) \;\ge\; \eta\,\big(1-\theta(L_0;L_0)\big) \quad (\eta>0 \text{ uniform in } a\ )$$

gives $(\mathrm{A}_{\mathrm{cb}})$ with $\varepsilon_0 \to \eta\varepsilon_0$ Proved here . None of $(\mathrm{A}_{\mathrm{cb}})$, $(\mathrm{C}_{\mathrm{cb}})$, (B_0) has been shown Assumption .

04

Reduction with the weak form

Even with the weak form (6), the iteration keeps the area exponent. But the jump step cannot be made with the weak form, so the base point has to be set sufficiently small at one scale.

Reduction Theorem in the Weak Form Proved here Assume frame decorrelation, and the lateral-widening inequality (weak form) on the dyadic sequence $R_k = 2^k R_0$, and set $P := \prod_k(1-\varepsilon_k) > 0$, $A := \ln C_{\mathrm{D}} + C'$, $u_k := \ln(1/\theta(R_k,R_k))$. If $u_0 > A/(3P)$, then for all k

$$u_k \;\ge\; \Big(P\,u_0 - \frac{A}{3}\Big)4^k \;=\; \gamma'\,R_k^2, \qquad \gamma' := \frac{Pu_0 - A/3}{R_0^2} > 0. \tag{10}$$

Proof Using frame decorrelation with $s=2$ gives $\ln(1/\theta(R_{k+1};T_{R_k}^2)) \ge 4u_k - \ln C_{\mathrm{D}}$. Putting this into (6) and using $0 \le 1-\varepsilon_k \le 1$ and $\ln C_{\mathrm{D}} \ge 0$ gives $u_{k+1} \ge (1-\varepsilon_k)(4u_k - \ln C_{\mathrm{D}}) - C' \ge 4(1-\varepsilon_k)u_k - A$. Setting $v_k := u_k/4^k$, $v_{k+1} \ge (1-\varepsilon_k)v_k - A\,4^{-(k+1)}$. For $P_k := \prod_{i<k}(1-\varepsilon_i)$ and $S_k := \sum_{j=1}^{k} 4^{-j}$ we show $v_k \ge P_k v_0 - A S_k$ by induction: for $k=0$ it is an equality. If it holds for k, then from $AS_k \ge 0$ and $1-\varepsilon_k \le 1$, $v_{k+1} \ge (1-\varepsilon_k)P_k v_0 - AS_k - A4^{-(k+1)} = P_{k+1}v_0 - AS_{k+1}$. From $v_0 = u_0 > 0$, $P_k \ge P$ and $S_k < 1/3$, $v_k \ge Pu_0 - A/3$. ∎

The strong form is the case $\varepsilon_k = 0$ ($P=1$), $C' = \ln(4C)$, and the condition there, $u_0 > (\ln C_{\mathrm{D}} + \ln 4C)/3 = \ln K/3$, is the same condition as $t_0 < K^{-1/3}$ in the Conditional

Reduction Theorem. The condition on w_0 in the Reduction Theorem in the Weak Form moves the role that the jump step played in the Conditional Reduction Theorem onto the assumption of the base point.

05

The strong form of the lateral-widening inequality is stronger than confinement — monotonicity of the slab tension

We define the string tension of the two-dimensional theory obtained by shrinking the transverse directions to T_L^2 (the slab tension) as

$$\sigma_{\mathrm{eff}}(L) \;:=\; \liminf_{M\to\infty} \frac{-\ln\theta(M;T_L^2)}{M^2} \quad (11)$$

The uniform slab tension ((1) of 26-00) is $\inf_L \sigma_{\mathrm{eff}}(L) > 0$.

Slab-Tension Monotonicity Proposition Proved here If the strong form (5) holds for all $R \geq L'$, then $\sigma_{\mathrm{eff}}(L') \geq \sigma_{\mathrm{eff}}(L)$ for $L_{\min}(a) \leq L \leq L'$.

Proof For $M \geq L'$, taking the logarithm of (5) gives $-\ln\theta(M;T_{L'}^2) \geq -\ln\theta(M;T_L^2) - \ln\bigl(C(L'/L)^2\bigr)$. Dividing by M^2 and taking the lower limit as $M\to\infty$, the constant term vanishes and $\sigma_{\mathrm{eff}}(L') \geq \sigma_{\mathrm{eff}}(L)$. ∎

So the strong form includes that the slab tension does **not decrease** in L. Confinement (the area law) needs only $\inf_L \sigma_{\mathrm{eff}}(L) > 0$, so the strong form is a stronger assumption than confinement. At small L the tension is expected to grow as $\sigma_{\mathrm{eff}} \propto \Lambda^{11/3}L^{5/3}$, and at large L to approach the tension σ_∞ of $\mathbb{R}^4$ Reading (physics); but if at $L \sim 1/\Lambda$, σ_{eff} goes once above σ_∞ and then comes back (overshoots), the strong form with constant C is false, while confinement can still hold. The weak form allows this kind of overshoot, as long as the sum of the fractions lost is finite.

On the numerical side, on the slab with $SU(2)$, $\beta = 2.5$, $M = 16$, the Creutz ratio of the 4×4 loop is $0.059,\ 0.061,\ 0.076,\ 0.071$ for $N_T = 4, 6, 8, 10$ (errors 0.009–0.002, 2000 measurements): it increases and saturates, and no significant overshoot is seen Reading . The Creutz ratio contains the short-distance Coulomb term, so we read only the trend in N_T, not the values. The lattice is at a single β and the range of N_T is narrow, so this is not a reading about the band as a whole. The table of measurements is in 26-09.

The form that widens the transverse directions in one direction only (making T^2 a rectangle $L_1 \times L_2$ and enlarging only L_1) is expected not to be treatable in the same way as the square form, because the small direction of the two behaves like the time of

finite temperature Reading (physics). The chain of this chapter uses only the square form $L_1 = L_2$.

06

Lattice artefacts and $L_{\min}(a)$

We state (5) and (6) restricted to $L \geq L_{\min}(a)$, where lattice artefacts can be neglected. $L_{\min}(a)$ is kept constant in physical units, and in lattice units $L_{\min}/a \to \infty$. The goal of the band (1) is a statement about the continuum limit uniform in a, so this restriction is natural.

That the restriction is needed also shows in the numbers. For $SU(2)$, $\beta = 2.5$, $M = 8$, going $N_T = 2 \to 4$ changes the vortex free energy as $-0.01 \pm 0.12 \to 0.63 \pm 0.18$ and the bias as $\theta \lesssim 0.06 \to 0.31$, a ratio of about 5 Reading . This sits at the boundary, within errors, of the $Cs^2 = 4C$ that the strong form allows at $s = 2$. It can be read as follows: on the twisted $2 \times 2\ T^2$ with $N_T = 2$, the vortex enters cheaply as a thin vortex on the lattice rather than as a smooth fractional instanton, and the slab tension comes out large. The strong form cannot be tested with values from small lattices.

07

Reading the Lean statements — `Doubling.iterate`, `decay`

The algebra of step 3 of the Conditional Reduction Theorem is two theorems in the Lean 4 file `Doubling.lean` (namespace `Doubling`). We read the statements in the words of the text.

`Doubling.iterate`: for a real number c and a real sequence $t : \mathbb{N} \to \mathbb{R}$, under the assumptions $0 \leq c$, $0 \leq t_k$ for all k, and $t_{k+1} \leq c^3 t_k^4$ for all k, we have $c\,t_k \leq (c\,t_0)^{4^k}$ for all k.

`Doubling.decay`: under the assumptions $0 < c$, $0 \leq t_k$, $t_{k+1} \leq c^3 t_k^4$, we have $t_k \leq (c\,t_0)^{4^k}/c$ for all k.

The K of the text is c^3 in Lean. What machine checking guarantees is only the algebra of these real inequalities. That t_k is the sector bias, and that the recursion (9) holds — that is, the base point at small T^2, frame decorrelation and the lateral-widening inequality — lie outside Lean. The axioms of the two theorems are, in the record, the three standard ones (`propext`, `Classical.choice`, `Quot.sound`), and they have passed this book's re-check (A-04).

08

What remains

The Conditional Reduction Theorem reduced the correct form of the band to three assumptions. The three are different in character.

- **The base point at small T^2** is a statement on the weak-coupling side, and a line of showing it under ultraviolet control and uniform acceptance of insertion has been considered (Part 25, 27-02).
- **Frame decorrelation**, read in terms of κ_{cb}, holds with constant 1 for all L by the Nested Supermultiplicativity Lemma of 26-05, and does not remain as an independent assumption (the Reduction Read in the Chessboard Density in § 03). The content uniform in L moves to $(\mathrm{C}_{\mathrm{cb}})$, which is the lateral-widening inequality (strong form) read in terms of κ_{cb}. In exchange, the base point at small T^2 and the lateral-widening inequality (strong form) must be read in terms of κ_{cb} (or the single line (B_0) added).
- **The lateral-widening inequality** is the only place in this reduction where non-abelian dynamics enters. It fails for U(1) and $\mathbb{Z}_2$, and is expected to hold for SU(2) in the dilute regime with the margin $5/3 = 11/3 - 2$ (26-03, [Reading] physics). It does not follow from structural inputs alone, such as reflection positivity or duality (26-04).

What is open is to show the strong form (or the weak form) of the lateral-widening inequality non-perturbatively through the region between the dilute regime and the confinement regime — $L \sim 1/\Lambda$. The difficulty of the band has gathered into this single inequality.

09

The table of the five grades and the dependency graph

Table 1 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	Nesting in the directions of the plane (2)	Cited	Mack–Petkova, 25-03	T^2 fixed	—
2	The base point at small T^2 (3)	Assumption	25-02, 27-02	$L_0 \geq L_{\min}(a)$	—
3	Frame decorrelation (4)	Assumption	26-05, A-06	Constant $C_{\mathrm{D}} \geq 1$	—
4	The lateral-widening inequality (strong form) (5)	Assumption	A-06	$L_{\min}(a) \leq L \leq L' \leq R$, square T^2	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
5	The lateral-widening inequality (weak form) (6)	Assumption	A-06	Dyadic sequence, $\sum \varepsilon_k < \infty$	—
6	The strong form is the case $\varepsilon_k = 0$, $C' = \ln 4C$ of the weak form	Proved here	§ 02	—	—
7	Iteration: if $t_{k+1} \le c^3 t_k^4$, then $ct_k \le (ct_0)^{4^k}$ and $t_k \le (ct_0)^{4^k}/c$	Proved here	§ 03 step 3	Real-number algebra	Doubling (`Doubling.iterate`) (assumptions: $0 \le c$, $0 \le t_k$, $t_{k+1} \le c^3 t_k^4$), Doubling (`Doubling.decay`) (assumptions: $0 < c$ and the same two)
8	Conditional Reduction Theorem: under the base point at small T^2, frame decorrelation and the lateral-widening inequality (strong form), $\ln(1/\theta(R_k, R_k)) \ge \gamma R_k^2$, and the area law on the slab	Proved here	Proof in § 03, the Area Law from the Area Exponent in 26-01	Under the three assumptions, dyadic sequence, $L \ge L_{\min}(a)$	— (only the iteration part; the iteration row of the table)
9	Reduction Theorem in the Weak Form: under frame decorrelation, the lateral-widening inequality (weak form) and $u_0 > A/(3P)$, $u_k \ge \gamma' R_k^2$	Proved here	Proof in § 04	Under the two assumptions and the condition on the size of the base point	—
10	Slab-Tension Monotonicity Proposition: under the strong form, σ_{eff} does not decrease in L	Proved here	Proof in § 05	$L \ge L_{\min}(a)$	—
11	σ_{eff} grows as $L^{5/3}$ at small L, and goes to σ_∞ at large L	Reading (physics)	§ 05, 26-03	Dilute regime, one loop / confinement regime	—
12	The Creutz ratio increases and saturates for $N_T = 4 \to 10$, no significant overshoot	Reading	§ 05, 26-09	SU(2), $\beta = 2.5$, $M = 16$, 2000 measurements, trend only	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
13	For $N_T = 2 \to 4$ the ratio of biases is about 5	Reading	§ 06	SU(2), $\beta = 2.5$, $M = 8$, at the boundary within errors	—
14	The lateral-widening inequality must be stated restricted to $L \geq L_{\min}(a)$	Reading (physics)	§ 06	Lattice artefacts on a small T^2	—
15	The lateral-widening inequality (strong form) fails for U(1) and $\mathbb{Z}_2$, with margin $5/3$ for dilute SU(2)	Reading (physics)	26-03	Dilute regime, one loop. "Within this reduction"	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  CIT  nesting in the directions of the plane (2)            T² fixed
 2  ASM  base point at small T² θ(L₀;T²_L₀) ≤ 1 − ε₀

15  RDG  lateral widening fails for U(1), Z₂; margin 5/3 for dilute SU(2)   26
```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The premises of the nodes of the two reduction theorems always include assumption rows (the base point at small T^2, frame decorrelation, the two forms of the lateral-widening inequality). The assumption rows do not contain the quantity of the conclusion (the area exponent of $\theta(R_k, R_k)$): the base point at small T^2 is a statement at one small scale, frame decorrelation a statement of nesting with T^2 fixed, and the lateral-widening inequality (strong form) a statement of comparison with the container fixed. The numerical rows (the Creutz ratio on the slab, the ratio of biases) and the estimate rows (the shape of the slab tension, the failure depending on the group) are premises of no theorem.

What this chapter can say

What is said	What is not said
Proved here Under the three of base point, frame decorrelation and the lateral-widening inequality (strong form), $\ln(1/\theta(R_k, R_k)) \geq \gamma R_k^2$ on the dyadic sequence of scales, and a tension on the slab independent of k (the Conditional Reduction Theorem)	Any of the three assumptions. The scales in between. Uniformity of the constants in a (it depends on the constants of the assumptions)
Proved here With the weak form too, the same conclusion if the base point is small enough at one scale (the Reduction Theorem in the Weak Form)	The weak form itself. A jump from the weak form alone
Proved here The strong form includes monotonicity of the slab tension and is stronger than confinement (the Slab-Tension Monotonicity Proposition)	That the slab tension does not overshoot
Reading The Creutz ratio on the slab increases and saturates. On a small T^2, lattice artefacts touch the boundary of the strong form	The behaviour of the slab tension across the whole band. Values on large lattices
Lean: the real-number algebra of the iteration (Doubling (`Doubling.iterate`, `Doubling.decay`))	That the bias satisfies the recursion (outside Lean)

Terms used in this chapter — nesting in the directions of the plane, the lateral-widening inequality (strong form, weak form), the base point at small T^2, frame decorrelation, the doubling iteration, jump, the slab tension σ_{eff}, overshoot, the scale of lattice artefacts $L_{\min}(a)$. Their meanings are in A-02 Glossary and A-06 Index of names.

Next chapter: 26-03 The only place where non-abelian enters — the $5/3 = 11/3 - 2$ that decides the sign of the lateral-widening inequality.

The only place where non-abelian enters

> This chapter is this book's own investigation. The established knowledge it builds on is in 25-02 and 3-05.

What this chapter shows — Where non-abelian dynamics enters within the reduction of 26-02. Of the three assumptions (the small-T^2 base point, frame decorrelation, the lateral-widening inequality) and the nesting inequality, only the lateral-widening inequality fails for U(1) and $\mathbb{Z}_2$, and we see that what fixes its sign is the exponent margin in the dilute regime $5/3 = 11/3 - 2$ — the margin by which the coefficient of asymptotic freedom $11/3$ beats the 2 of the number of positions of a lump in the plane (the transverse two-dimensional entropy). For contrast we set side by side that abelian flux can only spread out uniformly, so that the vortex free energy of U(1) increases when T^2 is widened, and that a vortex of $SU(2)$ can localise in a scale-invariant self-dual lump.

Prerequisite chapters — 26-01 (the sector bias θ, the U(1) count), 26-02 (the three assumptions and the Conditional Reduction Theorem), 25-02 (vortices and fractional instantons), 3-05 (instantons and the Bogomolny bound), 4-06 (asymptotic freedom), 5-06 (U(1) and the non-abelian).

Said first — The "only place" of the title is a way of speaking **within this reduction**. In another reduction (the renormalisation comparison of 26-06), the non-abelian input enters a place of a different form. The counts of the behaviour of U(1), $\mathbb{Z}_2$ and $SU(2)$ are counts that the original paper itself states to be estimates, and in this chapter too they carry the label [Reading] (physics). We say nothing outside the dilute regime and one loop. The propositions set out on paper are only an elementary lemma that flux spreads out uniformly, and arrangements of logic.

The order of this chapter

1. The question — what fixes the sign of the lateral-widening inequality
2. Abelian flux can only spread out uniformly — the Flux-Equalisation Lemma and the counts for U(1) and $\mathbb{Z}_2$
3. A non-abelian vortex can localise in a scale-invariant lump — the self-dual lump with $Q = \frac{1}{2}$
4. The margin $5/3 = 11/3 - 2$ — the count for a dilute gas and the Tanizaki–Ünsal formula
5. The only place "within this reduction" — the Contrapositive of the Reduction, and its limits
6. Numerical signs — the vortex free energy when T^2 is widened (Table 2)
7. The table of the five grades and the dependency graph

01

The question — what fixes the sign of the lateral-widening inequality

The notation is as in 26-01 § 01 and 26-02 § 01. $\theta(R;T^2_L)$ is the sector bias, in a typical frame, of the container $D\times T^2_L$ of size R in the planar directions (area A_D), with the twist $n_{12}=1$ fixed on the transverse torus T^2_L (area $A_T=L^2$). The Conditional Reduction Theorem of 26-02 derived the correct form of the band, $\ln(1/\theta(R,R))\geq cR^2$, from three assumptions. The third of them was the lateral-widening inequality (strong form)

$$\theta(R;T^2_{L'})\;\leq\;C\Big(\frac{L'}{L}\Big)^2\,\theta(R;T^2_L)\qquad(L_{\min}(a)\leq L\leq L'\leq R)\tag{1}$$

If we widen the transverse T^2 while keeping the container fixed, which way does the sector bias θ move? The smaller θ is, the greater the disorder of the sector (the more vortices), so the question is whether widening the transverse directions makes vortices **costlier** (θ moves towards 1) or **not costlier**. Even if they become costlier, (1) allows it only up to the factor s^2 of the number of positions ($s=L'/L$).

We write the answer of this chapter first. In an abelian theory the flux of a vortex can only spread out uniformly over the whole transverse cross-section, so the wider the transverse directions, the costlier the vortex, and (1) fails. In $SU(2)$ a vortex can localise in a self-dual lump of size about L, and its action does not depend on the size, so classically the cost of widening the transverse directions is 0. The remaining quantum effects lean, in the dilute regime, to the side of asymptotic freedom, and (1) is expected to hold with margin $5/3$.

02

Abelian flux can only spread out uniformly

First we set out one elementary fact about the classical action.

Flux-Equalisation Lemma Proved here Let Ω be a planar region of area $|\Omega|$, and f a square-integrable real function on Ω with $\int_\Omega f=\Phi$. Then

$$\int_\Omega f^2\;\geq\;\frac{\Phi^2}{|\Omega|},\tag{2}$$

with equality only when f is almost everywhere equal to the constant $\Phi/|\Omega|$ on Ω.

Proof (2) follows from the Cauchy–Schwarz inequality $\big(\int_\Omega f\cdot 1\big)^2\leq\int_\Omega f^2\cdot\int_\Omega 1$. Equality holds only when f and 1 are proportional, that is, only when f is constant. ∎

The action of an abelian gauge field, $\frac{1}{2e^2}\int F_{\mu\nu}F_{\mu\nu}$, is the square of the field strength: a linear field theory. Consider a configuration in which the same flux Φ passes through each cross-section $D\times\{y\}$ ($y\in T^2_L$) of the container $D\times T^2_L$. Using the Flux-Equalisation Lemma on each cross-section and integrating over the transverse T^2_L, we get

$$\frac{1}{2e^2}\int_{D\times T^2_L}F_{34}^2\;\geq\;\frac{A_T}{2e^2A_D}\,\Phi^2\tag{3}$$

Proved here (under the condition that the flux through each cross-section is the same Φ; a lower bound on the classical action). Equality holds for the configuration in which the flux spreads out uniformly over the whole container, and **localising the flux only increases the action**. The right-hand side is proportional to the transverse area A_T, so if we fix the container and widen the transverse directions by a factor s, the minimal action of the flux π (corresponding to the sector $\sigma_D = -1$) becomes s^2 times larger. An abelian vortex becomes costlier when the transverse directions are widened: that is the answer at the classical level.

The count at the quantum level is as in 26-01 § 03 Reading (physics). Seen at long distance on the slab $T^2_L \times \mathbb{R}^2$, U(1) in the Coulomb phase is a two-dimensional U(1) (coupling e^2/A_T), and the partition function with flux Φ is the Poisson sum over wrappings k, $Z(\Phi) \propto \sum_k e^{ik\Phi} e^{-e^2 A_D k^2/(2A_T)}$. This is the sum over k of the classical action $\frac{A_T}{2e^2 A_D}(\Phi + 2\pi k)^2$ of (3), rewritten with the Poisson summation formula, and when $q := e^{-e^2 A_D/(2A_T)}$ is small

$$\theta(R; T^2_L) \;\approx\; 2q \;=\; 2\exp\Big(-\frac{e^2 A_D}{2A_T}\Big), \qquad \ln\frac{1}{\theta} \;\approx\; \frac{e^2 A_D}{2A_T} \;\propto\; A_D\, L^{-2}. \tag{4}$$

If the transverse directions are widened by a factor s, A_T becomes s^2 times larger and q becomes q^{1/s^2}, so $\theta_{\text{new}} \approx 2(\theta_{\text{old}}/2)^{1/s^2}$. The ratio is

$$\frac{\theta(R; T^2_{sL})}{\theta(R; T^2_L)} \;\approx\; 2^{\,1-1/s^2}\, \theta(R; T^2_L)^{-(1-1/s^2)} \;\longrightarrow\; \infty \qquad (\theta(R; T^2_L) \to 0,\ s > 1) \tag{5}$$

and it cannot be bounded by any constant Cs^2. **For U(1), the lateral-widening inequality (1) fails** Reading (physics; one line of algebra once (4) is granted). The weak form (the lateral-widening inequality (weak form) of 26-02) also fails, because the slab tension goes to 0 like e^2/L^2 Reading (physics).

The four-dimensional $\mathbb{Z}_2$ theory is, at weak coupling (large β), in a non-confining phase (5-10). There the flux through the container creates a wall of area A_T spanning the whole transverse T^2, and its tension does not depend on A_D. Widening the transverse directions increases the cost of the wall in proportion to A_T, and (1) fails Reading (physics). What the two abelian theories have in common is that **the cost of the flux increases with the transverse area**: in U(1) because of linearity (the Flux-Equalisation Lemma), in $\mathbb{Z}_2$ because of the area of the wall.

03

A non-abelian vortex can localise in a scale-invariant lump

In $SU(2)$ things change. On $T^2_L \times \mathbb{R}^2$ with the twist $n_{12} = 1$, the topological charge Q can take half-integer values ('t Hooft's twist, 25-01 Cited). And the action has the Bogomolny bound

$$S \;\geq\; \frac{8\pi^2}{g^2}\,|Q| \tag{6}$$

(3-05 Cited), with equality for self-dual (or anti-self-dual) configurations. A configuration with $Q = \frac{1}{2}$ — a fractional instanton — has action at least $4\pi^2/g^2$, and plays the role of a vortex that flips the planar sector (25-02).

The right-hand side of (6) depends neither on the size L of T^2 nor on the size R of the container. This is because the classical action of four-dimensional Yang–Mills does not change under a change of scale (the coupling g is dimensionless, 24-07 § 01). The estimate of the original paper is that the minimal-action configuration with $Q = \frac{1}{2}$ is a self-dual lump localised in a region of size about L, whose action equals the bound $4\pi^2/g^2$ and does not depend on the ratio of the transverse and longitudinal sizes Reading (physics). On the lattice, it has been measured that the action of cooled fractional instantons approaches $\pi^2\beta$ from below (with $\beta = 4/g^2$, $4\pi^2/g^2 = \pi^2\beta$; the values obtained by cooling are upper bounds on the minimal action on the lattice) (the table in 25-02).

Here the difference from the Flux-Equalisation Lemma of § 02 becomes clear.

- **Abelian**: the action is a quadratic form, so the minimal action for a given flux is attained by the configuration that spreads the flux out uniformly, and its value is proportional to the transverse area A_T ((3)). Localising does not make it cheaper; one pays the cost over the whole region it is spread over.
- **Non-abelian**: the self-duality equations are non-linear, and a solution of finite action $4\pi^2/g^2$ can be localised to a size of about L. As long as the container is large enough to hold the lump ($R \geq L'$), widening the transverse directions from L to L' only requires re-spreading the lump, and the classical cost is 0.

This is not a difference of local kinematics, but a difference in the existence of solutions of the self-duality equations — in non-linearity. Since at the classical level the cost of lateral widening is 0, the sign of (1) is fixed by quantum effects: the number of positions of the vortices, and the running of the coupling. That is the count of the next section.

04

The margin $5/3 = 11/3 - 2$

The count for a dilute gas. For $L\Lambda \ll 1$ (Λ is the scale of dimensional transmutation, 4-07), the coupling $g(L)$ is small, and the vortices (lumps with $Q = \pm\frac{1}{2}$) can be treated as a dilute gas, far apart from one another. For $SU(N)$, Tanizaki–Ünsal derived the ground-state energy and the string tension from the facts that on a small twisted T^2 the centre vortices behave like points on the plane $\mathbb{R}^2$ and that the weight of each is $Ke^{-SI/N}$ ($S_I = 8\pi^2/g^2$, with K the prefactor per unit area):

$$E_k(\theta) \;=\; -2Ke^{-SI/N}\cos\frac{\theta - 2\pi k}{N} \;\sim\; -\Lambda^2(\Lambda L)^{5/3}\cos\frac{\theta - 2\pi k}{N}, \qquad T_R \;\sim\; \Lambda^2(\Lambda L)^{5/3}\sin^2\frac{\pi|R|}{N} \quad (\theta =$$

(Tanizaki–Ünsal, eqs. (2.32) and (2.37) Cited , dilute regime, one loop). The θ here is the vacuum angle, a symbol different from this book's sector bias θ. The exponent $5/3$ comes out as follows: from the one-loop running of the coupling $8\pi^2/g^2(L) = \frac{11N}{3}\ln\frac{1}{L\Lambda}$ (4-06 Cited) we get $e^{-SI/N} = (L\Lambda)^{11/3}$, and from the size L of a lump the number of positions per unit area is $1/L^2$, so $(L\Lambda)^{11/3}/L^2 = \Lambda^2(\Lambda L)^{5/3}$.

We move on to the sector bias. In $SU(2)$, let ζ be the density per unit area of vortices and antivortices together, and approximate the positions of the vortices by independent Poisson points Reading (physics; the dilute-gas approximation). The sector σ_D of the container is $(-1)^n$ for the number n of vortices inside D. For n in a Poisson distribution with mean m,

$$\mathbb{E}\big[(-1)^n\big] \;=\; \sum_{n\ge 0} e^{-m}\frac{m^n}{n!}(-1)^n \;=\; e^{-2m} \qquad (8)$$

so Proved here (an elementary identity), putting $m = \zeta A D$,

$$\theta(R;T_L^2) \;\approx\; e^{-2\zeta A D}, \qquad \ln\frac{1}{\theta} \;\approx\; 2\zeta A D \;\propto\; A D\,\Lambda^{11/3}L^{5/3} \qquad (\Lambda \text{ fixed}) \qquad (9)$$

Reading (physics; dilute regime, one loop). Set beside (4), the power in L of $\ln(1/\theta)$ with the container fixed is as follows.

Table 1 The power in L of $\ln(1/\theta)$ with the container fixed (estimates; four dimensions, weak-coupling side)

Theory	Form of the vortex cost	Power of $\ln(1/\theta)$	On widening the transverse directions	Lateral-widening inequality (1)
$U(1)$ (Coulomb phase)	The flux spreads out uniformly over the transverse cross-section (the Flux-Equalisation Lemma)	L^{-2}	θ moves towards 1	Fails ((5))
$\mathbb{Z}_2$ (weak coupling)	A wall of area A_T	— (with the wall cost $\propto L^2$, $\theta \to 1$)	θ moves towards 1	Fails
$SU(2)$ (dilute regime)	A self-dual lump of size L, weight $(L\Lambda)^{11/3}$, density of positions $1/L^2$	$L^{+5/3} = L^{11/3-2}$	θ decreases	Holds (the ratio is at most 1)

The power $5/3$ for $SU(2)$ is the difference between the coefficient of asymptotic freedom $11/3$ and the 2 of the number of positions of a lump in the plane (what this part has been calling "the transverse two-dimensional entropy", Figure 2 of 26-00). The power -2 for U(1) can be read as the form in which there is no asymptotic-freedom term and only the term of the number of positions remains. **The margin $5/3 > 0$ by which asymptotic freedom beats the transverse two-dimensional entropy is the sign of the lateral-widening inequality itself** Reading (physics).

From (9), the ratio when the transverse directions are widened by a factor s in $SU(2)$ in the dilute regime is

$$\frac{\theta(R;T_{sL}^2)}{\theta(R;T_L^2)} \;\approx\; \exp\Big(-2A D\big(\zeta(sL)-\zeta(L)\big)\Big) \;\le\; 1 \qquad (10)$$

($\zeta \propto L^{5/3}$ is increasing), and (1) holds with $C = 1$, without using the factor s^2 Reading (physics). But (9) and (10) can be used only in the dilute regime $L\Lambda \ll 1$. In the confining regime ($L\Lambda \gg 1$) one expects $\ln(1/\theta) \approx \sigma A D - \ln(A_T/\xi^2)$ (ξ is the correlation length); the dependence on A_T is then only the logarithm of the entropy of the position of the vortex sheet, and (1) is expected to hold within the factor s^2 Reading (physics). **There is no estimate that passes non-perturbatively between the two regimes, $L \sim 1/\Lambda$ — the band.**

05

The only place "within this reduction"

We set out the components of the chain of the Conditional Reduction Theorem of 26-02 according to how they behave when the group is changed.

- **The nesting in the planar directions** ((2) of 26-02) is a statement that comes from the Markov property — that conditioning on the frame makes the insides of the containers independent — and from the container identity of Mack–Petkova, and it does not use the non-commutativity of the group Cited .
- **The base point at small T²** is an estimate that holds for U(1) too. Putting $R = L$ in (4), $\theta(L, L) \approx 2e^{-e^2/2}$ is a constant less than 1 independent of L (26-01 § 03) Reading (physics).
- **Frame decorrelation**, if L is fixed, is replaced under reflection positivity of z by the chessboard density κ_{cb} (26-05), and its structure is the same for $\mathbb{Z}_2$ and U(1) too (26-04). There is no estimate that U(1) fails in the form uniform in L (the uniform slab gap); U(1) is expected to fail only on the side of the uniform slab tension Reading (physics, 26-05 § 05).
- **The lateral-widening inequality** fails for U(1) and $\mathbb{Z}_2$ (§ 02), and is expected to hold with margin $5/3$ for $SU(2)$ in the dilute regime (§ 04).

Contrapositive of the Reduction Proved here If, in some theory, the conclusion of the Conditional Reduction Theorem of 26-02 ($\ln(1/\theta(R_k, R_k)) \geq \gamma R_k^2$ on a dyadic sequence of scales, and a tension on the slab independent of k) is false, then at least one of the base point at small T², frame decorrelation and the lateral-widening inequality (strong form) is false in that theory.

Proof The contrapositive of the Conditional Reduction Theorem. ∎

For U(1) at weak coupling, the tension on the slab is estimated to go to 0 like e^2/L^2 (26-01 § 03), and the conclusion of the Conditional Reduction Theorem is false. By the Contrapositive of the Reduction one of the three assumptions is false, and in the list above the base point at small T² holds and the lateral-widening inequality (strong form) fails. **Within this reduction, the only assumption that is necessarily used to exclude U(1) and $\mathbb{Z}_2$ is the lateral-widening inequality**, and that is where non-abelian dynamics enters Reading (physics; resting on estimates of the behaviour of U(1), $\mathbb{Z}_2$ and $SU(2)$).

Two qualifications go with this way of speaking.

- **It depends on the reduction.** "The only place" is a way of speaking within the chain of 26-02. In another reduction that splits the band into "β-monotonicity" and "the renormalisation comparison" (26-06), asymptotic freedom enters through the shift of the coupling in the comparison, $\beta' < \beta$. It is natural to read this as the same physics entering a differently shaped inequality in each reduction, but the precise correspondence between the two reductions has not been shown.
- **The estimates of the sign are only at the two ends.** The margin $5/3$ is a count in the dilute regime ($L\Lambda \ll 1$) at one loop, and the "only a logarithm" of the confining regime is also an estimate. There is no tool that shows the lateral-widening inequality in the band $L \sim 1/\Lambda$. The difficulty of the band is concentrated in this one interval of scales, within this one inequality.

06

Numerical signs — the vortex free energy when T^2 is widened

These are values of the vortex free energy $\Delta F = F_v$ (the ratio to the partition function with the twist flux n_{34} inserted, $\theta = \tanh(\Delta F/2)$) when the transverse T^2 is widened to $N_T \times N_T$, in the global form in which the container is the whole of the planar directions (T^2_M with period M) ((8) of 26-01), measured by replica exchange and Bennett's acceptance-ratio method [Reading] . The lattice is $N_T^2 \times M^2$, with twist $n_{12} = 1$ and the Wilson action. The errors are the estimates given by the source, and the source does not state the number of seeds.

Table 2 ΔF when the transverse T^2 is widened (global form; [Reading])

Theory, β, M	$N_T = 2$	4	6	8
$U(1)$, $\beta = 1.5$, $M = 8$	-0.03 ± 0.04	0.83 ± 0.11	2.10 ± 0.47	5.14 ± 0.78
$SU(2)$, $\beta = 2.5$, $M = 8$	-0.01 ± 0.12	0.63 ± 0.18	0.33 ± 0.22	1.51 ± 0.29
$U(1)$, $\beta = 1.5$, $M = 12$	—	0.20 ± 0.21	1.35 ± 0.30	1.72 ± 0.47
$SU(2)$, $\beta = 2.5$, $M = 12$	—	0.57 ± 0.22	0.42 ± 0.24	-0.15 ± 0.36
$SU(2)$, $\beta = 2.4$, $M = 8$	—	0.31 ± 0.10	—	0.11 ± 0.25

The reading is as follows [Reading] .

- For $U(1)$, at both values of M, ΔF increases when the transverse directions are widened (the vortex becomes costlier). At $M = 8$, θ is $0.39,\ 0.78,\ 0.99$ at $N_T = 4, 6, 8$, and $\ln(1/\theta)$ goes $0.93 \to 0.012$ for $N_T = 4 \to 8$ (about a factor of 80 smaller). This is the direction predicted in § 02.
- For $SU(2)$ the increase is much gentler, or there is none. At $M = 8$, $\beta = 2.5$, $\ln(1/\theta)$ goes $1.19 \to 0.45$ for $N_T = 4 \to 8$ (about a factor of 2.6 smaller), and the ratio of θ, $0.64/0.31 \approx 2$, is within the $4C$ that the lateral-widening inequality (strong form) allows at $s = 2$. At $M = 12$ and at $\beta = 2.4$, ΔF decreases for $N_T = 4 \to 8$. The exception is $N_T = 8$ at $\beta = 2.5$, $M = 8$ (the symmetric torus $N_T = M$), where ΔF rises from 0.33 to 1.51.

We write the limits with the same weight. Since this is a regime where θ is of order 1, the ratio of θ for U(1) is also held to about 2.5 because $\theta \leq 1$, and the discriminating power in this geometry is weak. β takes one or two points for each theory, and $\beta = 1.5$ for U(1) and $\beta = 2.5$ for $SU(2)$ are not matched to the same physics. The errors are 0.04–0.8. The values at $N_T = 2$ are in the region of lattice artefacts (26-02 § 06). **These are signs of a direction, not the conclusion of a test of the lateral-widening inequality.** The detailed tables of the measurements are in 25-08 and 26-09.

```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The nodes that stand on paper are four: the Flux-Equalisation Lemma, the lower bound on the abelian action, the Poisson identity and the Contrapositive of the Reduction, all of them elementary. The claims of the chapter (that the margin 5/3 = 11/3 − 2 fixes the sign, and that within this reduction only the lateral-widening inequality separates the groups) are "Reading (physics)", and their premises include estimate rows (the Coulomb phase of U(1), the self-dual lump of SU(2), the bias of the dilute gas). The numerical row (the direction of Table 2) is not a premise of any conclusion. There is no node for the lateral-widening inequality itself. It is placed as an assumption in the ledger of conditions of 27-02.

What this chapter can say

What is said	What is not said
Proved here For the abelian action, the minimal action for a given flux is attained by the uniformly spread configuration and is proportional to the transverse area (under the condition of the same flux through each cross-section; classical action)	A proof, as a theorem, of the quantum U(1) count (4)

Terms used in this chapter — the lateral-widening inequality, the sector bias θ, the self-dual lump (fractional instanton), the dilute gas, the margin $5/3$, the transverse two-dimensional entropy, the Coulomb phase, the crossover band (the band). Their meanings are in A-02 Glossary and A-06 Index of names.

Next chapter: 26-04 Structure alone cannot cross — why reflection positivity and duality alone do not give the lateral-widening inequality.

2026-10-15 · chapter Yang–Mills and the mass gap Part 26 The crossover band the negative lemma, the electric flux, reflection positivity of z · Kiichi, Shiori and Rin

Structure alone cannot cross

> This chapter is this book's own investigation. § 01 is established knowledge; § 05 is a map of open questions.

What this chapter shows — We set out the structural tools of lattice gauge theory — the positivity of the transfer matrix, the centre and duality identities, reflection positivity, the symmetries of the lattice, the finite lemmas — in the language of the twisted slab, and check that every one of them holds as it stands for $\mathbb{Z}_2$ and U(1). From this follows the negative lemma: **from this set of inputs alone**, the lateral-widening inequality cannot be derived. To cross the band one needs a dynamical input that excludes the non-confining phase. On the way, we set out with proofs two things that can certainly be said from the side of structure: the electric-flux form of the sector bias, $\theta = Y(1)/Y(0) \geq 0$, and the positivity of reflections through lattice points for the z ensemble. The latter is an input to the chessboard estimate of the next chapter.

Prerequisite chapters — 26-01 (the sector bias and the global form (8)), 26-02 (the lateral-widening inequality), 26-03 (that it fails for U(1) and $\mathbb{Z}_2$), 5-03 (reflection positivity and the transfer matrix), 25-01 (the twist and 't Hooft flux), A-04 (Lean).

Said first — The negative lemma is a statement of the form "**from this set of inputs alone**": an arrangement of logic with the list of inputs made explicit. It does not say that none of the inputs is of any use (reflection positivity is used in 26-05). "The lateral-widening inequality fails for U(1) and $\mathbb{Z}_2$" is an estimate of 26-03 ([Reading], physics), so the last step of the conclusion of the negative lemma inherits that label. What was checked in Lean is only the spectral algebra of the electric-flux form and the algebra of the final sum in reflection positivity.

The order of this chapter

1. The list of structural inputs — what we call "structure"
2. The electric-flux form — $\theta = Y(1)/Y(0) \geq 0$ and the tanh comparison
3. Reflection positivity of z — reflections through lattice points, and how transverse reflections break down under the twist
4. Lemma that Structural Inputs Alone Do Not Suffice — from this set of inputs alone

5. The inputs needed — what excludes the non-confining phase
6. Reading the Lean statements — `FluxDuality`, `ReflPos`
7. The table of the five grades and the dependency graph

01

The list of structural inputs — what we call "structure"

Of the five inputs in this section, three (positivity of the transfer matrix, the centre and duality identities, the lattice symmetries) summarise existing knowledge. The introduction is in 5-03 § 05 (the transfer matrix) and 5-03 § 04 (reflection positivity).

In lattice gauge theory with the Wilson action on the lattice $\Lambda = (\mathbb{Z}/L_1) \times (\mathbb{Z}/L_2) \times (\mathbb{Z}/M)^2$, we place the background twist $n_{12} = 1$ in the two transverse directions 1 and 2 (25-01). Directions 3 and 4 are the plane. What this chapter calls the **structural inputs** is the following set $\mathcal{I}$ of five.

1. **Positivity of the transfer matrix**: the transfer matrix T with a planar direction (3 or 4) as time is a positive operator (5-03, Osterwalder–Seiler, Lüscher Cited).
2. **The centre and duality identities**: inserting twist flux is inserting a centre transformation, and it can be decomposed by the projections onto electric flux ('t Hooft Cited). The Electric-Flux Decomposition Lemma of § 02 is one of this form.
3. **Reflection positivity in the planar directions**: the positivity of reflections through lattice points in directions 3 and 4 for the z ensemble with the twist fixed (the reflection positivity of z in § 03).
4. **Symmetries of the lattice**: translations, rotations, reflections, and the fact that they preserve the class of the twist.
5. **The finite lemmas**: the container identity and nesting (25-03), the slab estimate $\sup_\Phi \theta_D \le \tanh(\beta L^2)^{|D|}$ (25-04), the flow lemma $\theta \le 1 - a$ (25-06). All of them use only properties of measures and finite sums.

The question is whether the lateral-widening inequality ((5) of 26-02) follows from $\mathcal{I}$. The answer, in § 04, is "it does not". Before getting there, we set out two things that can certainly be said about the sector bias within $\mathcal{I}$.

02

The electric-flux form — $\theta = Y(1)/Y(0) \geq 0$

Take the lattice to be $T^2_{L1\times L2} \times T^2_{M\times M}$, and write $Z(1, n34)$ for the partition function with, in addition to $n12 = 1$, the twist flux $n34 \in \{0, 1\}$ through the plane (3,4) inserted. The global bias of (8) of 26-01 was

$$\theta \;:=\; \frac{Z(1,0) - Z(1,1)}{Z(1,0) + Z(1,1)} \;=\; \tanh\frac{F_v}{2}, \qquad e^{-Fv} := \frac{Z(1,1)}{Z(1,0)} \quad (1)$$

We choose direction 3 as time. The space at one time is $T^2_{L1\,L2} \times T^1_M$ (directions 1, 2, 4), and in it there is the spatial magnetic flux $m_4 = n_{12} = 1$. The transfer matrix $T_3 \geq 0$ commutes with the centre transformation $\hat{C}_4$ of direction 4 (the operation that multiplies the links going once round direction 4 by the centre element -1), and $\hat{C}_4^2 = 1$. When space is split by the eigenvalues $(-1)^{e4}$ of $\hat{C}_4$, $e_4 \in \{0, 1\}$ is the **electric flux** in direction 4 ('t Hooft Cited). Let the projections be P_e and put

$$Y(e) \;:=\; \mathrm{Tr}\big(P_e\, T_3{}^M\big) \qquad (e = 0, 1) \quad (2)$$

This defines Y(e).

Electric-Flux Decomposition Lemma (the electric-flux form) Proved here In the setting above, with $Y(0), Y(1) \geq 0$,

$$Z(1,0) = Y(0) + Y(1), \qquad Z(1,1) = Y(0) - Y(1). \quad (3)$$

Hence when $Z(1,0) + Z(1,1) > 0$, $\theta = Y(1)/Y(0) \geq 0$. If moreover the positivity assumption for the twisted partition function holds, then $\theta \leq 1$; that is, with $F_v \geq 0$, $0 \leq \theta \leq 1$.

Proof The partition function is the trace of the transfer matrix, $Z(1,0) = \mathrm{Tr}\, T_3{}^M$, and the twist $n34 = 1$ through the plane (3,4) is the same as inserting $\hat{C}_4$ somewhere around the time circle, so $Z(1,1) = \mathrm{Tr}(\hat{C}_4 T_3{}^M)$ ('t Hooft's construction Cited). Substituting $\hat{C}_4 = P_0 - P_1$ and $1 = P_0 + P_1$ gives (3). P_e is an orthogonal projection commuting with T_3, so $P_e T_3{}^M P_e = P_e T_3{}^M$ is a positive operator and its trace is at least 0. When $Z(1,0) + Z(1,1) = 2Y(0) > 0$, putting (3) into (1) gives $\theta = 2Y(1)/2Y(0)$. From $Z(1,1) = Y(0) - Y(1) \geq 0$, $Y(1) \leq Y(0)$. ∎

Two remarks. First, $\theta \geq 0$ and $|Z(1,1)| \leq Z(1,0)$ are **spectral** facts that follow from (3) and $Y(e) \geq 0$ alone, but the positivity assumption for the twisted partition function needed for $\theta \leq 1$ is not. $Z(1,1)$ is at least 0 because it is the integral of a positive function containing the twisted plaquette weight $e^{-\frac{\beta}{2}\mathrm{tr}U_p}$, but this is the positivity of the Boltzmann weight and does not follow from the spectrum of the transfer matrix.

Second, the Electric-Flux Decomposition Lemma is a lattice version of 't Hooft's electric–magnetic duality: "the vortex free energy (magnetic flux) is small $\Longleftrightarrow$ the state with electric flux $e_4 = 1$ is heavy compared with $e_4 = 0$". In the confining regime $Y(1)/Y(0)$ is expected to be small because of the electric string tension Reading (physics, 26-05 § 04).

We add one elementary lemma, used when writing lateral widening in the global form.

tanh Comparison Lemma Proved here Let $\theta = \tanh(F/2)$, $\theta' = \tanh(F'/2)$, $F, F' \geq 0$. If $F' \leq KF$ $(K \geq 1)$, then $\theta' \leq K\theta$.

Proof $\tanh$ is monotonically increasing and concave on $[0, \infty)$ with $\tanh 0 = 0$, so for $K \geq 1$, $\tanh(Kx) \leq K \tanh x$ (for a concave function g with $g(0) = 0$, $g(x) = g(\frac{1}{K} \cdot Kx + (1 - \frac{1}{K}) \cdot 0) \geq \frac{1}{K} g(Kx)$). Hence $\theta' = \tanh(F'/2) \leq \tanh(KF/2) \leq K \tanh(F/2) = K\theta$. ∎

That is, lateral widening in the form of the vortex free energy, $F_v(L') \leq C(L'/L)^2 F_v(L)$, implies lateral widening in the form of the bias.

03

Reflection positivity in z — reflections through lattice points, and transverse reflections

Setting. Take the torus $\Lambda = (\mathbb{Z}/L)^2 \times (\mathbb{Z}/M)^2$ with M even. The variables are the links $U_\ell \in SU(2)$ and the plaquette variables $z_p \in \{\pm 1\}$, and we impose the following constraints.

- For every three-dimensional cube c, $\prod_{p \in \partial c} z_p = 1$ (z is a closed $\mathbb{Z}_2$ 2-cochain).
- Fixing the global class, $n_{12}(z) := \prod_{p \in \Pi} z_p = -1$. Π is a (1,2) plane with (x_3, x_4) fixed, and since z is closed this does not depend on the position of Π.

The measure is

$$d\mu \;=\; Z^{-1} \prod_{\ell} dU_\ell \sum_{z} \mathbf{1}[\delta z = 1]\, \mathbf{1}[n_{12}(z) = -1]\, \exp\Big(\frac{\beta}{2} \sum_{p} z_p \operatorname{tr} U_p\Big) \tag{4}$$

(dU is the Haar measure). This is the ensemble of 26-01 § 01 with the twist summed over, with the transverse twist fixed.

Reflection. Let Θ be the reflection through lattice points in direction 3, $x_3 \mapsto -x_3 \pmod M$. The fixed planes are $P_0 = \{x_3 = 0\}$ and $P_1 = \{x_3 = M/2\}$. It acts on links by $U_{(x,\mu)} \mapsto U_{(\Theta x, \mu)}$ for directions $\mu \neq 3$ and by $U_{(x,3)} \mapsto U^{-1}_{(\Theta x - e_3, 3)}$ for direction 3, on plaquette variables by $z_p \mapsto z_{\Theta p}$, and on functions by $(\Theta G)(U, z) := G(\Theta U, \Theta z)$.

Reflection positivity of z Proved here For any bounded function G depending only on the variables of the right half $\Lambda_+ = \{0 \le x_3 \le M/2\}$ (including the variables on the planes $P_0 \cup P_1$), $\langle G \cdot \Theta G \rangle_\mu \ge 0$. The same holds for direction 4.

Proof We show it in five steps.

Step 1 (splitting the variables). Split the variables into three. φ: the variables on the planes $P_0 \cup P_1$ (the links in directions 1, 2, 4 within the planes, and the z of the plaquettes of types (1,2), (1,4), (2,4) within the planes). ψ_+: the right variables (the direction-3 links leaving $0 \le x_3 < M/2$, the links in other directions with $0 < x_3 < M/2$, the plaquettes of type $(3,\nu)$ with $[x_3, x_3+1] \subset [0, M/2]$, and the z of in-plane-type plaquettes with $0 < x_3 < M/2$). $\psi_- := \Theta\psi_+$: the left variables. Θ does not move φ.

Step 2 (decomposing the weight). The plaquette weight $e^{\frac{\beta}{2} z_p \operatorname{tr} U_p}$ belongs to exactly one of right, left and the planes, since p does, and goes into that one. The weights of plaquettes on the planes go into $A(\varphi)$. The cube constraints split in the same way: a cube containing direction 3 spans $[x_3, x_3+1]$ and so depends only on the variables of one side and of the planes; a cube not containing direction 3 depends only on the right variables if $0 < x_3 < M/2$, and only on the plane variables if it lies on a plane. The global constraint n_{12}, measured on $\Pi \subset P_0$, is a function of φ. So the weight has the form $W = A(\varphi)\, F(\psi_+, \varphi)\, F'(\psi_-, \varphi)$, with $A \ge 0$, $F \ge 0$.

Step 3 (the relation between the left and right factors). The action and the constraints are invariant under Θ. Even when the orientation of a plaquette is reversed, in $SU(2)$ we have $\operatorname{tr} U_{\Theta p} = \operatorname{tr} U_p^{-1} = \operatorname{tr} U_p$. Cubes go to cubes, and the plane on which n_{12} is measured is fixed. Hence $F'(\psi_-, \varphi) = F(\Theta\psi_-, \varphi)$.

Step 4 (invariance of the measure). The Haar measure is invariant under taking inverses, and the counting measure of z is invariant under permutations.

Step 5 (positivity). From the above,

$$Z\,\langle G \cdot \Theta G \rangle \;=\; \int d\varphi\, A(\varphi) \Big[\int d\psi_+ F(\psi_+, \varphi) G(\psi_+, \varphi) \Big] \Big[\int d\psi_- F(\Theta\psi_-, \varphi) G(\Theta\psi_-, \varphi) \Big] \;=$$

∎

The algebra from the last equality to the inequality (in the version with finite sums) is checked by ReflPos in Lean (`ReflPos.refl_pos`) (§ 06). The algebra, after splitting into factors, of the Cauchy–Schwarz form that follows from positivity, $\langle G \cdot \Theta H \rangle^2 \le \langle G \cdot \Theta G \rangle \, \langle H \cdot \Theta H \rangle$ (for real G, H), is ReflPos (`ReflPos.refl_cs`). This is an input to the Chessboard Estimate (26-05).

The reflection positivity of z is the Osterwalder–Seiler argument for reflections through lattice points Cited (5-03) with the $\mathbb{Z}_2$ plaquette variables and the closedness constraint added. The key points are that each cube constraint fits on one side plus the planes, and that the global class n_{12} lies in a plane orthogonal to the direction of reflection (3) and can be measured on the plane P_0.

Transverse reflections. If we try the same argument with reflections in directions 1 and 2, the twist gets in the way.

Lemma on the Non-Positivity of Lateral Reflections Proved here In $SU(2)$, write $e^{\frac{\beta}{2}\mathrm{tr}U} = \sum_j c_j \chi_j(U)$ (χ_j is the character of spin j, $c_j = \frac{2(2j+1)}{\beta} I_{2j+1}(\beta) > 0$). Then the twisted plaquette weight is

$$e^{-\frac{\beta}{2}\mathrm{tr}U} = \sum_j (-1)^{2j} c_j \chi_j(U) \quad (5)$$

and the coefficients for half-integer j are negative. Hence, with the twist fixed, the weights of plaquettes straddling the plane of a reflection in the transverse directions 1 and 2 are not of positive type, and the standard argument for reflection positivity does not hold there.

Proof -1 is a centre element of $SU(2)$, and $-\mathrm{tr}\,U = \mathrm{tr}(-U)$, $\chi_j(-U) = (-1)^{2j}\chi_j(U)$. Hence (5) follows from $e^{-\frac{\beta}{2}\mathrm{tr}U} = e^{\frac{\beta}{2}\mathrm{tr}(-U)} = \sum_j c_j \chi_j(-U)$. The formula for c_j and its positivity are the standard expansion via the modified Bessel functions $I_n(\beta) > 0$ ($\beta > 0$) Cited . Being a weight of positive type (coefficients of the character expansion at least 0) is the property the standard argument needs for the plaquettes straddling the plane of reflection, and (5) does not satisfy it. ∎

The consequence of the Lemma on the Non-Positivity of Lateral Reflections is that **reflection positivity gives no convexity or monotonicity in the transverse size** L. The lateral-widening inequality is a comparison in L, so the road to obtaining it from reflections is closed from the start. What the Lemma on the Non-Positivity of Lateral Reflections says is that the standard argument cannot be used; it does not show that positivity of transverse reflections fails for all functions.

04

The negative lemma — from this set of inputs alone

Lemma that Structural Inputs Alone Do Not Suffice (the negative lemma) Proved here The set of structural inputs $\mathcal{I}$ of § 01 (positivity of the transfer matrix, the centre and duality identities (including the Electric-Flux Decomposition Lemma), reflection positivity in the planar directions (the reflection positivity of z), the symmetries of the

lattice, the finite lemmas) holds, with the same proofs, in the four-dimensional Wilson theory in which the group is changed from $SU(2)$ to $\mathbb{Z}_2$ or U(1) and the twist variables are kept as ± 1. Hence, if there were an argument deriving the lateral-widening inequality using $\mathcal{I}$ alone, the same argument would derive the lateral-widening inequality for $\mathbb{Z}_2$ and U(1) too. Contrapositively, **if the lateral-widening inequality is false for either $\mathbb{Z}_2$ or U(1), it cannot be derived from this set of inputs alone**.

Proof For each input, we check the properties of the group it uses.

- Positivity of the transfer matrix: the Osterwalder–Seiler argument holds for the Wilson action of a compact group, for actions whose character-expansion coefficients are positive. $e^{\beta \operatorname{Re} U_p}$ for $\mathbb{Z}_2$ and U(1) satisfies this Cited .
- The centre and duality identities: all that is used is that -1 is in the centre of the group (the centre of $\mathbb{Z}_2$ and of U(1) is the group itself and contains -1), and that twist flux is the insertion of a centre transformation. The proof of the Electric-Flux Decomposition Lemma goes through as it stands.
- Reflection positivity: the only properties of the group used in the proof of the reflection positivity of z are $\operatorname{tr} U_{\Theta p} = \operatorname{tr} U_p^{-1} = \operatorname{tr} U_p$ in step 3 and the invariance of the Haar measure under inverses in step 4. For U(1), writing the action with $\operatorname{Re} U_p$, $\operatorname{Re} U^{-1} = \operatorname{Re} U = \operatorname{Re} U$; for $\mathbb{Z}_2$, $U^{-1} = U$; both hold.
- Symmetries of the lattice: the definitions of the action and of the class of the twist have a form independent of the group, so they are the same.
- The finite lemmas: the container identity uses independence conditioned on the frame (the Markov property), the slab estimate uses conditioning on the orbits of flips of the plaquette variables, and the flow lemma uses only stationarity; none uses the non-commutativity of the group.

The first half is shown, so the second half is logic: if an argument uses only the properties of $\mathcal{I}$, it gives the same conclusion in every theory that satisfies $\mathcal{I}$. ∎

The premise of the Lemma that Structural Inputs Alone Do Not Suffice, "the lateral-widening inequality is false for $\mathbb{Z}_2$ or U(1)", is the estimate of 26-03 § 02 Reading (physics; the count for the Coulomb phase of U(1) and the count for the wall of $\mathbb{Z}_2$ at weak coupling). Granting it, the conclusion is that **the lateral-widening inequality does not follow from the structural inputs alone**. This last step inherits the label of its premise, [Reading] (physics).

The same argument applies as it stands to the weak form (the lateral-widening inequality (weak form) of 26-02) and to the uniform slab tension. For U(1) and $\mathbb{Z}_2$ the slab tension is estimated to go to 0 as L grows, so neither follows from the same set of inputs alone Reading (physics).

We also write what the Lemma that Structural Inputs Alone Do Not Suffice does not say. First, it does not say that $\mathcal{I}$ is useless for the band. If L is fixed, the reflection positivity of z replaces frame decorrelation by the chessboard density κ_{cb} (26-05). Second, what comes out when one dynamical input is added to $\mathcal{I}$ is outside the lemma. Third, at strong coupling (small β) U(1) also confines, so what the lemma separates is not the groups themselves but **whether there is a non-confining phase**.

The thin-vortex floor — tools of structure alone give only the floor. Even when correlation inequalities and covering comparisons are added to the structural inputs, what follows is a lower bound (a floor) that does not distinguish between groups. For the $SU(2)$ Wilson measure on the slab $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$, for every real β, every $N, M \geq 1$ and background $n_{12} \in \{0,1\}$,

$$\theta = \frac{Z_{n34=0} - Z_{n34=1}}{Z_{n34=0} + Z_{n34=1}} \;\leq\; \tanh\!\left(N^2|\beta|\right)^{M^2} \qquad (6)$$

holds Proved here (the thin-vortex floor. The $SU(2)$ system is bounded above by a $\mathbb{Z}_2$ sign system, and the four-dimensional $\mathbb{Z}_2$ system is moved to a two-dimensional system of plaquettes and evaluated in closed form. Checked in Lean as a theorem about the concrete $SU(2)$ Wilson measure). The type of the inequality lies on the line of Mack–Petkova and Fröhlich Cited (not yet checked against the text of the originals). When the coupling is positive, in terms of the tension, $\sigma_N(\beta) \geq -\ln\tanh(N^2\beta) \approx 2e^{-2N^2\beta}$, which goes rapidly to 0 with N and is not uniform in N (inside the strong-coupling window there is a form in which the rate per unit area does not depend on the transverse size; the prefactor remains. Outside the window there is no uniform form. 20-06). The right-hand side is the value of a thin vortex made by stacking N^2 plaquettes along the plane, and the same comparison holds in the same form for the $\mathbb{Z}_2$ system. A comparison of this type becomes an equality for the Gaussian model, which sits at the limit of the class of models it applies to, so the comparison alone does not give that the floor keeps being exceeded at a uniform rate (the tension-doubling inequality of 26-06 § 08) Reading . Where the Lemma that Structural Inputs Alone Do Not Suffice says "does not follow from this set of inputs alone", the same point said from the side of what does follow is "what follows is only the floor". Above the floor is where the non-abelian dynamical input of § 05 is needed. The statement and proof of this floor are in 21-02.

05

The inputs needed — what excludes the non-confining phase

By the Lemma that Structural Inputs Alone Do Not Suffice, an argument that crosses the band must use at least one input outside $\mathcal{I}$. That input must be false for U(1) and $\mathbb{Z}$

2 at weak coupling — the non-confining phase. The candidates that the study of this book can name are all properties of non-abelian dynamics.

Table 1 Candidate inputs needed for the band (none is shown; the labels are estimates for the candidates)

Input	For U(1) and $\mathbb{Z}_2$	Where it enters	Chapter
Asymptotic freedom (the sign of the running of the coupling)	U(1) does not run or runs the other way; $\mathbb{Z}_2$ has no continuous running	The margin $5/3$ in the dilute regime; $\beta' < \beta$ in the renormalisation comparison	26-03 § 04, 26-06
Localisation in a self-dual lump (non-linearity)	Abelian flux can only spread out uniformly	The classical cost of lateral widening is 0	26-03 § 03
Ultraviolet control (multiscale analysis)	For U(1), a different form (conformal at long distance)	The base point at small T^2	the base point at small T^2 in 26-02, 27-02

Each row of Table 1 is an estimate, [Reading] (physics), and none of the inputs is in a form usable in the band $L \sim 1/\Lambda$. On the strong-coupling side, there is a line of argument by a polyhedral expansion in which the lateral-widening inequality holds with the constant $C \approx 1$ (there is a report that the factor $(L'/L)^2$ is consistent with the literature on the leading strong-coupling term (Münster 1981), but checking is not yet done). However, an estimate uniform in the planar size M has not been confirmed, and this book places it under [Assumption]. At strong coupling U(1) also confines, so this row does not contradict the Lemma that Structural Inputs Alone Do Not Suffice.

The Lemma that Structural Inputs Alone Do Not Suffice makes explicit a result that was expected; there is no surprise in it. Its role is to give one **touchstone** for reading arguments about the band: if an argument proceeds using only the properties of $\mathcal{I}$, it gives the same conclusion for U(1), so there is an error somewhere. The record in 26-08 of a road that drew the criticism that it does not distinguish U(1) is a real example of this touchstone.

06

Reading the Lean statements — `FluxDuality`, `ReflPos`

The spectral part of the Electric-Flux Decomposition Lemma and the algebra of step 5 of the reflection positivity of z are five theorems in the Lean 4 files `FluxDuality.lean` and `ReflPos.lean`. We read the statements in the words of the text. All of them are statements about sums of real numbers over a finite set ι (or Φ, Ψ).

`FluxDuality.split`: for families of reals $t, c : \iota \to \mathbb{R}$, under the assumption "for every i, $c_i = 1$ or $c_i = -1$", $\sum_i t_i - \sum_i c_i t_i = 2\sum_{c_i=-1} t_i$ and $\sum_i t_i + \sum_i c_i t_i = 2\sum_{c_i=1} t_i$. In

the text t_i are the eigenvalues of T_3^M and c_i the eigenvalues of $\hat{C}_4$, and the two formulas are $Z(1,0) \mp Z(1,1) = 2Y(1),\ 2Y(0)$ of (3).

`FluxDuality.twisted_le`: under the assumptions "for every i, $0 \le t_i$" and "$c_i = \pm 1$", $\left|\sum_i c_i t_i\right| \le \sum_i t_i$. This is $|Z(1,1)| \le Z(1,0)$ of the text.

`FluxDuality.bias_mem`: under the assumptions "$0 \le t_i$", "$c_i = \pm 1$", "$0 \le \sum_i c_i t_i$", "$0 < \sum_i t_i + \sum_i c_i t_i$", $0 \le \theta \le 1$ for $\theta := (\sum t - \sum ct)/(\sum t + \sum ct)$. **The third assumption $Z_{11} := \sum ct \ge 0$ is used for $\theta \le 1$**; it is not a spectral fact, and corresponds to the positivity of the Boltzmann weight in the text.

`ReflPos.refl_pos`: for finite sets Φ, Ψ and real functions $A : \Phi \to \mathbb{R}$, $F, G : \Psi \to \Phi \to \mathbb{R}$, under the assumption "for every φ, $0 \le A(\varphi)$", $\sum_\varphi \sum_{\psi_1} \sum_{\psi_2} A(\varphi) F(\psi_1, \varphi) F(\psi_2, \varphi) G(\psi_1, \varphi) G(\psi_2, \varphi) \ge 0$. It is the finite-sum version of $\int A \left| \int FG \right|^2 \ge 0$ in step 5 of the reflection positivity of z, and the sign of F does not matter.

`ReflPos.refl_cs`: under the same assumption $0 \le A$, for $g(\varphi) := \sum_\psi F(\psi, \varphi) G(\psi, \varphi)$ and $h(\varphi) := \sum_\psi F(\psi, \varphi) H(\psi, \varphi)$, $\left(\sum_\varphi A\, g\, h\right)^2 \le \left(\sum_\varphi A\, g^2\right)\left(\sum_\varphi A\, h^2\right)$. It writes the Cauchy–Schwarz form for reflections, $\langle G \cdot \Theta H \rangle^2 \le \langle G \cdot \Theta G \rangle \langle H \cdot \Theta H \rangle$, as algebra after the weight has been split into factors.

What machine checking guarantees is only this algebra of finite sums and real numbers. That the transfer matrix is positive, that it commutes with $\hat{C}_4$, that the twist is the insertion of $\hat{C}_4$, that the weight splits into the form $A \cdot F \cdot F$ (steps 1–4 of the reflection positivity of z), and the Haar measure lie outside Lean; the proofs in the text and the literature carry them. The axioms of the five theorems are, in the record, the three standard ones (`propext`, `Classical.choice`, `Quot.sound`), and they pass this book's re-check (A-04).

07

The table of the five grades and the dependency graph

Table 2 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	Positivity of the transfer matrix $T \ge 0$	Cited	Osterwalder–Seiler, Lüscher, 5-03	Wilson action of a compact group	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
2	The twist $n34$ is the insertion of the centre transformation $\hat{C}_4$; e_4 is an eigenvalue of $\hat{C}_4$	Cited	't Hooft, 25-01	Groups whose centre contains -1	—
3	Electric-Flux Decomposition Lemma: $Z(1,0) = Y(0) + Y(1)$, $Z(1,1) = Y(0) - Y(1)$, $\theta = Y(1)/Y(0) \geq 0$	Proved here	Proof in § 02 $\Longleftarrow$ 1, 2	$T^2_{L_1 L_2} \times T^2_{M \times M}$, $n_{12} = 1$, $Z(1,0) + Z(1,1) > 0$	FluxDuality (`FluxDuality.split`) (assumption: $c_i = \pm 1$), `twisted_le` (assumptions: $0 \leq t_i$, $c_i = \pm 1$)
4	$\theta \leq 1$ ($F_v \geq 0$)	Proved here	§ 02 $\Longleftarrow$ 3	Uses the positivity assumption for the twisted partition function (positivity of the Boltzmann weight)	FluxDuality (`FluxDuality.bias_mem`) (assumptions: $0 \leq t_i$, $c_i = \pm 1$, $Z_{11} \geq 0$, $Z_{10} + Z_{11} > 0$)
5	tanh Comparison Lemma: if $F' \leq KF$ ($K \geq 1$), then $\tanh(F'/2) \leq K \tanh(F/2)$	Proved here	Proof in § 02 (concavity of $\tanh$)	$F, F' \geq 0$	—
6	Reflection positivity of z: positivity of reflections through lattice points in directions 3 and 4 for the z ensemble	Proved here	Proof in § 03 (the Osterwalder–Seiler argument with z and the constraints added)	$SU(2)$, M even, twist $n_{12} = 1$ fixed	ReflPos (`ReflPos.refl_pos`) (only the algebra of step 5; assumption: $0 \leq A$), `refl_cs` (assumption: $0 \leq A$)
7	Character-expansion coefficients $c_j = \frac{2(2j+1)}{\beta} I_{2j+1}(\beta) > 0$	Cited	Standard expansion (cross-checked numerically)	$SU(2)$, $\beta > 0$	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
8	Lemma on the Non-Positivity of Lateral Reflections: the twisted plaquette weight has negative coefficients for half-integer j; transverse reflections are not of positive type	Proved here	Proof in § 03 ⟸ 7	Twist fixed, reflections in directions 1 and 2	—
9	Lemma that Structural Inputs Alone Do Not Suffice: $\mathcal{I}$ holds for $\mathbb{Z}_2$ and U(1) too, and an argument from $\mathcal{I}$ alone gives the same conclusion there	Proved here	Proof in § 04 ⟸ 1, 3, 6	The form "from this set of inputs alone"; twist ± 1	—
10	For U(1) and $\mathbb{Z}_2$ the lateral-widening inequality is false	Reading (physics)	26-03 § 02	Weak coupling, an estimate	—
11	The lateral-widening inequality (strong and weak forms) and the uniform slab tension do not follow from the structural inputs alone	Reading (physics)	§ 04 ⟸ 9, 10	On top of the estimate that the lateral-widening inequality is false for U(1) and Z_2	—
12	Reflection positivity gives no convexity or monotonicity in the transverse size L	Proved here	§ 03 ⟸ 8	In the sense that the standard argument cannot be used	—
13	At strong coupling the lateral-widening inequality holds with $C \approx 1$	Assumption	Line of argument: polyhedral expansion (an estimate uniform in the planar size is unconfirmed)	Small β	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
14	In the confining regime $Y(1)/Y(0)$ is small because of the electric string tension	Reading (physics)	26-05 § 04	$L\Lambda \gg 1$, an estimate	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The nodes that stand on paper are the Electric-Flux Decomposition Lemma, $\theta \leq 1$, the tanh Comparison Lemma, the reflection positivity of z, the Lemma on the Non-Positivity of Lateral Reflections, the Lemma that Structural Inputs Alone Do Not Suffice, and the absence of convexity and monotonicity; they rest on the literature rows (positivity of the transfer matrix, the insertion of the centre transformation, the character-expansion coefficients). Only the claim of the chapter title (that the lateral-widening inequality and the uniform slab tension do not follow from the structural inputs alone) has an estimate row (that the lateral-widening inequality is false for U(1) and Z_2) as a premise, and it is "Reading (physics)". The assumption row (that the lateral-widening inequality holds at strong coupling) is not a premise of any conclusion.

The machine-checked form of reflection positivity is in 20-01, and the sign of θ is in 21-06.

What this chapter can say

What is said	What is not said
Proved here The global bias of the sector is the ratio of electric fluxes $\theta = Y(1)/Y(0) \in [0,1]$ (the upper bound uses the positivity of the weight)	An estimate of the size of $Y(1)/Y(0)$. The electric string tension in the band
Proved here The z ensemble with the twist fixed is positive under reflections through lattice points in directions 3 and 4. Transverse reflections are not of positive type because of the twist	That positivity of transverse reflections fails for all functions. Convexity in L
Proved here The set of structural inputs $\mathcal{I}$ holds for $\mathbb{Z}_2$ and U(1) too, and an argument from $\mathcal{I}$ alone gives the same conclusion there (from this set of inputs alone)	What comes out when a dynamical input is added to $\mathcal{I}$
Reading (physics) The lateral-widening inequality and the uniform slab tension do not follow from the structural inputs alone	A proof, as a theorem, that the lateral-widening inequality is false for U(1) and $\mathbb{Z}_2$
Lean: the spectral algebra (FluxDuality (`FluxDuality.split`, `FluxDuality.twisted_le`, `FluxDuality.bias_mem`)) and the algebra of the final sum of the reflection (ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`))	The transfer matrix, the centre transformation, the decomposition of the weight, the Haar measure (outside Lean)

The chessboard and simultaneous flips

> This chapter is this book's own investigation. § 04 and § 05 are a map of open questions; § 06 is guide material.

What this chapter shows — The second assumption of the reduction in 26-02, "frame decorrelation", was the assumption that the product of the biases of containers sharing a frame splits into a product of typical values. If the size L of the transverse torus is fixed, the reflection positivity of z (the Reflection-Positivity Theorem for z in 26-04) and the Chessboard Estimate replace this assumption by **a single density** κ_{cb}. On a slab with L fixed, the Wilson loop is bounded by $\kappa_{\mathrm{cb}}^{n(C)}$, and the only work left is the estimate $\kappa_{\mathrm{cb}} < 1$. As tools for that estimate we set side by side the slab estimate and simultaneous flips, and we also write why simultaneous flips cannot be used to test the band. Finally we see that the band is concentrated into two uniformities, "the uniform slab tension" and "the uniform slab gap".

Prerequisite chapters — 26-02 § 02 (frame decorrelation), 26-04 § 03 (z reflection positivity), 25-03 (containers), 25-04 (slab confinement), 25-06 (the flow lemma and simultaneous flips), 5-03 (reflection positivity).

Said first — The paper results of this chapter (the Chessboard Estimate with the Lateral Size Fixed and the Simultaneous-Flip Estimate) are statements of the form **if L is fixed**. There is not a single estimate uniform in L. The two uniformities of the band remain [Assumption]. The Chessboard Estimate itself is a standard tool (Fröhlich–Israel–Lieb–Simon); what is new is only the construction that applies it to the biases of containers. The subscript of the symbol κ_{cb} is there to distinguish it from the other κ of this book (§ 06).

The order of this chapter

1. What is replaced — frame decorrelation, and the power lost to Hölder
2. The Chessboard Estimate — the chessboard with the lateral size fixed, and the density κ_cb
3. Upper bounds on κ_{cb} — the slab estimate and the Simultaneous-Flip Estimate, and their limits
4. Where the band appears again — the dilute regime, the confining regime, and in between

5. The band concentrated — the uniform slab tension and the uniform slab gap (Table 1)
6. The uses of the symbol κ compared (Table 2)
7. The table of the five grades and the dependency graph

01

What is replaced — frame decorrelation, and the power lost to Hölder

The notation is as in 26-01 § 01. The sector bias $\theta_D(\Phi) = |\mathbb{E}[\sigma_D \mid \Phi]|$ of a container $D \times T_L^2$ is a function of the frame Φ, and if mutually disjoint containers D_j in the plane lie inside the loop C, then

$$|\langle W(C)\rangle| \;\le\; \mathbb{E}\prod_j \theta_{D_j}(\Phi) \qquad (1)$$

(Mack–Petkova Cited). The right-hand side is the mean of a product of factors **sharing the same frame**. If the factors were independent it would split into $\prod_j \mathbb{E}\theta_{D_j}$, but the frame field is connected between containers, so it does not. If we use the Hölder inequality, $\mathbb{E}\prod_{j=1}^{n}\theta_j \le \prod_j (\mathbb{E}\theta_j^n)^{1/n}$, each factor on the right is the n-th root of the mean of the n-th power of θ; this is not a product of typical values θ, and a power proportional to the area is lost (in the nested form only $\mathbb{E}\theta_{2R}^4 \le \mathbb{E}\theta_R^4$ comes out).

So 26-02 § 02 set frame decorrelation,

$$\theta(sR; T_L^2) \;\le\; C_{\mathrm{D}}\,\theta(R; T_L^2)^{s^{\measuredangle}} \qquad (2)$$

as an assumption Assumption . (2) played two roles: the power of the nesting (the jump step and the doubling step of the Conditional Reduction Theorem of 26-02), and the bridge from the bias to the Wilson loop (the Area Law from the Area Exponent in 26-01). This chapter moves the role of splitting the product, **on a slab with L fixed**, to a single translation-invariant quantity.

02

The chessboard estimate — the density κ_{cb}

Setting. Consider the z ensemble with the twist $n_{12} = 1$ fixed ((4) of 26-04) on the lattice $(\mathbb{Z}/L)^2 \times (\mathbb{Z}/M)^2$. Divide the plane (3,4) into square blocks Q_t of side B ($t \in \mathcal{T}$, including the boundary lattice points), and let M be a multiple of $2B$. Inside each block put one container $D_t \times T_L^2$, at positions carried into one another by reflections.

Chessboard Estimate (Fröhlich–Israel–Lieb–Simon) Cited Suppose the measure is reflection positive for reflections in planar directions 3 and 4 through all the lattice planes on the boundaries of the blocks. For each t let f_t be a bounded real function depending only on the variables of the block Q_t (boundary included), and let $f_t^{(s)}$ be the function obtained by carrying f_t to the block Q_s by a composition of reflections. Then

$$\Big|\Big\langle \prod_{t\in\mathcal{T}} f_t \Big\rangle\Big| \;\le\; \prod_{t\in\mathcal{T}} \Big\langle \prod_{s\in\mathcal{T}} f_t^{(s)} \Big\rangle^{1/|\mathcal{T}|}. \tag{3}$$

This is the standard argument of Fröhlich–Israel–Lieb–Simon, obtained by using the reflection Cauchy–Schwarz form repeatedly (26-04 § 03; Lean's ReflPos (`ReflPos.refl_cs`) is the algebra after splitting into those factors). (The original paper is Fröhlich–Israel–Lieb–Simon (1978). In this book we checked from the abstract of M. Biskup's lecture notes, arXiv:math-ph/0610025, that this is the standard form of obtaining the Chessboard Estimate from reflection positivity.)

In the z ensemble, reflection positivity is given by the reflection positivity of z in 26-04. The reflection positivity of z speaks of reflections through $x_3 = 0$ and $x_3 = M/2$, but the measure is invariant under translations in direction 3, so the same holds for reflections through any lattice plane $x_3 = c$. Direction 4 is the same.

Next we check that the bias is a function of the block. Given the frame, the interiors of the containers $D_t \times T_L^2$ are conditionally independent, and the conditional distribution depends only on the variables of the shell just outside the container (the Markov property). Since the container lies inside the block, the shell lies in the block, and $\theta_t := \theta_{D_t}$ is a function of the variables of Q_t. Also, a reflection preserves the measure and carries the sector $\sigma_D = \prod_{p\in D\times\{y_0\}} z_p$ to the sector of the reflected container, so the function obtained by carrying θ_t to the block Q_s by reflection is θ_s.

Chessboard Estimate with the Lateral Size Fixed (the chessboard with L fixed) Proved here Fix L and M. In the setting above, put

$$\kappa_{\mathrm{cb}} \;:=\; \Big(\mathbb{E}\prod_{t\in\mathcal{T}} \theta_t\Big)^{1/|\mathcal{T}|} \tag{4}$$

Then for every subset $S \subset \mathcal{T}$, $\mathbb{E}\prod_{t\in S}\theta_t \le \kappa_{\mathrm{cb}}^{|S|}$. In particular, if $n(C)$ is the number of blocks whose container lies wholly inside the loop C,

$$|\langle W(C)\rangle| \;\le\; \kappa_{\mathrm{cb}}^{\,n(C)}. \tag{5}$$

Proof In (3) put $f_t = \theta_t$ if $t \in S$ and $f_t = 1$ if $t \notin S$. Since $\theta_t \ge 0$, the left-hand side is $\mathbb{E}\prod_{t\in S}\theta_t$. On the right, the factors with $t \in S$ are $\big(\mathbb{E}\prod_{s\in\mathcal{T}}\theta_s\big)^{1/|\mathcal{T}|} = \kappa_{\mathrm{cb}}$, because $\theta_t^{(s)} = \theta_s$

as seen above, and the factors with $t \notin S$ are 1. Hence $\mathbb{E}\prod_{t\in S}\theta_t \le \kappa_{\mathrm{cb}}^{|S|}$. For (5), take D_j in (1) to be the containers inside C and use this estimate. ∎

Since a block of side B occupies the area B^2, (5) gives the lower bound $\ln(1/\kappa_{\mathrm{cb}})/B^2$ on the tension (for square loops whose side is a multiple of B). **With L fixed, z reflection positivity has closed, so the gap to the area law on the slab has become only the estimate $\kappa_{\mathrm{cb}} < 1$** Proved here (a statement with L and M fixed). No assumption about the distribution of the frame, such as frame decorrelation (2), is needed.

κ_{cb} is the geometric mean per block of the product of the biases when containers are placed in all blocks at once. It is not "the bias of one typical container" but "a quantity that looks at all containers at once", so the correlation of the frames is absorbed into κ_{cb}. In exchange, the smallness of κ_{cb} can no longer be read as a property of one container.

Nested Supermultiplicativity Lemma Proved here Take the container to be the whole interior of the block (let D_t be all the (3,4) plaquettes in the interior of Q_t, so that the shell $\partial Q_t \times T_L^2$ lies in the closed block Q_t). Write $\kappa_{\mathrm{cb}}(R;L)$ for (4) for blocks of side R (with M fixed). For an integer $s \ge 1$, if $2sR$ divides M, then for all L

$$\kappa_{\mathrm{cb}}(sR;L) \;\le\; \kappa_{\mathrm{cb}}(R;L)^{s^2}. \quad (5a)$$

Proof A large block Q'_u of side sR is the union of s^2 small blocks of side R, and since the (3,4) plaquettes lie in the interiors of the blocks, the sector is $\sigma'_u = \prod_{t\subset u}\sigma_t$. The union Φ' of the shells of the small blocks contains the union Φ of the shells of the large blocks, and by the Markov property the small containers are conditionally independent given Φ', so $\theta'_u = |\mathbb{E}[\sigma'_u \mid \Phi]| \le \mathbb{E}[\prod_{t\subset u}\theta_t \mid \Phi]$ ((2) of 26-02, the nested form of Mack–Petkova). $X_u := \prod_{t\subset u}\theta_t$ is a function of the variables of the closed large block u, and given Φ the interiors of the large blocks are conditionally independent, so $\prod_u \mathbb{E}[X_u \mid \Phi] = \mathbb{E}[\prod_u X_u \mid \Phi]$. Averaging, $\mathbb{E}\prod_u \theta'_u \le \mathbb{E}\prod_t \theta_t$. The numbers of blocks satisfy $|\mathcal{T}| = s^2|\mathcal{T}'|$, so take the $1/|\mathcal{T}'|$-th power of both sides. ∎

The Nested Supermultiplicativity Lemma does not use reflection positivity. It uses only the Markov property and the nested form, and the constant is 1, independent of L, R and s. The Chessboard Estimate is needed only for the step down from κ_{cb} to a single container ($\mathbb{E}\theta_t \le \kappa_{\mathrm{cb}}$) and to the Wilson loop ((5)). The abstract form on a finite probability space, with the large block as a fibre of s^2 small blocks and the inequality of means placed as an assumption, is Lean: LatticeGaugeNestedBlocks (nested_supermultiplicative). The Markov property is outside Lean.

03

Upper bounds on κ_{cb} — the slab estimate and simultaneous flips, and their limits

(i) The slab estimate. For each face $p \in D$ of the container, the operations that flip the z on the face $\{p\} \times T_L^2$ commute with one another, each flips the sector, and none changes the frame. Conditioning on their orbit gives $\mathbb{E}[\sigma_D \mid \text{orbit}] = \pm \prod_{p \in D} \tanh X_p$, and since $|X_p| \le \beta L^2$, $\sup_\Phi \theta_D(\Phi) \le \tanh(\beta L^2)^{|D|}$ (25-04 Proved here). From $\theta_t \le \sup \theta$,

$$\kappa_{\mathrm{cb}} \;\le\; \tanh(\beta L^2)^{|D|} \;<\; 1. \quad (6)$$

So the area law on a slab with L fixed already follows. But the tension is $-\ln \tanh(\beta L^2) \approx 2e^{-2\beta L^2}$ (per unit area), which for $\beta = 2.5$, $L = 4$ is $2e^{-80}$. **An estimate that goes through the supremum (sup) over frames gets worse superexponentially in L,** so an estimate uniform in L can only come from a mean form — a quantity like κ_{cb}.

(ii) Simultaneous flips. The flow lemma (25-06) says that for any Markov kernel K that preserves the conditional distribution $\mu(\cdot \mid \Phi)$ of the interior of the container, if $a(\Phi)$ is the probability that the sector changes in one step, then $\theta_D(\Phi) \le 1 - a(\Phi)$ Proved here (it uses only stationarity; reversibility is not needed).

Simultaneous-Flip Estimate Proved here With the frame held fixed, run a stationary kernel independently for one step inside each of the mutually disjoint containers D_t ($t \in S$), starting from the conditional distribution. Then

$$\mathbb{E} \prod_{t \in S} \theta_t \;\le\; \mathbb{P}\big(S\text{: no container sector changes}\big). \quad (7)$$

Proof Fix the frame Φ. The interiors of the containers are conditionally independent and the kernels also run independently, so the conditional probability that no container changes is $\prod_{t \in S}(1 - a_t(\Phi))$. From the flow lemma, $\theta_t(\Phi) \le 1 - a_t(\Phi)$, so $\prod_t \theta_t(\Phi) \le \mathbb{P}(\text{none changes} \mid \Phi)$. Averaging over Φ gives (7). ∎

The right-hand side of (7) is a quantity that can be measured by Monte Carlo, so with $S = \mathcal{T}$, $\kappa_{\mathrm{cb}} \le \mathbb{P}(\text{none changes})^{1/|\mathcal{T}|}$ becomes a tool that estimates the upper bound on the Wilson loop **in the correct direction**. The natural kernel is the dynamically driven insertion (25-06, acceptance probability $\min(1, e^{-W})$).

(iii) The limits. The flip probability a of a one-step kernel is, in the range measured, away from 1 (0.6–0.73 for the driven-insertion kernel with acceptance $\min(1, e^{-W})$, 25-08 Computed). So what (7) can guarantee is of the form $\theta_t \le \theta_0$ (with θ_0 a constant less than 1), and κ_{cb} cannot be made small exponentially in the area. Even if this is uniform in L for blocks of size $B \sim L$, the lower bound on the tension that comes out is $\ln(1/\theta_0)/L^2 \to 0$, which is only the naive form of the band treated by the Tension Lower Bound from the

Naive Form in 26-01 — a form that U(1) also satisfies Proved here (logic). **Simultaneous flips cannot be used to test the band.** To check the correct form of the band, $\theta \le e^{-cL^2}$, one needs a kernel with $a \to 1$, and no construction of one is known (25-06 § 07). Treating the measurements of simultaneous flips as "the numerical face of the band" has been withdrawn (25-08); the correct use of this tool is the lower bound on the tension of a slab with L fixed — the estimation of κ_{cb}.

04

Where the band appears again — the dilute regime, the confining regime, and in between

The Chessboard Estimate with the Lateral Size Fixed was a statement with L fixed. When L moves, the block size B needed to show $\kappa_{\mathrm{cb}} < 1$, and the quality of the estimate, change from scale to scale. Everything below is an estimate Reading (physics).

- **The dilute regime ($\Lambda L \ll 1$).** For a container of side ℓ, $\mathbb{E}[-\ln \theta_D] \approx \sigma_{\mathrm{TU}} \ell^2$, with $\sigma_{\mathrm{TU}} \propto \Lambda^2 (\Lambda L)^{5/3}$ (26-03 § 04). The influence of the frame decays over distances of about L/π. The criterion holds, but the blocks needed have $B \gtrsim \sigma_{\mathrm{TU}}^{-1/2}$, and their volume grows exponentially in $1/g^2(L)$.
- **The confining regime ($\Lambda L \gg 1$).** In the form of the electric flux (the Electric-Flux Decomposition Lemma of 26-04), $\theta \approx Y(1)/Y(0) \approx c\,\sigma L^2 e^{-\sigma \ell^2}$ (the factor L^2 is the entropy of the transverse position of the electric string). The block size needed grows only as $\sqrt{\ln L}$.
- **In between ($\Lambda L \sim 1$) — the band.** Two uniformities are needed (§ 05).

As $a \to 0$, both B and L become infinite in lattice units, so checking finitely many boxes is not enough. An inequality that connects the scales is needed, and that is the problem of the band.

Why the usual Dobrushin-type criteria cannot be used. With the frame fixed, the sectors do not interact with one another. All the dependence is in the frame field, and since a continuous field follows the boundary, the influence coefficient measured in total variation is nearly 1. Conditions of the Dobrushin, Dobrushin–Shlosman and van den Berg–Maes type are not satisfied as they stand, and we expect another input to be needed, such as contraction on good blocks (of the type of Bałaban's multiscale analysis) Reading (physics). The original papers of these criteria have not been checked in this book.

05

The band concentrated — the uniform slab tension and the uniform slab gap

In the language of the chessboard, the band is concentrated into the following two statements of uniformity. Neither has been shown, and we set them as assumptions.

The uniform slab tension Assumption The string tension of the two-dimensional theory obtained by shrinking the transverse directions to T^2_L (the slab tension, (11) of 26-02) is positive uniformly in L:

$$\inf_{L \geq L_0} \sigma_{\mathrm{eff}}(L) \;>\; 0 \qquad (\text{physical units, uniform in the lattice spacing } a). \tag{8}$$

In the language of containers it has the form $\inf_L \mathbb{E}[-\ln \theta_D]/(\ell\Lambda)^2 > 0$ and corresponds to the content of the lateral-widening inequality (weak form) of 26-02. The chessboard criterion only carries it to the area law. For U(1) the tension is $\sim e^2/L^2$ for every L, and it is expected to fail **here only** Reading (physics).

The uniform slab gap Assumption That κ_{cb} can be compared across scales: that the estimates of the correlations between biases, of the probability of bad blocks and of the fluctuations of the shells are uniform in L (this corresponds to the mass gap of the slab being uniform in L). This is what frame decorrelation (2) of 26-02 really is when made uniform in L. By the Nested Supermultiplicativity Lemma (§ 02), within a fixed L the density κ_{cb} can be carried from scale R to sR with constant 1, so the content of this statement that is uniform in L moves to the comparison across L

$$(\mathrm{Ccb}) \quad \kappa_{\mathrm{cb}}(R; L') \leq C\,(L'/L)^2\,\kappa_{\mathrm{cb}}(R; L) \qquad (L_{\min}(a) \leq L \leq L' \leq R)$$

— the lateral-widening inequality of 26-02 read in terms of κ_{cb} Paper (the Reduction Read in the Chessboard Density in 26-02 § 03). There is no nesting in the lateral directions (tiling T^2_{2L} by four copies of T^2_L makes the twist $4 \equiv 0 \pmod 2$), so the ensemble with $n_{12} = 1$ cannot be formed).

Table 1 The band concentrated (labels per row; conditions in the same row)

Statement	Label	Conditions in the same row	Correspondence with 26-02	For U(1)
The chessboard with L fixed: $\lvert\langle W\rangle\rvert \leq \kappa_{\mathrm{cb}}^{n(C)}$	Proved here	L and M fixed; under the reflection positivity of z (26-04 § 03)	Takes over, at fixed L, the role of frame decorrelation of "splitting the product"	Holds as well
$\kappa_{\mathrm{cb}} < 1$ (fixed L)	Proved here	From the slab estimate (6). The tension is extremely small, $\approx 2e^{-2\beta L^2}$	—	Holds as well

Statement	Label	Conditions in the same row	Correspondence with 26-02	For U(1)
The uniform slab tension (8)	Assumption	Physical units, uniform in a	The content of the weak form of the lateral-widening inequality	Expected to fail [Reading]
The uniform slab gap	Assumption	Estimates of correlations, bad blocks and shell fluctuations uniform in L. Read in terms of κ_{cb}, within a fixed L constant 1 by the Nested Supermultiplicativity Lemma, and the rest is $(\mathrm{C}_{\mathrm{cb}})$	Frame decorrelation made uniform in L	No estimate that it fails [Reading]

In this way the non-abelian content of the band is placed on the side of the uniform slab tension, and the probabilistic content of crossing scales on the side of the uniform slab gap. Read in terms of κ_{cb}, the content of the uniform slab gap that is uniform in L moves to $(\mathrm{C}_{\mathrm{cb}})$ and becomes the same statement as the lateral-widening inequality Paper (the Nested Supermultiplicativity Lemma). The logical relation to the uniform slab tension (8) (whether one follows from the other) has not been examined.

06

The uses of the symbol κ compared

This book has used κ in several senses. The chessboard density of this chapter is written κ_{cb}, and the subscript is never dropped. Table 2 lists the other quantities written with the same letter. The quantities are not related to one another.

Table 2 Quantities written with the letter κ

Symbol	Meaning	Chapter
κ_{cb}	The chessboard density: the geometric mean per block of the product of the biases of the containers of all blocks (4)	This chapter, 26-00 Table 1
κ (the one-sided bridge)	The comparison constant of the One-Sided Bridge Proposition (of the form $C_P \geq \kappa \xi^2$)	23-01 § 06
κ_{BE}	The lower bound on the Bakry–Émery curvature	24-09
$\hbar\kappa$, κ_f	An upper bound on the strength of the coupling to neighbouring sites; the strength of the Brascamp–Lieb cross term	23-06
$\kappa = 3/1000$	The lower bound outside the defects in Barta's row	23-09
κ (Part 24)	The comparison constant between the Langevin metric and the metric of the kinetic term	24-09
$\kappa_{\mathrm{C7}}(k)$	The convexity constant of a chain of length k (the same quantity as $\kappa(k)$ of 23-11)	26-07
κ_w	Adapted stiffness: the variance of the force along the generator of the twist (width w; one of the candidate quantities for the band)	26-10

The whole correspondence of symbols is in A-01.

07

The table of the five grades and the dependency graph

Table 3 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	The container estimate (1)	Cited	Mack–Petkova, 25-03	The ensemble summed over twists	—
2	Frame decorrelation (2)	Assumption	26-02, A-06	Constant C_{D}	—
3	Reflection positivity of z (directions 3 and 4, any lattice plane)	Proved here	26-04 § 03, translation invariance	$SU(2)$, twist fixed, M even	ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`) (algebra only; assumption: $0 \le A$)
4	The Chessboard Estimate (3)	Cited	Fröhlich–Israel–Lieb–Simon (checked from the abstract of lecture notes)	Under reflection positivity, $2B \mid M$	—
5	θ_t is a function of the variables of the block and is carried to θ_s by reflection	Proved here	§ 02 (Markov property, reflection invariance of the measure)	The container is placed inside the block	—
6	Chessboard Estimate with the Lateral Size Fixed: $\mathbb{E}\prod_S \theta_t \le \kappa_{\mathrm{cb}}^{\lvert S\rvert}$, $\lvert\langle W(C)\rangle\rvert \le \kappa_{\mathrm{cb}}^{n(C)}$	Proved here	Proof in § 02 $\Longleftarrow$ 1, 3, 4, 5	If L is fixed (M also fixed)	—
7	The slab estimate $\sup_\Phi \theta_D \le \tanh(\beta L^2)^{\lvert D\rvert}$, hence $\kappa_{\mathrm{cb}} < 1$	Proved here	25-04, § 03 (6)	L fixed, tension $\approx 2e^{-2\beta L^2}$	—
8	The Flow Lemma $\theta \le 1 - a$	Proved here	25-06	Stationary kernel (reversibility not needed)	FluxLemma (`FluxLemma.flip_le_one_sub_abs`) (assumptions: $w \ge 0$, $K \ge 0$, row sums 1, w stationary, $\sum w = 1$, $\sigma = \pm 1$)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
9	Simultaneous-Flip Estimate: $\mathbb{E}\prod_S \theta_t \leq \mathbb{P}(\text{none changes})$	Proved here	Proof in § 03 $\Longleftarrow$ 8	Frame fixed, one independent step, starting from the conditional distribution	—
10	The flip probability of a one-step kernel levels off at about $\frac{1}{2}$	Reading	Measurements of 25-08	The driven-insertion kernel	—
11	Simultaneous flips give only an estimate of the naive form and cannot be used to test the band	Proved here	§ 03 (iii) $\Longleftarrow$ 9, the Tension Lower Bound from the Naive Form in 26-01	Logic assuming the levelling off of the one-step flip probability	—
12	Criteria and block sizes in the dilute and confining regimes	Reading (physics)	§ 04	$\Lambda L \ll 1$, $\Lambda L \gg 1$, estimate	—
13	Dobrushin-type criteria cannot be used as they stand	Reading (physics)	§ 04	The estimate that the influence coefficient is nearly 1; original papers not yet checked	—
14	The uniform slab tension (8)	Assumption	§ 05, A-06	Physical units, uniform in a	—
15	The uniform slab gap	Assumption	§ 05, A-06	Uniform in L	—
16	U(1) fails only in the uniform slab tension	Reading (physics)	§ 05	Estimate of the tension $\sim e^2/L^2$	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The main conclusion of this chapter (the Chessboard Estimate with the Lateral Size Fixed) stands on paper, and its only premises are literature rows (the container estimate, the Chessboard Estimate) and paper rows (the reflection positivity of z, block functions and reflection). The assumption row (frame decorrelation) is not among the premises of this conclusion — that is the point of this chapter. "Simultaneous flips cannot be used to test the band" is a row of logic, but it has a measurement row (the levelling off of the one-step flip probability) as a premise, so it is a statement within the range where that levelling off holds. The two assumptions of the band (the uniform slab tension, the uniform slab gap) do not contain the quantity of the conclusion (κ_{cb} with L fixed), and are placed in the ledger of conditions of Part 27 (27-02).

The machine-checked form of the chessboard estimate is in 22-01.

What this chapter can say

What is said	What is not said
Proved here If L is fixed, z reflection positivity and the chessboard estimate bound the Wilson loop by $\kappa_{\mathrm{cb}}^{n(C)}$, and frame decorrelation is not needed	An estimate of κ_{cb} uniform in L (the uniform slab gap)
Proved here Simultaneous flips are a tool that estimates κ_{cb} in the correct direction, and with a one-step kernel they cannot be used to test the band	A kernel with $a \to 1$. A numerical test of the band

What is said	What is not said

Terms used in this chapter — frame decorrelation, the Chessboard Estimate, the chessboard density κ_{cb}, block, simultaneous flips, the Flow Lemma, the uniform slab tension, the uniform slab gap, the crossover band (the band). Their meanings are in A-02 Glossary and A-06 Index of names.

Next chapter: 26-06 Renormalisation comparison — a comparison that distinguishes groups — another reduction, which splits the band into β-monotonicity and the renormalisation comparison.

Renormalisation comparison — a comparison that distinguishes groups

This chapter is this book's own investigation. § 04, § 07 and § 08 are a map of open questions.

What this chapter shows — We split the crossover band into two statements. One is that, with the lattice geometry held fixed, the vortex free energy increases in β (β-monotonicity). The other is that the lattice obtained by doubling the whole lattice can be compared, up to a constant factor, with the original lattice at a stronger coupling (the renormalisation comparison). Asymptotic freedom enters only through the "direction of strengthening the coupling" $\beta' < \beta$ of the renormalisation comparison. β-monotonicity looks like an easy component, but it turned out to be a problem of the same weight as the monotonicity in β of the string tension in lattice units. The renormalisation comparison holds at both the strong-coupling end and the one-loop end, but on the strong-coupling side it is a line of proof with extremely crude constants, and on the weak-coupling side it is a computation at the one-loop level. In the band between them, comparing $SU(2)$ and $U(1)$ numerically, the direction of the comparison does not change over the whole band for $SU(2)$, and for $U(1)$ it reverses at the position of the known phase transition. Finally, from the fact that the band is a bounded interval in β, we prove an elementary lemma that reduces the renormalisation comparison inside the band to "the two-sided area law at fixed β (with an error of the order of the perimeter)", and say where in the band the difficulty gathers.

Prerequisite chapters — 26-01 (the correct form of the band, $\ln(1/\theta) \geq cL^2$), 26-02 (reduction to a single inequality), 25-01 (the twisted T^2 and 't Hooft flux), 25-07 (why fixed maps fail, and the one-loop table), 4-06 (asymptotic freedom), 5-02 (the strong-coupling expansion), 5-06 ($U(1)$ and the non-abelian).

Said first — The level is [Res]. This chapter does not show the renormalisation comparison at any β of the band. What it shows is the range and conditions in which the comparison holds at the two ends, numerical readings, and one reduction lemma (§ 06). The assumption of the reduction lemma contains the unsolved problem of

confinement at intermediate coupling on the four-dimensional $SU(2)$ lattice. We write the chessboard density as κ_{cb}.

The order of this chapter

1. Splitting the band in two — β-monotonicity and the renormalisation comparison
2. β-monotonicity is not easy — rewritten with the electric flux, it stands beside the monotonicity of the string tension
3. The comparison that holds at the two ends — the strong-coupling end and the one-loop end (Table 1)
4. The map over β — labels interval by interval (Figure 1)
5. Numerics — doubling the lattice — $SU(2)$ and $U(1)$ (Tables 2–4)
6. The band is a bounded interval — the Lemma Reducing the Comparison inside the Band, and the Corollary Crossing the Band in Finitely Many Steps
7. The four faces of the band in the middle — candidate local quantities (Table 5)
8. Conditions an argument closing the band must satisfy — the criterion "distinguish from the U(1) transition"
9. What cannot be said
10. The table of the five grades and the dependency graph — Table 6

01

Splitting the band in two — β-monotonicity and the renormalisation comparison

The object is the slab of 25-01. On the lattice $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ we put the $SU(2)$ Wilson action and insert the twist $n_{12} = 1$ in the $(1,2)$ plane. We take the flux n_{34} of the $(3,4)$ plane as the sector, and write the vortex free energy as

$$\Delta F(N,M,\beta) \;=\; -\ln \frac{Z_{n_{34}=1}(N,M,\beta)}{Z_{n_{34}=0}(N,M,\beta)}, \qquad \theta = \tanh \frac{\Delta F}{2} \tag{1}$$

θ is the quantity used in 't Hooft's criterion, and the correct form of the band was "$\ln(1/\theta(L,L)) \geq cL^2$ uniformly in L" (26-01). The larger the vortex free energy, the smaller θ, which is the confining side.

We split the statement that crosses the band into the following two Assumption (both set as unproved statements).

$$\text{(Mon)}\quad \frac{\partial}{\partial\beta}\Delta F(N,M,\beta)\ \geq\ 0 \qquad \text{(with the lattice geometry fixed)}\ (2)$$

$$\text{(RG-cmp)}\quad \Delta F(2N,2M,\beta)\ \leq\ K\cdot\Delta F(N,M,\beta'),\qquad \beta'<\beta,\qquad K \text{ independent of } N,M$$

> The formula label (Mon) stands for β-monotonicity, and (RG-cmp) for the renormalisation comparison (names as in A-06). The (Mon) of (5) below is the same.

The left-hand side of (2) can be written as an equality, as an average of the difference of actions: $\partial_\beta\Delta F=\langle\Delta S\rangle$ (the difference of the average actions in the sectors with and without a vortex) Proved here (just differentiate the partition function in β). (3) is the comparison that a vortex on the lattice coarsened by a factor 2 costs no more than a vortex on the lattice of the original size at a stronger coupling.

The scope of (2). (2) is a statement about the slab of this chapter — the group $SU(2)$, the background twist $n_{12}=1$ and the slab geometry $(\mathbb{Z}/N)^2\times(\mathbb{Z}/M)^2$. It is not a general property of non-abelian groups: on small lattices for the finite non-abelian groups Q_8 and D_4 there are points where $\partial_\beta\Delta F<0$ even without a background twist, and, with the background, there are points where it fails in geometries that are long in the transverse directions Reading (floating-point values from transfer matrices of finite groups; two independent implementations agree). On the other hand, for the $\mathbb{Z}_2$ sign system, whose only variables are the signs of the plaquettes, monotonicity of the type of (2) ($\mathbb{Z}_2$ monotonicity) holds for non-negative couplings Proved here (a proof of correlation-inequality type; the statement for abstract sign systems was checked in Lean; the application to the lattice of the four-dimensional torus is on paper).

Together, the two give a line that crosses the band. Iterating (3) as $\beta_0>\beta_1>\beta_2>\cdots$, the vortex free energy on the lattice enlarged 2^k times is bounded by K^k times the value on the original lattice at coupling β_k. Once β_k enters the strong-coupling range, the vortex free energy there is small with an area exponent, and it becomes doubly exponentially small with each step, so it beats the loss K^k. (2) plays the role of an adjustment: nothing is lost if, in the course of the iteration, β' is chosen smaller than necessary.

The rate form of (3). The constant K in (3) is bookkeeping; the content is a comparison of slab tensions. Write the slab tension, and that quantity multiplied by the number of plaquettes, as

$$\sigma_N(\beta) := \lim_{M\to\infty} \frac{-\ln \Delta F(N,M,\beta)}{M^2}, \qquad s(N,\beta) := N^2 \sigma_N(\beta) \quad (3')$$

(assuming the limit exists; otherwise the lower limit). Taking the logarithm of both sides of (3), dividing by M^2 and letting $M \to \infty$, K disappears, and what remains is $s(N,\beta') \le s(2N,\beta)$ Proved here (this form follows from (3); the converse needs control of the difference between ΔF and the area term). In this book, this rate form is read as the main form of the renormalisation comparison. If one looks only at symmetric boxes $N = M$ and allows $K > 1$, $\beta' < \beta$ holds even for $U(1)$ Reading. What forces $\beta' \ge \beta$ is the side $M \to \infty$ with N fixed, and the rate form carries that direction.

Asymptotic freedom enters only through $\beta' < \beta$ in (3). (2) is a statement of a form that contains no mechanism that distinguishes groups. For $\mathbb{Z}_2$ and $U(1)$, it follows from Ginibre's inequality when there is no twisted background, but the slab of this chapter has the twist $n_{12} = 1$, and in that case it does not follow from Ginibre's inequality even for $\mathbb{Z}_2$ Assumption (the application of Ginibre's inequality has not been checked against the text of the original source). The direction of (3), on the other hand, changes with the group. For $U(1)$ one loop gives $\beta' \ge \beta$, and the iteration does not head for strong coupling: it fails, correctly. That $\beta' < \beta$ for the non-abelian $SU(2)$ is a restatement of asymptotic freedom (4-06), that is, of the effective coupling becoming stronger when the lattice is coarsened. In this sense (3) has to be "a comparison that distinguishes groups".

Example. At the strong-coupling end, (3) holds with $K \approx 4$ (§ 03). Doubling the lattice makes the area of the vortex sheet 4 times larger, and it balances at the β' that makes the rate $\sigma(\beta)$ of the area exponent 4 times larger, that is, $\sigma(\beta') = 4\sigma(\beta)$. For $\beta = 1.0$, $\beta' \approx 0.013$ (Table 1). At strong coupling the coupling moves a long way in one step.

Tomboulis (2007) tried to build a comparison of type (3) with Migdal–Kadanoff decimation, and Ito–Seiler and Kanazawa pointed out that the flow heads for strong coupling also for $U(1)$ Cited (Ito–Seiler reduce the remaining step to the inequality $A(\alpha) > A^{+}(\alpha)$ of their eq. (3.5), and write that it has not been shown). The history and the checking are in 26-08. What this chapter needs is just one point: a comparison that does not distinguish groups cannot cross the band.

Looking again at the direction of the comparison in the language of effective actions: at tree level the coarse action of the genuine one step is no greater than the Migdal–Kadanoff action (in the coarse directions it is smaller, down to 1/4, and it agrees at long wavelengths); in the language of couplings this is $\beta/4 \le \beta' \le \beta$, the direction favourable to confinement Proved here (lower side) Reading (the upper side is the numerics of the measured boxes). It still cannot be used for the comparison, because the inequality of partition functions $Z \le Z_{\mathrm{MK}}$ does not lift to the form with the coarse

variables fixed. In the one-loop asymptotics the speed of the Migdal–Kadanoff flow (0.2503 per step) is only slightly slower than the genuine speed 0.2575, and the direction is favourable; but in U(1) neither runs, and the difference between the groups shows up on the Migdal–Kadanoff side only in an exponentially small flow Reading . The one-step sandwich $\langle W\rangle_L < \langle W\rangle_R < \langle W\rangle_{\mathrm{MK}}$ of the same observable holds in all 12 rows for SU(2) and U(1), and does not distinguish the groups Reading (Metropolis, $4^4 \to 2^4$, $8^4 \to 4^4$, $\beta \in \{2, 4, 8\}$).

The inequality $A(\alpha) > A^{+}(\alpha)$ to which Ito–Seiler reduced the problem is the same as the monotonicity "the vortex free energy grows with the coupling", and in the numerics of small boxes it holds even for deconfined U(1) Reading (4^4, one direction of the MK image, $\alpha \in \{0.9, 1.0\}$). What has to distinguish the groups is the extension beyond it, and the device that moves the interpolation parameter away from 1.

Measuring "the Migdal–Kadanoff flow is slower than the genuine flow" with the twist free energy, over one step of the orbit (2.47 → 2.19 in the effective β), in the $4^4/2^4$ box the genuine one step looked faster by 0.15 converted to Wilson's β ($R = 1.34(7)$); but in $6^4/3^4$ the difference is 0.02(2) ($R = 1.17(20)$), which is within the resolution of the measurement (statistics, and the systematic floor of 0.1–0.25 of the ΔF method). The speeds of the two flows look nearly equal inside the band, and the 7% discretisation of the 2^4 box may have produced most of the initial difference Reading .

02

β-monotonicity is not easy — rewritten with the electric flux, it stands beside the monotonicity of the string tension

β-monotonicity looks like "a structural component that can probably be shown". In fact it is not easy. Rewriting it with the electric flux makes this clear.

Splitting the partition function of the sector with flux n_{34}, by the Fourier transform on $\mathbb{Z}_2$, into the partition functions Y_0, Y_1 with electric flux $e \in \{0, 1\}$ gives $Z_{n_{34}=0} = Y_0 + Y_1$, $Z_{n_{34}=1} = Y_0 - Y_1$. Setting $E_e = \frac{d}{d\beta} \ln Y_e$,

$$\frac{\partial \Delta F}{\partial \beta} = \frac{2\, Y_0 Y_1\, (E_1 - E_0)}{Y_0^2 - Y_1^2}, \qquad \theta = \frac{Y_1}{Y_0} \quad (4)$$

Proved here Proof. Differentiate $\Delta F = \ln(Y_0 + Y_1) - \ln(Y_0 - Y_1)$, insert $Y_e' = E_e Y_e$ and bring to a common denominator; the numerator is $(E_0 Y_0 + E_1 Y_1)(Y_0 - Y_1) - (E_0 Y_0 - E_1 Y_1)(Y_0 + Y_1) = 2 Y_0 Y_1 (E_1 - E_0)$. The expression for θ is $\tanh(\Delta F/2) = (e^{\Delta F} - 1)/(e^{\Delta F} + 1)$ with $e^{\Delta F} = (Y_0 + Y_1)/(Y_0 - Y_1)$ inserted. ∎

If $Y_1 > 0$ (the positive case of $\theta = Y(1)/Y(0) \geq 0$ in 26-04), then from (4)

$$(\mathrm{Mon}) \iff E_1 \geq E_0 \iff \theta \text{ increases in } \beta \iff \text{the electric-flux free energy } -\ln(Y_1/Y_0)$$

Proved here . In the confining phase, the free energy of the electric flux is of the order of the product of the string tension and the length the flux passes through. So it can be read that, if β-monotonicity holds on every lattice, it follows that the string tension in lattice units σa^2 decreases in β Assumption (basis: the step connecting the electric-flux free energy with the string tension has not been written out). **The monotonicity in β of the string tension in lattice units has not been proved for $SU(2)$.** Even the monotonicity in β of the expectation value of the Wilson loop has not been shown, as far as we searched. β-monotonicity is a problem at least of the same weight as this Assumption . The initial estimate that "β-monotonicity is structural and can probably be shown" is corrected here.

The partial results to hand are the following Assumption (the proofs of none of them are set out in this book). In two dimensions with 1 or 2 sheets (by the monotonicity of the conditional energy of the $O(4)$ chain); near $\beta \to 0$ on any fixed lattice; near $\beta \to \infty$ in the twisted n_{12} background ($\partial_\beta \Delta F$ approaches a positive constant because $SU(2)$ has no flat connection carrying both n_{12} and n_{34}). No counterexample has been found in any of the closed two-dimensional formulas ($N \leq 100$, $\beta \leq 20$), the exhaustive enumeration of $2 \times 2 \times 2 \times 1$ for $\mathbb{Z}_2$, or the four-dimensional Monte Carlo on 1^4 and 2^4 Reading .

Two reasons why it gets stuck are recorded. In the Mack–Petkova representation, when the $SO(3)$ configuration carries a twist class, the conditional Ginibre inequality goes the wrong way, and $\partial_\beta \Delta F$ becomes exactly "the difference of the two contributions we want to measure". In the character expansion, in three or more dimensions the sign of the spin-network integrals is not fixed Reading (physical estimate).

Consequence. The chain across the band does not need β-monotonicity on every lattice. If (3) is shown directly in the form $\Delta F(2N, 2M, \beta) \leq K \Delta F(N, M, \beta')$, the freedom in choosing β' absorbs the role of β-monotonicity. So below we concentrate on the renormalisation comparison.

03

The comparison that holds at the two ends — the strong-coupling end and the one-loop end

The strong-coupling end

We write the coefficient of the character expansion of the Wilson action in the fundamental representation as $u(\beta) = I_2(\beta)/I_1(\beta)$ ($u \approx \beta/4$ as $\beta \to 0$). Expanding the

vortex free energy of the slab by the strong-coupling expansion (5-02), the leading terms are the N^2 flat sheets wrapping the $(3,4)$ plane (area M^2, weight u^{M^2}). The record contains a proposition and a line of proof of the following form.

Strong-Coupling-End Expansion Proposition. There are absolute constants u_0, K_0, C such that, for $u(\beta) \le u_0$ and all $N, M \ge 2$,

$$\Delta F(N,M,\beta) = 2N^2 e^{-\sigma_N(\beta) M^2}(1+\epsilon), \qquad |\epsilon| \le C M^2 (K_0 u)^{\max(1, M/100)} \le C' u \tag{6}$$

holds. σ_N depends on β, N and n_{12} but not on M, and $\sigma_\infty = -\ln u - 4u^4 + O(u^5)$. Assumption (line: in the polymer expansion the sign of the twist is fixed by the $\mathbb{Z}_2$ homology class; integrating the flat parts of the sheet by gluing two-dimensional characters gives exactly u^{M^2}; a Peierls estimate for contours on the sheet. The bookkeeping of the interaction between volume polymers and sheet contours (step 5 of the proof) is sketched, and the proof is not set out in this book. The form of the expansion is of the Münster (1981) type, but the text of the original source has not been checked)

Comparison at the Strong-Coupling End. Defining β' by $\sigma_N(\beta') = 4\sigma_{2N}(\beta)$, for all N, $M \ge 2$, $\Delta F(2N, 2M, \beta)/\Delta F(N, M, \beta') = 4(1 + O(u))$, $\beta' < \beta$, $u' = u^4(1 + O(u^4))$ Assumption (algebra on top of the Strong-Coupling-End Expansion Proposition).

The constants are extremely crude: $u_0 \approx 10^{-80}$, which in β is about 4×10^{-80}. On paper, the strong-coupling end is closed only in the range of extremely strong coupling. This is a matter of constants, and there is a prospect of large improvement by tightening the counting, but the expansion in flat sheets stops at roughening ($\beta_R \approx 1.9$), so the strong-coupling side alone cannot cover the band Reading (physical estimate). $U(1)$ also confines at strong coupling and satisfies (3). The difference between the groups appears on the weak-coupling side.

Table 1 The root β' of the leading-order strong-coupling equation $u(\beta') = u(\beta)^4$ (the movement of the coupling in one step) Reading

β	$u(\beta)$	β'	$\beta - \beta'$
0.5	0.1237	0.0009	0.499
1.0	0.2402	0.0133	0.987
1.5	0.3441	0.0561	1.444
2.0	0.4331	0.1409	1.859

The β of Table 1 lie outside the range of the Strong-Coupling-End Expansion Proposition ($u \le u_0$). The table is a rough guide to the direction and size of the comparison from the leading terms only, not a claim that the comparison holds.

The one-loop end

On the weak-coupling side we build (3) as a variational inequality. For a measurable bijection T carrying the measure μ_0 of the sector $n_{34}=0$ to the sector 1, the Gibbs variational principle gives

$$\Delta F \;=\; \mathbb{E}_{\mu_0}\big[S\circ T - S - \ln J_T\big] - \mathrm{KL}\big(T_{\#}\mu_0 \,\|\, \mu_1\big) \;\le\; \mathbb{E}_{\mu_0}\big[S\circ T - S - \ln J_T\big] \quad (7)$$

Cited (the standard form of the Gibbs variational principle; J_T is the Jacobian of T). The right-hand side is written only with averages in μ_0, so the estimate needs only one side. We consider the following construction: block the configuration of the fine lattice $(2N,\beta)$ and map it to the coarse lattice (N,β'), use a nearly optimal insertion map on the coarse lattice, and carry the fluctuations when going back to the fine lattice. Depending on how the fluctuations are carried, the one-loop answer splits in two.

The one-loop count is done with the trace of the heat kernel of the $SU(2)$ fluctuations (Feynman gauge) in a constant background magnetic field B. Per volume, apart from $1/(16\pi^2 s^2)$, the vector (4 polarisations) gives $\frac{Bs}{\sinh Bs}(2+2\cosh 2Bs)$ and the ghosts give $-2\frac{Bs}{\sinh Bs}$. Inserting $\frac{x}{\sinh x} = 1-\frac{x^2}{6}+O(x^4)$ and $\cosh 2x = 1+2x^2+O(x^4)$ for $x = Bs$,

$$\underbrace{\frac{x}{\sinh x}(2+2\cosh 2x) - \frac{2x}{\sinh x}}_{\text{total}} = 2+\tfrac{11}{3}x^2+O(x^4), \qquad \underbrace{\frac{4x}{\sinh x} - \frac{2x}{\sinh x}}_{\text{orbital only}} = 2-\tfrac{1}{3}x^2+O(x^4)$$

and the $+4$ in $\frac{11}{3} = -\frac{1}{3}+4$ comes from the spin term $\cosh 2Bs$ Proved here (one-loop level; the expansion is a two-line computation). $\frac{11}{3}$ is the coefficient of asymptotic freedom. The table and the details of the derivation are in 25-07; here we use only the conclusion.

- In **an isometric comparison** (a map isometric in the fluctuations: the identity map, translation in the group, gauge transformation, Migdal–Kadanoff-type decimation), the estimate (7) is the first-order trace $\frac{1}{2}\operatorname{tr}((M_B - M_0)M_0^{-1})$, and the contribution of the spin term is exactly 0. The estimate is worse than the orbital value alone, so what it can give is at best the $-\frac{1}{3}$ side, that is, $\beta' \ge \beta + 0.023$ (per doubling): the direction against asymptotic freedom, the same direction as $U(1)$ Proved here (one-loop level).
- In **a comparison that reshapes the fluctuations** (changing the shape of the fluctuations by an optimal linear map of determinant 1), the exact $\frac{1}{2}\ln\det$ is reproduced with error $\sim \Delta F^2/n$ (n is the number of degrees of freedom), giving $\beta' = \beta - 0.258$ (per doubling) Proved here (one-loop level).

Where the numbers come from: with $\beta = 4/g^2$ and $b_0 = 22/(48\pi^2)$, the one-loop movement of the coupling per doubling is $\beta - \beta' = 4 \cdot 2b_0 \ln 2 = 0.2575$. For the orbital part alone, replacing $\frac{11}{3}$ by $-\frac{1}{3}$ gives $0.2575 \times (-\frac{1}{11}) = -0.0234$ Proved here (arithmetic).

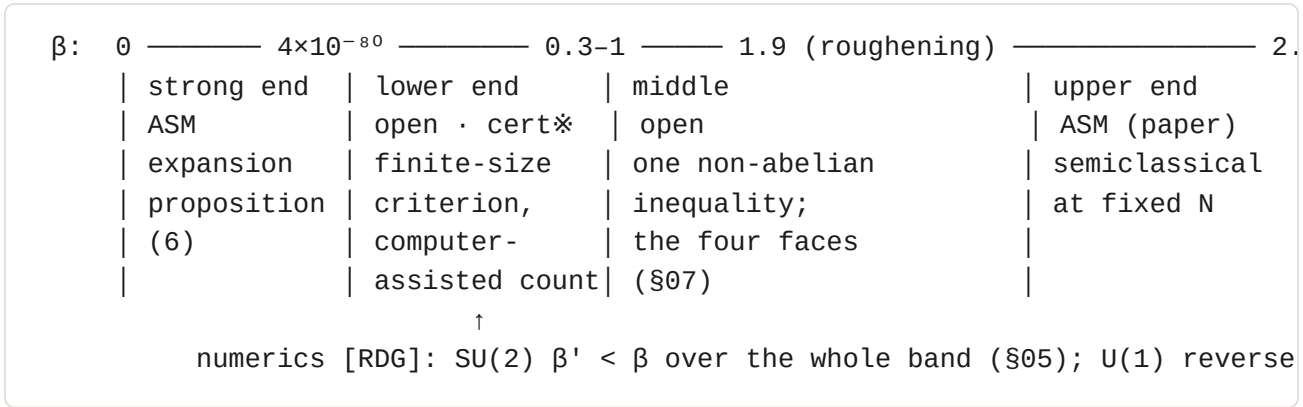
This explains as a number, at the one-loop level, why the method of Tomboulis (decimation = isometric) could not distinguish groups. The mechanism that sees asymptotic freedom lies in the reshaping of the fluctuations. What remains is to control the error in the estimate of the reshaped transport (the local KL near the vortex sheet and the higher loops) at intermediate coupling and in large fields, and this is open.

Always read the statements at the two ends with their conditions. One cannot say "the renormalisation comparison holds at both ends, so only the width of the band remains". The strong-coupling side is a line, part of whose bookkeeping is sketched, in the range $u \le u_0 \approx 10^{-80}$, and the weak-coupling side is a computation at the one-loop level. A non-perturbative weak-coupling comparison has not been shown at any β.

04

The map over β — labels interval by interval

Figure 1 sets out, over the β of the Wilson action, the status of the renormalisation comparison and of confinement interval by interval. The boundaries of the intervals are rough guides, and none of them is a threshold of a theorem.



- **The strong-coupling end** Assumption : the Strong-Coupling-End Expansion Proposition. With the constant $u_0 \approx 10^{-80}$ as it stands, the proof cannot be set out in the book, so it is "Assumption". At the same strong-coupling end there are results of this book checked in Lean (20-06): the area law, and a vortex floor whose rate per unit area does not depend on the transverse size (the prefactor remains). Both are statements at fixed lattice spacing, only inside the strong-coupling window (β below about 10^{-3}), and are not the renormalisation comparison itself. Outside the window there is no form uniform in the transverse size.

- **The lower end** ($\beta \approx 0.3$–1): open. However, the upper side of the two-sided area law at fixed β at the strong-coupling end has been extended (※ in Figure 1). Splitting an element of $SU(2)$ into a centre sign and a section of $SO(3)$ ($U = \sigma V$), the twist free energy is sandwiched by means of ratios for a $\mathbb{Z}_2$ gauge glass with the $SO(3)$ background frozen (couplings $|K_p| \le \beta$, signs random) Paper . Checking the Kotecký–Preiss criterion Cited for the polymer expansion of its closed sheets (the form, uniform in the background, of the mixing of box magnetic flux δ_C (26-10 § 03)) by full enumeration up to 10 plaquettes and a tree bound on the tail, $|\Delta F(N, M, \beta)| \le 8aN^2 e^{-bM^2}$ ($a = 0.0454$, $b = 0.01$; lowering β makes b larger) holds for $N, M \ge 11$ and all $\beta \le 0.1039$ Computer-assisted (interval arithmetic; for all $N, M \ge 2$, $\beta \le 0.0680$. The final arithmetic of the rational version $\beta \le 0.1029$ is Lean: CenterFluxPolymerCertificate (tree_k, kp_bound, kp_lt_one, rate_rational, final_real). $\tanh \beta \le \beta$, the lemma of the induction on trees and the KP theorem are outside Lean). This is of the form of the upper side of the two-sided area law at fixed β; the rate b is much smaller than the true σ, and there is no lower side (an upper bound on the string tension). The same splitting holds for $U(1)$ and for $\mathbb{Z}_2$, so this estimate does not distinguish groups and cannot cross the transition $\beta \approx 0.44$ of pure $\mathbb{Z}_2$ Reading . $\beta \ge 0.12$ cannot be shown at the threshold of the enumeration. It is likely an estimate of a known type, and no novelty is claimed. The candidates above that are a Dobrushin–Shlosman-type finite-size criterion using the influence $\delta(L_0, \beta)$ on the inside when the centre magnetic flux on the boundary of the box is changed, and a road that shows the growth constant of the admissible sheets by computer-assisted enumeration and raises u_0 to 0.04–0.12 (the range of the prospect is a physical estimate). Neither is expected to reach above $\beta \approx 1$.
- **The middle** ($\beta \approx 1$–2.7): open. One inequality that uses non-commutativity is needed, and there are four candidate local quantities to carry it (§ 07).
- **The upper end** (large β at fixed N): for the direction of confinement there is a paper proof in the Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3, which came out of this book's study; $-\ln \theta \ge c\beta^{-a} e^{-\beta(S_* + \varepsilon)} M^2$ at fixed N). However, it cites the general chessboard theorem and a Morse–Bott lemma, and the proof is not set out in this book, so we label it "Assumption" Assumption . The reverse estimate uniform in M, and whether the rate S_* equals the minimal action $S_{\min}$, are open. Increasing N is the same problem as the middle.
- **One loop** Proved here : (8) of § 03 and the two comparisons. This is the perturbative level.

How the width of the band is counted depends on where the lower end is put. The strong-coupling expansion is considered numerically effective up to about $\beta \approx 0.3$–0.5, and the record writes this band as "roughly 0.5 to 2.7 in the β of the Wilson action"

Reading (physical estimate). On paper the band is much wider, $[4 \times 10^{-80},\ 2.7]$, because u_0 is so small.

05

Numerics — doubling the lattice

We test the renormalisation comparison directly with numerics. The procedure is to measure the vortex free energy on the fine lattice and read off, from the ΔF curve of the coarse lattice, the β' of the coarse lattice that gives the same value. Every measurement makes samples that cross sectors by replica exchange and obtains the free-energy difference by Bennett's acceptance ratio method (BAR). The errors are statistical; at some points the difference between two runs with different seeds (initial values of the random numbers) is 1–2 times the displayed error, so the errors may come out on the small side. Every number is a reading, not a proof Reading .

Table 2 Doubling the whole lattice of the slab: $(N, M) = (4, 8) \to (8, 16)$ $(n_{12} = 1)$ Reading

Group	β	$\Delta F(4, 8, \beta)$	$\Delta F(8, 16, \beta)$	Seeds	Matching β'	$\beta - \beta'$
$SU(2)$	2.7	2.97 ± 0.33	0.92 ± 0.30 (weighted mean of 0.65 ± 0.39 and 1.31 ± 0.48)	2	≈ 2.57 (2.45–2.65 including the error of the curve)	$\approx +0.13$ ($+0.05$–$+0.25$)
$SU(2)$	2.6	1.43 ± 0.19	-0.50 ± 0.34 (consistent with 0)	2	$\lesssim 2.45$	$\gtrsim +0.15$
$SU(2)$	2.5	0.63 ± 0.18	0.41 ± 0.34	1	2.2–2.5	0–$+0.3$
$U(1)$	1.5	0.83 ± 0.11	2.32 ± 0.45 (48 replicas, minimum exchange acceptance rate 0.37)	1	> 1.7 (outside the curve)	< -0.2

The curves on the coarse side are, for $SU(2)$, $\Delta F(4, 8, \beta') = 0.05, 0.00, 0.31, 0.63, 1.43, 2.97$ at $\beta' = 2.2, 2.3, 2.4, 2.5, 2.6, 2.7$, and for $U(1)$, $0.42, 0.55, 0.83, 0.92, 1.46$ at $\beta' = 1.3$–1.7. For $SU(2)$, doubling lowers the vortex free energy ($2.97 \to 0.92$ at $\beta = 2.7$), and the matching β' is smaller than β. For $U(1)$ it rises ($0.83 \to 2.32$, about 3σ), and $\beta' > \beta$. The direction of the comparison separated for the two groups. The first $U(1)$ run (32 replicas) had a minimum exchange acceptance rate of 0.03 and mixed badly, and is not used.

Table 3 ΔF on the symmetric torus N^4 $(n_{12} = 1)$, and β' for one step $2^4 \to 4^4$. One seed each Reading

Group	β	$\Delta F(2^4)$	$\Delta F(4^4)$	$\beta - \beta'$
$SU(2)$	1.75, 2.0	0.573, 1.39	0.01, -0.03	> 0.75 ($\beta' < 1.0$ = outside the 2^4 curve)
$SU(2)$	2.25	2.71	0.50	0.53
$SU(2)$	2.5	4.29	2.46	0.30

Group	β	$\Delta F(2^4)$	$\Delta F(4^4)$	$\beta - \beta'$
$SU(2)$	2.75	5.95	5.10	0.13
$SU(2)$	3.0	7.88	7.33	0.07
$U(1)$	0.9	1.15	0.05	> 0.3
$U(1)$	1.0	1.80	1.07	$+0.12$
$U(1)$	1.1	2.46	2.71	-0.04
$U(1)$	1.2	3.10	3.68	-0.11
$U(1)$	1.4	4.18	4.46	-0.05

The errors are 0.01–0.08 on 2^4 and 0.03–0.26 on 4^4. For $SU(2)$, $\beta - \beta' > 0$ at every β that can be read (1.75–3.0), that is, the step function of one step has no fixed point. The closer to strong coupling, the larger the movement in one step, in a form that connects to the strong-coupling values of Table 1. The decrease to 0.07 on the weak-coupling side is likely a lattice artefact, because 2^4 is too small for the one-loop regime. For $U(1)$, **the sign reverses between** $\beta = 1.0$ **and** 1.1. This is at the position of the known phase transition $\beta_c \approx 1.01$: in the confining phase $\beta' < \beta$, in the Coulomb phase $\beta' > \beta$.

Table 4 $4^4 \to 8^4$ for $SU(2)$ ($n_{12} = 1$). ΔF is the simple mean of the per-seed values, and the error is half the difference between seeds Reading

β	$\Delta F(4^4)$	$\Delta F(8^4)$	Seeds (8^4)	$\beta - \beta'$
2.3	—	-0.04 ± 0.10 (≈ 0)	1	$\gtrsim 0.1$
2.5	2.46 (1 seed)	0.48 ± 0.48	1	$\approx +0.25$ ($+0.19$–$+0.5$)
2.7	4.72 ± 0.25	3.11 ± 0.46	2	$+0.16$ ($+0.13$–$+0.19$)
2.9	6.56 ± 0.33	4.68 ± 0.63	3	$+0.20$ ($+0.12$–$+0.29$)
3.0	7.58 ± 0.25	5.78 ± 0.40	2	$+0.18$ ($+0.14$–$+0.25$)

For the 4^4 curve we also used the points $\beta = 2.6$ (3.96 ± 0.13, 1 seed), 2.75 (5.18 ± 0.10) and 2.8 (5.60 ± 0.27). For $4^4 \to 8^4$ too, $\beta - \beta' > 0$ at every β measured, with a mean of about $+0.2$. This is close to the one-loop asymptotic value 0.258 and to the value of about 0.23 expected from the known values of $a\sqrt{\sigma}$ Reading .

How to read this. The test of the sign of the step function distinguishes whether there is a phase transition. $U(1)$ reverses at the position of the transition, and $SU(2)$ does not reverse in the range measured. This is the numerical face of the criterion "distinguish from the U(1) transition" of § 08. However, the lattices are small, up to 8^4, the β points are few, and there are only 1–3 seeds. "For $SU(2)$ the sign does not change over the whole band" is a reading on these lattices and points.

06

The band is a bounded interval — reduction to the area law at fixed β

The band is a bounded closed interval $I = [\beta_a, \beta_b]$ in β. A comparison that crosses infinitely many scales shrinks to finitely many steps on a bounded interval. We write this in the form of the following lemma.

Assumption of two-sided area laws inside the band (the two-sided area law at fixed β on the band I). There are constants $N_1, M_0 \geq 2$, $c_-, c_+ > 0$, $p \geq 0$ and a function $\sigma_N(\beta) > 0$ such that

- Two-sided area law at fixed β: for all $\beta \in I$, $N \geq N_1$, $M \geq M_0$, $c_- N^2 e^{-\sigma_N(\beta) M^2 - pM} \leq \Delta F(N, M, \beta) \leq c_+ N^2 e^{-\sigma_N(\beta) M^2 + pM}$.
- Uniform positivity and continuity of the rate: with $\sigma_* := \inf_{N \geq N_1,\, \beta \in I} \sigma_N(\beta) > 0$, for some $\delta > 0$: if $\beta, \beta' \in I$ and $|\beta - \beta'| \leq \delta$, then for all $N \geq N_1$, $\sigma_N(\beta') \leq \sigma_{2N}(\beta) + \sigma_*$.

The upper side of the two-sided area law at fixed β is the area law (with an error pM of the order of the perimeter), and the lower side is that "vortices are not too cheap", that is, an upper bound on the string tension. The uniform positivity and continuity of the rate says that the rate is uniformly positive on the band and does not change much when β is moved a little.

Lemma Reducing the Comparison inside the Band. Under the assumption of two-sided area laws inside the band, for $\beta \in I$, $\beta' \in [\beta - \delta, \beta) \cap I$, $N \geq N_1$, $M \geq M_0$,

$$\Delta F(2N, 2M, \beta) \leq K \cdot \Delta F(N, M, \beta'), \qquad K = 4 \frac{c_+}{c_-} \exp\Big(\frac{9p^2}{8\sigma_*}\Big) \tag{9}$$

holds. K does not depend on N, M or β.

Proved here Proof. Since $2N \geq N_1$ and $2M \geq M_0$, the upper side of the two-sided area law at fixed β gives $\Delta F(2N, 2M, \beta) \leq c_+ (2N)^2 e^{-\sigma_{2N}(\beta)(2M)^2 + p(2M)} = 4c_+ N^2 e^{-4\sigma_{2N}(\beta) M^2 + 2pM}$. The lower side gives $\Delta F(N, M, \beta') \geq c_- N^2 e^{-\sigma_N(\beta') M^2 - pM}$. Setting $\eta := 4\sigma_{2N}(\beta) - \sigma_N(\beta')$, the uniform positivity and continuity of the rate gives $\eta \geq 3\sigma_{2N}(\beta) - \sigma_* \geq 2\sigma_*$ (using $\sigma_{2N}(\beta) \geq \sigma_*$). The ratio is

$$\frac{\Delta F(2N, 2M, \beta)}{\Delta F(N, M, \beta')} \leq 4 \frac{c_+}{c_-} e^{-\eta M^2 + 3pM} \leq 4 \frac{c_+}{c_-} e^{9p^2/(4\eta)} \leq 4 \frac{c_+}{c_-} e^{9p^2/(8\sigma_*)}$$

The second inequality is the maximum $9p^2/(4\eta)$ of the quadratic $-\eta M^2 + 3pM$, and the third is $\eta \geq 2\sigma_*$. ∎

Corollary Crossing the Band in Finitely Many Steps. The band can be crossed in at most $\lceil(\beta_b - \beta_a)/\delta\rceil$ steps, and the loss over them is K to the power of the number of steps, a constant independent of N and M Proved here . The same proof goes through if β' is lowered further, as long as it satisfies $\sigma_N(\beta') \le 4\sigma_{2N}(\beta) - 2\sigma_*$.

Calibration. The Strong-Coupling-End Expansion Proposition ((6)) gives the two-sided area law at fixed β with $p = 0$ and $c_\pm = 2(1 \pm C'u)$. Then (9) holds with $K = 4(1 + C'u)/(1 - C'u)$, which agrees with $4(1 + O(u))$ of the Comparison at the Strong-Coupling End in § 03 Proved here (the Strong-Coupling-End Expansion Proposition is an assumption, so the agreement is an agreement of form).

What the Lemma Reducing the Comparison inside the Band says. The renormalisation comparison inside the band reduces to "confinement at fixed β (two-sided asymptotics with an error of the order of the perimeter)" at each β of the band. The comparison across scales itself is not needed. The band is entered when the physical box is large, so the two-sided area law at fixed β is needed only in the range where N, M is sufficiently larger than the correlation length $\xi(\beta)$.

What the Lemma Reducing the Comparison inside the Band does not say. The assumption of two-sided area laws inside the band is unproved at every β of the band. The upper side is itself the unsolved problem of confinement at intermediate coupling on the four-dimensional $SU(2)$ lattice. As far as we searched, there is no proof of confinement on the four-dimensional $SU(2)$ lattice at $\beta \approx 1$. The lower side (an upper bound on the string tension to the accuracy of the order of the perimeter) has not been written out either. The lemma does not depend on the group; all the non-commutativity is in the assumption of two-sided area laws inside the band. For $U(1)$ ($\beta \in (1.01, 2.7)$), the assumption of two-sided area laws inside the band is false, so no conclusion follows. This lemma is a reduction, not a tool, and we do not say it has made the band easier.

Where the difficulty gathers Reading (physical estimate). After the Lemma Reducing the Comparison inside the Band, what remains inside the band are problems at fixed β (estimates uniform in the volume, non-convex large fields, the absence of a phase transition). The difficulty of crossing scales does not vanish from inside the band; it gathers at **the upper end of the band** and at **the seam with ultraviolet control**. At the upper end of the band, $\xi(\beta)$ exceeds 10 in lattice units, and the road of checking the two-sided area law at fixed β by computations in finite boxes stops on size. And beyond the upper end of the band ($\beta \to \infty$) is the range taken on by ultraviolet control (7-07), and the two must be joined with the same constant. In terms of the three roots of 24-07 § 05, inside the band it is the source "no global gauge fixing" (the non-convexity of large fields) and excluding a phase transition, and the seam at the upper end is the

source "no expansion linking scales" (there is no expansion that joins the ultraviolet and the infrared).

Example. On the strong-coupling side ($u \le u_0$), a statement of exactly the form of the base point at small T^2 exists as the Strong-Coupling-End Expansion Proposition (at the level of a line of proof). The work of pushing the lower end of the band up to $\beta \approx 0.3$–1 (the lower end of § 04) is, in the words of the Lemma Reducing the Comparison inside the Band, "widening the interval on which the two-sided area law at fixed β holds", and needs no comparison across scales.

07

The four faces of the band in the middle

It has been narrowed down to this: crossing the band in the middle needs one inequality that uses non-commutativity. On **which local quantity to write it in**, there are four candidates. We call them "faces" in the sense that it is enough to show any one of them uniformly in the scale, in a form that fails for $U(1)$. Table 5 lists only the names and the expected behaviour; the detailed examination is in 26-10. Every row is an estimate Reading (physical estimate).

Table 5 The four faces of the band in the middle (expectation rows are physical estimates; numbers are readings)

Face	Local quantity	Expectation for $SU(2)$	Where it fails for $U(1)$
κ_w	Softness in the twist direction: the variance of the force along the generator of the twist (in a strip of width w)	Decreases with w (the soft direction of Nielsen–Olesen; a non-perturbative version of the one-loop $+4$ spin term)	No spin term, $\kappa_w \ge c\beta$
$\delta(L_0)$	The total variation distance on the inner cube when the centre magnetic flux on the boundary of the box is changed	Goes to 0 exponentially in L_0	Remains $O(\beta)$ in the Coulomb phase
$f(\ell)$	The twist free energy of an $\ell \times \ell$ column with its outer frame held fixed	Of the type $e^{-\sigma \ell^2}$	Of the type $\pi^2\beta/\ell^2$ ($\approx 2\beta$ for $\mathbb{Z}_2$)
Pressure margin	The pressure difference $p_\infty - p_{G,L}$ between the system with and without the twist pattern (the exponent of the chessboard density κ_{cb})	A positive margin remains and gives the area law at fixed β	Does not produce a small κ_{cb}

A numerical example. Measuring the column face $f(\ell)$ by the twist bias $\mathbb{E}|\theta_B|$ on $T_4^2 \times \ell \times \ell$ with the outer frame held fixed, $SU(2)$ ($\beta = 2.3$) gives $0.23, 0.07, 0.09$ at $\ell = 4, 5, 6$, and the Coulomb phase of $U(1)$ ($\beta = 1.3$) gives $0.61, 0.49, 0.41$ (0.25 at $\ell = 8$); for $\ell \ge 5$,

$SU(2)$ is 1/5 to 1/7 of $U(1)$ Reading . However, the $SU(2)$ values are close to the statistical floor, and at this size $e^{-\sigma \ell^2}$ cannot be told apart from a power.

For each of the four faces, the comparison across scales (for example $f(2\ell, 2N, \beta) \leq Kf(\ell, N, \beta')$) is a local version with the same difficulty as the global renormalisation comparison, and has not become easier. What changing the face gains is that the object of the proof becomes "a statement about a finite region with its boundary held fixed".

08

Conditions an argument closing the band must satisfy — the criterion "distinguish from the U(1) transition"

The criterion "distinguish from the U(1) transition". $U(1)$ has, inside this band ($\beta \approx 1.01$), a phase transition to a non-confining phase. An argument that closes the band must show that $SU(2)$ has no phase transition, distinguishing it from $U(1)$. This is of the same weight as the unsolved problem that "four-dimensional $SU(2)$ has no transition to a non-confining phase at zero temperature", and proposals that do not satisfy this condition are discarded from the start.

The sign of the step function in § 05 was the numerical face of this criterion. Put another way, **a proof that closes the band is a proof that the direction $\beta' < \beta$ of the comparison does not change over the whole band for $SU(2)$**. Purely structural arguments (reflection positivity, duality, the transfer matrix) hold in the same form for $\mathbb{Z}_2$ and $U(1)$, so they alone do not satisfy the criterion (26-04). Renormalisation that does not distinguish groups (the isometric comparison, the Migdal–Kadanoff flow) does not satisfy it either (§ 03).

Even without closing the whole band at once, there are intermediate goals that satisfy the criterion "distinguish from the U(1) transition".

1. $\Delta F(L, L) \to 0$ (at any speed). In the Coulomb phase of $U(1)$, $\Delta F(L, L)$ tends to $\pi^2 \beta_R /2 - \ln 2$ (the classical half-flux value $\pi^2 \beta_R/2$ minus $\ln 2$ for the two orientations $\pm\pi$ of the half flux; β_R is the renormalised coupling), and in the non-confining phase of $\mathbb{Z}_2$ it increases, so showing this would exclude the known non-confining phases Assumption (the behaviour of the phases is an estimate). It does not give the mass gap. Numerically, for $U(1)$ ($\beta = 1.2$), $2^4 \to 4^4$ is flat at $3.10 \to 3.68$, and for $SU(2)$ ($\beta = 2.75$) it is $5.95 \to 5.10$ Reading .
2. The tension-doubling inequality: there are $\delta_0 > 0$ and N_1 such that $4\sigma_{2N}(\beta) \geq e^{\delta_0} \sigma_N(\beta)$ for all $N \geq N_1$, that is, $s(2N, \beta) \geq e^{\delta_0} s(N, \beta)$ (notation as in the rate form of the renormalisation comparison in § 01). In the Coulomb phase of $U(1)$, s is constant

across scales and sits exactly on the boundary $\delta_0 = 0$, and in the non-confining phase of $\mathbb{Z}_2$, $s \to 0$ and it is on the negative side, so it satisfies the criterion "distinguish from the U(1) transition" Reading (the values for the three phases come from closed-form models and small lattices). What follows is $s(2^k N_1) \geq e^{k\delta_0} s(N_1) \to \infty$, which excludes the Coulomb phase and the non-confining phases of discrete groups Proved here (the arithmetic of iteration). To pass to the first statement above, $\Delta F(L, L) \to 0$, control of the difference between the values on symmetric boxes and the slab tension is needed separately. Neither the mass gap nor the area law follows. Its row in the list of premises is in 28-04.

3. $\ln(1/\theta(L, L)) \geq cL^2/\ln L$ (nearly the area law). Through the Tomboulis–Yaffe inequality Cited, the Wilson loop decreases faster than the perimeter law (of the type $\langle W \rangle \leq 2\exp(-cA/\ln A)$).
4. The band itself: $\ln(1/\theta(L, L)) \geq cL^2$ (26-01).

Reading the band in the language of the gap — the band comparison (in the language of the gap). The vortex free energy is a quantity on the side of electric flux $e \neq 0$ ((4)(5) of § 02), while the mass gap needs the side $e = 0$. A comparison crossing the band on the neutral side can be written as the absence of a fixed point of the doubling map of $x(L) = L\, m_0(L)$, the gap of the box measured in units of the box size; that is, in the form $x(2L) \geq x(L) + \delta$ on the interval of the band (with δ independent of the lattice spacing) Assumption. In the Coulomb phase of $U(1)$, x stays at the photon value 2π (in a periodic box $x(2L)/x(L) = 1/\cos(\pi/2L) \to 1$), so this form satisfies the criterion "distinguish from the U(1) transition" Paper. The form of a ratio of rates, $m_0(2L) \geq (\frac{1}{2} - \varepsilon) m_0(L)$, is satisfied trivially by $U(1)$, with $m_0(2L)/m_0(L) = 1/(2\cos(\pi/2L)) > \frac{1}{2}$, so it cannot be used to distinguish Paper. The content of the distinction lies in the step δ being uniform. Of the four faces (§ 07), κ_W and $\delta(L_0)$ (extended to all boundary conditions) also act on the neutral side, while $f(\ell)$ and the pressure margin are quantities on top of the centre twist and belong only to the side of confinement Reading. The Tomboulis–Yaffe inequality is a structural inequality that holds with the same proof for $U(1)$, and its output is in the charged sector, so it is a tool for stepping down to the side of confinement, not a tool for the band comparison (in the language of the gap) Reading. The criterion on the gap side is narrower than the one on the confinement side, in that it need not exclude the non-confining phase of $\mathbb{Z}_2$ (which also has a gap). None of these rows has been shown.

The test models other than U(1) (Z_2, finite non-abelian groups, the adjoint Higgs limit, mixed actions, SU(N), G_2) are listed in 26-12.

09

What cannot be said

(a) We show neither the renormalisation comparison nor β-monotonicity at any β of the band.

(b) The strong-coupling end is a line, part of whose bookkeeping is sketched, in the range $u \le u_0 \approx 10^{-80}$. The weak-coupling end is at the one-loop level, not a non-perturbative claim. Do not read "it holds at both ends" with these two conditions removed.

(c) The Lemma Reducing the Comparison inside the Band is a reduction, and the assumption of two-sided area laws inside the band contains an unsolved problem. We do not say that the lemma made the band easier.

(d) The numbers of § 05 are readings on small lattices up to 8^4, with few β and 1–3 seeds, and are not evidence that there is no phase transition.

(e) The four faces of Table 5 are candidates, and none of them has an estimate uniform in the scale.

(f) The relation between β-monotonicity and the monotonicity of the string tension includes a step that is a reading (§ 02). Nor do we say that β-monotonicity is false.

10

The table of the five grades and the dependency graph

Table 6 The rows of this chapter ("—" marks a row with no machine checking; the rows of this chapter have no Lean column)

Row	Statement (one line)	Grade	Basis	Scope
1	$\partial_\beta \Delta F = \langle \Delta S \rangle$	Proved here	§ 01	With the lattice geometry held fixed
2	The Gibbs variational principle (7)	Cited	§ 03	Measurable bijection T
3	(4)(5): β-monotonicity $\Leftrightarrow E_1 \ge E_0$ $\Leftrightarrow \theta$ increases in β	Proved here	§ 02	$Y_1 > 0$
4	β-monotonicity has the same weight as the β-monotonicity of the string tension in lattice units	Assumption	§ 02 (the step connecting the electric flux with the tension has not been written out)	On every lattice
5	Partial results on β-monotonicity (1 and 2 sheets in two dimensions, $\beta \to 0$, $\beta \to \infty$ in the twisted background)	Assumption	§ 02 (the proofs are not set out in the book)	The conditions of each case

Row	Statement (one line)	Grade	Basis	Scope
6	Strong-Coupling-End Expansion Proposition: the form (6) of the vortex free energy at the strong-coupling end	Assumption	Line: the bookkeeping of step 5 of the proof is sketched	$u \le u_0 \approx 10^{-80}$, N, $M \ge 2$
7	The Comparison at the Strong-Coupling End $K = 4(1 + O(u))$, $\beta' < \beta$	Assumption	Algebra on top of the Strong-Coupling-End Expansion Proposition	As above
8	The expansion (8) of the heat-kernel trace: $\frac{11}{3} = -\frac{1}{3} + 4$	Proved here	§ 03	One loop, constant background
9	The isometric comparison gives $\beta' \ge \beta + 0.023$ (against asymptotic freedom)	Proved here	§ 03, 25-07	One-loop level, per doubling
10	The comparison that reshapes the fluctuations gives $\beta' = \beta - 0.258$	Proved here	§ 03, 25-07	One-loop level, per doubling
11	Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3; the direction of confinement at fixed N and large β)	Assumption	A paper proof in the paper (with citations). Not set out in the book	Fixed N
12	Table 2: for $(4, 8) \to (8, 16)$, $SU(2)$ gives $\beta' < \beta$, $U(1)$ gives $\beta' > \beta$	Reading	§ 05	Lattices, β and seeds as in the table
13	Tables 3 and 4: for $SU(2)$ the sign does not change; for $U(1)$ it reverses at $\beta = 1.0$–1.1	Reading	§ 05	Up to 8^4, 1–3 seeds
14	Lemma Reducing the Comparison inside the Band: the comparison (9) inside the band under the assumption of two-sided area laws inside the band	Proved here	§ 06	Two-sided area law at fixed β, uniform positivity and continuity of the rate, $N \ge N_1$, $M \ge M_0$
15	Corollary Crossing the Band in Finitely Many Steps: the band can be crossed in finitely many steps, with a loss independent of N, M	Proved here	§ 06	As above
16	Calibration: $K = 4(1 + C'u)/(1 - C'u)$ in the form of the Strong-Coupling-End Expansion Proposition	Proved here	§ 06	Agreement of form (the Strong-Coupling-End Expansion Proposition is an assumption)

Row	Statement (one line)	Grade	Basis	Scope
17	The difficulty gathers at the upper end of the band and at the seam with ultraviolet control	Reading	§ 06 (physical estimate)	—
18	The four faces of the band in the middle and their expectations	Reading	§ 07 (physical estimate)	—
19	The criterion "distinguish from the U(1) transition": the transition of $U(1)$ inside the band, and the condition on an argument closing the band	Reading	§ 08 (the position of the transition is a known numerical value; physical estimate)	—

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The two-sided area law at fixed β and the uniform positivity and continuity of the rate are written as conditions in the row of the Lemma Reducing the Comparison inside the Band and are not made nodes, because the assumption rows do not contain the quantity of the conclusion (the comparison that crosses the band). Among the nodes of this chapter there is no node for the comparison at any β of the band, none for confinement, and none for the mass gap.

What this chapter can say

What is said	What is not said
Proved here β-monotonicity and its restatement (4)(5) in terms of the electric flux. That, at the one-loop level, the isometric comparison gives only the direction against asymptotic freedom ($\beta' \geq \beta + 0.023$), and the comparison that reshapes the fluctuations gives $\beta - \beta' = 0.258$	β-monotonicity itself. The non-perturbative weak-coupling comparison
Proved here Lemma Reducing the Comparison inside the Band: that the comparison inside the band reduces to the two-sided area law at fixed β (the assumption of two-sided area laws inside the band)	A proof of the assumption of two-sided area laws inside the band at any β. Having made the band easier
Assumption The Comparison at the Strong-Coupling End ($u \leq u_0 \approx 10^{-80}$, part of the bookkeeping sketched). The upper end at fixed N (the Confinement Lower Bound by Fractional Instantons; Theorem A of Paper 3)	A proof set out in the book. Raising u_0 to a practical range
Reading That on lattices up to 8^4 the direction of the comparison does not change for $SU(2)$ and reverses at the position of the transition for $U(1)$	Evidence that there is no phase transition. The same reading on large lattices

Terms used in this chapter — the crossover band, β-monotonicity, the renormalisation comparison, the isometric comparison, the comparison that reshapes the fluctuations, the step function, the four faces, the criterion "distinguish from the U(1) transition", the reduction lemma. Their meanings are in A-02 Glossary.

Next chapter: 26-07 The band seen from the side of time — the statement corresponding to the band on the road of Part 23, and why the first-step wall, the "summit-curvature shortfall wall", is a miniature of the band and not the band.

The band seen from the side of time

> This chapter is this book's own investigation. § 06 is a map of open questions.

What this chapter shows — Part 23 was a road that approaches the mass gap from the side of Langevin time (relaxation of a stochastic dynamics). This chapter states exactly which statement on that road corresponds to the crossover band, and settles the relation between the band and the wall, the "summit-curvature shortfall wall", at which Part 23 actually stops. There are two answers. (1) The four-dimensional goal of Part 23 (the physical-unit target level of 23-15) is a statement uniform over all scales — that the upper side of the diffusive-relaxation-time assumption (the relaxation-time upper-bound assumption) and the one-sided bridge hold with the same constant as $\beta \to \infty$ — and it must cross the band. (2) The first-step wall, the "summit-curvature shortfall wall", is a miniature of the band, but it is not the band. This is because its crossover length is fixed classically by the first conjugate point of the Jacobi equation at the summit (about 7.84 sites), does not depend on $\hbar$, and is finite in lattice units. The length $1/\Lambda$ of the four-dimensional band is born by quantisation and diverges in lattice units. The two walls **are of the same type and differ in content**. We put this into a comparison table of six columns.

Prerequisite chapters — 23-15 § 07 (the three levels of the goal), 23-01 § 06 (the one-sided bridge), 23-09 § 06 (the curvature $\frac{15}{4}$ of one site at the summit, and 4), the short-core step of 23-11 § 05 (convexity up to length 7), 24-06 (paying with rarity), 24-07 (precisely because it is four-dimensional; the three sources of difficulty), 26-06 (the renormalisation comparison and the four faces), 4-07 (dimensional transmutation).

Said first — The level is [Res]. The only proofs set out are the computation of the Jacobi equation at the summit and of the first conjugate point in § 02, the proof of the Hidden-Convexity Proposition in § 03, and the one line of algebra in § 01. The contrast between the two walls is a physical estimate, and the statement that crosses the band is itself an assumption on either road. A note on words: 23-01 § 05 in Part 23 uses the word "band statement" for the statement that C_P lies in a range of width a constant times the square of a length (the range of constant-multiple width = the band). The "band" of this chapter is the "crossover band" of Part 26 (the crossover at $L \sim 1/\Lambda$), a different word. The list of places where "band" is used in other senses in Parts 23 and 24 is in 26-00 Table 0. It is also different from the "window" of Parts 23 and 24 (the site window, the $\hbar$ window, the time window). The convexity constant up to length 7 is written $\kappa_{\mathrm{C7}}(k)$, to distinguish it from the chessboard density κ_{cb} (the same quantity as $\kappa(k)$ of 23-11).

The order of this chapter

1. The statement on the road of Part 23 that corresponds to the band — the physical-unit target level, and uniformity with the same constant
2. The wall of the first step is fixed by a classical length — the Jacobi equation at the top and the first conjugate point
3. The type is the same — different tools at the two ends, the worst-case estimate stops in the middle, and on to averaging tools
4. The content differs — the origin of the crossover length, rare and typical, phase transitions
5. The comparison table of the two walls — six columns (Table 1)
6. A supplement to Part 23 — the road of blocks and mixing — towards the third branch of 23-15
7. What cannot be said
8. The table of the five grades and the dependency graph — Table 2

01

The statement on the road of Part 23 that corresponds to the band — the physical-unit target level, and uniformity with the same constant

Part 23 split the goal of the mass gap on the four-dimensional lattice into three levels (23-15 Table 5): the lattice target level, that the correlation length is finite at each β on the lattice; the physical-unit target level, that the lattice mass measured in physical units, $m_{\mathrm{lat}}(\beta)/a(\beta)$, tends to a positive finite value Δ_∞; and the continuum target level, that the gap is positive in the continuum theory. On the road from the side of time, the physical-unit target level is what corresponds to the band.

The lower half of the physical-unit target level (that the mass does not collapse to 0) follows by one line of algebra from two statements: the upper-bound assumption, the upper side of the diffusive-relaxation-time assumption ((14) of 23-01 § 05), and the one-sided bridge (in the form of the One-Sided Bridge Proposition of 23-01 § 06).

$$\exists\,\beta_0,\ C,\ \kappa>0\ \ \forall \beta\ge\beta_0:\qquad \underbrace{a(\beta)^2\,C_P(\beta)\ \le\ C}_{\xi^2\uparrow},\qquad \underbrace{C_P(\beta)\ \ge\ \kappa\,\xi(\beta)^2}_{\text{one-sided bridge}}\ \ (1)$$

$$\Longrightarrow\qquad \frac{m_{\mathrm{lat}}(\beta)}{a(\beta)}\ =\ \frac{1}{a(\beta)\,\xi(\beta)}\ \ge\ \sqrt{\kappa/C}\qquad (\beta\ge\beta_0)\ \ (2)$$

Proved here Proof. From the two parts of (1), $\kappa\xi^2 a^2 \le a^2 C_P \le C$; taking the reciprocal of the square root of both sides gives (2). ∎ (The same algebra as (16) of 23-01 § 06. C_P is the Langevin Poincaré constant of the Wilson measure, $\xi = 1/m_{\mathrm{lat}}$ the correlation length in lattice units, and $a(\beta)$ the lattice spacing.)

The content of (1) lies in the order of the two quantifiers: C **and** κ **do not depend on** β, that is, it holds with the same constant on all lattices as $\beta\to\infty$. The one-sided bridge can be shown, for continuous time and a finite spatial lattice, as a proposition with named assumptions, but its lifting to the four-dimensional lattice is only a prospect of form Assumption (the row of the fourth step in 24-07 Table 2). The upper-bound assumption is an assumption in four dimensions Assumption.

Why this statement crosses the band Reading (physical estimate). As β grows, the lattice spacing $a(\beta)$ goes to 0, and the correlation length in lattice units grows like $\xi(\beta)\propto e^{3\pi^2\beta/11}$ (the one-loop bookkeeping, 23-03 Table 2). The Wilson measure at one fixed β contains all scales from one lattice step up to $\xi(\beta)$, and the effective coupling at the scale of length L is small for $L\ll 1/\Lambda$, becomes $O(1)$ at $L\sim 1/\Lambda$, and beyond that enters strong-coupling behaviour. $C_P(\beta)$ is a supremum over all test functions, so it includes the slowest relaxation, that is, the behaviour at the longest scales. So showing (1) with a C independent of β includes passing, with the same constant, at every β, through the scales at which the effective coupling becomes $O(1)$ — the crossover band. The goal of the road from the side of space (the uniform slab tension: a tension positive uniformly in L, 26-00) is a statement of the same type. That the two roads arrive at a statement of one type, "the same constant at every scale", is what the confluence of Part 26 means.

This uniformity takes up again something Part 23 already said. The end of 23-15 § 07 wrote that what is missing is not the number of steps but uniformity, holding at every scale with the same constant, and that it appears at the first step in a form uniform as $\hbar\to 0$ and on the four-dimensional lattice in a form uniform as $\beta\to\infty$. The question of this chapter is whether that first-step version is **the same thing** as the four-dimensional band.

02

The wall of the first step is fixed by a classical length — the Jacobi equation at the top and the first conjugate point

First, the place. The first step is the path measure $\mu\propto e^{-S/\hbar}$ of the double well in 0+1 dimensions, with

$$S(z)=\sum_i\Big[\frac{(z_{i+1}-z_i)^2}{2\varepsilon}+\varepsilon V(z_i)\Big],\qquad V(z)=\frac{(z^2-1)^2}{8},\qquad \varepsilon=\tfrac12\ \ (3)$$

(23-04). The wall appears in the conditional measure on the interval (the core) $Q_k=[-x_c,0]^k$ ($x_c=0.89$, Neumann faces) in which the path stays between the summit $z=0$ and the well, and the goal is that its Poincaré constant is uniform in the length k of the core, the end values and $\hbar$ (the core Poincaré uniformity assumption, 23-15 § 02).

The Hessian at the top configuration $z\equiv 0$ is the tridiagonal $\mathrm{tridiag}(-2,\frac{15}{4},-2)$, and the diagonal $\frac{15}{4}$ of one row falls short of the sum of couplings 4 by $\frac14$ (23-09 § 06). We reread this shortfall in the language of the calculus of variations.

The Jacobi equation at the top. Linearising the Euler–Lagrange equation of S at the top $z\equiv 0$ gives, for the displacement u_n,

$$-2u_{n-1}+\tfrac{15}{4}\,u_n-2u_{n+1}=0\ \ (4)$$

For general ε the diagonal is $2/\varepsilon+\varepsilon V''(0)=2/\varepsilon-\varepsilon/2$ and the coupling to neighbours is $1/\varepsilon$, and (4) can be written $u_{n-1}+u_{n+1}=(2-\varepsilon^2/2)u_n$. Substituting $u_n=e^{\pm in\theta}$, the characteristic equation is $2\cos\theta=2-\varepsilon^2/2$, that is,

$$\cos\theta=1-\frac{\varepsilon^2}{4}\qquad (\varepsilon=\tfrac12\ \text{gives}\ \cos\theta=\tfrac{15}{16},\ \ \theta=0.35542\ldots)\ \ (5)$$

and since $|\cos\theta|<1$, the solution is a rotation $u_n=\sin(n\theta)$ ($u_0=0$). Seen through the linearisation $\ddot u=V''(0)u=-\frac12 u$ of the Euclidean equation of motion $\ddot z=V'(z)$ too, the top is not a point of exponential departure but a point of rotation.

The first conjugate point. The position $n=\pi/\theta$ at which the solution starting from $u_0=0$ next becomes 0 is the first conjugate point. At $\varepsilon=\frac12$,

$$\frac{\pi}{\theta}=8.8391\ldots,\qquad \frac{\pi}{\theta}-1=7.8391\ldots\ \approx\ 7.84\ \ (6)$$

Proved here (the numerical value of $\theta=\arccos(15/16)$. As an independent check, running the recursion (4) from $u_0=0,u_1=1$ gives $u_8=0.844>0$, $u_9=-0.164<0$, and the zero of the linear interpolation is 8.837).

The threshold of convexity = the conjugate point. The smallest eigenvalue of the Hessian $\mathrm{tridiag}(-2, \frac{15}{4}, -2)$ at the top of a lump of length k with both ends fixed is

$$\kappa_{\mathrm{C7}}(k) \;=\; \tfrac{15}{4} - 4\cos\frac{\pi}{k+1} \;=\; 8\sin^2\frac{\pi}{2(k+1)} - \frac{1}{4} \quad (7)$$

(the closed formula for the eigenvalues of a tridiagonal matrix), and it is positive only when $\pi/(k+1) > \theta$, that is, $k+1 < \pi/\theta$. From (6), it is positive for $k \le 7$ and negative for $k \ge 8$ Proved here ($\kappa_{\mathrm{C7}}(7) = 0.0545$, $\kappa_{\mathrm{C7}}(8) = -0.0088$. The difference between numerical diagonalisation and (7) is of order 10^{-15} for $k = 5$–10). "Convex up to length 7, broken from 8" (the Short-Core Convexity Lemma of 23-11 § 05) is exactly the discrete version of the Jacobi criterion of the calculus of variations: whether a conjugate point falls in the interval $[0, k+1]$.

This length is classical and does not depend on $\hbar$. $\hbar$ never appears in (4)–(7). What appears is only the form of the action S (the coefficient $1/\varepsilon$ of the kinetic term and the curvature at the top $V''(0) = -\frac{1}{2}$). The limit taken at the first step is $\hbar \to 0$ with $\varepsilon = \frac{1}{2}$ fixed, so the crossover length stays at about 7.84 sites throughout the limit and is finite in lattice units. In units of time it is $\varepsilon \cdot \pi/\theta \approx 4.42$, close to the value $\pi/\sqrt{|V''(0)|} = \pi\sqrt{2} \approx 4.44$ (the half period of rotation at the top) in the limit where time is made continuous. Sending ε to 0 makes the number of sites grow as $1/\varepsilon$, but that is not the limit the problem of the first step takes.

Example. For $\varepsilon = \frac{1}{4}$ it is $\pi/\theta - 1 \approx 16.75$ sites, which in units of time is ≈ 4.44. As a number of sites the length changes with the step; as a physical time it is fixed by the number $V''(0)$ in the action.

A numerical agreement with the mixing length (the mechanism is different). The number of sites over which the influence of the worst end value (the top) drops below 10^{-2} in total variation hardly moves for $\hbar = 10^{-2}$–10^{-5} and is about 9; changing the step to $\varepsilon = 0.35, 0.5, 0.7, 0.9$ gives $12, 9, 7, 5$, numerically close to $\pi/\theta = 12.7, 8.8, 6.3, 4.9$ Reading . But the mechanism is not "staying near the top for half a period". The optimal path as $\hbar \to 0$ starts going down from the top at once and reaches the corner $-x_c$ of the box in a finite number of steps (7 at $\varepsilon = \frac{1}{2}$), and the mixing length is roughly that number of steps plus 2 Reading . Why the two values are close is not known. What this chapter claims about the conjugate point is only the convexity threshold of (7).

03

The type is the same — different tools at the two ends, the worst-case estimate stops in the middle, and on to averaging tools

Setting the two walls side by side shows the same type Reading (physical estimate; a comparison of types, implying no statement on either side).

There are different tools at the two ends. At the first step, short lumps ($k \le 7$) are bounded uniformly in the end values and $\hbar$ by the convexity of (7) (the Short-Core Convexity Lemma Proved here), and inside the wells local Poincaré within the phase (the in-phase local Poincaré condition, 23-06) works. In the four-dimensional band, the expansion works at the strong-coupling end, and the one-loop comparison at the weak-coupling end (26-06 § 03; on the strong-coupling side the line of argument for $u \le u_0 \approx 10^{-80}$, on the weak-coupling side the one-loop level).

In the middle, the estimate of the worst configuration stops. At the first step, every tool that takes the worst configuration as its entrance comes back to the same one-line shortfall $\frac{15}{4} < 4$ Proved here (each row is a two-line computation).

- The one-site Dobrushin influence coefficient: the conditional one-site measure is $\frac{15}{4}$-convex, and with the coupling $1/\varepsilon = 2$ to neighbours the influence from one neighbour is $\le 2/\frac{15}{4} = \frac{8}{15}$, and from two $\frac{16}{15} > 1$.
- The influence of a block of length 7: by Brascamp–Lieb and an entrywise comparison of M-matrices, the influence from the left end to the right end is $2\,(M_7^{-1})_{71} = 2 \cdot 2^6/\det M_7 \approx 1.18 > 1$ (7×7 for $M_7 = \mathrm{tridiag}(-2, \frac{15}{4}, -2)$, $\det M_7 = 1770735/16384 \approx 108.08$).
- The Otto–Reznikoff criterion: it needs the positivity of $\mathrm{tridiag}(-2, \frac{15}{4}, -2)$, which fails on the infinite chain with lower end $-\frac{1}{4}$.

In the four-dimensional band, the road that estimates with the worst frame plays the same role. The tension that comes out of the slab-confinement estimate $\sup_\Phi \theta \le \tanh(\beta L^2)^{\ell^2}$ (25-04) is $\sigma \ge -\ln\tanh(\beta L^2) \approx 2e^{-2\beta L^2}$, which gets worse superexponentially in L ($2e^{-80}$ at $\beta = 2.5$, $L = 4$). Structural inputs alone (reflection positivity, duality, the transfer matrix) hold in the same form for $\mathbb{Z}_2$ and $U(1)$, and cannot cross the band (26-04). Each side has a "worst single point": at the first step the face $x \equiv 0$ where every site is at the top, in four dimensions the place where the plaquettes are at the centre element -1.

Moving to averaging tools, there is a prospect that uniformity comes out. At the first step, the correlation length of the transfer operator gets shorter as $\hbar$ is made smaller (from 1.68 to 0.48 as $\hbar = 0.1$ goes to 3×10^{-4}) Reading , and the influence of the worst end value also vanishes over a length almost independent of $\hbar$ (§ 02). This is because the rarity of configurations near the top ($P(z > -0.5) \approx 10^{-252}$ at $\hbar = 3 \times 10^{-4}$) Reading is paid automatically inside the transfer operator ("paying with rarity" of 24-06 § 06). On the four-dimensional side, if L is fixed, frame decorrelation is replaced by the single chessboard density κ_{cb} (an averaged quantity) (26-05). Estimates across scales are entrusted to one of the four faces (26-06 § 07) Assumption .

A first-step version of the averaging tool has been proposed down to a concrete form (§ 06). We set out, with proof, the uniqueness proposition at its entrance.

Hidden-Convexity Proposition. For any $\varepsilon > 0$, $c > 0$, $l \geq 1$ and end values $a, b \in [-c, 0]$, the action S (with the V of (3) and both ends fixed at a, b) has exactly one local minimum on the box $[-c, 0]^l$, and it is the global minimum.

Proved here Proof. Put $z_i = -\sqrt{\rho_i}$ ($\rho_i \in [0, c^2]$). (i) $(z_{i+1} - z_i)^2 = \rho_{i+1} + \rho_i - 2\sqrt{\rho_i \rho_{i+1}}$, and the geometric mean $\sqrt{xy}$ is concave on $[0, \infty)^2$, so $-\sqrt{\rho_i \rho_{i+1}}$ is convex. (ii) The end term $(z_1 - a)^2 = \rho_1 + a^2 - 2|a|\sqrt{\rho_1}$ is also convex, since $-\sqrt{\rho_1}$ is convex (likewise at the right end). (iii) $V(z) = (z^2 - 1)^2/8 = (\rho - 1)^2/8$ is strictly convex in ρ with second derivative $\frac{1}{4}$. Hence $\tilde{S}(\rho) := S(-\sqrt{\rho})$ is strictly convex on the convex set $[0, c^2]^l$ with $\nabla^2 \tilde{S} \geq (\varepsilon/4) I$, and its local minimum is unique and global. $\rho \mapsto -\sqrt{\rho}$ is a homeomorphism from $[0, c^2]^l$ to $[-c, 0]^l$, so the local minima correspond to each other. ∎

What the Hidden-Convexity Proposition says is the uniqueness of the minimum, not a Poincaré inequality. The Dirichlet form is written in the flat metric of z, so convexity in the coordinates ρ does not give Bakry–Émery as it stands. Writing the measure in ρ attaches $\prod_i (2\sqrt{\rho_i})^{-1}$ to the density, and the concavity of its logarithm breaks convexity only for $\rho_i \lesssim \sqrt{2\hbar/\varepsilon}$ (a thin layer very close to the summit) (comparing $\frac{\varepsilon}{4\hbar}$ with $\frac{1}{2\rho^2}$). One can read the non-convexity of the "summit-curvature shortfall wall" as moving from what looked, in the coordinate z, like lumps at the summit of length 8 or more, to rare thin layers site by site in the coordinate ρ Assumption (the argument that pays for this layer with rarity has not been built).

04

The content differs — the origin of the crossover length, rare and typical, phase transitions

Even with the same type, three points that decide the weight of the wall differ Reading (physical estimate).

(i) The origin of the crossover length. The crossover length of the first step is the first conjugate point (about 7.84 sites), a classical length fixed only by numbers written in the action S (the coefficient of the kinetic term and the curvature at the top). Throughout the limit $\hbar \to 0$ it stays finite in lattice units (§ 02). The length of the four-dimensional band is $1/\Lambda$, and the action has no ruler of length (in four dimensions the coupling is dimensionless, 24-07 § 01). The length is born by quantisation, in the one-loop bookkeeping in the form $\Lambda = \mu \exp(-1/(2b_0 g^2(\mu)))$ (dimensional transmutation, 4-07) Cited , and in lattice units $1/(a\Lambda)$ diverges like $e^{3\pi^2 \beta/11}$ as $\beta \to \infty$. All derivatives of $\exp(-1/g^2)$ vanish at $g = 0$, so this length appears at no order of the expansion in the coupling.

(ii) Whether bad configurations are rare or typical. At the first step, configurations near the summit are rare (the 10^{-252} of § 03), and the currency of "paying with rarity" of 24-06 works. In the four-dimensional band, the bad configurations (thick centre vortices, fractional instantons) are the mechanism of confinement itself, and are typical. The rate of rarity runs out in the band. This is the same point as the row of the source "no expansion linking scales" in 24-07 § 05 (in the infrared, configurations for which the Gaussian approximation fails become typical, and there is no currency of rarity).

(iii) Whether a phase transition is possible. The core of the first step is a one-dimensional nearest-neighbour chain over a compact one-site space. The transfer operator is a positive integral kernel, so there is no phase transition that would prevent estimates uniform in the length of the chain Assumption (a fact about the principal eigenvalue of positive integral kernels; the same bibliography as [001] of 23-15 Table 1, the original still to be obtained). At fixed β in four dimensions, an estimate uniform in the volume has the same weight as "there is no phase transition", and $U(1)$ actually has a transition inside the band ($\beta \approx 1.01$). An argument that closes the band must distinguish itself from $U(1)$: this is the criterion "distinguish from the U(1) transition" (26-06 § 08).

One decisive difference follows from (i). At the first step, if one chooses a **finite** block (length 12) longer than the crossover length, a two-stage road stands: analysis around a single minimum inside the block, and strong mixing between blocks (§ 06). In four dimensions the crossover length $1/\Lambda$ diverges in lattice units, so there is no finite block longer than it. **So we cannot expect the tools of the first step to cross the band as they are.** The "dimensionless coupling = no classical length" of 24-07 § 01 is the reason for this difference.

A supplement. Through the reduction lemma of 26-06 § 06, the inside of the band becomes "an estimate uniform in the volume at fixed β", a statement of the same form as the wall of the first step (an estimate uniform in the length k at fixed $\hbar$). Three things are common: a fixed parameter, uniformity in the volume, and passing through a non-convex region. That the weights still differ is because of (ii) and (iii). And after the reduction, the difficulty of crossing scales gathers at the seam between the upper end of the band and ultraviolet control (ibid. § 06). At the first step there is no flow of the coupling (among the sources of difficulty, the source "dimensionless coupling" is absent), so there is nothing corresponding to this seam.

05

The comparison table of the two walls

Table 1 gathers § 02– § 04 into six columns. The label of each cell is written inside the cell. Comparisons of type (readings across rows) are all estimates Reading .

Table 1 The wall of the first step and the four-dimensional band (columns (1)–(6))

	(1) Place and object	(2) Crossover length and its origin	(3) Tools that work at the two ends	(4) Tools that stop in
The first-step wall, the "summit-curvature shortfall wall"	The path measure of the double well in 0+1 dimensions ($\varepsilon = \frac{1}{2}$, $\hbar \to 0$). The Poincaré constant of the conditional measure on the core $[-x_c, 0]^k$, uniform in k, the end values and $\hbar$ (the core Poincaré uniformity assumption)	The first conjugate point at the summit, $\pi/\theta - 1 \approx 7.84$ sites, $\cos\theta = 1 - \varepsilon^2/4$. A classical length fixed by the action alone, independent of $\hbar$, finite in lattice units Proved here	Short lumps: convexity for $k \le 7$ (the Short-Core Convexity Lemma, $\kappa_{C7}(7) = 0.0545$) Proved here . Inside the wells: local Poincaré within the phase (the in-phase local Poincaré condition; labels per row in 23-06)	Curvature at the wc the rows of Dobrusl of length 7 (≈ 1.18),), Brascamp–Lieb a back to $\frac{15}{4}$ against 4 worst point is the fa
The four-dimensional band	The vortex free energy of the slab $(\mathbb{Z}/N)^2 \times (\mathbb{Z}/M)^2$ ($n_{12} = 1$) of the four-dimensional $SU(2)$ lattice. $\ln(1/\theta(L,L)) \ge cL^2$ uniformly in L (26-01)	$1/\Lambda$. The action has no length (the coupling is dimensionless); it is born by quantisation (dimensional transmutation) Cited . Diverges in lattice units as $\beta \to \infty$	The strong-coupling expansion ($u \le u_0 \approx 10^{-80}$, part of the bookkeeping sketched) Assumption . The one-loop comparison (with reshaped fluctuations, $\beta - \beta' = 0.258$) Proved here (one-loop level)	The worst frame: su gets worse superexp 04). Structural inpu for $\mathbb{Z}_2$ and $U(1)$ (26- comparison goes ag freedom (26-06). Th centre element -1

How to read Table 1. Reading columns (3)–(5) across, the type is the same (different tools at the two ends, the worst-case estimate stops in the middle, then averaging tools); comparing columns (2) and (6) down, the content differs (whether the origin of the length is classical or quantum, whether a phase transition is possible). The answer to the question "can the summit-curvature shortfall wall be written in the same words as the band?" is: **the type can be written in the same words, and the content (the origin of the crossover length) differs**.

06

A supplement to Part 23 — the road of blocks and mixing

The following road has been proposed as a candidate for supporting the core Poincaré uniformity assumption without going through the LSI constant A_W of the site window (23-09). As the third branch, "the road of blocks and mixing", of the fork of Part 23 (23-15 § 02), its table of rows and dependency graph are in the subsection on the road of blocks and mixing in 23-15. Here we write only the skeleton needed for the relation to the band.

1. **Block LSI** Assumption : on blocks of length $\ell_B \ge 12$ (avoiding the conjugate point ≈ 7.84 and the length 8 at which convexity breaks), uniform in the end values and $\hbar$. The entrance is the Hidden-Convexity Proposition (§ 03) Proved here ; the curvature at the minimiser for the worst end values $\lambda_*(12) \ge 0.255$ Reading (interval arithmetic for the minimisers at the four corners remains); and Witten's Morse theory together with the Menz–Schlichting decomposition, which derive from a single non-degenerate minimum that there are no exponentially small eigenvalues (the form at the corners of a Neumann box not yet checked).
2. **Strong mixing** Assumption : in three stages — the optimal path as $\hbar \to 0$ reaches the corner of the box within 7 steps from every starting point (the record is a 50-digit KKT certificate, the Hidden-Convexity Proposition and Topkis monotonicity; Reading until it is checked whether this is interval arithmetic with outward rounding), concentrates within a width $\approx 0.8\sqrt{\hbar}$, and has a Doeblin overlap in the boundary layer at the corner — one gets $\mathrm{TV}(n) \le (1-\delta)^{\lfloor n/10 \rfloor}$ with δ independent of $\hbar$. The second and third stages are along the lines of the constrained Laplace method.
3. **The standard theorem for one-dimensional chains** Assumption : from block LSI and strong mixing, an LSI uniform in the length of the chain (of the Zegarlinski and Martinelli–Olivieri type; the version for compact continuous spins not yet checked). Poincaré follows from LSI and reaches the core Poincaré uniformity assumption.

Where it stands. Even if the road of blocks and mixing closes, the first step does not close. The rows common to the two roads (the tube, the reduced kink gas, the cross term, the extension of the in-phase local Poincaré condition and others: the 13 common rows of 23-15 Table 1) remain on the road of blocks and mixing too. If a mild dependence on $\ln(1/\hbar)$ remains in the mixing length, the power statement ($\ln CP / \ln \xi \to 2$) is expected to be unaffected, but rows that need the constant to be uniform in $\hbar$ are affected (details in the subsection on the road of blocks and mixing in 23-15).

The relation to the band. The road of blocks and mixing is the first-step version of the stage "move to averaging tools" in the type of § 03. And as in § 04 (i), its key was that there is "a finite block longer than the crossover length". The four-dimensional band has no such finite block. Even if the road of blocks and mixing succeeds at the first step, we cannot say it gives a tool that crosses the band. In the form carried over to four dimensions (a box criterion with fixed boundary + strong mixing, the face $\delta(L_0)$), that "strong mixing" is precisely where $U(1)$ breaks Reading (physical estimate).

07

What cannot be said

(a) Neither half of the statement (1) that crosses the band has been shown in four dimensions. (2) is one line of algebra on top of (1).

(b) The comparison of the types of the two walls (§ 03, § 04, readings across the rows of Table 1) is an estimate, and we do not say that results at the first step imply anything in four dimensions. Only the form of the statement lifts (23-03 § 06).

(c) All we claim about the conjugate point is that the convexity threshold of (7) is fixed by the first conjugate point. The reason for the numerical agreement with the mixing length is not known.

(d) The rows of the road of blocks and mixing, apart from the Hidden-Convexity Proposition, are "Assumption" and "Reading". We do not say that the road of blocks and mixing closes the first step.

(e) That a one-dimensional chain has no phase transition is a statement resting on bibliography whose original has not been obtained.

(f) That four dimensions "has no finite block" is not a claim that the road of blocks is impossible in four dimensions. It means that the form of the first-step tools does not carry over as it is.

08

The table of the five grades and the dependency graph

Table 2 The rows of this chapter (the rows of this chapter have no Lean column)

Row	Statement (one line)	Grade	Basis	Scope
1	(1) $\Longrightarrow$ (2): $m_{\mathrm{lat}}/a \geq \sqrt{\kappa/C}$	Proved here	§ 01 (the same algebra as (16) of 23-01)	$\beta \geq \beta_0$
2	The one-sided bridge $CP \geq \kappa\xi^2$	Proved here	23-01 § 06	Continuous time, finite spatial lattice, the ground-state assumption, the stationary path-measure assumption, the metric comparison assumption
3	Lifting the one-sided bridge to the four-dimensional lattice	Assumption	24-07 Table 2	—
4	The upper-bound assumption: $a^2CP \leq C$, with C independent of β	Assumption	23-01 § 05	Four dimensions, $\beta \geq \beta_0$
5	Showing (1) with the same constant includes crossing the band	Reading	§ 01 (physical estimate)	—
6	The Jacobi equation at the summit (4) and $\cos\theta = 1 - \varepsilon^2/4$	Proved here	§ 02	$V = (z^2-1)^2/8$
7	The first conjugate point $\pi/\theta - 1 = 7.839\ldots$	Proved here	§ 02 (two independent counts)	$\varepsilon = \frac{1}{2}$
8	(7): $\kappa_{C7}(k) > 0 \iff k+1 < \pi/\theta \iff k \leq 7$	Proved here	§ 02, the short-core step of 23-11	$\varepsilon = \frac{1}{2}$, summit configuration
9	The crossover length does not depend on $\hbar$ and is finite in lattice units as $\hbar \to 0$	Proved here	§ 02 (no $\hbar$ in (4)–(7))	$\hbar \to 0$ with ε fixed
10	The numerical closeness of the mixing length ≈ 9 and π/θ (the mechanism is the time to reach the corner)	Reading	§ 02	$\hbar = 10^{-2}$–10^{-5}, four values of ε
11	The worst-configuration tools (Dobrushin, blocks, Otto–Reznikoff) come back to $\frac{15}{4}$ against 4	Proved here	§ 03	$\varepsilon = \frac{1}{2}$
12	The worst-frame estimate gets worse superexponentially in L	Proved here	25-04	With N and the lattice spacing fixed
13	The Hidden-Convexity Proposition (uniqueness of the minimum)	Proved here	§ 03	End values $a, b \in [-c, 0]$, box $[-c, 0]^l$
14	The non-convexity moves, in the coordinate ρ, to a thin layer $\rho \lesssim \sqrt{2\hbar/\varepsilon}$ (a reading)	Assumption	§ 03	—

Row	Statement (one line)	Grade	Basis	Scope
15	$1/\Lambda$ is born through dimensional transmutation and diverges in lattice units	Cited	4-07, 24-07 § 01	One-loop bookkeeping

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The "Proved here" nodes of this chapter are the one line of algebra, the linear computations at the summit (the Jacobi equation, the first conjugate point, the convexity threshold, the classical length, the worst-configuration tools), and the Hidden-Convexity Proposition; the statements that cross the band (the upper-bound assumption in four dimensions, and showing it with the same constant) are "Assumption" and "Reading". There is no node for the mass gap.

What this chapter can say

What is said	What is not said
Proved here That the lower half of the physical-unit target level follows in one line from the upper-bound assumption and the one-sided bridge with the same pair of constants	The upper-bound assumption and the bridge in four dimensions. The physical-unit target level itself
Proved here That the convexity threshold of the first step (length 7) is fixed by the first conjugate point $\pi/\theta - 1 \approx 7.84$ of the Jacobi equation at the summit and does not depend on $\hbar$. That the worst-configuration tools come back to $\frac{15}{4}$ against 4. The Hidden-Convexity Proposition	The core Poincaré uniformity assumption itself. Why the mixing length is close to the conjugate point
Reading That the two walls are of the same type, and differ in the origin of the crossover length (classical vs quantum), rare vs typical, and whether there is a phase transition (Table 1)	Implications of first-step results for four dimensions. A tool that crosses the band
Assumption That the road of blocks and mixing (block LSI + strong mixing) is a candidate for supporting the core Poincaré uniformity assumption	Proofs of each stage of the road of blocks and mixing (apart from the Hidden-Convexity Proposition)

the ledger of exclusions, why they stopped, the selection criteria · Kiichi, Shiori and Rin

A map of the roads tried and stopped

> This chapter is a map of open questions. § 03 is established knowledge; § 04 is this book's own investigation.

What this chapter shows — We gather into one ledger the roads that were tried in order to cross the crossover band, and that stopped. The ledger has three layers: thirty roads (§ 02); roads discarded, or limited in scope, in the study of the band chapters (§ 05); and three ideas that turned out to be no more than restatements of roads in the ledger (§ 06). Each row carries "why it stopped" and its origin, and the label of the reason is set per row. For rows that rest on literature, only literature checked against the original carries [Cited]; literature not checked is marked "not yet checked". Three roads are looked at in detail: that the average over local containers stays at $R/\ln R$ in four dimensions (§ 03); the claim of Tomboulis (2007) by Migdal–Kadanoff interpolation, and the criticism that it does not distinguish U(1) (§ 03); and that the comparison principle with the twisted T^2 fails numerically (§ 04). Finally we set out the selection criteria that a new candidate should pass first (§ 07).

Prerequisite chapters — 26-00 (the breakdown of the band), 26-01 (the correct form of the band), 26-02 (the lateral-widening inequality), 25-03 (containers), 25-04 (slab confinement), 26-06 (the renormalisation comparison), 23-10 § 04 (the seven types of breakage).

Said first — This page is a map of the record and sets out no new theorem. "Stopped" means "it was found that this set of inputs cannot cross the band"; it does not mean that the parts of that road are of no use elsewhere (slab confinement, for example, is a theorem that holds for every β once the lattice spacing and T^2 are fixed). Most of the reasons for stopping are judgements at the level of physical estimates; negations with proofs are few. The labels are set per row to keep that distinction.

The order of this chapter

1. How to read the ledger — what "stopped" means and how labels are set
2. Thirty roads — why they stopped, and their origins (Table 1)
3. Two roads that had stopped in the literature — the average over local containers, and Migdal–Kadanoff interpolation

4. The comparison principle with the twisted T^2 — true at one loop, false numerically
5. Roads discarded, or limited in scope, in the band chapters (Table 2)
6. Three that were only restatements (Table 3), and the questions of type (Table 4)
7. The selection criteria and calibration against the literature (Table 6)
8. The table of the five grades and the dependency graph

01

How to read the ledger — what "stopped" means and how labels are set

The study in this book tried many roads in search of a tool that crosses the band. Every road stops in the end at the same single point: **there is no non-perturbative principle showing that, at intermediate coupling, disorder becomes stronger as the scale is enlarged**. Setting the ways of stopping side by side, three lessons come up again and again.

- Tools that work only in a perturbative regime (weak or strong coupling) cannot cross the band.
- Local operations cannot change topological quantities such as the twist sector.
- The sources of monotonicity (correlation inequalities, reflection positivity) work in the opposite direction to the mechanism of confinement (disorder).

The purpose of the ledger is not to repeat the same road. When a new candidate is thought of, we first check whether it is a restatement of something in this ledger (§ 06 gives examples).

The columns of each row are as follows.

- **Road**: a one-line summary of the idea tried.
- **Why it stopped**: where the road became unable to cross the band.
- **Label**: the label of the reason for stopping. Proved here means the reason has a proof on paper (set out in a chapter of this book); Cited means it rests on literature checked against the original; Computer-assisted is computer assistance; Reading is a numerical reading; "Reading (physics)" is a judgement at the level of a physical estimate. Even when the reason is an estimate, the judgement not to re-examine the road does not change. But a road stopped for a reason that is an estimate can be reopened if there is a new input.

- **Origin**: the record of this book's study, or the literature. Literature checked against the original is marked [Cited]; literature not checked is marked "not yet checked".

A note on words. In this part, following the convention of 26-00 § 02, we write "band", and distinguish it from the "window" of Parts 23 and 24 (the site window, the ħ window, the time window).

02

Thirty roads — why they stopped, and their origins

Numbers 1–28 in Table 1 are roads that this book's study tried in search of a principle that crosses the band; 29 and 30 are roads found to have already stopped in the literature when that study was re-checked by another hand. The labels are labels of "why it stopped".

Table 1 Thirty roads (labels are labels of why it stopped; "this book's study" is the record of the study in this book)

#	Road	Why it stopped	Label	Origin
1	Reflection positivity, chessboard estimates	The inequality points the wrong way, and only one side (the lower bound) of the flux free energy comes out	Reading (physics)	This book's study. The chessboard itself is in 26-05
2	Continuous monotonicity in the box size L (the Feynman–Hellmann derivative)	There is no correlation inequality for $SU(2)$ that fixes the sign of the difference	Reading (physics)	This book's study
3	Checking finitely many L by interval arithmetic	In four dimensions the size of the computation is out of reach. In the hierarchical model an interval-arithmetic certificate could be made (551 sectors, passed on re-running all sectors; a result for the hierarchical model only)	Reading (physics: a judgement of scale), Computer-assisted (hierarchical model only)	This book's study
4	Projection to $\mathbb{Z}_2$ and GKS (the splitting $SO(3) \times \mathbb{Z}_2$)	The premise of the splitting was rejected by four-dimensional data	Reading	This book's study
5	The infrared bound (Fröhlich–Simon–Spencer)	The wrong direction. It is the inequality on the side that shows a massless phase	Reading (physics)	Fröhlich–Simon–Spencer (not yet checked)

#	Road	Why it stopped	Label	Origin
6	Proof by contradiction extending the result for a small T^2 continuously in L	There is no quantity that excludes a fixed point, and it comes back to the band itself	Reading (physics)	This book's study
7	Kramers–Wannier duality	It only restates the band as a one-variable inequality (the magnetic flux free energy is smaller at scale $2L$ than at L)	Reading (physics)	This book's study (the duality itself not yet checked)
8	Local entropy and finite-energy arguments	Topological conservation: a local closed surface in $\mathbb{R}^4$ meets a plane an even number of times, so local operations do not change the twist sector	Reading (physics)	This book's study
9	Slab confinement	With the lattice spacing and T^2 fixed, the area law holds for every β. A bound uniform in N is the band itself, and the tension goes to 0 in the continuum limit	Proved here (the theorem with N fixed)	25-04
10	GKS for the $\mathbb{Z}_2$ effective model of centre vortices	Removing the frustration also removes the mechanism of confinement	Reading (physics)	This book's study
11	The Nishimori structure	**Withdrawn** (annealed and quenched were confused; negated numerically)	—	This book's study
12	The data-processing inequality	No channel independent of the sector can be built. It becomes a detector that tells sectors apart, but not a driving force that produces disorder	Reading (physics)	This book's study
13	Group averaging over thick vortices	It works on a small T^2, but on $\mathbb{R}^4$ it comes back to the problem of the tension of the vortex sheet	Reading (physics)	This book's study
14	Renormalising the worst flip cost	It becomes monotonically non-increasing, but decrease is not guaranteed	Reading (physics)	This book's study
15	Percolation of vortex sheets	Stochastic domination needs a worst-case lower bound, and reduces to strong coupling	Reading (physics)	This book's study

#	Road	Why it stopped	Label	Origin
16	Stability of the gap, Lieb–Robinson bounds	Works only inside the perturbative radius, and reduces to strong coupling	Reading (physics)	This book's study
17	Convexity in the coupling of the sheet	Only the cost of thin sheets is visible	Reading (physics)	This book's study
18	Adaptive averaging over the shape of the sheet	A rewriting of a partition of unity; a tautology	Reading (physics)	This book's study
19	Volume independence at large N_c	The band comes back, changed into the effective volume $N_c L$	Reading (physics)	This book's study
20	Positivity of the coefficients of the character expansion	It follows automatically from reflection positivity, and carries no new information	Reading (physics)	This book's study
21	Extracting monotonicity from the hierarchical model (ratio ordering, TP_2 and the like)	False in general	Reading	This book's study
22	Single-site Bakry–Émery curvature	The single-site gap is always positive; the wall lies in the influence between plaquettes	Reading (physics)	This book's study
23	Monotone quantities from strong subadditivity, a lattice version of the a-theorem	The lattice-only version does not distinguish phases. The version that does needs rotation invariance, which is available only after crossing the band (circular)	Reading (physics)	This book's study (Casini–Huerta-type arguments not yet checked)
24	Curvature of the space of gauge orbits, renormalisation of a membrane gas, tools for sharp phase transitions	The curvature correction is $O(1)$ and cannot cancel the negative $O(\beta)$ of the Hessian of the action, reducing to strong coupling / four-dimensional membranes have no screening mechanism / the surface representation of $SU(2)$ has weights that change sign, and no FKG	Reading (physics)	This book's study

#	Road	Why it stopped	Label	Origin
25	Spin and the index theorem (counting soft modes)	At one loop it is a restatement of asymptotic freedom, and the non-perturbative part comes back to the band	Reading (physics)	This book's study
26	Renormalisation of curvature (Bakry–Émery curvature and O'Neill's formula, the curvature-dimension condition of the quotient)	Negative curvature is not preserved by coarse-graining. Following the effective one-link weight on a one-dimensional chain by convolution, the minimum of the curvature gets worse at the first step ($SU(2)$: $-6 \to -14$; $U(1)$: $-4 \to -8$)	Reading	This book's study
27	The comparison principle with the twisted T^2 (for all loops)	True at one loop, false non-perturbatively by numerics (§ 04)	Reading	This book's study (§ 04)
28	The multiscale Bakry–Émery criterion (the Polchinski equation)	It can pass non-convex regions, but scale-by-scale control of the renormalised potential is the band itself. The version for compact groups is also not in place	Reading (physics)	Bauerschmidt–Bodineau (not yet checked)
29	Averaging over local vortex containers	The identity is known, and with the container length fixed it reaches only $R/\ln R$ in four dimensions (§ 03)	Cited	Mack–Petkova (1980), Kovács–Tomboulis hep-lat/0108017. 25-03 § 06
30	Monotonicity of the vortex free energy by Migdal–Kadanoff interpolation	The key inequality ((3.5) of Ito–Seiler; the interpolation-parameter commonality inequality) has not been shown outside strong coupling. The argument does not distinguish $U(1)$ (§ 03)	Cited	Tomboulis arXiv:0707.2179, Ito–Seiler arXiv:0711.4930, Kanazawa arXiv:0805.2742

N_c in Table 1 is the number of colours, a different quantity from the size N of T^2_N. Number 11 is kept here as a single line only. Its content was withdrawn, so it is not used elsewhere in this book.

Note that most labels in Table 1 are "Reading (physics)". Most of the reasons for stopping are not counterexamples or negative theorems but estimates of the form "this road comes back to the band itself at this point". The rows with proofs are number 9 (slab confinement is a theorem with N fixed, and is not uniform in N) and, in Table 2,

the stopped road "isometric comparison", the stopped road "structural inputs only", the stopped road "flip certificate" and the stopped road "supremum estimate over frames" (the scope is in the brackets of each row's label). Numbers 29 and 30 of Table 1 are the "Cited" rows that had stopped in the literature. The "Computer-assisted" of number 3 is a result on the hierarchical model and says nothing about the four-dimensional lattice (the hierarchical model is a different thing from four dimensions in that Migdal–Kadanoff decimation is exact there).

03

Two roads that had stopped in the literature — the average over local containers, and Migdal–Kadanoff interpolation

This section summarises existing knowledge (two roads that had stopped in the literature). The introduction is in 17-02 § 05.

Numbers 29 and 30 in Table 1 are roads that, after this book's study had tried them itself, were found to have already stopped in the literature. Both were checked against the text of the original [Cited].

The average over local vortex containers — only up to R/ln R in four dimensions

The identity that, with the frame (the outside of the container) fixed, the signs of the sectors inside the containers become independent and the Wilson loop is bounded by the product of the biases of the containers, was the Container Identity of 25-03 § 03. This is the "vortex container" identity of Mack–Petkova (1980), written in eqs. (18)–(22) of Kovács–Tomboulis (hep-lat/0108017). The only differences are that we wrote the sectors with the sum ensemble and took the average over the frame rather than the maximum; this book claims no novelty.

§ 3 of the same paper states the limit of this road in four dimensions. The length of a container passing through a point inside a rectangular loop with sides $T \times R$ ($T > R$) is of order R^2, and to keep the cost of the container constant the width of its cross-section must be fattened to order $\sqrt{\ln R}$. Only about $RT/\ln R$ independent containers fit inside the loop, and what comes out is

$$V(R) \;\geq\; \text{const} \cdot \frac{R}{\ln R} \qquad \text{(Kovács–Tomboulis, eq. (25))} \quad (1)$$

and no more [Cited]. A linear potential (the area law) needs a single fat container the size of the loop. This is exactly the global form of Tomboulis–Yaffe (26-01 § 04), the same condition as crossing the band.

In one line, the reason it stopped is: **the road of laying out containers of fixed length independently does not reach the area law on** $\mathbb{R}^4$. On a slab with a small T^2, the

length of the container (the area of the vortex sheet) stops at the area of T^2, so this obstacle does not appear (25-03 § 06). The obstacle comes back when T^2 is widened — that is, in the band.

Monotonicity of the vortex free energy by Migdal–Kadanoff interpolation

Tomboulis (arXiv:0707.2179) claimed confinement at every coupling for four-dimensional $SU(2)$. The flow of the argument is as follows [Cited].

1. By Migdal–Kadanoff-type decimation (lattice spacing $a \to ba$), build upper and lower bounds on the partition function ((3.4) and (3.7) of the original).
2. Interpolate their coefficients with a parameter t, and obtain a representation in which decimation becomes an equality at some value t^* ((3.12), (3.16), (3.35)). Build the same representation in the twisted sector ((4.19), (4.26)).
3. **The key step**: that the same t^* can be taken in the untwisted and the twisted sectors ((5.14)). This is to be derived from the inequality $A \geq A^+$ ((5.15)), and it is stated that showing it at strong coupling is enough.
4. In conclusion, the true vortex free energy is at most the vortex free energy of the decimated system ((5.22)). The decimated system flows to strong coupling, so the strong-coupling expansion gives $F \sim L\, e^{-\hat{\sigma} A}$, and the Tomboulis–Yaffe inequality gives the area law.

Against this there are two criticisms [Cited].

- **Ito–Seiler (arXiv:0711.4930)**: that t^* can be taken in common for the two sectors reduces to their inequality (3.5), $A(\alpha) > A^+(\alpha)$, which has not been shown outside strong coupling. Further, the Migdal–Kadanoff flow goes to strong coupling **regardless of whether the group is abelian or non-abelian**, so if the argument went through as it stands, $U(1)$ would also confine at every coupling. Four-dimensional $U(1)$ has a non-confining phase, so an input that distinguishes groups is needed somewhere.
- **Kanazawa (arXiv:0805.2742, Appendix A)**: the continuity argument in the interpolation parameter does not hold (a counterexample is given). It is not shown which step of the argument fails for $U(1)$. For any compact connected group the Migdal–Kadanoff flow goes to strong coupling, so the renormalisation side cannot distinguish $U(1)$ from $SU(2)$, and **all the non-abelian content goes into the existence of t^***.

Footnote 10 of the original itself writes that "for abelian systems, inequalities of type (5.15) follow from the Griffiths inequalities". Together with the remaining steps this

would show confinement for $U(1)$, a sign that the argument does not distinguish groups.

In one line, the reason it stopped is: **a renormalisation that does not distinguish groups cannot be an argument that closes the band**. This is an example in the literature of the criterion "distinguish from the U(1) transition" of 26-06 § 08 (show that $SU(2)$ has no transition, distinguishing it from the transition that $U(1)$ has inside the band, at $\beta \approx 1.01$). The lateral-widening inequality of this book (26-02 § 02) restricts the comparison to the form "change only the geometry, within one theory and one coupling", and has a form that fails for $U(1)$ (26-01 § 03, 26-09 § 02). But the difficulty of showing it is of the same type, and it is still needed across the band.

Relatedly, Theorem 1 of Kanazawa (arXiv:0805.2742) is an identity relating the ratio of twisted partition functions on lattices of different sizes to a ratio at shifted couplings, but it also holds for $U(1)$, so it says nothing about confinement [Cited]. Another paper of Ito–Seiler (arXiv:0803.3019) is not yet checked.

04

The comparison principle with the twisted T² — true at one loop, false numerically

This is number 27 of Table 1. **The comparison principle** is the claim that for every planar loop C

$$\langle W(C)\rangle_{\mathbb{Z}^4} \;\le\; \langle W(C)\rangle_{\mathbb{Z}^2\times T^2_N,\; n_{12}=1} \tag{2}$$

holds (the right-hand side is the twisted slab, 25-04 § 02). If it held, then together with slab confinement (the area law for every β with N fixed) it would give the area law for every β on $\mathbb{Z}^4$. That is why it was worth trying.

True at one loop [Reading]. Comparing with the heat kernel of fluctuations around the background, the inequality holds at each time. The colour weight of the sum over images is $c(n) = 4\cdot\mathbf{1}[n\in(2\mathbb{Z})^2] - 1$, and we checked this numerically to machine precision (a numerical check at the one-loop level; no proof on paper is set out).

False non-perturbatively [Reading]. By Monte Carlo we compared the twisted slab on the lattice $16\times16\times N_T\times N_T$ (the $\mathbb{R}^2$ directions periodic with 16, T^2 with N_T) with 16^4 ($SU(2)$, Wilson action).

Test of the comparison principle (plaquette expectation values; parentheses give the statistical error in the last digit)

β	N_T	**Twisted slab**	16^4	**Reading**

β	N_T	Twisted slab	16^4	Reading
2.1	2	0.52952(67)	0.53494(40)	The slab is lower: 7σ taking errors from both sides, 5.5σ in an independent rerun. $W(2,2)$ is also lower
1.8	2	0.43966(56)	0.44129(18)	The slab is lower (about 2.7σ)
2.4	2	0.6275(10)	0.6300(2)	The slab is lower (about 2.4σ)
2.6	6, 8	Signs that the twisted slab overshoots 16^4 downwards (2.5σ and 1.9σ in the plaquette)		Undetermined

Taking C in (2) to be a single plaquette, the right-hand side is the plaquette of the slab and the left-hand side the plaquette of 16^4. At $\beta = 2.1$, $N_T = 2$ the slab is 7σ lower, so (2) fails for small loops. This can be read as the frustration of the twist (the cost of forcing a twist into a small T^2) lowering the plaquette [Reading] (physics). The overshoot on the weak-coupling side ($\beta = 2.6$) lacks statistics and is not settled.

Further, at $N = 1$ it contradicts the scaling behaviour of asymptotic freedom [Reading] (physics). The slab theorem gives $\sigma_{\mathrm{tw}}(1) \geq -\ln\tanh\beta \approx 2e^{-2\beta}$, but if the scaling behaviour of asymptotic freedom is accepted, $\sigma_\infty a^2 \propto e^{-(6\pi^2/11)\beta} = e^{-5.38\beta}$, and at large β (2) points the other way.

In one line, the reason it stopped is: **an ordering that holds at one loop breaks down non-perturbatively, starting from small loops**. Two criteria come out of this (§ 07): the criterion "not a rewording of one loop" (it is a non-perturbative estimate) and the criterion "not broken by small loops" (it does not fail at short scales, or it has a form that claims only large loops). The asymptotic form for large loops only ($\sigma_{\mathrm{tw}}(L) \leq \sigma_\infty$) has not been refuted, but there is no mechanism to show it, and it hits the same wall as number 2 of Table 1 (there is no inequality for $SU(2)$ that fixes the sign of the difference).

One positive observation also remains [Reading] (physics). At weak coupling the twisted T^2 is close to infinite volume already from small N_T, and approaches it from the opposite side to the untwisted case. This fits the picture of adiabatic continuity, but there are signs that the approach is not monotone, a fact unfavourable to tools based on monotonicity.

05

Roads discarded, or limited in scope, in the band chapters

In the study of Parts 25 and 26 there are, apart from Table 1, roads that were discarded and roads whose usable scope was limited. Table 2 gathers them. The first five (1–5) are "roads discarded", the rest "roads limited in scope".

Table 2 Roads discarded, or limited in scope, in the band chapters (labels are labels of why it stopped)

#	Road	Why it stopped	Label	Chapter
1	**Isometric comparison**: isometric comparisons (the identity map, group translation, gauge transformation, decimation)	In a comparison that does not change the shape of the fluctuations, the contribution of the one-loop spin term $+4$ is exactly 0, and only $\beta' \geq \beta + 0.023$ (the anti-asymptotic-freedom direction) comes out	Proved here (one-loop level)	25-07, 26-06 § 03
2	**Structural inputs only**: structural inputs only (reflection positivity, duality, the transfer matrix, the centre identities)	They hold as they are for $\mathbb{Z}_2$ and $U(1)$ too, so they cannot distinguish groups (the negative lemma)	Proved here (in the form "from this set of inputs alone")	26-04
3	**Deterministic squeeze**: getting the area law by a squeeze between deterministic maps	The remainder (relative entropy) of the Transport Identity (the Gibbs variational principle) grows with the area of the vortex sheet, so the form $e^{-\sigma A}$ does not come out. It can be used for the qualitative goal $\Delta F(L, L) \to 0$	Reading (physics)	26-10 § 02
4	**Glassy squeeze**: a squeeze by the $\mathbb{Z}_2$ glass in the upper half of the band	For $\beta \gtrsim 2$ the mean effective $\mathbb{Z}_2$ coupling is 1.1–1.9, far above the pure $\mathbb{Z}_2$ transition point 0.44, and the glass is on the side of the ordered phase. The squeeze is loose	Reading	26-09 § 08, 26-10 § 03
5	**Flip certificate**: using flip certificates (flipping containers) and simultaneous flips to test the band	The flip probability a of a one-step kernel levels off at about 1/2, and $\theta \leq 1 - a$ gives only $\sigma \geq c/L^2$ (a weak form that $U(1)$ also satisfies)	Proved here ($\theta \leq 1 - a$), Reading (the levelling off of a)	25-06, 26-01 § 02
6	**Supremum estimate over frames**: bounds using the supremum over frames $\sup_\Phi$	Of the form $\tanh(\beta L^2)^{\ell^2}$, getting worse superexponentially in L. For uniformity only forms averaged over the frame can be used	Proved here	25-04 § 02
7	**Dobrushin-type criterion**: using the usual Dobrushin, Dobrushin–Shlosman and van den Berg–Maes criteria with frames	The continuous field follows the boundary, and the influence coefficients are close to 1	Reading (physics)	(literature not yet checked)

#	Road	Why it stopped	Label	Chapter
8	**β-monotonicity from easy parts**: taking β-monotonicity as the easy component, band = β-monotonicity + the renormalisation comparison	β-monotonicity turned out to be a problem of the same weight as the monotonicity in β of the string tension in lattice units (a correction)	Reading (physics)	26-06 § 02
9	**One-directional lateral widening**: restricting lateral widening to one direction only	Doubtful in view of the behaviour of the spatial string tension at high temperature (lattice measurements by Bali et al., not yet checked); restricted to the square shape only	Reading (physics)	26-02 § 02
10	**Transport by Wilson flow**: using the Wilson flow to transport vortex insertions	Negative numerically. The form recast as forward transport (Moser-type) is open	Reading	25-06
11	**Conformal frame**: the conformal frame $H^2 \times S^2$ (turning scale into position)	Negative on examination: hyperbolic nesting does not increase the number of containers, and the core stays in the same place	Reading (physics)	26-10 § 04
12	**Strong-coupling expansion only**: covering the band with the strong-coupling expansion alone	The expansion about flat surfaces stops at roughening ($\beta_R \approx 1.9$, not yet checked)	Reading (physics)	26-06 § 04

06

Three that were only restatements, and the questions of type

When thinking of a new candidate, we first check that it is not a restatement of something in the ledger. Table 3 lists three ideas that, when the band candidates were examined, were not made candidates but judged to be restatements of the ledger.

Table 3 Three ideas that were only restatements

#	Idea	What it was a restatement of	Label
1	**Approach of the holonomy to Haar**: that the law of the holonomy of large loops approaches the Haar measure (the boundary holonomy centralises under the Weyl measure)	The decay of the part odd under the centre (half-integer representations) is the Wilson area law itself, a restatement of the ring made by the column decomposition and the Tomboulis–Yaffe inequality. The even part (adjoint representations) has a perimeter law and does not help to distinguish groups	Reading (physics)

#	Idea	What it was a restatement of	Label
2	**Anomaly of the centre and the θ term**: consistency of the mixed anomaly between the centre and the θ term	A kinematic constraint (the criterion "dynamical" of § 07). At $\theta = 0$ it forces nothing	Reading (physics)
3	**Success in the hierarchical model**: taking success in the hierarchical model (a model in which Migdal–Kadanoff decimation is exact) as evidence for the band	In the hierarchical model $U(N)$ also confines, so it is no test of the criterion "uses non-commutativity essentially"	Reading (physics)

The study of detours in Part 23 (23-10 § 04) extracted seven types from failures on the double well in 0+1 dimensions. The individual detour plans do not overlap directly with four-dimensional candidates, but the questions of type apply to four-dimensional candidates as they are. Table 4 lists those questions.

Table 4 The seven types of breakage, and the questions to put to a new candidate

Type	One line	Question to put to the candidate
1	There is one source (the curvature at one site at the top)	On the side of the worst configuration, what is being paid?
2	Structural factors that enter as ratios have a ceiling	Does it change the defect set, or does it only move the factor of the ratio?
3	Paying for the same place twice	Have the places paid been drawn in the same figure?
4	Confusing currencies (the speed of exit and rarity)	Does the step that pays for rarity go through entropy?
5	The address of the difficulty	Which quantity does the difficulty rest on?
6	The mismatch between the direction of fluctuation and the soft direction	Is a vector being collapsed to a scalar?
7	Transfer	Is the sum an invariant (does another column become heavier by as much as the lightened column)?

The candidate rules of Part 24 (Table 3 of 24-08 § 02) can also be used here, not as exclusions but as a record of "which root they do not work on". No candidate has "works" written in the column of the root that connects the ultraviolet and the infrared (source: no expansion linking scales, of 24-07), and the "coupling window" (a word of Part 24, 24-06) that appears in the rarity class closed by one step of coarse-graining (rule of axiomatising scale + rule of the rarity class) was a rewording of that root. Anyone who says a band candidate works on the lack of an expansion linking scales must name an input different from every candidate.

```
07
```

The selection criteria and calibration against the literature

Turning the reasons for stopping inside out gives candidate conditions that a tool crossing the band should satisfy. Table 6 sets those conditions side by side with the ways of stopping they came from. All are candidates for necessary conditions, not sufficient conditions that guarantee crossing the band if satisfied [Reading] (physics). Especially heavy are the four "uses non-commutativity essentially", "not a rewording of one loop", "crosses the smallest band" and "distinguish from the U(1) transition".

Table 6 The selection criteria (with the ways of stopping they came from)

Criterion	Content	Way of stopping it came from
Stands on the lattice alone	Holds on the lattice alone (does not rely on rotation invariance)	Number 23 of Table 1
Distinguishes phases	Distinguishes phases (fails in a massless phase, or the limiting values differ)	Number 23 of Table 1
Does not rely on positivity	Does not rely on positivity or FKG	Number 24 of Table 1 (the surface representation of $SU(2)$ has weights that change sign)
Uses non-commutativity essentially	**Uses non-commutativity essentially**. A principle that gives the same conclusion in models with a massless phase, such as four-dimensional $U(1)$ or two-dimensional $O(2)$, is wrong	Number 30 of Table 1, "structural inputs only" of Table 2, "success in the hierarchical model" of Table 3
Compatible with asymptotic freedom	Compatible with asymptotic freedom	The contradiction at $N = 1$ in § 04
Handles topological sectors	Can handle topological sectors (twists)	Number 8 of Table 1
Not a rewording of one loop	Is **a non-perturbative estimate, not a rewording of one loop**	Numbers 25 and 27 of Table 1
Dynamical	Is dynamical (uses the action and the flow of the coupling). Kinematic constraints alone (duality, reflection positivity, anomalies, positivity of the partition function) cannot reach, since a non-confining phase can also exist without contradiction	"Structural inputs only" of Table 2, "anomaly of the centre and the θ term" of Table 3
Passes through non-convex regions	Can pass through non-convex (negatively curved) regions. Tools based only on convexity, log-concavity or lower bounds on curvature cannot be used in the band	Number 26 of Table 1

Criterion	Content	Way of stopping it came from
Crosses the smallest band	**Can cross the smallest band**: in two-dimensional asymptotically free models (the $O(N)$ model at large N, the Gross–Neveu model), with the ultraviolet cutoff removed. A monotone quantity that cannot cross this cannot cross four dimensions either	Calibration against the literature (below)
Not broken by small loops	Does not fail for small loops (short scales). Or has a form that claims only large loops	§ 04
Non-isometric linearisation	The linearisation of the comparison map is not isometric in the fluctuations	"Isometric comparison" of Table 2
Distinguish from the U(1) transition	**Shows that $SU(2)$ has no transition, distinguishing it from the transition that $U(1)$ has inside the band** ($\beta \approx 1.01$)	Number 30 of Table 1, 26-06 § 08

Behind the criterion "crosses the smallest band" is the fact that even for the two-dimensional $O(3)$ model, exponential decay at all temperatures at the lattice level (Polyakov's conjecture) is unsolved (as stated in the lecture notes of Peled–Spinka, arXiv:1708.00058; not yet checked). A tool that shows a uniform gap in four dimensions must at least have the power to show that.

Calibration against the literature. Where is the current frontier on each side of the band? Only literature whose checking is complete is marked [Cited].

- The strong-coupling side: Cao–Nissim–Sheffield (arXiv:2505.16585) showed, for $U(N)$ lattice Yang–Mills, the area law for all N at β below a $\beta_0(d)$ depending only on the dimension d [Cited]. The same authors, in arXiv:2509.04688, check the mass-gap condition of Durhuus–Fröhlich (1980) by methods of stochastic dynamics and obtain the area law in the 't Hooft regime ($\beta \lesssim c_d N$) [Cited]. Both are results on the strong-coupling side and do not reach β inside the band. This book's Lean also contains an area law only inside the strong-coupling window, and a vortex floor whose rate per unit area does not depend on the transverse size (20-06; the lattice spacing is fixed, and the prefactor remains). This does not reach the band either.
- The universality of the band: there is a paper that states explicitly that, for every version of the Gross–Neveu model, there is no proof of chiral symmetry breaking in the limit with the ultraviolet cutoff removed (Fabbri–Goller arXiv:2606.13075, not yet checked). The infrared analysis of two-dimensional models at large N (Kopper–Magnen–Rivasseau 1995, Kopper 1999) is with an ultraviolet cutoff (not yet checked).
- Computer-assisted renormalisation: a result showing with computer assistance the flow near the high-temperature fixed point in two-dimensional tensor renormalisation (Ebel–Kennedy–Rychkov arXiv:2506.03247, not yet checked) can be

seen as one of the current frontiers. It is far from the band of four-dimensional $SU(2)$.

In summary, **within what we have examined, there is no proof of mass generation in an asymptotically free theory in the limit with the ultraviolet cutoff removed**. The existence of the continuum limit of four-dimensional Yang–Mills was shown by the construction published on 2026-11-10 (at the level of the committee's assessment; Volume 2), but it does not show the mass gap. The band is not a hole peculiar to this book's road, but the unsolved core common to asymptotically free theories. This sentence, however, is a statement about what we have examined, and includes literature not yet checked.

A table that rearranges the reasons for stopping by type of argument is Table 2 of 16-11.

08

The table of the five grades and the dependency graph

The labels of each row of Tables 1–3 are placed in the tables. The rows this page sets out itself are the following fourteen.

Table 7 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	The Container Identity with the frame fixed is the container identity of Mack–Petkova	Cited	Kovács–Tomboulis eqs. (18)–(22)	Differing only in the sum ensemble and the averaged form	—
2	Independent containers of fixed length give only up to $V(R) \gtrsim R/\ln R$ in four dimensions	Cited	Kovács–Tomboulis eqs. (23)–(25)	$\mathbb{R}^4$, independent containers	—
3	The key step of Migdal–Kadanoff interpolation reduces to the interpolation-parameter commonality inequality and has not been shown outside strong coupling	Cited	Ito–Seiler arXiv:0711.4930	The argument of Tomboulis arXiv:0707.2179	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
4	The Migdal–Kadanoff flow goes to strong coupling regardless of the group, and the renormalisation side does not distinguish $U(1)$ from $SU(2)$	Cited	Kanazawa arXiv:0805.2742, Appendix A	Any compact connected group	—
5	The comparison principle holds at one loop	Reading	§ 04 (the heat-kernel inequality at each time, numerically)	One-loop level	—
6	The comparison principle fails at $\beta = 2.1$, $N_T = 2$	Reading	The table in § 04	$16^2 \times 2^2$ against 16^4, 7σ (independent rerun 5.5σ)	—
7	The comparison principle at $N = 1$ contradicts the scaling behaviour of asymptotic freedom	Reading (physics)	§ 04	As long as the scaling behaviour of asymptotic freedom is accepted	—
8	Slab confinement holds for every β with N and the lattice spacing fixed, and is not uniform in N	Proved here	25-04	N fixed, lattice spacing fixed	The Lean column of 25-04
9	An isometric comparison gives only the direction $\beta' \geq \beta + 0.023$	Proved here	25-07	One-loop level	—
10	Structural inputs alone cannot distinguish groups	Proved here	26-04	"From this set of inputs alone"	—
11	The reasons for stopping of the remaining rows of Tables 1, 2 and 3	Reading (physics)	This book's study	The conditions of each row	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
12	In the hierarchical model a certificate can be made by interval arithmetic over finitely many sectors	Computer-assisted	Number 3 of Table 1	Hierarchical model only. Says nothing about the four-dimensional lattice	—
13	The frontier on the strong-coupling side is the area law at small β for all N	Cited	Cao–Nissim–Sheffield arXiv:2505.16585, 2509.04688	$\beta \le \beta_0(d)$, $\beta \lesssim c\,dN$	—
14	The thirteen selection criteria (Table 6) are candidates for necessary conditions on a tool that crosses the band	Reading (physics)	§ 07	Candidates for necessary conditions, not sufficient conditions	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
 1  CIT  the Container Identity is known                          Kovács–Tombouli
 2  CIT  independent containers reach only R/ln R ⟸ 1              R⁴

```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The row of the selection criteria is the only node on the conclusion side, and its label is "Reading (physics)". No row of this page shows either that the band can be crossed or that it cannot. A stopped road is only recorded as "cannot cross with this set of inputs"; a road that adds something to those inputs lies outside the ledger.

What this chapter can say

What is said	What is not said
Cited The average over local containers reaches only $R/\ln R$ in four dimensions. The argument by Migdal–Kadanoff interpolation has an unproved key step and does not distinguish groups	That the claim of Tomboulis (2007) is false (what can be said is that an unproved step remains)
Reading That the comparison principle fails for small loops ($\beta = 2.1$, $N_T = 2$, 7σ, rerun 5.5σ)	That the asymptotic form for large loops only is false
Proved here Slab confinement, the isometric comparison, the negative lemma for structure alone (under the conditions of each chapter)	That roads adding something to these cannot cross
Reading (physics) The reasons for stopping of the remaining roads, and the selection criteria	Proofs of most of the reasons for stopping. That a tool meeting the criteria crosses the band

The thirty roads, roads discarded in the band chapters, restatements, the selection criteria	This book's study	The record of this book's study (the ledger of exclusions, and the examination of band candidates)

Terms used in this chapter — the ledger of exclusions, why it stopped, vortex container, the comparison principle, Migdal–Kadanoff decimation, the isometric comparison, the selection criteria, the crossover band (the band), β-monotonicity, the renormalisation comparison. Their meanings are in A-02 Glossary.

Next chapter: 26-09 The measured record — the numbers this part cites, on one page.

The measured record

This chapter is this book's own investigation. The established knowledge it builds on is in 5-07 and 5-01.

What this chapter shows — We gather on one page the numbers that Part 26 cites. When the small twisted T^2 is widened, the vortex free energy of $U(1)$ rises and that of $SU(2)$ does not (§ 02). The string tension of the slab increases with T^2 and saturates, with no significant overshoot visible (§ 03). The β-dependence of the vortex free energy (§ 04). When the whole lattice is doubled, the $SU(2)$ vortex becomes cheaper and the $U(1)$ vortex costlier (§ 05). The sign of the step function of one step flips for $U(1)$ at the known phase transition $\beta_c \approx 1.01$, and does not flip for $SU(2)$ in the range measured (§ 06). The width needed to keep the column bias small with the outer frame held fixed hardly grows with N for $SU(2)$, and grows for $U(1)$ (§ 07). A diagnosis of the $\mathbb{Z}_2$ glass representation (§ 08).

Prerequisite chapters — 25-01 (the twisted T^2 and flux), 26-01 (the sector bias θ), 26-02 (the lateral-widening inequality), 26-06 (the renormalisation comparison), 5-07 (the Monte Carlo method).

Said first — Every number on this page is a numerical reading [Reading]. The lattices are small, up to 8^4; the points in β and the numbers of seeds (initial values of the random numbers) and frames are few; the errors are statistical only and may come out on the small side. No row is evidence of crossing the band; each is a record of a tendency, for choosing the direction of candidates. Each row states the lattice size, β, the number of seeds or frames, and the error. Rows for which the record does not state the number of seeds are marked "not recorded".

The order of this chapter

1. How we measured, and symbols — the vortex free energy, the sector bias, notes on artefacts
2. Widening the T² — $U(1)$ rises, $SU(2)$ does not (Tables 1–3)
3. The string tension of the slab — it increases and saturates (Tables 4 and 5)
4. The β-dependence of the vortex free energy (Table 6)

5. Doubling the whole lattice (Tables 7–10)
6. The sign of the step function — the $U(1)$ contrast (Table 11)
7. The column bias — the $\ell \times N$ scan (Tables 12–14)
8. A diagnosis of the $\mathbb{Z}_2$ glass (Table 15)
9. Artefacts of small lattices — a list of cautions for reading
10. The table of the five grades and the dependency graph

01

How we measured, and symbols

The lattice. The slab lattice is $(\mathbb{Z}/N_T)^2 \times (\mathbb{Z}/M)^2$; the first two directions (size N_T) are the small T^2, and the remaining two (size M) stand in for the plane $\mathbb{R}^2$. The T^2 carries the 't Hooft twist $n_{12} = 1$ (25-01). A symmetric torus is written N^4. The action is the Wilson action $-\frac{\beta}{2}\sum_p z_p \operatorname{tr} U_p$ ($SU(2)$) and its $U(1)$ version.

The vortex free energy. We write the free-energy difference with the sector in which the flux n_{34} in the planar directions is changed as

$$\Delta F = F(n_{34}=1) - F(n_{34}=0) = -\ln \frac{Z(n_{34}=1)}{Z(n_{34}=0)} \quad (1)$$

and set the sector bias to $\theta = \tanh(\Delta F/2)$ (the same quantity as F_v of 26-01 § 04). The larger ΔF, the costlier the vortex (the harder it is to enter), and θ approaches 1. In the confinement regime one expects $\Delta F \to 0$.

How we measured. ΔF is obtained by replica exchange (exchanging configurations between replicas with interpolated couplings to produce samples that span the sectors) and by Bennett's acceptance-ratio method (BAR). The errors are statistical. At some points the difference between two runs with different seeds is 1–2 times the stated error, so the errors may come out on the small side. The string tension of the slab is read from the Creutz ratio

$$\chi(R) = -\ln \frac{W(R,R)\,W(R-1,R-1)}{W(R,R-1)\,W(R-1,R)} \quad (2)$$

($W(R,T)$ is the $R \times T$ Wilson loop). The Creutz ratio at small R includes the Coulomb term and overestimates the tension, so we read only the tendency, not the absolute value.

Notes on artefacts (in advance). Cautions common to all the tables are listed in § 09. In particular, $N_T = 2$ is the regime of lattice artefacts, 2^4 is too small to see one-loop behaviour, and column-bias values of about 0.1 are at the statistical floor.

02

Widening the T² — U(1) rises, SU(2) does not

We hold the size M in the planar directions fixed and widen only the size N_T of the T^2. This is a test of the sign of the lateral-widening inequality (26-02 § 02).

Table 1 $\Delta F(N_T)$, $M = 8$ ($n_{12} = 1$, replica exchange + Bennett's acceptance ratio method; number of seeds not recorded) [Reading] — the numbers are the same measurement given in 25-08 Table 3. We do not copy them here.

For $U(1)$, widening the T^2 makes ΔF increase sharply, and θ goes $0 \to 0.39 \to 0.78 \to 0.99$. $SU(2)$ goes $0 \to 0.63 \to 0.33 \to 1.51$, much more gently ($\theta$ goes $0 \to 0.31 \to 0.16 \to 0.64$). Under $N_T = 4 \to 8$, $\ln(1/\theta)$ goes $0.93 \to 0.012$ for $U(1)$ (about 1/80), and $1.18 \to 0.45$ for $SU(2)$ (about 1/2.6). In this geometry, however, θ is of order 1 and the ceiling $\theta \leq 1$ weakens the power to discriminate; and $N_T = 8 = M$ for $SU(2)$ is the symmetric torus 8^4 (physical size $L\sqrt{\sigma} \approx 1.5$). $\beta = 1.5$ for $U(1)$ and $\beta = 2.5$ for $SU(2)$ are not matched to the same physical size.

Table 2 $\Delta F(N_T)$, $M = 12$ (remeasured with a larger container) [Reading] — the numbers are the same measurement given in 25-08 Table 4. We do not copy them here.

For $U(1)$ at $N_T = 8$, 24 replicas gave 0.54 ± 0.53 with poor mixing; we give the value with 40. The number of seeds is not recorded.

Table 3 $SU(2)$, $\beta = 2.4$, $M = 8$ [Reading] — the numbers are the same measurement given in 25-08 Table 5. We do not copy them here.

Reading [Reading]. In three settings ($M = 8$ and 12 at $\beta = 2.5$, $M = 8$ at $\beta = 2.4$), the vortex free energy of $SU(2)$ does not increase when the transverse T^2 is widened (except for the symmetric point $N_T = M = 8$ at $\beta = 2.5$, $M = 8$). For $U(1)$ it increases at both values of M. This is a numerical sign of the sign of the lateral-widening inequality. The errors are large, 0.1–0.5, and there are only two points in β. That $N_T = 8$ at $\beta = 2.4$ is smaller than the same point at $\beta = 2.5$ fits with the same lattice being physically larger at $\beta = 2.4$ ($L\sqrt{\sigma} \approx 2.2$ against 1.5).

03

The string tension of the slab — it increases and saturates

One of the necessary conditions for the uniform slab tension (26-02) is that the string tension of the slab $\sigma_{\mathrm{eff}}(N_T)$ does not overshoot much in N_T. We measured the Creutz ratio (2) for $SU(2)$, $\beta = 2.5$, $M = 16$. The four-dimensional value is $\sigma a^2 \approx 0.036$.

Table 4 Creutz ratios of the slab, 400 measurements ($SU(2)$, $\beta = 2.5$, $N_T \times N_T \times 16 \times 16$; number of seeds not recorded) [Reading] — the numbers are the same measurement given in 25-08 Table 6. We do not copy them here.

Table 5 The same setting with five times the statistics (2000 measurements) and $N_T = 10$ [Reading] — the numbers are the same measurement given in 25-08 Table 7. We do not copy them here.

Reading [Reading]. The peak in $\chi(4)$ at $N_T = 6$ seen with 400 measurements (0.089 ± 0.013, about 2.3σ from $N_T = 8$) became 0.061 ± 0.004 with 2000 measurements; it was a statistical fluctuation. $\chi(4)$ increases over $N_T = 4 \to 8$ and nearly saturates at $N_T = 10$ with 0.071 (1.7σ from $N_T = 8$). No significant overshoot is visible. $\chi(4)$ includes the Coulomb term, so it comes out larger than the four-dimensional $\sigma a^2 \approx 0.036$. We read only the tendency in N_T, and β is a single point.

04

The β-dependence of the vortex free energy

Table 6 $SU(2)$, $N_T = 4$, $M = 8$ ($4 \times 4 \times 8 \times 8$, $n_{12} = 1$, replica exchange + Bennett's acceptance ratio method, number of seeds not recorded) [Reading]

β	2.2	2.3	2.4	2.45	2.5	2.55	2.6	2.7
ΔF	0.05 ± 0.05	0.00 ± 0.05	0.31 ± 0.10	0.30 ± 0.13	0.63 ± 0.18	0.66 ± 0.13	1.43 ± 0.19	2.97 ± 0.33

Reading [Reading]. Within the errors, it increases monotonically in β. The reading is that this does not contradict β-monotonicity (26-06 § 02) (β-monotonicity has not been shown for $SU(2)$). For $\beta \le 2.3$ the vortex is nearly free ($\theta \approx 0$), and at $\beta = 2.6$–2.7 it becomes costly sharply. This can be read as the fixed lattice $4 \times 4 \times 8 \times 8$ becoming physically small and entering the dilute regime ($\theta \to 1$). The points at 2.45 and 2.55 are interpolation points added for the fit in § 05.

05

Doubling the whole lattice

We test the renormalisation comparison (26-06 § 05) directly. We measure ΔF on the fine lattice (all directions doubled) and read off, from the curve of the coarse lattice

(Table 6 and others), the β' of the coarse lattice that gives the same value. The prediction of asymptotic freedom is $\beta' < \beta$ for $SU(2)$, and $\beta' \geq \beta$ for $U(1)$, which does not run.

Table 7 Slab $(N_T, M) = (4, 8) \to (8, 16)$ $(n12 = 1)$ [Reading]

Group	β	$\Delta F(4, 8, \beta)$	$\Delta F(8, 16, \beta)$: per seed	Combined	Seeds	Matching β'	$\beta - \beta'$
$SU(2)$	2.7	2.97 ± 0.33	0.65 ± 0.39, 1.31 ± 0.48 (the second run has a minimum exchange acceptance rate of 0.10)	0.92 ± 0.30 (error-weighted mean)	2	≈ 2.57 (2.45–2.65 including the error of the curve)	$\approx +0.13$ ($+0.05$–$+0.25$)
$SU(2)$	2.6	1.43 ± 0.19	-0.57 ± 0.46, -0.41 ± 0.51	-0.50 ± 0.34 (consistent with 0)	2	$\lesssim 2.45$	$\gtrsim +0.15$
$SU(2)$	2.5	0.63 ± 0.18	0.41 ± 0.34	—	1	2.2–2.5	0–$+0.3$
$U(1)$	1.5	0.83 ± 0.11	2.32 ± 0.45 (48 replicas, minimum exchange acceptance rate 0.37)	—	1	> 1.7 (outside the curve)	< -0.2

The coarse-lattice curve for $U(1)$ is $\Delta F(4, 8, \beta') = 0.42, 0.55, 0.83, 0.92, 1.46$ ($\beta' = 1.3, 1.4, 1.5, 1.6, 1.7$). The first run for $U(1)$ (32 replicas) gave -0.18 ± 0.12, but the minimum exchange acceptance rate was 0.03 and the mixing poor, so it is not used.

Reading [Reading]. For $SU(2)$, doubling lowers the vortex free energy ($2.97 \to 0.92$ at $\beta = 2.7$), and the matching β' is smaller than β. For $U(1)$ it rises ($0.83 \to 2.32$, about 3σ), and $\beta' > \beta$. The direction of the comparison separates between the two groups. The $+0.13$ at $\beta = 2.7$ is somewhat smaller (about 1.5σ) than the one-loop 0.258 and than the roughly 0.23 expected from the known values of $a\sqrt{\sigma}$. The record notes that the reversed direction for $U(1)$ may also include artefacts of the small lattice.

Next, on the symmetric torus N^4, we look at the two steps $2^4 \to 4^4$ and $4^4 \to 8^4$.

Table 8 $SU(2)$, $\Delta F(N^4, \beta)$ on the symmetric torus ($n12 = 1$, one seed each) [Reading]

β	1.0	1.25	1.5	1.75	2.0	2.25	2.5	2.75	3.0
2^4	0.034	0.094	0.213	0.573	1.39	2.71	4.29	5.95	7.88
4^4	0.01	−0.01	0.01	0.01	−0.03	0.50	2.46	5.10	7.33

The errors are 0.01–0.08 at 2^4 and 0.03–0.26 at 4^4. The β' of the single step $2^4 \to 4^4$ (fitting the 4^4 values to the 2^4 curve) is as in Table 9.

Table 9 The single step $2^4 \to 4^4$ for $SU(2)$ [Reading]

β	≤ 2.0	2.25	2.5	2.75	3.0
β'	< 1.0 (outside the curve)	1.72	2.20	2.62	2.93

β	≤ 2.0	**2.25**	**2.5**	**2.75**	**3.0**
$\beta - \beta'$	> 0.75–1	0.53	0.30	0.13	0.07

At every readable β (1.75–3.0), $\beta - \beta' > 0$; that is, the step function of one step has no fixed point. The motion per step grows towards strong coupling; that it falls to 0.07 on the weak-coupling side is seen as an artefact of 2^4 being too small for the one-loop regime.

Table 10 $4^4 \to 8^4$ for $SU(2)$. ΔF is given per seed and as their simple mean (the error is half the difference between seeds; for three runs, the mean and the spread) [Reading]

β	$\Delta F(4^4)$: per seed → combined	$\Delta F(8^4)$: per seed → combined	Seeds (8^4)	$\beta - \beta'$
2.1	—	-0.04 ± 0.17	1	— (≈ 0)
2.3	—	-0.04 ± 0.10	1	$\gtrsim 0.1$
2.5	2.46 (1 run)	0.48 ± 0.48	1	$\approx +0.25$ ($+0.19$–$+0.5$)
2.6	3.96 ± 0.13 (1 run)	—	—	—
2.7	4.96, 4.47 → 4.72 ± 0.25	3.57, 2.65 → 3.11 ± 0.46	2	$+0.16$ ($+0.13$–$+0.19$)
2.75	5.10, 5.26 → 5.18 ± 0.10	—	—	—
2.8	5.33, 5.87 → 5.60 ± 0.27	—	—	—
2.9	6.88, 6.23 → 6.56 ± 0.33	5.68, 3.52, 4.84 → 4.68 ± 0.63	3	$+0.20$ ($+0.12$–$+0.29$)
3.0	7.33, 7.83 → 7.58 ± 0.25	5.38, 6.17 → 5.78 ± 0.40	2	$+0.18$ ($+0.14$–$+0.25$)

Reading [Reading]. For $4^4 \to 8^4$ too, $\beta - \beta' > 0$ at every β measured, with a mean of about $+0.2$. This is close to the one-loop asymptotic value 0.258 and to the roughly 0.23 expected from the known values of $a\sqrt{\sigma}$. At some points the difference between seeds is 1–2 times the stated error (at $\beta = 2.9$, 8^4 gives 5.68 and 3.52), and we read the errors as quite likely on the small side. The reading with added seeds came closer to the asymptotic behaviour than the single-seed reading ($+0.08$–$+0.13$). It also fits the reading of the 8×16 slab at $\beta = 2.7$ (Table 7, $+0.13$).

06

The sign of the step function — the U(1) contrast

We carried out the same $2^4 \to 4^4$ scan for $U(1)$. Four-dimensional $U(1)$ has a phase transition at $\beta_c \approx 1.01$ from the confining phase to the Coulomb phase.

Table 11 $U(1)$, $\Delta F(N^4, \beta)$ on the symmetric torus and the single step $2^4 \to 4^4$ ($n_{12} = 1$, one seed each, errors not recorded) [Reading]

β	**0.6**	**0.8**	**0.9**	**1.0**	**1.1**	**1.2**	**1.4**	**1.6**
2^4	0.14	0.62	1.15	1.80	2.46	3.10	4.18	5.23

β	0.6	0.8	0.9	1.0	1.1	1.2	1.4	1.6
4^4	0.00	0.00	0.05	1.07	2.71	3.68	4.46	5.85
$\beta - \beta'$	> 0.3	> 0.3	> 0.3	$+0.12$	-0.04	-0.11	-0.05	< 0

Reading [Reading]. The sign of $\beta - \beta'$ for $U(1)$ flips between $\beta = 1.0$ and 1.1. This is the position of the known phase transition $\beta_c \approx 1.01$. In the confining phase $\beta' < \beta$, and in the Coulomb phase $\beta' > \beta$. For $SU(2)$, the same scan gave $\beta - \beta' > 0$ at every β measured (Tables 9 and 10). The sign of the step function of one step works as a diagnostic that tells whether there is a phase transition. This is the numerical face of the criterion "distinguish from the U(1) transition" (26-06 § 08), which an argument that closes the band must satisfy.

What this sign test can say is only that, on lattices up to 8^4 and at the β points of the table, the sign for $SU(2)$ did not change. It is not evidence that $SU(2)$ has no phase transition.

Relatedly, there are two readings [Reading] concerning the intermediate goal of seeing $\Delta F(L, L) \to 0$ at any rate (26-06 § 08). For $U(1)$ ($\beta = 1.2$), $2^4 \to 4^4$ gives $3.10 \to 3.68$, flat, which does not contradict the picture of heading towards the classical half-flux value in the Coulomb phase. For $SU(2)$ ($\beta = 2.75$), it falls, $5.95 \to 5.10$.

07

The column bias — the ℓ × N scan

We measure the column face $f(\ell)$ (26-10 § 02). The outer frame of the column $T^2_N \times \ell \times \ell$ is taken from an equilibrium configuration and held fixed; for each frame, the conditional free energy $\Delta F_B = \ln Z_B(+)/Z_B(-)$ when a sheet of n_{34} is put inside the column, and the bias $\theta_B = \tanh(\Delta F_B/2)$, are obtained by replica exchange + Bennett's acceptance ratio method, and we take $\mathbb{E}|\theta_B|$ over the frames. It is this $\mathbb{E}|\theta_B|$ that enters the Chessboard Estimate (26-05). $SU(2)$ is at $\beta = 2.3$, and $U(1)$ at $\beta = 1.3$ in the Coulomb phase.

Table 12 Varying ℓ at $N = 4$ (numbers of frames in parentheses) [Reading]

ℓ	$SU(2)$, $\beta = 2.3$: $\mathbb{E}\lvert\theta_B\rvert$	$U(1)$, $\beta = 1.3$: $\mathbb{E}\lvert\theta_B\rvert$
2	0.93 ± 0.06 (5)	—
3	0.58 ± 0.17 (4)	0.95 ± 0.05 (4)
4	0.23 ± 0.04 (12)	0.61 ± 0.21 (4)
5	0.07 ± 0.03 (12)	0.49 ± 0.09 (12)
6	0.09 ± 0.04 (4)	0.41 ± 0.06 (12)

ℓ	$SU(2)$, $\beta = 2.3$: $\mathbb{E}\lvert\theta_B\rvert$	$U(1)$, $\beta = 1.3$: $\mathbb{E}\lvert\theta_B\rvert$
8	—	0.25 ± 0.05 (8)

For $\ell \geq 5$, the column bias of $SU(2)$ is 1/5 to 1/7 of that of $U(1)$. $U(1)$ decreases slowly (about $\ell^{-1.4}$ over $\ell = 5 \to 8$), while $SU(2)$ drops to 1/3 over $\ell = 4 \to 5$. The values of $SU(2)$ for $\ell \geq 5$, however, are close to the floor made by the per-frame statistical errors (which bias $|\theta_B|$ positive), and at these sizes one cannot decide whether it is $e^{-\sigma\ell^2}$ or a power. The sign can change from frame to frame (for $SU(2)$ at $\ell = 4$, the mean of ΔF_B is -0.05). In frames where the holonomy around the block is close to -1, the sector with the sheet is favoured.

Table 13 Varying N at $\ell = 5$ (numbers of frames in parentheses) [Reading]

N	$SU(2)$, $\beta = 2.3$	$U(1)$, $\beta = 1.3$
4	0.07 ± 0.03 (12)	0.49 ± 0.09 (12)
6	0.20 ± 0.05 (6)	0.97 ± 0.01 (6)
8	0.39 ± 0.05 (5; the sixth frame stopped partway at the time limit)	—

With ℓ fixed, the bias approaches 1 with N for both groups. While the bias is small, it grows roughly in proportion to N^2 ($\Delta F_B \propto N^2 f(\ell)$), and the proportionality coefficient for $SU(2)$ is about 1/7 of that for $U(1)$. The difference between the groups should appear in how the ℓ needed to keep θ small grows, so we varied both ℓ and N.

Table 14 The $\ell \times N$ scan: $\mathbb{E}\lvert\theta_B\rvert$ (numbers of frames in parentheses) [Reading]

	$\ell = 4$	**5**	**6**	**7**	**8**	**10**
$SU(2)$, $\beta = 2.3$, $N = 4$	0.23 (12)	0.07 (12)	0.09 (4)	0.11 (4)		
$SU(2)$, $N = 6$	0.43 (4)	0.20 (6)	0.15 (4)	0.08 (4)		
$SU(2)$, $N = 8$	0.43 (4)	0.38 (5)	0.13 (4)	0.29 ± 0.06 (3)		
$U(1)$, $\beta = 1.3$, $N = 4$	0.61 (4)	0.49 (12)	0.41 (12)		0.25 (8)	0.27 (4)
$U(1)$, $N = 6$		0.97 (6)	0.98 (4)		0.51 (4)	0.45 (4)

Reading [Reading]. For $SU(2)$, at every one of $N = 4, 6, 8$, the bias falls to the statistical floor (about 0.1) at $\ell \approx 6$–7, and the needed ℓ hardly grows with N. For $U(1)$, even at $N = 4$ it stays at 0.27 at $\ell = 10$, and at $N = 6$ it is 0.45 even at $\ell = 10$; the needed ℓ grows with N, and the fall is slower. The 0.29 at $N = 8$, $\ell = 7$ comes from only 3 frames (cut off at the time limit); that it is larger than the 0.13 at $\ell = 6$ we take as a fluctuation due to the small number of frames (all 3 frames have $\Delta F_B > 0$, 0.43–0.85). This does not contradict the expectation ($\ell \sim \sqrt{\ln N}$ for $SU(2)$, $\ell \propto N$ for $U(1)$), but the lattices are small and the frames few, so the form of the growth cannot be determined.

A diagnosis of the Z_2 glass

Writing $U = \sigma V$ ($\sigma \in \mathbb{Z}_2$, V a section of $SO(3)$), the twisted sector becomes "a $\mathbb{Z}_2$ random-plaquette gauge model on an $SO(3)$ background" (26-10 § 03). The effective $\mathbb{Z}_2$ coupling per plaquette is $K_p = (\beta/2)|\mathrm{tr}\, U_p|$, and the frustration (a $\mathbb{Z}_2$ monopole) is a cube c for which $\prod_{p \in \partial c} \mathrm{sign}\, \mathrm{tr}\, U_p = -1$.

Table 15 $SU(2)$, periodic 8^4, heat bath with 150 thermalisation sweeps and 100 measurements (number of seeds not recorded, errors not recorded) [Reading]

β	$\langle P \rangle$	Fraction with $\mathrm{tr}\, U_p < 0$	$\langle K \rangle$	Fraction with $K < K_c = 0.4407$	Frustrated cubes	p_{eff}
1.0	0.243	0.297	0.455	0.494	0.481	0.209
1.5	0.363	0.204	0.741	0.282	0.452	0.162
2.0	0.501	0.109	1.120	0.149	0.349	0.091
2.3	0.602	0.051	1.437	0.081	0.216	0.045
2.5	0.653	0.029	1.660	0.051	0.140	0.027
2.7	0.686	0.018	1.870	0.034	0.093	0.017

p_{eff} is the frustration density ρ of the cubes, converted to a probability of independent sign flips by $(1 - 2p_{\mathrm{eff}})^6 = 1 - 2\rho$. K_c is the transition point of pure $\mathbb{Z}_2$ gauge theory, and the value to compare with is the Nishimori multicritical point $p_c \approx 0.11$ of the four-dimensional random-plaquette gauge model (checking not yet done).

Reading [Reading]. For $\beta \gtrsim 2.0$, the mean coupling $\langle K \rangle$ is 3–4 times K_c, and $p_{\mathrm{eff}} < 0.11$. The $\mathbb{Z}_2$ glass is likely on the side of the ordered phase. For $\beta \lesssim 1.5$, $p_{\mathrm{eff}} \geq 0.16$, and soft plaquettes ($K < K_c$) are 28–49%: the disordered side. The conversion to independent signs is crude (soft plaquettes and frustration are correlated), so the boundary is a rough guide. From this diagnosis, the glass road is limited to the lower half of the band (the stopped road "glassy squeeze" of 26-08 § 05).

09

Artefacts of small lattices — a list of cautions for reading

- **$N_T = 2$ (and 2^4) is the regime of lattice artefacts.** At $N_T = 2$ one side of the T^2 is two lattice sites, the frustration of the twist is large, and it is far from the continuum picture (a gas of fractional instantons). That the $\beta - \beta'$ of the single step $2^4 \to 4^4$ falls to 0.07 on the weak-coupling side (Table 9) is also seen as due to 2^4 being too small for the one-loop regime. Values at $N_T = 2$ are kept as "a reference for the direction".

- **The ceiling of θ.** In geometries where θ is of order 1 ($M = 8$ of Table 1), $\theta \leq 1$ holds the ratio down and weakens the power to discriminate between the groups.
- **The statistical floor.** The column bias $\mathbb{E}|\theta_B|$ is biased positive by the per-frame statistical errors. Values of about 0.1 are close to the floor, and one cannot decide between an area exponent and a power (Tables 12 and 14).
- **The Coulomb term.** The Creutz ratio at small R includes the Coulomb term and overestimates the tension (Tables 4 and 5).
- **Poor mixing.** Runs with a small minimum replica-exchange acceptance rate (replicas 24 and 32 for $U(1)$, the 0.10 of the second $SU(2)$ run) fluctuate strongly in value. Runs we did not use are noted under the tables.
- **Number of seeds and errors.** There are 1–3 seeds. At some points the difference between two runs with different seeds is 1–2 times the stated error, so the errors are quite likely on the small side.
- **How β is matched.** The β of $U(1)$ and of $SU(2)$ are not matched to the same physical size. What we compare is only the direction (sign) within each group.
- **A withdrawn measurement.** We have withdrawn reading the measurement that flips containers simultaneously as "the numerical face of the band". The flip probability of the one-step kernel levels off at about 1/2, and what comes out is only the weak form, which $U(1)$ also satisfies (the stopped road "flip certificate" of 26-08 § 05). The measurement itself is in 25-08.

10

The table of the five grades and the dependency graph

All the rows of this page are numerical readings. The label is "Reading", with " (physics)" added for readings that include a physical estimate.

Table 16 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	Widening the T^2 increases ΔF for $U(1)$ and not for $SU(2)$	Reading	Tables 1–3	$M = 8, 12$, $\beta = 2.4$, 2.5 ($SU(2)$), $\beta = 1.5$ ($U(1)$), $N_T \leq 8$	—
2	The slab $\chi(4)$ increases with N_T and saturates, with no significant overshoot	Reading	Tables 4 and 5	$\beta = 2.5$, $M = 16$, 2000 measurements, $N_T \leq 10$	—
3	ΔF increases in β	Reading	Table 6	$4 \times 4 \times 8 \times 8$, $\beta = 2.2$–2.7	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
4	Doubling the whole lattice: $\beta' < \beta$ for $SU(2)$, $\beta' > \beta$ for $U(1)$	Reading	Tables 7–10	$(4,8) \to (8,16)$, $2^4 \to 4^4$, $4^4 \to 8^4$, 1–3 seeds	—
5	$\beta - \beta'$ for $4^4 \to 8^4$ averages about $+0.2$, close to the one-loop 0.258	Reading	Table 10	$\beta = 2.5$–3.0, 1–3 seeds	—
6	The sign of the single step for $U(1)$ flips between $\beta = 1.0$ and 1.1; for $SU(2)$ it does not flip in the range measured	Reading	Tables 9 and 11	$2^4 \to 4^4$, one seed	—
7	The ℓ that keeps the column bias small hardly grows with N for $SU(2)$, and grows for $U(1)$	Reading	Tables 12–14	$N \le 8$, $\ell \le 10$, 3–12 frames	—
8	The $\mathbb{Z}_2$ glass is on the ordered side for $\beta \gtrsim 2$ and on the disordered side for $\beta \lesssim 1.5$	Reading (physics)	Table 15	8^4; the conversion to independent signs is crude	—
9	The measurements 1–7 do not contradict the directions of the lateral-widening inequality, the renormalisation comparison and the criterion "distinguish from the U(1) transition"	Reading (physics)	§ 02–§ 07	Tendencies on small lattices. Not evidence	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

```
1  RDG  widening T²: U(1) rises, SU(2) does not                M = 8, 12
2  RDG  slab tension increases and saturates                   β = 2.5, 2000 m
3  RDG  ΔF increases in β                                      4×4×8×8
4  RDG  doubling test: SU(2) β' < β, U(1) the opposite ⟸ 3     1–3 seeds
5  RDG  β − β' ≈ +0.2 for 4⁴ → 8⁴ ⟸ 4                         1–3 seeds
6  RDG  sign of the step function: U(1) flips at β_c ⟸ 4       2⁴ → 4⁴
7  RDG  ℓ × N of the column bias                               N ≤ 8, ℓ ≤ 10
8  RDG  diagnosis of the Z₂ glass                              8⁴
9  RDG  consistency of directions ⟸ 1, 2, 4, 6, 7              tendency
```

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. This page has no "Proved here", "Cited" or "Assumption" rows. Nor does it have nodes for the statements that cross the band (the uniform slab tension, the lateral-widening inequality, the renormalisation comparison); those are placed as assumptions in the ledger of conditions of Part 27 (27-02).

What this chapter can say

What is said	What is not said
Reading That on small lattices the directions of $SU(2)$ and $U(1)$ separate in every test: widening the T^2, doubling the lattice, widening the column	Behaviour on large lattices. Determining the values. The lateral-widening inequality and the renormalisation comparison themselves
Reading That the sign of the step function for $U(1)$ flips at the position of the known transition, and that for $SU(2)$ it does not flip in the range measured	That $SU(2)$ has no phase transition
Reading (physics) That the $\mathbb{Z}_2$ glass is on the ordered side in the upper half of the band	The position of the phase boundary of the glass (the conversion is crude)

Sources and reproduction

Item	Kind	Source / tools
All the tables	Reading	The record of numbers from this book's study (numerical computations of vortex insertion: the global flux free energy, the string tension of the slab, the β-dependence, tests of the renormalisation comparison, scans of the step function on the symmetric torus, the $U(1)$ contrast, the added $4^4 \to 8^4$ runs and the combining of seeds, the twist cost of a column, the diagnosis of the $\mathbb{Z}_2$ glass), and the numerical section of the survey of roads that would close the crossover band. Replica exchange and Bennett's acceptance ratio method, heat bath, Creutz ratios
The phase transition $\beta_c \approx 1.01$ of $U(1)$	Reading	Known numerical lattice values (5-06)
The Nishimori multicritical point $p_c \approx 0.11$	Checking not yet done	Numerical literature on the four-dimensional random-plaquette gauge model
The one-loop 0.258	Proved here	Chapter 25-07 (one-loop level)

Terms used in this chapter — the vortex free energy ΔF, the sector bias θ, the Creutz ratio, replica exchange, Bennett's acceptance ratio method, the step function, the column bias $\mathbb{E}|\theta_B|$, the $\mathbb{Z}_2$ glass, frustration. Their meanings are in A-02 Glossary.

Next chapter: 26-10 Candidate new viewpoints — into inequalities for which local quantities these tendencies might be grown.

Candidate new viewpoints

> This chapter is a map of open questions. It marks the boundary between the parts that close and the parts that do not.

What this chapter shows — We have narrowed things down to this point: crossing the middle of the crossover band needs one inequality that uses non-commutativity (26-06 § 07). This chapter sets out candidates for the local quantity in which to write that one inequality. For the four faces — the softness of the twist direction κ_W, the flux mixing of the box $\delta(L_0)$, the twist cost of the column $f(\ell)$, the pressure margin — we write the local quantity that carries each, why we expect it to hold for $SU(2)$, where it breaks for $U(1)$, and whether there are numbers (§ 02). We then give the $\mathbb{Z}_2$ glass representation, restricted to the lower half of the band (§ 03), the conformal frame $H^2 \times S^2$, which turned out negative on examination (§ 04), and three new candidates — reduction by the compactness of the band, the log-concavity of the Weyl measure and the height–azimuth decomposition, and the local step function of the column (§ 05).

Prerequisite chapters — 26-06 (the renormalisation comparison, the list of the four faces, the reduction lemma), 26-08 (stopped roads and the selection criteria), 26-09 (the measured record), 25-03 (containers), 26-01 (the correct form of the band).

Said first — The candidates on this page are all **at the level of physical estimates**. None of them closes the band, and none gives a theorem at any β in the band. Paper proofs are set out only for the elementary facts that serve as footholds for the candidates (the transport identity, the Jensen sandwich, the density of a projection, and so on), each labelled "Proved here". We do not give numbers for the chances that a candidate succeeds (such numbers are only an aid to judgement, not numbers with a basis).

The order of this chapter

1. How to read the candidates — the checkpoints a candidate must pass
2. The four faces of the band in the middle (Table 1)
3. The $\mathbb{Z}_2$ glass — restricted to the lower half of the band
4. The conformal frame $H^2 \times S^2$ — negative on examination
5. Three new candidates — reduction by compactness, the Weyl measure, the step function of the column
6. Five other candidates (Table 2)
7. What cannot be said

8. The table of the five grades and the dependency graph

01

How to read the candidates — the checkpoints a candidate must pass

The candidates on this page are set out after passing the selection criteria of 26-08 § 07 as checkpoints. In particular, we name the following four for each candidate.

- **Does it use non-commutativity essentially?** A candidate that gives the same conclusion for $U(1)$ is wrong. This is why we write "where it breaks for $U(1)$" for each candidate. A table that widens the opponents of the test beyond U(1) is in 26-12.
- **Is it not a rewording of one loop?** A quantity that at one loop becomes asymptotic freedom itself is not enough on its own.
- **Does it not fail at small scales?** Claims are put in a form restricted to outside the lattice artefacts, such as $\ell \geq \ell_{\min}$.
- **Does it distinguish from the transition of $U(1)$ within the band ($\beta \approx 1.01$)?**

For each candidate we write (i) the local quantity that carries it, (ii) why we expect it to hold for $SU(2)$ (the place where non-commutativity enters), (iii) where it breaks for $U(1)$ and $\mathbb{Z}_2$, (iv) the check against the ledger (26-08), (v) whether there are numbers. The labels are "Proved here" for elementary facts, "Reading" for numbers, and "Reading (physics)" for estimates.

02

The four faces of the band in the middle

There are four candidates for the local quantity in which to write the non-abelian inequality that crosses the band. We call them "faces" in the sense that it suffices to show any one of them, uniformly in the scale, in a form that fails for $U(1)$. For every face, a comparison across scales (for example $f(2\ell, 2N, \beta) \leq K f(\ell, N, \beta')$) is a local version of the same difficulty as the global renormalisation comparison, and does not become easier. What changing the face gains is that the object of the proof becomes "a statement about a finite region with its boundary held fixed".

Table 1 The four faces (expectations and reasons are physical estimates; numbers are readings)

Face	Local quantity that carries it	Why we expect it to hold for $SU(2)$	Where it breaks for $U(1)$, $\mathbb{Z}_2$	Numbers
Softness of the twist direction κ_w	The variance of the force along the generator of the twist, within a band of width w (adapted stiffness)	Decreases with w. The soft direction of Nielsen–Olesen; a non-perturbative version of the one-loop spin term $+4$	$U(1)$ has no spin term, so $\kappa_w \geq c\beta$. $\mathbb{Z}_2$ has no continuous path and can use only thin sheets (2β per unit area)	None

Face	Local quantity that carries it	Why we expect it to hold for $SU(2)$	Where it breaks for $U(1)$, $\mathbb{Z}_2$	Numbers
Flux mixing of the box $\delta(L_0$)	The total variation distance of the law of the inner cube when the centre flux at the boundary of the box is changed	Goes to 0 exponentially with L_0	In the Coulomb phase of $U(1)$ it stays at $O(\beta)$	None
Twist cost of the column $f(\ell)$	The conditional free energy of the twist and the bias $\mathbb{E}\lvert\theta_B\rvert$ of the column $T^2_N \times \ell \times \ell$ with its outer frame held fixed	Of type $e^{-\sigma\ell^2}$	$U(1)$ is of type $\pi^2\beta/\ell^2$, $\mathbb{Z}_2$ is $\approx 2\beta$	Yes (26-09 § 07)
Pressure margin	The pressure difference p $\infty - pG,L$ between the system with the twist pattern and the system without it (the exponent of the chessboard density κ cb)	A positive margin remains at intermediate β	$U(1)$ does not produce a small κ_{cb}	None

The softness in the twist direction $\kappa_{\mathcal{W}}$ — joining sectors by transport

The foothold is an identity for the free energy given by a map that carries one sector to the other. Take a measurable bijection T (Jacobian J_T) from the configuration space of sector 0 to that of sector 1; let μ_0, μ_1 be the Gibbs measures of the two sectors and $\Delta F = -\ln(Z_1/Z_0$). Then

$$\Delta F \;=\; \mathbb{E}_{\mu 0}\left[S \circ T - S - \ln J_T\right] \;-\; \mathrm{KL}\big(T_{\#}\mu 0 \,\big\|\, \mu 1\big) \quad (1)$$

holds [Proved here].

Proof. By the change of variables, $Z_1 = \int e^{-S(Tx)} J_T(x)\, dx$, so setting $G := S \circ T - S - \ln J_T$ we have $Z_1/Z_0 = \mathbb{E}_{\mu 0}[e^{-G}]$. The measure $\tilde{\mu} \propto e^{-G}\mu_0$ is μ_1 pulled back by T^{-1}, and $\mathrm{KL}(\mu_0 \|$ $\tilde{\mu}) = \mathbb{E}_{\mu 0}[G] + \ln \mathbb{E}_{\mu 0}[e^{-G}]$. Since T is a bijection, $\mathrm{KL}(\mu_0 \| \tilde{\mu}) = \mathrm{KL}(T_{\#}\mu_0 \| \mu_1)$. Rearranging gives (1). ∎

The first term of (1) is "the action cost of the map", and the second is the remainder. If the map T is deterministic, the remainder (the relative entropy) grows with the area of the vortex sheet, so an area law of type $e^{-\sigma A}$ does not come out [Reading] (physics) (the stopped road "deterministic squeeze" of 26-08 § 05). The goal of the transport road is therefore not the area law but the qualitative $\Delta F(L, L) \to 0$ (the intermediate goal of 26-06 § 08).

(ii) Why we expect it to hold for $SU(2)$ [Reading] (physics). The "adapted" map that carries sectors along the generator of the twist is a triangular change of variables with $J_T = 1$: a map that preserves volume while changing the shape of the fluctuations. It is the non-perturbative version of the principle of 25-07 — that what hides the antiscreening $+4$ is not

preserving volume but not changing the shape of the fluctuations. κ_w is the size of the fluctuations of the action cost of that map, and we expect it to decrease with w if the soft direction of Nielsen–Olesen works within a band of width w.

(iii) Where it breaks. $U(1)$ has no spin term, and $\kappa_w \geq c\beta$ remains. $\mathbb{Z}_2$ has no continuous path joining the sectors and can use only thin sheets (2β per unit area). **(iv) The ledger**: there is a risk of hitting item 25 of Table 1 (spin and the index theorem are a restatement of asymptotic freedom at one loop); the dividing line is whether the non-perturbative part can be cut out as an estimate of the variance κ_w. **(v) Numbers**: none.

The mixing of box magnetic flux $\delta(L_0)$ — a finite-box criterion

A candidate for a gauge version of a Dobrushin–Shlosman-type finite-size criterion. The form of the goal is "if $\delta(L_0, \beta) \leq \varepsilon_d$, then the area law"; the criterion itself has not been written down [Reading] (physics). It does not use correlation inequalities (GKS), so it does not hit the obstacle that $SU(2)$ has no GKS (items 2 and 4 of Table 1).

For $SU(2)$ we expect $\delta(L_0)$ to go to 0 exponentially with L_0. In the Coulomb phase of $U(1)$, in the Villain model in the Gaussian approximation, the relative entropy stays at $O(\beta)$ independent of L_0 (a count at the level of estimates) [Reading] (physics). Caution: if the ordinary Dobrushin criterion is used with a frame, the continuous field follows the boundary and the influence coefficient becomes nearly 1 (the stopped road "Dobrushin-type criterion" of 26-08). $\delta(L_0)$ is a quantity that changes only the centre flux precisely to avoid this following. No numbers.

The twist cost of a column $f(\ell)$ — the same quantity as the Wilson loop of the box

Given the skeleton Σ (the outer frame of the columns), the interiors of the columns are conditionally independent, so

$$|\theta| \;\leq\; \mathbb{E} \prod_B |\theta_B(\Sigma)| \qquad (2)$$

holds [Proved here] (the same framework as the Container Identity of 25-03 § 03, with no new content). What is new is how $f(\ell)$ is read. The electric flux in a box with its outside held fixed is **the same quantity as the area law of the Wilson loop of the box** [Reading] (physics). This closes a loop: the Tomboulis–Yaffe inequality (from θ to the Wilson area law, 26-01 § 04) and (2) (from the Wilson area law of the box to θ).

Two things are missing to go round the loop (open): the comparison between periodic and fixed boundary conditions, and the loss of $\ln N$. The estimate is that even if the loss remains, $\ln(1/\theta(L, L)) \geq cL^2/\ln L$ comes out, and through Tomboulis–Yaffe this gives $\langle W \rangle \leq 2 \exp(-cA/\ln A)$ (decay faster than the perimeter law) [Reading] (physics).

There are numbers (26-09 § 07) [Reading]. On $T_4^2 \times \ell \times \ell$ with the outer frame held fixed, $\mathbb{E}|\theta_B|$ for $SU(2)$ ($\beta = 2.3$) at $\ell \geq 5$ is 1/5 to 1/7 of that for $U(1)$ ($\beta = 1.3$), and the ℓ needed to keep

θ small hardly grows for $SU(2)$, staying at 6–7 for $N \le 8$, while it grows for $U(1)$. At these sizes, the difference between fixed and periodic boundary conditions does not seem to matter. The values for $SU(2)$, however, are close to the statistical floor, and $e^{-\sigma \ell^2}$ cannot be told apart from a power.

The pressure margin — a computer-assisted squeeze

We write the chessboard density as $\kappa_\Lambda = \exp(|B|(p_{G,\Lambda} - p_\Lambda))$ (p_G is the pressure of the system with the twist pattern, $|B|$ the volume of a tile). From above: if the pattern is reflection-symmetric, the periodic transfer matrix is positive, and the monotonicity of Schatten norms gives $p_{G,\Lambda} \le p_{G,L}$ (Λ a multiple of L). From below: $p_\Lambda \ge p_\infty$, together with a lower bound p_{lb} on the infinite-volume pressure taken from a dual certificate of the loop-equation bootstrap (the method of Kazakov–Zheng; checking not yet done). Combined, $\kappa_\Lambda \le \exp(|B|(p_{G,L} - p_{\mathrm{lb}}))$ becomes uniform in Λ, and an explicit area law for the tension comes out at fixed β — that is the estimate [Reading] (physics).

This face does not cross the band (uniformly in the lattice spacing). What it could give is confinement at fixed β for four-dimensional $SU(2)$ at intermediate coupling (for example $\beta = 1.0$). In the range we searched, no proof of that was found. Combined with the reduction of § 05 (the candidate "reduction by compactness of the band"), a result of this kind at fixed β becomes a component of the band as it stands. $\beta = 1.2$ for $U(1)$ should not produce a small κ, and can be used as a control. No numbers.

03 The Z_2 glass — restricted to the lower half of the band

Writing an element of $SU(2)$ as $U = \sigma V$ ($\sigma \in \mathbb{Z}_2$, V a section of $SO(3)$), the partition function of a twisted sector can be written $Z_n = \int d\omega\, Z_n(\omega)$. $Z_n(\omega)$ is the partition function of a $\mathbb{Z}_2$ gauge theory with couplings $\beta J_p(\omega)$ fixed by the $SO(3)$ background ω ($J_p = \frac{1}{2}\operatorname{tr} V_p$, with random signs) and twist n. Setting $X(\omega) = \ln Z_0(\omega)/Z_1(\omega)$ and $P_n(d\omega) \propto Z_n(\omega) d\omega$, we have

$$\mathbb{E}_{P_1}[X] \;\le\; \Delta F \;\le\; \mathbb{E}_{P_0}[X] \qquad (\Delta F = \ln Z_0/Z_1) \tag{3}$$

[Proved here].

Proof. The left side follows from $Z_0/Z_1 = \int Z_1(\omega) e^{X(\omega)} d\omega / Z_1 = \mathbb{E}_{P_1}[e^X] \ge e^{\mathbb{E}_{P_1} X}$ (Jensen). Likewise the right side from $Z_1/Z_0 = \mathbb{E}_{P_0}[e^{-X}] \ge e^{-\mathbb{E}_{P_0} X}$. ∎

The right-hand side of (3) is the twist free energy of a $\mathbb{Z}_2$ random-plaquette gauge model quenched in the $SO(3)$ background. This representation alone exists in the same form for $U(1)$, so it does not satisfy the criterion "distinguish from the U(1) transition". The distinction between groups enters **dynamical quantities**: the frustration of the background ($\mathbb{Z}_2$ monopoles) and the density of soft plaquettes [Reading] (physics).

Result of the diagnosis (26-09 § 08) [Reading]. On 8^4, for $\beta \gtrsim 2.0$ the mean of the effective $\mathbb{Z}_2$ coupling is 1.1–1.9, well above the transition point 0.44 of pure $\mathbb{Z}_2$, and p_{eff}, the frustration converted to independent signs, is 0.017–0.09, below the Nishimori multicritical point 0.11. **In the upper half of the band, the glass is on the side of the ordered phase**. The $SO(3)$ field already distinguishes the sectors ($|X|$ is large), and the sandwich (3) becomes very loose. Confinement there can be read as carried by the $SO(3)$ part (thick centre vortices). This fits the physical picture that centre vortices are thick at weak coupling [Reading] (physics).

For $\beta \lesssim 1.5$, $p_{\text{eff}} \geq 0.16$, soft plaquettes are 28–49%, and the glass is on the disordered side. **The glass road is therefore restricted to the lower half of the band**. We have discarded it for the upper half (the stopped road "glassy squeeze" of 26-08 § 05). A candidate use in the lower half is a variant of the mixing of box magnetic flux: condition the outside on the $SO(3)$ part only, flip only the centre flux at the boundary (the $\mathbb{Z}_2$ sign), and measure the total variation distance $\delta_c(L_0, \beta)$ of the inner law. The $SO(3)$ frame does not move, so the obstacle of the continuous field following the boundary (Dobrushin-type criterion) is avoided. The only coupling left is the $\mathbb{Z}_2$ glass. In the upper half of the band δ_c should also be close to 1, and this variant belongs to the work of pushing up the lower end of the band (26-06 § 04) [Reading] (physics).

04

The conformal frame H² × S² — negative on examination

The space $\mathbb{R}^4$ with one straight line removed is conformal to $H^2 \times S^2$ [Proved here]: with r the distance from the line and t the coordinate along the line,

$$dt^2 + dr^2 + r^2 d\Omega^2 \;=\; r^2\Big[\frac{dt^2 + dr^2}{r^2} + d\Omega^2\Big] \quad (4)$$

and the bracket is the product of the hyperbolic plane H^2 (the upper half-plane model) and the unit sphere. If a 't Hooft line is placed on the line, every sphere surrounding the line carries $\mathbb{Z}_2$ flux 1 (an exact analogue of $n_{12} = 1$). And the sphere $\{t\} \times S^2_r$ corresponding to a point $(t, r) \in H^2$ winds an odd number of times with a loop C in the half-plane if and only if (t, r) lies inside the region enclosed by C [Proved here] (the intersection of C with the three-dimensional ball spanned by the sphere is the intersection of the segment $\{t\} \times [0, r)$ with C). This avoids the topological obstacle that stopped the road using local closed surfaces in $\mathbb{R}^4$ (item 8 of Table 1: a closed surface meets a plane an even number of times) by using the line as "the outside". Near the line ($r \to 0$) is the region of small spheres (weak coupling), far away ($r \to \infty$) is the infrared: **scale turns into position**.

The promise went only this far; on examination the result was negative [Reading] (physics).

- A container at height r with hyperbolic size 1 has Euclidean size of order r and carries a sphere S^2_r. This is the band quantity $\theta(r, r)$ itself (with S^2 in place of T^2).

- Hyperbolic nesting: the hyperbolic area of a unit container at height $2r$ (about $[-r, r] \times [r, 3r]$) is $2r\,(1/r - 1/(3r)) = 4/3$, and only 1–2 unit containers at height r fit inside it [Proved here] (computation of an integral). Hyperbolic area does not change under shape-preserving dilation, so nesting does not increase the number of sub-containers; what comes out is about $\theta(2r) \le \theta(r)^{1.3}$, not the exponent 4 of planar nesting.
- The hyperbolic area of a loop in the half-plane (from height d to $d+\ell$, length T) is $T(1/d - 1/(d+\ell)) \approx T/d$, and a uniform θ_0 independent of height gives only the perimeter law. The area law needs $\theta \le e^{-c(r\Lambda)^2}$ for unit containers at height r: the same condition as the band.

Conclusion: the conformal frame puts renormalisation into the language of space as "change of scale = translation in H^2", but kinematics alone does not give the area law, and the core (the growth of disorder through asymptotic freedom) remains in the same place. Its value lies in the clarity of a framework that states the $\mathbb{R}^4$ stage (16-09) without going through slabs. The relation between loops in the measure with a 't Hooft line and loops in $\mathbb{R}^4$ without the line is open, and there is a precedent of the comparison principle failing (26-08 § 04).

05

Three new candidates

We examined eight candidates for the band, and put three of them here (the rest are in § 06). The reasons for the choice: the reduction by compactness of the band is a reduction that can be written reliably on paper, and it moves "where the band is really hard"; the candidate "log-concavity of the Weyl measure" is a two-dimensional checkpoint that can be tried more cheaply than four dimensions, and is one of the few forms that does not fall into the type in which the source of monotonicity and the mechanism of disorder point in opposite directions (the lesson of 26-08 § 01); the candidate "local step function of a column" can be tried directly with the existing numerical tools for the column, and lets us look at the criterion "distinguish from the U(1) transition" directly.

Reduction by compactness of the band

(i) In one line. The band is a bounded closed interval $I = [\beta_a, \beta_b]$ in β, so the renormalisation comparison within the band holds by lowering β' only a little from β, and the band can be crossed in finitely many steps. All that is needed is "confinement at fixed β (two-sided asymptotics with errors of perimeter order)" at each β in the band.

This is set out with a proof as the Lemma Reducing the Comparison inside the Band of 26-06 § 06 [Proved here] (under the two-sided area law at fixed β, the uniform positivity and continuity of the rate, $N \ge N_1$, $M \ge M_0$). Here we write only its meaning as "a viewpoint".

(ii) The local quantity that carries it. Two-sided estimates of the vortex free energy in large volume at fixed β. As local quantities, the area rate $\sigma_N(\beta)$ of the column bias at $\ell \gg \xi(\beta)$,

and the error p of perimeter order.

(iii) Where non-commutativity enters [Reading] (physics). The lemma itself does not depend on the group. Non-commutativity enters entirely through the assumption (confinement for $SU(2)$ within the band). This candidate is a reduction, not a tool, and serves to move the place of the difficulty. After the reduction, what remains within the band is a problem at fixed β (estimates uniform in the volume, non-convex large fields, absence of a phase transition), and the difficulty across scales gathers at the upper end of the band (where the correlation length $\xi(\beta)$ grows sharply in lattice units) and at the seam with ultraviolet control.

(iv) Where it breaks. For $U(1)$ ($\beta \in (1.01, 2.7)$) and $\mathbb{Z}_2$ (on the weak-coupling side of the transition) the assumption is false, so no conclusion follows either. The criterion "distinguish from the U(1) transition" is carried by the assumption.

(v) Check against the ledger. Unlike item 6 of Table 1 (a proof by contradiction extending continuously from a small T^2), the only continuity used is the continuity in β of finite-volume quantities. It is in the same spirit as the idea of considering the step function of the continuum-limit coupling on a bounded interval, but here we stop at the lattice β and do not pass through the continuum limit.

(vi) Relation to known results. On the strong-coupling side, a statement of exactly this form exists at the level of a strand (the Strong-Coupling-End Expansion Proposition of 26-06 § 03). A proof of confinement for the four-dimensional $SU(2)$ lattice at $\beta \approx 1$ within the band was not found in the range we searched (the front line on the strong-coupling side is at small β, 26-08 § 07). Chatterjee (arXiv:2006.16229; abstract checked, text not yet checked) gives a result of the form: if the centre is non-trivial and correlations decay exponentially under arbitrary boundary conditions, then centre symmetry is not broken, and if it is not broken there is confinement. This could be an entrance to qualitative confinement at fixed β, but it does not give the perimeter-order precision of the two-sided area law at fixed β.

(vii) What is needed next. A road that gives the upper side of the two-sided area law at fixed β for each β by finite-box criteria (the mixing of box magnetic flux, the pressure margin), and a road that gives the lower side (that vortices are not too cheap = an upper bound on the string tension) by a variational trial vortex. Both are problems at fixed β, and boxes of size about $\xi(\beta)$ suffice, but at the upper end of the band $\xi(\beta)$ exceeds 10 in lattice units, and finite-box computations in four dimensions stop on scale (item 3 of Table 1). No numbers.

The log-concavity of the Weyl measure, and the height–azimuth decomposition

(i) An elementary fact [Proved here]. The density of the uniform measure on the unit sphere $S^{n-1} \subset \mathbb{R}^n$ projected onto one coordinate t is

$$\rho_n(t) \;\propto\; (1-t^2)^{(n-3)/2}, \qquad t \in [-1,1] \quad (5)$$

Proof. The slice at height t is a sphere S^{n-2} of radius $\sqrt{1-t^2}$, whose area is proportional to $(1-t^2)^{(n-2)/2}$, and the width (length along the sphere) of the band of height dt is $dt/\sqrt{1-t^2}$. Multiplying gives (5). ∎ Hence for $n \geq 3$, ρ_n is log-concave (flat at $n = 3$), and at $n = 2$ it is log-convex (the arcsine distribution). For $SU(2) \cong S^3$ ($n = 4$), the density of $t = \frac{1}{2}\operatorname{tr} U$ is $\propto \sqrt{1-t^2}$ (the Weyl measure); for $U(1) = S^1$ it is $\propto 1/\sqrt{1-t^2}$.

In the two-dimensional $O(3)$ model, writing the spin as $s = (\sqrt{1-t^2}\cos\varphi,\ \sqrt{1-t^2}\sin\varphi,\ t)$, the uniform measure on S^2 is $dt\,d\varphi/(4\pi)$ ($n = 3$ of (5)), and $s_i \cdot s_j = \sqrt{(1-t_i^2)(1-t_j^2)}\cos(\varphi_i - \varphi_j) + t_i t_j$, so the model of the azimuths φ conditioned on the heights t is an XY model with couplings $J_{ij} = \beta\sqrt{(1-t_i^2)(1-t_j^2)} \geq 0$ [Proved here]. There is no frustration.

(ii) The local quantity that carries it. The effective azimuthal coupling $J_{\text{eff}}(b)$, measured in the coarse variables of a $b \times b$ block, and the fluctuations of the height.

(iii) Why we expect it to hold [Reading] (physics). The conditioned azimuth model is ferromagnetic, so the Ginibre inequality for XY (checking not yet done) can be used in the right direction: lowering the couplings lowers the correlations. What exponential decay needs is also an upper bound on correlations, so **the source of monotonicity and the mechanism of disorder point the same way**. The disorder comes from the fluctuations of the height, that is, from the measure (5) with $n \geq 3$. $O(2)$ has no height.

(iv) Where it breaks. $O(2)$: there is no height, and the azimuths remain XY with coupling β (the KT phase). Four-dimensional $U(1)$: there is no degree of freedom for the direction of the class (S^2). $\mathbb{Z}_2$: there is no continuous azimuth.

(v) Check against the ledger, and risks. Unlike items 22 (one-point Bakry–Émery) and 26 (renormalisation of curvature) of Table 1, it uses not curvature but the log-concavity of a projection and a conditional Ginibre inequality. Unlike item 10 of Table 1 (GKS for $\mathbb{Z}_2$), the conditioned model has no frustration. There are two risks. (a) There is an argument of Patrascioiu–Seiler (not yet checked) for the opposite conclusion (that $O(3)$ may have a KT-type phase) through embeddings of the equatorial direction, and this candidate stands at the site of that dispute. (b) At the level of a single site, the typical values of J_{ij} exceed the KT threshold, and the comparison says nothing. If it works, it works only at the block level, where there is no direct Ginibre comparison, and there is the risk of the transfer type of detour.

(vi) To four dimensions. One needs a representation in which the remaining $U(1)$, conditioned on n in $U = t + i\sqrt{1-t^2}\,n \cdot \sigma$ ($n \in S^2$ the direction of the class), is ferromagnetic, but this has not been constructed. Showing exponential decay at all temperatures for the two-dimensional lattice $O(n)$ ($n \geq 3$) (Polyakov's conjecture) is unsolved (the criterion "crosses the smallest band" of 26-08 § 07).

(vii) Numbers. None. The form of the first test is fixed: measure $J_{\text{eff}}(b)$ for the two-dimensional $O(3)$ ($\beta = 1.5, 1.7$), the control $O(2)$ (the KT phase and the disordered phase),

and the auxiliary $O(4)$ (whose height density $\sqrt{1-t^2}$ is the same as for $SU(2)$); if J_{eff} stays above the KT guide even at sizes at which correlations of $O(3)$ have already decayed, discard this candidate. If J_{eff} falls with b for $O(2)$, the measurement is lowering the coupling mechanically, and the result is not used. A block-level Ginibre comparison does not exist as a theorem, so even if it passes it remains a watch on a necessary condition.

The local step function of a column

(i) In one line. Replace the renormalisation comparison of the global ΔF by a comparison of column quantities with the outer frame held fixed:

$$f(2\ell, 2N, \beta) \;\le\; K \cdot f(\ell, N, \beta')^{c}, \qquad \beta' < \beta, \;\; \ell \ge \ell_{\min} \quad (6)$$

(K and c independent of ℓ and N). **(ii) The local quantity that carries it.** The conditional twist free energy ΔF_B and the bias $\theta_B = \tanh(\Delta F_B/2)$ of the column $T^2_N \times \ell \times \ell$ (the outer frame held fixed at an equilibrium configuration). Two quantities are compared: the median over frames of ΔF_B (with sign) and $\mathbb{E}|\theta_B|$.

(iii) Why we expect it to hold [Reading] (physics). In the existing numbers (26-09 § 07), the ℓ needed to keep θ small hardly grows with N for $SU(2)$, and grows for $U(1)$. Non-commutativity enters where the vortex can localise in a lump of the size of T^2 (a fractional instanton), because its action, by the Bogomolny bound, does not depend on the size of T^2 (25-02).

(iv) Where it breaks. In the Coulomb phase of $U(1)$ the flux spreads uniformly and the column bias decreases only as a power (about $\ell^{-1.4}$ over $\ell = 5 \to 8$), so the local β' should come out at or above β. For $\mathbb{Z}_2$ the sheet tension remains, likewise.

(v) Check against the ledger. Unlike item 27 of Table 1 (comparison of boundary conditions and geometries), it compares the same object at two scales. Nor does it use the correlation inequalities of item 2 of Table 1. Because of the criterion "not broken by small loops", small ℓ (3 or less) may fail through lattice artefacts, so the claim takes the form $\ell \ge \ell_{\min}$. It is a local version of the step function of the coupling defined with twisted boundary conditions (the method of de Divitiis et al.; not yet checked).

(vi) Numbers. There are as yet no numbers measuring (6) itself. The form of the test is fixed: fine side $(N, \ell) = (4, 4)$, coarse side $(2, 2)$ (and, if time allows, $(4, 6)$ and $(2, 3)$), with $SU(2)$ at $\beta = 2.3$, and $U(1)$ in the confining phase at $\beta = 0.9$ and in the Coulomb phase at $\beta = 1.3$. The prediction: $\beta' < \beta$ for $SU(2)$; for $U(1)$, $\beta' < \beta$ at $\beta = 0.9$ and $\beta' \ge \beta$ at 1.3 (the sign flips with the phase). If the sign does not separate between the two $U(1)$ points, this observable does not distinguish phases, and the candidate is lowered a grade. $(2, 2)$ has large artefacts, so it is treated as a sign until confirmed with $(4, 6)/(2, 3)$.

(vii) Difficulty. Showing (6) is a local version of the same difficulty as the global renormalisation comparison (the opening of § 02). What is gained is that the object of the

proof becomes "a statement about a finite region with its boundary held fixed", and that the assumption of the reduction by compactness of the band (the two-sided area law at fixed β) can be written in the language of columns.

06

Five other candidates

Of the eight candidates examined, we give the remaining five in one line each, with the reason none was given priority over the three of § 05. All are labelled "Reading (physics)"; those that include an elementary identity have "Proved here" added in their row.

Table 2 Five other candidates

Candidate	One line	Why it was not given priority	Label
Confinement as sign cancellation	Under the twist-summed measure P (weight $Z_0(\omega) + Z_1(\omega)$), $\theta = \mathbb{E}_P[\tanh(X/2)]$. Even if the glass is in the ordered phase in the upper half of the band ($\lvert X\rvert$ large), θ is small if the signs of X cancel	The distinction between groups appears in the growth as N is made large, so it is close to a restatement of the same quantity as the column face $f(\ell)$. Numerically it needs the ratio of partition functions of a disordered $\mathbb{Z}_2$ gauge theory for each ω, which is large in scale	Proved here (the identity only rewrites the definition $(Z_0 - Z_1)/(Z_0 + Z_1)$ of θ in terms of ω), Reading (physics)
Centre-only influence coefficients	The $\delta_c(L_0, \beta)$ of § 03. Condition the outside on the $SO(3)$ part only, and flip only the centre flux at the boundary	In the upper half of the band δ_c should also be close to 1: for the lower half of the band only (on the side of the work of pushing up the lower end of the band)	Reading (physics)
Diffusion of the sign of the flux by the flow of $\mathbb{Z}_2$ monopoles	The sign flux through each plane changes only by the parity of the number of closed $\mathbb{Z}_2$ monopole curves crossing between planes. The flux mixes through the winding density of monopoles	A $\mathbb{Z}_2$ version of the $U(1)$ monopole picture; the criterion "uses non-commutativity essentially" is weak. There is a dispute over whether confinement survives with monopole-suppressed actions (not yet checked)	Reading (physics)
Determinant in self-dual coordinates	In each sector, the difference between sectors of the Jacobian when the measure is viewed as a push-forward to the anti-self-dual part	A large risk of hitting item 25 of Table 1 (spin and the index theorem are a restatement of asymptotic freedom at one loop). The lattice has no self-dual decomposition	Reading (physics)

Candidate	One line	Why it was not given priority	Label
A quantitative version, uniform in N, of "discrete 1-form symmetry is not broken" for the slab reduced to two dimensions	Read slab confinement as a lattice version of a statement of the type that discrete 1-form symmetry is not spontaneously broken in two dimensions, and make its quantitative version (tension $\geq$ the density of walls of the cheapest sector) uniform in N	As a road, this is exactly the road of increasing N in the semiclassics of a small T^2 (of the same weight as the adiabatic continuity conjecture of Tanizaki–Ünsal); only the reading is new. The dimension conditions in the literature on generalised symmetries are not yet checked	Reading (physics)

07

What cannot be said

- (a) None of the candidates closes the band. For none of them have we shown a theorem at any β in the band.
- (b) The reduction by compactness of the band is a reduction, and we do not say it has made the band easier. The assumption of two-sided area laws inside the band contains confinement at intermediate coupling on the four-dimensional $SU(2)$ lattice (unsolved).
- (c) Even if the two-dimensional test of the log-concavity of the Weyl measure passes, it implies nothing for Polyakov's conjecture or for four dimensions. A block-level Ginibre comparison does not exist as a theorem.
- (d) We do not say that two-dimensional results lift to four dimensions. Only the form of the statement lifts.
- (e) The $SU(2)$ expectations of the four faces are all estimates. Only the column face $f(\ell)$ has numbers, and those are tendencies on small lattices.
- (f) The negative verdict on the conformal frame is a judgement at the level of estimates, that "kinematics alone does not give the area law"; it does not rule out roads that add other inputs in that frame.
- (g) We do not say that the candidates on this page are not combinations of known facts. The lemma of the reduction by compactness of the band and the log-concavity of the projection in the Weyl-measure candidate may be written somewhere.

08

The table of the five grades and the dependency graph

The candidates on this page are all "Reading (physics)". Paper proofs are set out only for the elementary facts that serve as footholds for the candidates.

Table 3 The rows of this chapter ("—" marks a row with no machine checking)

Row	Statement (one line)	Grade	Basis	Scope	Machine checking

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
1	The free-energy identity (1) for a bijection carrying one sector to the other	Proved here	§ 02 softness in the twist direction	A measurable bijection with a well-defined Jacobian	—
2	For a deterministic map the remainder grows with the area of the sheet, and the area law does not come out	Reading (physics)	Softness in the twist direction in § 02, "deterministic squeeze" of 26-08	—	—
3	The column decomposition $\lvert\theta\rvert \le \mathbb{E}\prod_B \lvert\theta_B(\Sigma)\rvert$	Proved here	Twist cost of a column in § 02, the framework of the Container Identity of 25-03	Conditional independence with the skeleton held fixed	—
4	Column bias: at $\ell \ge 5$, $SU(2)$ is 1/5 to 1/7 of $U(1)$, and the needed ℓ does not grow for $SU(2)$	Reading	26-09 § 07	$\beta = 2.3$ ($SU(2)$), 1.3 ($U(1)$), $N \le 8$, 3–12 frames	—
5	The $SU(2)$ expectations of the four faces, and where they break for $U(1)$ and $\mathbb{Z}_2$	Reading (physics)	§ 02 Table 1	Estimate	—
6	The Jensen sandwich (3) of the $\mathbb{Z}_2$ glass	Proved here	§ 03	The $U = \sigma V$ representation	—
7	The glass is on the ordered side in the upper half of the band; the glass road is restricted to the lower half	Reading (physics)	§ 03, 26-09 § 08	8^4; the conversion is crude	—
8	$\mathbb{R}^4 \setminus \text{line} \cong H^2 \times S^2$ (conformal), and the parity criterion for spheres and loops	Proved here	§ 04 (4)	—	—
9	The hyperbolic nesting area $4/3$, the hyperbolic area of a half-plane loop $\approx T/d$	Proved here	§ 04	Computation of an integral	—
10	In the conformal frame kinematics alone does not give the area law, and the core remains in the same place	Reading (physics)	§ 04	Negative on examination	—

Row	Statement (one line)	Grade	Basis	Scope	Machine checking
11	Reduction by compactness of the band: the comparison within the band reduces to two-sided area laws at fixed β	Proved here	The Lemma Reducing the Comparison inside the Band of 26-06 § 06	Two-sided area law at fixed β, uniform positivity and continuity of the rate, $N \geq N_1$, $M \geq M_0$	—
12	The projected density (5), and the height–azimuth decomposition of $O(3)$ (XY with couplings $J_{ij} \geq 0$)	Proved here	§ 05 log-concavity of the Weyl measure	—	—
13	The mechanism of the log-concavity of the Weyl measure: the source of monotonicity and the mechanism of disorder point the same way	Reading (physics)	§ 05 log-concavity of the Weyl measure	No block-level comparison exists as a theorem	—
14	The prediction (6) of the local step function of a column: $\beta' < \beta$ for $SU(2)$; for $U(1)$ the sign flips with the phase	Reading (physics)	§ 05 local step function of a column	$\ell \geq \ell_{\min}$. No numbers for (6)	—
15	The identity $\theta = \mathbb{E}_P[\tanh(X/2)]$ of the candidate "confinement as sign cancellation"	Proved here	§ 06 Table 2	A rewriting of the definition of θ	—

The dependency graph (the numbers of premises are smaller than the number of the conclusion):

The check is to see by eye that every number to the right of a "⟸" is smaller than the number on the left. There are no cycles. The conclusion-side nodes (the expectations of the

four faces, the scope of the glass road, the negative result for the conformal frame, and the mechanism and prediction of two of the three new candidates) are all "Reading (physics)", and the "Proved here" nodes are either elementary facts serving as footholds for the candidates, or a reduction whose proof is in another chapter. This page has no node for a statement that crosses the band.

What this chapter can say

What is said	What is not said
Proved here The elementary facts that serve as footholds for the candidates: the transport identity, the column decomposition, the Jensen sandwich of the glass, the conformal equivalence and the parity criterion, the projected density and the height–azimuth decomposition, $\theta = \mathbb{E}_P[\tanh(X/2)]$	That estimates crossing the band follow from them
Proved here That the comparison within the band reduces to two-sided area laws at fixed β (the Lemma Reducing the Comparison inside the Band of 26-06, under the assumption of two-sided area laws inside the band)	A proof of the assumption of two-sided area laws inside the band at any β. That the band has been made easier
Reading (physics) For the four faces and the three candidates, why we expect them to hold for $SU(2)$ and where they break for $U(1)$	An estimate uniform in the scale for any face or candidate
Reading (physics) That the $\mathbb{Z}_2$ glass road is restricted to the lower half of the band; that the conformal frame does not give the area law by kinematics alone	That the glass road pushes up the lower end of the band in the lower half

Terms used in this chapter — the four faces, the adapted stiffness κ_w, the flux mixing of the box $\delta(L_0)$, the twist cost of the column $f(\ell)$, the pressure margin, the $\mathbb{Z}_2$ glass, frustration, the conformal frame, the compactness of the band, the Weyl measure, height and azimuth, the local step function of the column, the crossover band (the band). Their meanings are in A-02 Glossary.

Next chapter: 26-11 Ultraviolet control — what it means to close at infinitely many steps — the foundation under the two roads. What closing in one step means, and where the series stopped.

2026-10-15 · chapter Yang–Mills and the mass gap Part 26 The crossover band ultraviolet control, guide to Part 15 · Kiichi, Shiori and Rin

Ultraviolet control — what it means to close at infinitely many steps

> This chapter is a guide. § 01 is a map of open questions.

What this chapter shows — When the lattice spacing a is sent to 0 and the number of renormalisation steps grows without bound, what does it mean to show, at every step and without the constants degrading, that "one step returns to the same form"? The body of this chapter has been expanded into the first half (15-00 to 15-10) of Part 15 "A record of attempts at ultraviolet control". This page keeps only the five lines of what this chapter shows, the statement of the decomposition of the ultraviolet wall, and a guide for each section.

Prerequisite chapters — 7-05 (the sequence of renormalisation group steps), 7-07 (four dimensions: Bałaban and MRS), 26-00 (confluence), 27-02 (the ledger of conditions).

Said first — This chapter deals with the "ultraviolet control" row of the ledger of conditions, a different task from the crossover band (the band). It deals only with the side of scales finer than the band. The continuum limit in a periodic cubic box was shown by the construction published on 2026-11-10 (at the level of the committee's assessment; Volume 2). What this chapter and Part 15 deal with is ultraviolet control on a different road set up by this book's study (small twisted boxes, and a form uniform in the lattice spacing), and that has not been shown. A construction with twisted boundary conditions and elongated boxes, and a statement in a form uniform in the lattice spacing, are not in the published construction either. What Part 15 gives is a statement of what has to be shown, line-by-line calculations, elementary lemmas, and numbers measured in the smallest systems; each of them only restates a part of ultraviolet control, or splits ultraviolet control into other conditions.

The order of this chapter

1. What this chapter shows — five lines
2. The decomposition of the ultraviolet wall — a class that closes with finitely many parameters, and three remainders (the statement only)
3. Guide to Part 15 — the order of reading

00

What this chapter shows

- Ultraviolet control means showing, at infinitely many steps and without the constants degrading, that the effective density "returns to the same form in one step". The number of steps is $K = \log_L(L_0/a) \to \infty$, and if the sum $\sum_k \delta_k$ of the one-step losses δ_k is finite uniformly in K, the constants survive Proved here (15-00).
- In four dimensions the coupling is dimensionless, so the sum of the losses of size g_k^2 per step diverges like $\ln K$ Proved here (arithmetic under the one-loop flow). That part must be absorbed exactly into the flow of the coupling, and the rest confined to a sum of finite size or to a form that contracts transversely (15-01, 15-03).
- For a group-valued field the measure of the fluctuations depends on the background, and that dependence η_k is the hard point. In the type where the law of the fluctuations does not depend on the background (a product of heat kernels, one per edge), the chain of one-step estimates for flat fields goes through unchanged on the group, giving $\eta = 0$ Proved here (one step only, without the Wilson action and without large fields; 15-07).
- In the smallest system, with the angle of the single coarse plaquette fixed, the slope $\sum f^2 = \beta'/\beta$ of the invariant curve and the transverse contraction $\lambda = \sum f^4 / \sum f^2$ are determined by a single projection, and $\lambda \le \max f^2$ Proved here (at tree level restricted to commuting configurations, one step seen through the marginal distribution of one coarse plaquette; 15-05). The source (the coefficient of θ^4 poured in at each step) is a number measured at one loop Reading .
- Parameters are best counted as "a one-parameter attracting class plus contracting shapes"; as a class that keeps the ratio of the quadratic couplings at 2, it does not close in one step Proved here , Reading ($SU(2)$, four in a row, leading term; 15-06). Bałaban's four-dimensional theorem assumes the smallness of the effective coupling, the theorem that removes this assumption is unpublished, and the one-step remainder including large fields (the net one-step bracket of the coupling) is not in the original sources Cited (15-02).

01

The decomposition of the ultraviolet wall — a class that closes with finitely many parameters, and three remainders

Take a family of weights $\{w_\theta\}$ indexed by finitely many parameters $\theta \in \Theta \subset \mathbb{R}^m$, and suppose one blocking step T

$$T\big(w_\theta\,(1+\rho)\big) = w_{\Phi(\theta)}\,\big(1 + r_\theta[\rho]\big) \quad (1)$$

takes the form (Φ is the flow of the parameters, $r_\theta[\rho]$ the remainder). We put a statement of the form that ultraviolet control follows, uniformly in the number of steps, from the following four Assumption (the form of the statement only; for details see 15-03 § 02).

- Class-closure condition: the number of parameters is finite independently of the step, and the class consists of the one-parameter attracting class of the one-step map and shape coordinates that contract at each step (the evidence in the smallest systems is in 15-06).
- Coupling-flow remainder condition: $\beta_{k+1} = \beta_k - 8b_0 \ln L + O(1/\beta_k)$.
- Shape remainder condition: of the type in which, with transverse contraction $\lambda < 1$ and one-step remainder $\varepsilon(\beta)$, the deviation is bounded by $\sup_j \varepsilon(\beta_j)/(1-\lambda)$ (15-03 § 04).
- Definition and continuity of the effective coupling: continuity within the domain of definition.

That the condition that the coupling stays small follows from the net one-step bracket of the coupling and the definition and continuity of the effective coupling is the Coupling-Smallness Induction Lemma Proved here (15-03 § 03; the net one-step bracket of the coupling written in the variable β is the coupling-flow remainder condition), and the upper bound on the deviation is the arithmetic of a geometric series Proved here. What has not been shown is that the class-closure condition and the coupling-flow remainder condition including large fields hold for the real four-dimensional step; these are the four open rows (15-08).

02

Guide to Part 15 — the order of reading

There are three reading orders (15-00 § 04): the shortest is 15-00 → 15-03 → 15-09, the line of calculation is 15-04 → 15-05 → 15-06, and the line of the wall is 15-02 → 15-07 → 15-08.

What this chapter can say

Can say	Cannot say
This page is a summary and a guide. What can be said is in the tables of each chapter of Part 15	Ultraviolet control in the form of this book's road (no chapter of Part 15 shows it; the continuum limit in a periodic cubic box was shown by the published construction)
Assumption The decomposition of the ultraviolet wall (the form of the statement)	That the class-closure condition, the coupling-flow remainder condition and the shape remainder condition hold for the real four-dimensional step

Sources and reproduction

The sources are in the source table of each chapter of Part 15 (the bibliography of the original sources is in the source table of 15-02).

Words used in this chapter — ultraviolet control, the number of steps, the same form, the three conditions of ultraviolet control, the decomposition of the ultraviolet wall, the class-closure condition, the coupling-flow remainder condition, the shape remainder condition, the continuity of the coupling, the attracting class, the transverse contraction. Their meanings are in A-02 Glossary.

Chapter to read next: 26-12 A sieve for arguments about the band — seven test models.
To read alongside: 15-00 Entrance — what ultraviolet control is.

A sieve for arguments about the band — seven test models

This chapter is a map of what is unsolved. § 05 is this book's study (computations on small lattices).

What this chapter shows — Arguments that would close the band have so far been tested against the criterion "distinguish from the U(1) transition" (26-06 § 08). This chapter widens the test models to seven: U(1) at weak coupling, Z_2 at weak coupling, finite non-abelian groups (the quaternion group, the binary icosahedral group and others), the adjoint-Higgs limit (which becomes the U(1) Wilson action), the first-order transition line of the SU(2) mixed fundamental + adjoint action and its endpoint, the bulk transition of SU(N), and the centreless group G_2. For each model we write which types of argument it rules out, and we give a table that sorts this book's Lean theorems and the candidate statements for the band into "true, false, not defined" for the seven models. In each cell we keep apart what was checked by this book's computations or Lean, what was checked in the literature, and what has not been checked. Finally we list, with their conditions, what was seen in computations on small lattices (counting flat connections of finite groups, the power law on a one-point lattice, the hysteresis of the mixed action, the U(1) constant with the aspect ratio fixed, a trial of the sign term by term). The overall map of ideas is in 16-11.

Prerequisite chapters — 26-04 Structure alone cannot cross, 26-06 Renormalisation comparison, 21-05 The minimal action of a vortex, 5-06 How U(1) differs from the non-abelian case, 5-10 Lattice gauge theory with finite groups.

Said first — This chapter gives no road across the band. There are no proofs in it. The seven models are tests for ruling out arguments, and no new theorem is put forward about any of them. Of the properties of these models, only those this book checked at the relevant place in an original source or a review are marked Cited ; the rest are written as "stated in the literature (not checked by this book)" and are not used as grounds in the text. **The discussion of the endpoint of the mixed action is at a fixed lattice spacing. It does not mean that the continuum SU(2) theory has no mass gap.** The view of widening the test models may itself be known to experts. This book writes it not as a new result but as a sieve used in this book's study.

The order of this chapter

1. How the sieve works — tests in two directions — quantities of confinement and quantities of the gap
2. The seven models — the properties of each, and the arguments it rules out
3. Types of argument, and the models that rule them out (Table 1)
4. Lean theorems and candidate statements for the band × the seven models (Table 2)
5. What was seen in computations on small lattices — five items
6. What this chapter does not say

Labels — Proved here = a hand count whose derivation is in this chapter / Cited = a fact from the literature checked at the relevant place in an original source or a review / Reading = a reading of this book's numbers on small lattices (with lattice, sweeps and seeds) / Assumption = a conjecture or expectation / Lean = a Lean theorem of this book (only inside the strong-coupling window, with the lattice spacing fixed). For details, see "Labels" in 6-00.

Notation. The SU(2) Wilson action is $\beta \sum_p (1 - \frac{1}{2} \operatorname{tr} U_p)$; the couplings of the mixed action are β_F for the fundamental representation and β_A for the adjoint representation; the hopping coupling of the adjoint Higgs is J. ΔF is the vortex free energy of a twisted box, and θ is the vortex ratio (19-02). The slab-tension quantity $s(N) = N^2 \sigma_N$ is the notation of 26-06, and is a different quantity from the one-loop slope s.

Words. The **maximal torus** is the abelian subgroup $\{\mathrm{diag}(e^{i\phi}, e^{-i\phi})\}$ of SU(2) (of the same form as U(1)). The **mixed action** is the Wilson action (the fundamental-representation term) with an adjoint-representation term added. A **first-order transition** is one in which the plaquette average and the like jump as functions of the coupling; a **critical endpoint** is the point where a line of first-order transitions ends. A **bulk transition** is a transition that comes from the lattice action and does not depend on temperature (a zero-temperature transition). It is a phenomenon on the lattice, not physics of the continuum limit. A **flat connection** (a flat configuration, in the wording of 21-07) is a configuration in which the holonomy of every plaquette equals the identity (or the sign of the twist, when there is a twist). The **frozen phase** is the phase of a finite-group gauge theory on the large-β side that sticks close to the flat connections.

01

How the sieve works — tests in two directions

If an argument that would close the band goes through in the same form in another model, and the conclusion is false in that model, then the argument is wrong somewhere or is not enough for the conclusion. This is the sieve. Until now the sieve was U(1) alone: U(1) has a transition inside the band ($\beta \approx 1.01$) to a non-confining phase, so an argument that closes the band must distinguish U(1) (26-06 § 08).

The sieve has two directions Assumption .

- An argument whose core is a **quantity of confinement** (the tension, the vortex ratio, the tension-doubling inequality and so on) must become false in a model that has a non-confining phase.
- An argument whose core is a **quantity of the gap** (the correlation length, mixing in a finite box) must be true in a model that does not confine but does have a gap. A quantity of confinement may be false there. The weak-coupling phase of Z_2 and the centreless group are candidates for this, but this book has not checked in the literature that they have a gap (model 2, model 7).

The mass gap and confinement are different statements (16-09 § 03), and the direction in which the sieve is used is decided by which kind of quantity the core statement is.

02

The seven models

Model 1 — U(1) at weak coupling

Properties. Four-dimensional U(1) lattice gauge theory has a non-confining phase at weak coupling. For the Villain form of the action, it has been shown that the expectation of the Wilson loop has a Coulomb-type lower bound and charges are not confined Cited (Guth 1980, checked in the abstract). Fröhlich–Spencer showed by a different method that four-dimensional U(1) lattice gauge theory has a deconfining transition to a massless (QED) phase; they write mainly in the Villain approximation and state in the text that all the results extend to the Wilson-action model (the extension uses techniques from another paper) Cited (1982, checked in the abstract and § 1 of the preprint). The position of the transition, $\beta \approx 1.01$, is a value from this book's record (26-06 § 04).

Its place on the SU(2) axis. Restricting elements of SU(2) to the maximal torus gives $\frac{1}{2}\operatorname{tr}\operatorname{diag}(e^{i\phi}, e^{-i\phi}) = \cos\phi$, so the SU(2) Wilson action $\beta(1 - \frac{1}{2}\operatorname{tr} U_p)$ is, on the maximal torus, the same expression as the U(1) Wilson action $\beta(1 - \cos\phi_p)$ (with the same β) Proved here . What can be said is only that the expressions for the action coincide; the SU(2) measure is not restricted to the maximal torus. The U(1) model at the same β is in the Coulomb phase for $\beta \gtrsim 1.01$. This book's estimate is that this section of the SU(2) axis is the section that needs an input distinguishing U(1) Assumption .

Arguments it rules out. Arguments using only reflection positivity, the centre and duality identities, and positivity of the transfer matrix (26-04). The renormalisation comparison with the aspect ratio fixed holds on the weak side with a uniform constant for U(1) too, so a comparison statement on the weak side does not distinguish U(1) (§ 05 (d)). What stops U(1) is where the trajectory crosses the section of the transition. However, with a quantification that stretches the aspect ratio, U(1) already fails on the weak side. When the core statement is written, the quantification must be stated explicitly.

Model 2 — Z_2 at weak coupling

Properties. Four-dimensional Z_2 lattice gauge theory has a first-order transition Cited (Creutz–Jacobs–Rebbi 1979, checked in the abstract; the position is the self-dual point $\beta \approx 0.44$, as stated in 26-06 § 04). The weak-coupling side is a non-confining phase; that it has a gap there is stated in the literature (not checked by this book).

Arguments it rules out. Arguments that claim to put a quantity of the gap at the core but use a quantity that becomes false at weak coupling in Z_2. The tension-doubling inequality is false in the non-confining phase of Z_2, since there the slab-tension quantity $s(N)$ goes to 0 (26-06 § 08) Reading . If the statement in the literature that the weak-coupling phase of Z_2 has a gap is correct, then the tension-doubling inequality is not a quantity needed for the gap. Under the same condition, a global logarithmic Sobolev inequality on the torus is expected to fail because mixing between holonomy sectors is slow, so it would not pass as a quantity of the gap Assumption .

Model 3 — finite non-abelian groups

The models. Finite subgroups of SU(2): the quaternion group Q_8 (order 8), the binary tetrahedral group (24), the binary octahedral group (48), the binary icosahedral group (120). All are non-abelian and contain -1 in the centre. A finite-group gauge theory is expected to enter a frozen phase at large β Assumption . The value of β at which it freezes is stated in the literature (not checked by this book).

Arguments it rules out. Arguments whose only input is "non-abelian as an algebra". Finite non-abelian groups are non-abelian, but at weak coupling they do not have the continuous fluctuations of SU(2) (asymptotic freedom). In this book's record there are points

where the covering inequality and monotonicity in β fail for Q_8 (21-01: monotonicity in β in three dimensions without background) Reading . The level of the values in the frozen phase is § 05 (a).

Model 4 — the adjoint-Higgs limit (which becomes the U(1) Wilson action)

The model. To the SU(2) Wilson action we add the term $-J\sum_{x,\mu} n(x)\cdot R(U_{x,\mu})\,n(x+\hat{\mu})$ of a unit vector $n(x)\in S^2$ at each site (adjoint representation) (R is the map from SU(2) to SO(3)).

The form at $J=\infty$ Proved here . As $J\to\infty$ the weight concentrates on configurations with $R(U_{x,\mu})n(x+\hat{\mu})=n(x)$. SO(3) acts transitively on S^2, so a gauge transformation can make $n(x)=e_3$ at every site. The condition then becomes $R(U)e_3=e_3$, that is, U commutes with σ_3, that is, U is an element of the maximal torus. The plaquette products then also lie in the maximal torus, and by the coincidence of the action expressions seen in model 1, the action becomes the U(1) Wilson action (with the same β). The remaining gauge freedom is U(1). That the limiting measure actually concentrates on this set is treated as a formal limit.

As a family. For every value of J, the group is continuous and non-abelian, the centre $\mathbb{Z}_2$ acts trivially on the adjoint field so centre symmetry remains, and the weights are positive Proved here . Reflection positivity is also expected to be kept in this family Assumption .

Arguments it rules out. Arguments that take only "the group is continuous and non-abelian, centre symmetry, positivity of the weights" as input and conclude confinement uniformly for all J in the family. These inputs are the same across the whole family, and $J=\infty$ is the U(1) Wilson action, which has the non-confining phase of model 1 (Fröhlich–Spencer, model 1) Cited . Adding the sign of asymptotic freedom to the inputs is not expected to change this Assumption . The one-loop coefficient of the continuum theory with one real adjoint scalar added (the theory of an adjoint scalar whose length is not fixed), in the normalisation of equation (3) of 4-06 ($16\pi^2 b_0$), is the $22/3$ of pure SU(2) minus $1/3$ for one real scalar (half of a complex scalar), which is 7 and remains positive Proved here . But the limiting theory at $J=\infty$ is itself U(1), and is not asymptotically free. What this model rules out are arguments that conclude confinement uniformly in J from inputs alone that hold for every J in the family.

Model 5 — the first-order transition line of the SU(2) mixed action and its endpoint

The model. The action $\sum_p\left[\beta_F\left(1-\frac{1}{2}\operatorname{tr}U_p\right)+\beta_A\left(1-\frac{1}{3}((\operatorname{tr}U_p)^2-1)\right)\right]$. $\beta_A=0$ is the Wilson action. The adjoint term does not see the sign of the centre.

Properties. In this generalisation of the SU(2) Wilson action (which includes the SU(2), SO(3) and Z_2 models as limits), four-dimensional Monte Carlo has reported that the first-order transition lines of SO(3) and Z_2 meet at a triple point and continue to a critical endpoint Cited (Bhanot–Creutz 1981, checked in the abstract). The position of the endpoint varies in the literature. The apparent endpoint that Bhanot–Creutz saw on small lattices is at about $(\beta_F,\beta_A)\approx(1.5,\,0.9)$ (as quoted in the text of Gavai). Gavai found no first-order bulk transition at $\beta_A=1.25$ on 6^4 to 16^4 lattices, and expects the endpoint to be at $\beta_A\geq 1.25$ Cited (Gavai 1996, checked in the abstract and the text). For a mixed action of the same type for SU(3), it has been reported that approaching the endpoint lowers the mass of the scalar (0^{++}) glueball while the masses of the other glueballs do not change, and that the endpoint is consistent with a critical point at which only the 0^{++} correlation length diverges Cited (Heller 1995, checked in the abstract; the ratio of the tension to the transition temperature is nearly constant). That the scalar mass goes to 0 at the SU(2) endpoint is stated in the literature (not checked by this book). That both sides of the line are confining phases is an inference from the line ending at the endpoint and connecting smoothly to the confining phase on the Wilson axis Assumption .

This book's computation. At $\beta_A=1.5$ and 2.0, strong hysteresis is seen even on a 4^4 lattice (§ 05 (c)) Reading . We do not read the position of the endpoint from this computation.

Arguments it rules out. Arguments that use "there is no transition on the β axis / the step map has no fixed point" over the class of local, reflection-positive, pure-gauge actions. Inside this class there are a line of first-order transitions and a critical endpoint. Those are facts specific to the Wilson axis, and do not extend to the class of actions. Since step 0 of the published construction is not the Wilson action but an effective action with a representation (16-03 § 05), this is not a decorative caution Assumption . Arguments that use "the rate is uniformly positive" over the class of actions cannot be decided by this model: across the first-order line the tension may only jump and remain positive, and what would break it is the gap closing at the endpoint. For the same reason, if at the endpoint the scalar mass goes to 0 in lattice units while the tension remains, then "if there is a tension, a soft argument uniform over the class of actions gives the gap" is false; but since this book has not checked this part for SU(2), we place it as cannot be decided (16-11 Table 3).

Caution. The endpoint is a phenomenon at a fixed lattice spacing. It does not mean that the continuum SU(2) theory has no mass gap. The lesson of this model is that what an argument about the band may use is "being on the renormalised trajectory", and that "being in the class of local, reflection-positive, pure-gauge actions" alone is not enough Assumption .

Model 6 — the bulk transition of SU(N)

Properties. For the plaquette action (Wilson action) of SU(N), it has been reported that the crossover between strong and weak coupling looks like a smooth crossover for SU(4) and is a strong first-order bulk transition for SU(6) Cited (Lucini–Teper–Wenger 2002, checked in the text). That it becomes first-order from SU(5) on, and that both sides of the transition are confining, are stated in the literature (not checked by this book).

Arguments it rules out. That arguments of the same type as for model 5 (arguments relying on the absence of a transition on the Wilson axis) do not extend to general SU(N). Anyone aiming at the mass gap for general SU(N) (A-08 § 06) must pass this sieve too.

Model 7 — the centreless group G_2

Properties. G_2 has a trivial centre, so a "quark" in the fundamental representation is screened by gluons, and the string between static quarks can break. Even so, G_2 gauge theory has been reported to confine (in the sense of the paper) Cited (Holland–Minkowski–Pepe–Wiese 2003, checked in the abstract). That it has a mass gap is stated in the literature (not checked by this book).

Arguments it rules out. Quantities written in terms of centre twists, vortices and the vortex ratio θ are not even defined for G_2 Proved here (there are no centre elements, so there is no twist). Arguments whose core is the tension-doubling inequality or the four faces of inequalities that use non-commutativity do not reach the mass gap for all groups. G_2 needs other quantities (the response to boundary fields and so on) (16-11 § 06).

03

Types of argument, and the models that rule them out

Table 1 Types of argument, and the models that rule them out ("rules out" means that the same inputs are present in that model too, and the conclusion is false or not defined there)

Type of argument (inputs)	Models that rule it out	Reason and label
Only reflection positivity, the centre and duality identities, positivity of the transfer matrix	U(1), Z_2	The same structure holds there too (26-04) Proved here
Only non-abelian as an algebra	Finite non-abelian groups	Non-abelian, but without continuous fluctuations. Failure of monotonicity (21-01, three dimensions, no background) Reading
Concluding confinement uniformly in the family from only: the group is continuous and non-abelian, centre symmetry, positivity of the weights	The adjoint-Higgs family ($J = \infty$ is U(1))	These are the same across the family (model 4) Proved here . The non-confining phase of the U(1) Wilson action Cited (Fröhlich–Spencer)
Being in the class of local, reflection-positive, pure-gauge actions, and "no transition on the axis / no fixed point of the step map"	The first-order line of the mixed action	Inside the class, a line of first-order transitions and a critical endpoint Cited Reading
"The rate is uniformly positive" over the class of actions, or "tension ⇒ gap" by a soft argument uniform over the class of actions	The endpoint of the mixed action (cannot be decided)	Fails only if the gap closes at the endpoint. The SU(3) analogue is Cited ; for SU(2) not checked by this book
No transition on the Wilson axis, for general SU(N)	The bulk transition of SU(N)	Strong first order for SU(6) Cited
Only quantities written with centre twists and vortices	G_2	The quantities are not defined Proved here
Claiming a quantity of the gap while using global mixing	Z_2 at weak coupling (if it has a gap)	Slow mixing between sectors Assumption . The gap of the weak-coupling phase of Z_2 is stated in the literature (not checked by this book)
A lossy renormalisation comparison with the aspect ratio fixed (weak side)	U(1) (does not rule it out on the weak side)	On the weak side it holds with a uniform constant for U(1) too (§ 05 (d)) Proved here Reading . The content of the distinction is pushed into the section of the transition

04

Lean theorems and candidate statements for the band × the seven models

Table 2 has as rows this book's Lean theorems (whether a theorem of the same type holds in the other model) and the candidate statements for the band, and as columns the SU(2) Wilson action (the reference) and the seven models. Labels in the cells: Lean this book's Lean, Proved here a derivation in this chapter, Reading numbers from this book's record, Cited checked in the literature. "—" is a cell this book has not checked, and is not filled in by conjecture. "Not defined" means that the model lacks something needed to define the quantity (a centre twist, a continuous generator).

Table 2 True, false, not defined

Row	SU(2) Wilson (reference)	U(1) weak coupling	Z_2 weak coupling	Finite non-abelian groups	Adjoint Higgs $J = \infty$	Endpoint of the mixed action	SU

Grounds for the cells.

- **The row $S_N > 0$** Proved here. The definition of S_N (21-05) fixes the frame of the block to the twisted vacuum (the configuration of action 0 with the quaternions $\mathbf{i}, \mathbf{j}$ on the links). In finite subgroups of SU(2) containing the quaternions $\mathbf{i}, \mathbf{j}$ (an anticommuting pair) — the four groups of this chapter — the twisted vacuum of the frame is made of $\mathbf{i}$ and $\mathbf{j}$ only, so it can be built as a configuration of the subgroup. Configurations whose interior links are restricted to elements of the subgroup are a subset of the SU(2) configurations, so the lower bound on the action is not smaller than the SU(2) lower bound. The SU(2) lower bound is positive uniformly in the size of the block (the theorem `VortexPos.Svortex_ge_unif` of 21-05). Hence the minimal action of a vortex is positive for the subgroups too (a one-line consequence of the Lean theorem). For abelian groups such as U(1) and Z_2, a single twist cannot be satisfied with action 0 (multiplying the plaquette products over a closed surface leaves only the sign of the twist), so there is no twisted vacuum of action 0 and the definition does not carry over.
- **Expectation under a transferred definition** Assumption. If the definition is transferred to a form without the background twist, the action of the configuration that spreads the measured twist flux π evenly over m^2 plaquettes, multiplied by the number N^2 of transverse positions, is $N^2 m^2 (1 - \cos(\pi/m^2)) \leq N^2 \pi^2 / (2m^2)$, which goes to 0 as the block is made large (Proved here: on the

transferred definition). The same spreading can be done in SU(2) too, inside the maximal torus, once the background twist is removed. The minimal action of a vortex is positive in SU(2) because only the central ± 1 commute with the background twisted vacuum (the quaternions $\mathbf{i}$, $\mathbf{j}$), so the flux cannot be spread continuously (the detour in 21-05).

- **The row of the tension-doubling inequality** Reading . In the Coulomb phase of U(1), $s(N)$ is constant independent of scale, exactly on the borderline; in the non-confining phase of Z_2, $s(N) \to 0$ (26-06 § 08; values from closed-form models and small lattices).
- **The "not defined" cells** Proved here . G_2 has a trivial centre, so quantities written with centre twists (θ, the vortex floors, the tension-doubling inequality, and all of the four faces that use twists or centre magnetic flux) do not exist. Softness in the twist direction uses a derivative along the generator of the twist, so it is not defined for discrete groups (Z_2, finite groups).
- **On the "—" cells.** As far as we have read the statements of this book's Lean theorems (A-04 Table 4g and the pages 21-05, 21-07, 20-06), the proofs of the strong-coupling window, reflection positivity, the chessboard, $\theta \geq 0$ and the thin-vortex floor rely not on the non-commutativity of SU(2) but on other structure of the group (the Dobrushin condition, reflection, the central element -1, compactness), and are expected to carry over to U(1), Z_2 and finite groups Assumption . Theorems that use the twisted vacuum (the thick-vortex floor, the minimal action of a vortex) do not carry over to U(1) and Z_2, definitions included. We have not transferred the proof of each theorem to the other models and checked it, so in the table these are "—". The estimate of the behaviour of the four faces for U(1) is in 26-06 § 07 Table 5 (a physical estimate).

What can be read from Table 2 Assumption . So far the only row whose value differs between the reference column and a model column is the tension-doubling inequality (false for U(1) and Z_2, Reading). The row $S_N > 0$ is true for finite non-abelian groups (Proved here), and its definition does not carry over to U(1). That the facts specific to SU(2) in this book are all facts about the action of configurations is in 16-11 § 03. If we set the criterion that a core candidate is chosen from statements that satisfy both "false for U(1) at weak coupling" and "false at a point of the type of the mixed-action endpoint (if the gap closes at the endpoint; for SU(2) not checked by this book)", then filling in the "—" of Table 2 becomes the next piece of work as it stands.

05

What was seen in computations on small lattices

All are floating-point computations on small lattices, and the values from one run go only as far as "seen" or "did not fail in the trial". The scripts are from this book's study, and were run again for this chapter (the results are written below).

(a) Counting flat connections of finite groups (the 1^4 lattice)

Setting. The 1^4 lattice (one site, four links, six plaquettes). In the frozen limit ($\beta \to \infty$) the partition function is proportional to the number of flat configurations. The untwisted side Z_0 is the number of quadruples of link elements that all commute with one another. The twisted side Z_1 is the number of quadruples with $[U_1, U_2] = -1$ (commutator -1) and the other five pairs commuting.

Hand count Proved here (Z_1 of Q_8). In $Q_8 = \{\pm 1, \pm\mathbf{i}, \pm\mathbf{j}, \pm\mathbf{k}\}$, the anticommuting pairs (U_1, U_2) are two non-central elements on different axes: $6 \times 4 = 24$ ways. U_3, U_4 commute with both U_1 and U_2, so they are the central ± 1: $2 \times 2 = 4$ ways. So $Z_1 = 96$.

Table 3 Numbers of flat connections (full enumeration; no seeds) Reading

Group	Order	Z_0	Z_1	$\ln(Z_0/Z_1)$
Q_8	8	736	96	2.037
Binary tetrahedral group	24	5856	96	4.111
Binary octahedral group	48	18816	384	3.892
Binary icosahedral group	120	76320	480	5.069

On running it again, Z_0 and Z_1 for the four groups agreed with the values above. Reading: in the frozen phase, the free energy of one twist is of the type of a constant independent of L (values seen on 1^4 only).

(b) The power law on a one-point lattice (SU(2), 1^4)

Hand count Proved here . The action is $S = \sum_{\mu<\nu}(1 - \frac{1}{2} z_{\mu\nu} \operatorname{tr} P_{\mu\nu})$, with twist $z_{12} = -1$. If the set of minimal-action configurations is a manifold of dimension m with non-degenerate transverse Hessian, then $Z(\beta) = \int e^{-\beta S}$ behaves as $Z \sim C\beta^{-(12-m)/2}$ (12 dimensions for four links), and $\beta\langle S\rangle = -\beta\, d\ln Z/d\beta \to (12-m)/2$. Twisted side: the minimum has U_1, U_2 anticommuting ($U_1 = i n_1 \cdot \sigma$, $U_2 = i n_2 \cdot \sigma$, $n_1 \perp n_2$: 3 dimensions) and $U_3, U_4 = \pm 1$. Since $m = 3$, $\beta\langle S\rangle \to 9/2$. Untwisted side: configurations in which the four links lie in one maximal torus (2 dimensions for the choice of torus + 4 angles: 6 dimensions), giving $\beta\langle S\rangle \to 3$. This family jumps in dimension at the central points, so a logarithmic correction is expected to enter from there Assumption . The ratio is $Z_1/Z_0 \sim c\beta^{-3/2}$ (with a logarithmic correction).

Computation Reading (Metropolis, 4000 chains × 3000 sweeps, the first 1000 sweeps discarded, one seed, errors only from the statistics of block averages).

β	**Twisted** $\beta\langle S\rangle$	**Untwisted** $\beta\langle S\rangle$
30	4.545(3)	2.862(2)
300	4.498(3)	2.897(2)
3000	4.497(2)	2.860(3)

Reading: the twisted side matches $9/2$ at $\beta = 300$ and 3000 ($\beta = 30$ gives 4.545), and the untwisted side is 0.10–0.14 below 3. The difference of power $-3/2$ was seen. The coefficient of the logarithm is not determined by this computation (the value at $\beta = 3000$ is lower than at 300, and there is a suspicion that thermalisation in the flat directions is slow). Rerun: $\beta = 300$ was run with the same seed, and agreed at 4.4977(33) and 2.8970(19).

(c) Hysteresis of the mixed action (SU(2), 4^4)

Setting Reading . The action of model 5, 4^4 periodic, Metropolis (simultaneous updates by sublattice). β_F is raised $0 \to 2.5$ and then lowered, 80 sweeps at each point, from a cold initial configuration. One seed for each β_A (two only for $\beta_A = 2.0$). We look at the maximum of "down − up" for the plaquette average $\frac{1}{2}\operatorname{tr} P$.

β_A	**Maximum of down − up (at that** β_F**)**	**Reading**
0	0.023 or less (everywhere)	No hysteresis. 0.49–0.52 at $\beta_F = 2.0$, 0.65 at 2.5
1.0	0.079 (1.25), 0.063 (1.5)	A size hard to distinguish from fluctuations
1.5	0.317 (1.0), 0.165 (1.25)	Strong
2.0	0.413 (0.5, 0.75), 0.205 (1.0). With another seed 0.516 (0.5), 0.430 (0.75), 0.311 (1.0)	Strong

Differences of the opposite sign appear in the same runs with sizes up to 0.08 ($+0.076$ at $\beta_A = 2.0$, $\beta_F = 0$, and so on), so differences of 0.08 or less are hard to distinguish from fluctuations in this computation. Reading: at $\beta_A = 1.5$ and 2.0, strong hysteresis was seen even on 4^4. The weak difference at $\beta_A = 1.0$ may be a finite-size effect of 4^4 (of the type of Gavai's re-examination, which reported the first-order transition disappearing on larger lattices). We do not read the position of the endpoint from this computation. Hysteresis also appears with slow dynamics, so neither the mass nor the tension at the endpoint comes out of this computation. Rerun: the four values of β_A were run with the same seeds, and all the values agreed.

(d) The U(1) constant with the aspect ratio fixed

Hand count Proved here . Using the slab approximation for the Coulomb phase of U(1) (equation (4) of 26-03, read with $e^2 = 1/\beta$, vortex area M^2 and transverse area N^2), $\theta(N, M, \beta) \approx 2\exp(-M^2/(2\beta N^2))$, and fixing the aspect ratio $r = M/N$, we get

$$\frac{\theta(2N, 2M, \beta)}{\theta(N, M, \beta')} = \exp\Big(\frac{r^2}{2}\Big(\frac{1}{\beta'} - \frac{1}{\beta}\Big)\Big)$$

which does not depend on N. Putting $\beta' = \beta - c$, $1/(\beta - c) - 1/\beta = c/(\beta(\beta - c))$ decreases in β, so uniformly over all $\beta \geq \beta_1$

$$K = \exp\Big(\frac{r^2 c}{2\beta_1(\beta_1 - c)}\Big) \quad (1)$$

gives the form of the renormalisation comparison $\theta(2N, 2M, \beta) \leq K\theta(N, M, \beta - c)$ (on the approximate formula).

Computation Reading (a numerical scan of the approximate formula: 4000 points in $\beta \in [\beta_1, 10^4]$, $N = 2, 4, 8, 16, 64$, $r = 1, 2, 4$; no seeds). The upper bound of the scan agreed with equation (1). Examples: with $c = 0.258$, $\beta_1 = 3$, $K = 1.016$, 1.065, 1.285 for $r = 1, 2, 4$. With $c = 0.258$, $\beta_1 = 10$, 1.0013, 1.0053, 1.0214. Running it again gave the same values.

Reading: on the weak side, the comparison with the aspect ratio fixed holds uniformly for U(1) too, in the form "runs to strong coupling at any speed c you like", and uses no non-commutativity at all. $K(r)$ grows without bound with r, so with a quantification that fixes the transverse size and stretches the longitudinal one, U(1) already fails on the weak side. The approximate formula drops the effect of monopoles (of order $e^{-c\beta}$ at finite β), so we have not checked whether the same constant holds for true U(1).

(e) A trial of the sign term by term (SU(2), 1^4)

Question. When each plaquette is given its own coupling β_p, does ΔF (on the background $z_{12} = -1$, with and without the measured twist z_{34}) increase in each β_p? We look at the sign of $\partial\Delta F/\partial\beta_p = \langle E_p\rangle_{z_{34}=-1} - \langle E_p\rangle_{z_{34}=+1}$ ($E_p = 1 - \frac{1}{2} z_p \operatorname{tr} P$) Proved here (the derivative of $\Delta F = \ln Z_{z_{34}=+1} - \ln Z_{z_{34}=-1}$).

Computation Reading (Metropolis, 3000 chains × 800 sweeps, the first 200 sweeps discarded, β_p uniform random in $[0.2, 3.0]$ for the 6 plaquettes; 6 sets without the adjoint term and 2 sets with adjoint $\beta_A = 1.0$, 48 differences in all). All 48 are positive, and the smallest difference is 0.029 (a set with one β_p at 0.2). The statistical ratios are 58–1700 (errors from block averages, which may come out small because of autocorrelation, but the signs do not move). Rerun: the first 2 sets (seed 1) were run, and all the values agreed.

Reading: 1^4 is a special lattice in which the six plaquettes are joined at one point, and β_p goes only up to 3, so we cannot say that "monotonicity term by term holds". The contrast with the failure of a similar monotonicity for the finite group Q_8 (21-01: monotonicity in β in three dimensions without background, under conditions different from this trial) is worth keeping on record. The next lattice to try is an elongated box (16-11 § 05).

06

What this chapter does not say

- It gives no road across the band. There are no proofs in it.
- The discussion of the endpoint of the mixed action is at a fixed lattice spacing, and does not mean that the continuum SU(2) theory has no mass gap. The position of the SU(2) endpoint varies in the literature, and this book has not checked that the scalar mass goes to 0 at the endpoint.
- We say neither true nor false for the "—" cells of Table 2.
- Of the properties of the seven models, those written as "stated in the literature (not checked by this book)" are not used as grounds for claims in the text.
- We draw no conclusions about large lattices or the continuum theory from values on small lattices.

What this chapter can say

Can say	Cannot say
Lean The reference column of Table 2 (this book's theorems, inside the strong-coupling window, with the lattice spacing fixed)	Theorems of the same type in the other models (the "—" cells)
Proved here That the expressions of the SU(2) and U(1) Wilson actions coincide on the maximal torus. That the adjoint Higgs at $J = \infty$ becomes the U(1) Wilson action (a formal limit). That with one real adjoint scalar the one-loop coefficient is 7 (positive). The row S_N (positive for finite subgroups; the definition does not carry over to abelian groups). The cells not defined for G_2 and discrete groups. $Z_1 = 96$ for Q_8. The count of powers on 1^4. The U(1) constant (1) with the aspect ratio fixed (on the approximate formula)	A check of the concentration of the limiting measure. A uniform constant for true U(1). $S_N = 0$ under the transferred definition
Cited The non-confining phase of U(1) (Villain action; the extension to the Wilson action in the text of Fröhlich–Spencer). The first-order transition of Z_2. The first-order line and critical endpoint of the mixed action, and the re-examination of the endpoint position (expected at $\beta_A \geq 1.25$). That the scalar mass drops near the SU(3) endpoint. The strong first-order bulk transition of SU(6). That G_2 has a trivial centre and its string can break	The mass at the SU(2) endpoint, the bulk transition of SU(5), the gap of Z_2 at weak coupling and of G_2, the freezing β of finite groups
Reading The numbers of flat connections of finite groups (full enumeration). $\beta\langle S\rangle$ of SU(2) on 1^4 (4000 × 3000, one seed). The hysteresis of the mixed action on 4^4 (80 sweeps per point, one seed for each β_A, two for $\beta_A = 2.0$). The 48 signs term by term (3000 × 800)	The position of the endpoint. That monotonicity term by term holds

Words used in this chapter — sieve, quantity of confinement, quantity of the gap, maximal torus, adjoint Higgs, mixed action, first-order transition, critical endpoint, bulk transition, centreless group, flat connection, frozen phase, twisted vacuum, hysteresis, aspect ratio, sign term by term. Their meanings are in A-02 Glossary.

Chapter to read next: 27-00 Entrance — the promise of this part. The overall map of ideas is in 16-11.

2026-10-15 · chapter Yang–Mills and the mass gap Part 27 Closing — conditional statements entrance, promise, map of four chapters · Kiichi, Shiori and Rin

Entrance — the promise of this part

> This chapter is a guide (the entrance to this part).

This part is a record of the study. The theorems that have been machine-checked are in Parts 20–22, and the current list of premises is in 28-04.

What this chapter shows — The promise on how Part 27 is written, and the differences that remain even when the ledger of conditions is empty. The figure of the two roads meeting at the band, shown again, and a map of 27-01 to 27-04.

Prerequisite chapters — 16-09 (the table of the seven stages a proof must contain). You can read this part without having finished Parts 23 to 26.

01

The promise of this part

Part 27 writes conditionally until the conditions disappear.

- The statement is split arrow by arrow, and each arrow carries a label. We call something a "theorem" only for arrows whose paper proof has been placed in this book. That is why the title of 27-01 is "the conditional statement".
- The conditions are placed one row at a time in the ledger of conditions (27-02). The ledger is written with the facts as they stand after the publication of 2026-11-10. The continuum limit in a periodic cubic box was shown by the published construction (at the level of the committee's assessment; Volume 2), but the form this book's road needs (twisted boundary conditions, elongated boxes, a form uniform in the lattice spacing) is not there, so the row of ultraviolet control remains. A row disappears when its paper proof has been placed in the book and, if it has a Lean entry, the re-check of that entry is done. As research advances, rows disappear, but they can also split and increase.
- Even if every row of the ledger disappears, the difference from the problem statement remains: the axioms on $\mathbb{R}^4$ (the infinite-volume limit, the recovery of rotations, non-triviality; the infinite-volume limit (along a subsequence) from a sequence of periodic boxes, and the reconstruction, were shown by the published construction, but the reduction from the family of twisted slabs on this book's road

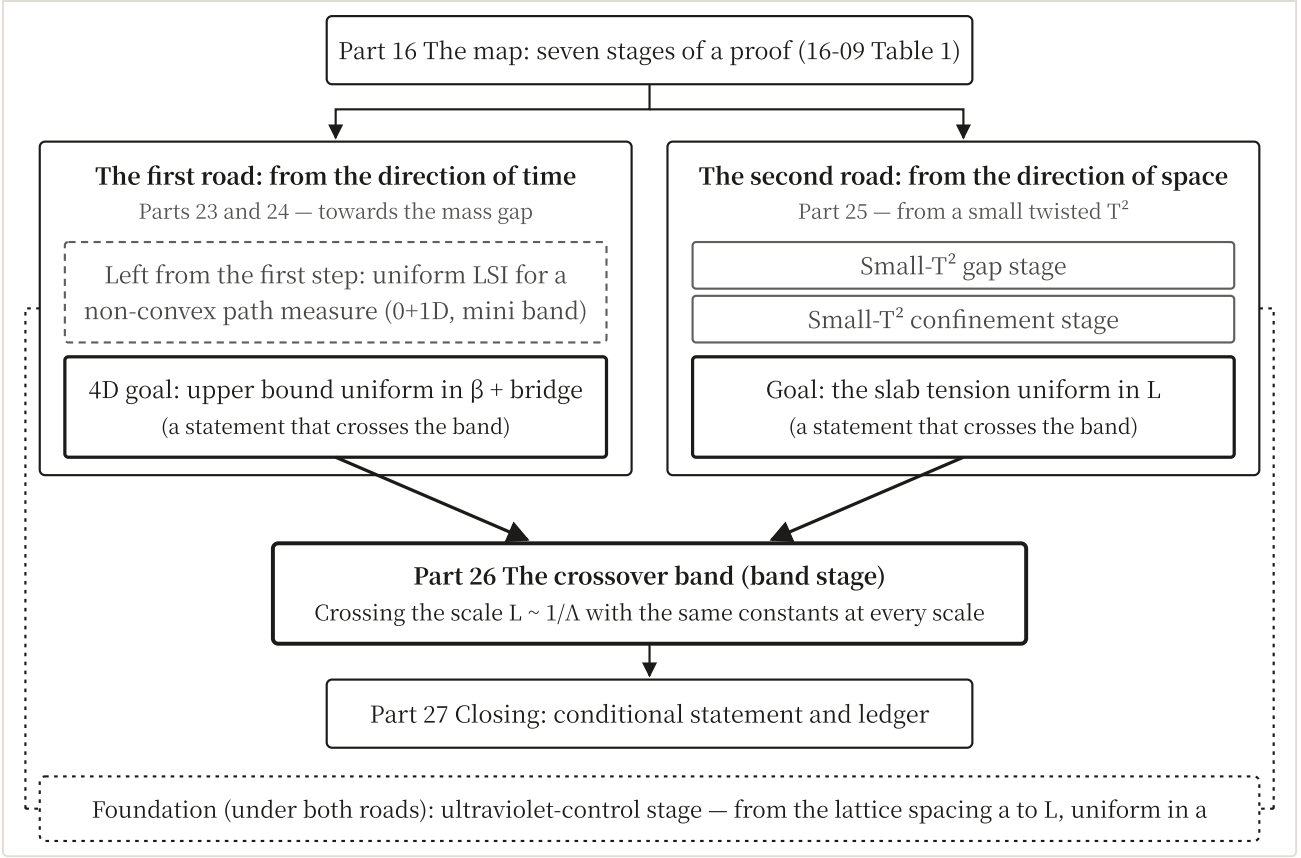
is open), all compact simple groups (existence was shown by the published construction for any compact simple group; the vortex tools cannot be used for groups without a centre), the arrow from the area law to the mass gap (tying the two roads together), and the verification and peer review of the whole. These four (the limit to R^4 [split into four rows in 27-02 Table 3], tying the two roads together, general groups, verification and peer review; seven rows with the breakdown) are placed in a separate frame outside the ledger (27-02 § 05). An empty ledger does not mean that the problem is solved.

- This part has no chapter called "solved".

02

The two roads meet at the band (shown again)

Figure 1 16-09 Figure 1, shown again. On both roads, the arrow flowing into the band leaves only from the row of the four-dimensional goal. The ultraviolet-control stage lies under both roads. Part 27 corresponds to the one box below the band



03

the conditional statement, a label for each arrow, the open arrow · Kiichi, Shiori and Rin

The conditional statement — the mass gap and confinement, arrow by arrow

> This chapter is a map of open questions. § 03 is this book's own investigation.

What this chapter shows — Under the assumptions of ultraviolet control, uniform acceptance of insertion, the base point at small T^2, frame decorrelation, the uniform slab tension, the uniform slab gap and tying the two roads together, which arrows the mass gap and confinement pass through. The gap comes out of the small-T^2 gap stage and the transfer matrix, and confinement out of the small-T^2 confinement stage and the band stage; we put a label on every single arrow. The only arrows whose paper proof we could place in the book are the algebra of the doubling iteration (the Doubling-Iteration Theorem) and slab confinement at fixed lattice spacing (the other arrow at fixed lattice spacing, the Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3), has a proof with citations in the paper, and its label in the book is Assumption). The arrow from the area law to the mass gap is open, and even the statement of what should be added has not been settled.

Prerequisite chapters — 16-09 (the table of the seven stages a proof must contain), 27-00 (the promise of this part), 25-04 (slab confinement), 25-05 (the insertion identities), 26-02 (reduction to a single inequality), 26-05 (the chessboard). The names and contents of the assumptions are in A-06 § 06, and the present state of each assumption is in 27-02 Table 2 (the rows of the ledger of conditions) and Table 3 (the differences that remain outside the ledger); this chapter refers to the assumptions by the names of the ledger rows.

Said first — This chapter shows neither the mass gap nor confinement. We do not title it "the conditional theorem" because many of the arrows that make up the statement have no paper proof. Only the arrows whose paper proof we could place in the book are called "theorems"; the rest are listed as labelled "arrows". Even if every row of the ledger of conditions disappears, a difference from what the problem statement requires remains (§ 05).

Order of this chapter

1. The form of the statement — the assumptions, the two conclusions, the two levels (Table 1)
2. The gap side — the small-T^2 gap and the transfer matrix (two arrows)
3. The confinement side — the arrows of small-T^2 confinement and of the band, the Doubling-Iteration Theorem
4. Tying the two roads together — the open arrow tying the two roads together, and the statement of the road from the direction of time
5. What cannot be said, and the differences that remain even when the ledger is empty
6. The label of each arrow, and the dependency graph — Table 2

01

The form of the statement — the assumptions, the two conclusions, the two levels

The statement of this chapter is not a single "if ... then" but a bundle of arrows. There are two conclusions.

- **The mass gap**: the spectrum of the transfer matrix (the Hamiltonian) above the vacuum is $\{0\} \cup [\Delta, \infty)$ with $\Delta > 0$ (4-11).
- **Confinement**: the expectation value of a large Wilson loop decreases exponentially in the area (the area law, 5-08).

The two are different statements. There is no known road that gets the gap from the area law, and "showing confinement also gives the gap" is a misconception (16-08). So this chapter derives the two conclusions each through its own bundle of arrows, and at the end places, still open, the arrow that joins the two on the same theory.

We also split the levels into two. The **theory on a small $\mathbf{T^2}$** is the theory on $\mathbb{R}^2 \times$ a small twisted T^2 (side L, 't Hooft twist $n_{12} = 1$), with the limit of lattice spacing $a \to 0$ taken. It is not what the problem statement requires but an intermediate target. The **theory on $\mathbf{R^4}$** is the theory on $\mathbb{R}^4$, reached from the theory on a small T^2 through the stage of widening the T^2 (the band) and the stage of the infinite-volume limit.

Table 1 lists the assumptions used. Their labels are all Assumption: rows without a proof. The names are taken from the contents.

Table 1 The assumptions placed by the statement of this chapter (the numbers are those of the dependency graph in § 06; the ledger column gives the row of 27-02; the stages are the seven stages a proof must contain, of 16-09)

No.	Ledger	Name	Contents (one line)	Stage	Label
1	Ultraviolet control	Ultraviolet control	From the lattice spacing a up to the scale L, a multiscale analysis uniform in a holds: locality and analyticity of the small-field effective action (the small-field analyticity condition), rarity of large fields (the large-field rarity condition), and the effective coupling stays in $(0, \gamma]$. The continuum limit in a periodic cubic box was shown by the published construction (Volume 2), but a construction with twisted boundary conditions or elongated boxes is not there (within what we searched). Ultraviolet control here is the still open condition that the same construction holds under twisted boundary conditions	Ultraviolet-control stage	Assumption
2	Uniform acceptance of insertion	Uniform acceptance of insertion	Under the small-field frame, the mean of $\tanh(W/2)$ for the dynamically driven vortex insertion is at most $1 - \delta$, uniformly in a (25-06)	Small-T^2 confinement stage	Assumption
3	Base point at small T^2	Base point at small T^2	At a small physical L_0, $\theta(L_0; T^2_{L_0}) \le 1 - \varepsilon_0$ (θ is the sector bias of the container, 25-03). The expected size is $\varepsilon_0 \propto (L_0\Lambda)^{11/3}$ (a one-loop estimate). In the outline it follows from ultraviolet control and uniform acceptance of insertion	Small-T^2 confinement stage	Assumption

No.	Ledger	Name	Contents (one line)	Stage	Label
4	Frame decorrelation	Frame decorrelation (form with L fixed)	The correlations between the frames of containers decay, and the Wilson-loop estimate $\mathbb{E}\prod\theta$ can be split into the product of the individual θ at the loss of a constant	Small-T^2 confinement stage, band stage	Assumption
5	Small-T^2 gap (form uniform in the lattice spacing)	Decay of block observables (form with L fixed)	The correlations of block observables decay exponentially at a rate $m \geq c/L$ uniform in a (the form placed by the research programme for the theory on a small T^2)	Small-T^2 gap stage	Assumption
6	A form inside positivity of the 't Hooft tension (the place of the input to the reduction is the renormalisation comparison)	Lateral-widening inequality	With the container fixed, widening the transverse T^2 by a factor s increases θ by a factor of at most Cs^2 (strong form), or a form in which the total loss is finite (weak form). The assumption when the band is stated in the form of the paper on the reduction of the band (26-02)	Band stage	Assumption
7	The weak form of positivity of the 't Hooft tension	Uniform slab tension	The string tension $\sigma_{\mathrm{eff}}(L)$ of the slab $T_L^2 \times \mathbb{R}^2$ is positive uniformly in L	Band stage	Assumption
8	Uniform decay of block observables	Uniform slab gap	The correlations of block observables decay exponentially, uniformly in the lattice spacing and in the slab size L (the premise of the arrow of the R^4 gap)	Band stage	Assumption
9	Limit to R^4 (outside the ledger)	The limit to $\mathbb{R}^4$	The infinite-volume limit, the OS axioms, the recovery of rotation invariance, uniqueness of the limit, non-triviality	R^4 stage	Assumption
10	Tying the two roads together (outside the ledger)	Tying the two roads together	That the gap road (carrying the small-T^2 gap stage through the band) and the confinement road (from the small-T^2 confinement stage and the band stage to $\mathbb{R}^4$) give both conclusions on the same theory on $\mathbb{R}^4$. The statement of what it suffices to assume has itself not been settled	Small-T^2 gap stage, small-T^2 confinement stage, R^4 stage	Assumption (statement not settled)

We state the correspondence with the ledger first. In the ledger, frame decorrelation (form with L fixed) corresponds to the row of frame decorrelation, and the uniform slab gap to the row of uniform decay of block observables; the lateral-widening inequality and the uniform slab tension are treated as forms inside the row of positivity of the 't Hooft tension. The non-abelian input to the reduction to the band is placed in the ledger in the row of the renormalisation comparison. The row of reflection positivity of z is a closed row (its proof is placed in 26-04 § 03; the algebra of the last step is also closed in Lean (ReflPos)), and in this chapter it is used inside the chessboard arrow. The limit to R^4 and tying the two roads together are differences outside the ledger; they are not work of removing assumptions but work of carrying the conclusion as far as the problem statement. We put them in the table in this chapter so that they can be named as premises of arrows.

We split the "frame decorrelation" of Table 1 into two forms. Frame decorrelation (form with L fixed) is the form for splitting the container estimate on the confinement side, and decay of block observables (form with L fixed) is the form placed by the research programme on the gap side of the theory on a small T^2. They are assumptions of the same family, but as sentences they are different, and decay of block observables (form with L fixed) contains the quantity of the conclusion (the rate m) (§ 02). θ is the sector bias of the container $\theta(R; T_L^2)$ (side of the container R, side of the transverse T^2 L), a quantity different from the θ of A-06 Table 6 (the exponent of accumulation of the shortfall).

02

The gap side — the small-T² gap stage and the transfer matrix

The arrow of the small-T² gap (theory on a small T²). Under ultraviolet control and decay of block observables (form with L fixed), the theory on $\mathbb{R}^2\times$ a small twisted T^2 exists (as a subsequential limit of the distributions of block observables), is reflection positive and invariant under translations of $\mathbb{R}^2$, and its transfer matrix satisfies $\|T_t\| \le e^{-mt}$, $m \ge c/L$ on the orthogonal complement of the vacuum Assumption . This is the form put forward as a proposition by the research programme for the theory on a small T², and the proof is at the stage of an outline. The conclusion corresponds to the ledger row of the small-T^2 gap.

To say precisely what this arrow contains: the transfer-matrix step is an abstract lemma of the vessel stage. It is the general fact that, for a self-adjoint contraction on a real inner-product space, if the correlations decay at rate m on a dense set then the operator norm is at most e^{-m}; it is independent of the physical measure. So what carries the content of the mass gap inside the arrow of the small-T² gap is the part "decays at rate $m \ge c/L$" of the assumption decay of block observables (form with L fixed). Decay of block observables (form with L fixed) contains the quantity of the conclusion, and the arrow of the small-T² gap is most accurately read as "an arrow that restates uniform decay of block correlations as a gap of the transfer matrix". That the twist removes the zero modes (the adjoint field has no zero modes, 25-01) is a reason to expect decay of block observables (form with L fixed) to hold, not a proof of it.

The arrow of the R⁴ gap (theory on R⁴). The gap $m \ge c/L$ of the arrow of the small-T² gap approaches 0 as $L \to \infty$, so as it stands it is not a gap on $\mathbb{R}^4$. Carrying it to $\mathbb{R}^4$ needs the mass gap of the slab to be uniform in L (the uniform slab gap), and further uses, inside the infinite-volume limit (the limit to R⁴), that uniform exponential decay passes to a gap of the transfer matrix of the limiting theory Assumption . Here too, the content of the gap lies in the band assumption (the uniform slab gap). The phrase "the gap comes from the small-T² gap stage and the transfer matrix" describes the case in which the gap of the small-T² gap stage could be carried through the band uniformly in L, and the carrying is the problem of the band itself (26-00).

03

The confinement side — the small-T² confinement stage and the band stage

On the confinement side there are two arrows with a paper proof at the stage of fixed lattice spacing; the arrows at the stage of sending the lattice spacing to 0 and at the stage of the band rest on assumptions.

Two arrows at fixed lattice spacing. (a) The arrow of slab confinement: with the lattice spacing and the size N of the T^2 (in lattice units) fixed, the area law holds for every β, and the tension is bounded by $\sigma \ge -\ln\tanh(\beta N^2) \approx 2e^{-2\beta N^2}$ Proved here (25-04). The tension is set by the cost of the surface of a thin $\mathbb{Z}_2$ vortex, and approaches 0 in the continuum limit. (b) The arrow of the fractional-instanton rate (the Confinement Lower Bound by Fractional Instantons): on the lattice $T^2_N \times T^2_M$ with fixed $N \ge 2$, block side $\ell \ge 2$, $\beta \ge 1$ and $M \in 2\ell\mathbb{N}$, the bias θ of the n_{34} flux satisfies $-\ln\theta \ge c(N,\ell)\,\beta^{-a} e^{-\beta(S_*(N,\ell)+\varepsilon(\beta))} M^2$, $\varepsilon(\beta) = O(\sqrt{\ln\beta/\beta})$ Assumption (no proof is placed in this book; a proof with citations is in the paper: it cites the Chessboard Estimate and the Morse–Bott lemma, and the rigidity constants are shown only to exist. The paper is a draft and has not been through outside checking. 25-02 § 07 (e)). S_* is the minimal action of a fractional instanton inside a frame frozen to the vacuum, and the statement says that the rate is set by fractional instantons, not by the $2N^2$ of a thin vortex. In the ledger this is the

confinement-direction row of the upper end of the renormalisation comparison. The Reverse Estimate at a Fixed Plane (Theorem B of Paper 3) of the same paper is the bound with the size M of the plane fixed. Neither is uniform in N, and neither says anything about the continuum limit.

The arrow of the small-T² area law (theory on a small T²). Under ultraviolet control and uniform acceptance of insertion, Wilson loops in the $\mathbb{R}^2$ plane of the theory on $\mathbb{R}^2\times$ a small twisted T^2 have an area law uniform in a Assumption . The expected form of the tension is $\sigma \geq c' e^{-F/g^2(L)}/L^2$ (F is expected to be the fractional-instanton action $4\pi^2$). Among the parts of the assembly, the insertion identities and the estimate of the mean are closed on paper and in a finite version in Lean (25-05, 25-06), and in the outline the large-deviation step reduces to a chessboard estimate of the same type as the large-field rarity condition of ultraviolet control. The base point at small T² corresponds to the conclusion of this arrow written in the language of the container's bias.

The arrow of the reduction of the band (the form of the reduction of the band). Under the base point at small T², frame decorrelation and the lateral-widening inequality, $\theta(R;T^2_R)\leq e^{-cR^2}$ Assumption (the conditional theorem of the paper on the reduction of the band). The proof in the paper on the reduction of the band is a sketch, and the part "frame decorrelation splits the product at the loss of a constant" is not written as a numerical inequality. In this book we rewrite the assumptions in the form of numerical inequalities, and then put the remaining algebra on paper as the Doubling-Iteration Theorem.

Doubling-Iteration Theorem

Let θ be a function giving a value in $[0,1]$ to each pair of positive lengths (R,L). Let $R_0>0$, $R_k=2^k R_0$, and suppose that for positive constants K_1,K_2, for every $k\geq 0$,

$\theta(2R_k;T^2_{R_k})\leq K_1\,\theta(R_k;T^2_{R_k})^4$ (nesting), $\theta(R_{k+1};T^2_{R_{k+1}})\leq K_2\,\theta(R_{k+1};T^2_{R_k})$ (lateral widenin

holds. Put $K=K_1K_2$, $t_k=\theta(R_k;T^2_{R_k})$. If $K^{1/3}t_0<1$, then for every k

$$\theta(R_k;T^2_{R_k})\;\leq\;K^{-1/3}\exp\bigl(-c\,R_k^2\bigr),\qquad c=\frac{\ln\bigl(1/(K^{1/3}t_0)\bigr)}{R_0^2}>0. \tag{2}$$

Proved here Proof. Since $2R_k=R_{k+1}$, applying the two parts of (1) in turn gives $t_{k+1}\leq K_2\,\theta(2R_k;T^2_{R_k})\leq K_1K_2\,t_k^4=Kt_k^4$. Putting $u_k=K^{1/3}t_k$ gives $u_{k+1}\leq u_k^4$, and by induction $u_k\leq u_0^{4^k}$. Since $4^k=(R_k/R_0)^2$, we have $u_0^{4^k}=\exp(-(R_k/R_0)^2\ln(1/u_0))$, and (2) follows. ∎ Lean Doubling (`Doubling.iterate`) (assumptions: $c\geq 0$, $t_k\geq 0$, $t_{k+1}\leq c^3t_k^4$; conclusion: $c\,t_k\leq(c\,t_0)^{4^k}$), Doubling (`Doubling.decay`) (the same assumptions and $c>0$; conclusion: $t_k\leq(c\,t_0)^{4^k}/c$). Read $c=K^{1/3}$.

The starting value $K^{1/3}t_0<1$ is made from the base point at small T² with a single big jump. If, in the nesting with $T^2_{L_0}$ fixed, $\theta(sL_0;T^2_{L_0})\leq C_1(1-\varepsilon_0)^{s^2}$, and, by lateral widening, $\theta(sL_0;T^2_{sL_0})\leq C_2s^2\,\theta(sL_0;T^2_{L_0})$ can be said, then the $t_0\leq C_1C_2s^2e^{-\varepsilon_0 s^2}$ at $R_0=sL_0$ becomes smaller than $K^{-1/3}$ for $s^2\gg\varepsilon_0^{-1}\ln(1/\varepsilon_0)$ Proved here (the same algebra).

The Doubling-Iteration Theorem is algebra, and all the content is in (1) and in the two inequalities of the jump. The nesting inequality is exact as a partition inside a container with T^2 fixed (25-03), but the sub-containers share frames and are correlated, so splitting into a product with constant K_1 needs frame decorrelation. The lateral-widening inequality is the assumption of Table 1 itself. That is why the label of the arrow of the reduction of the band is Assumption, and only the part that is the Doubling-Iteration Theorem could be put on paper.

The arrow from the container estimate to the area law (from the form of the reduction to the area law). From $\theta(R;T_R^2) \le e^{-cR^2}$ and frame decorrelation, by the container estimate (the container identity of Mack–Petkova, 25-03 Cited), an area law with tension uniform in L Assumption . The global version that does not use frames uses the ratio of twisted partition functions and the Tomboulis–Yaffe inequality Cited , and in exchange the base point has to be shown globally (26-01).

The chessboard arrow, and the arrow from the two uniformities to the area law (the chessboard form). With the size of the T^2 fixed, from the reflection positivity of z Proved here (a proposition of the paper on the reduction of the band; ReflPos (`ReflPos.refl_pos` , `ReflPos.refl_cs`) is the algebra of the core, 26-04) and the Chessboard Estimate Cited , frame decorrelation is replaced by a single density κ_{cb}, and $|\langle W(C)\rangle| \le \kappa_{\mathrm{cb}}^{n(C)}$ Proved here (a statement with L fixed, 26-05). In this language the band becomes two uniformities, and under the uniform slab tension and the uniform slab gap an area law with tension uniform in L follows Assumption . Reading the uniform slab gap in terms of κ_{cb}, the power in the nesting within a fixed T_L^2 holds with constant 1 for all L (the Nested Supermultiplicativity Lemma of 26-05 Paper), and the content of the uniform slab gap uniform in L moves to the comparison across L, (C $_{\mathrm{cb}}$) — the lateral-widening inequality read in terms of κ_{cb} (the Reduction Read in the Chessboard Density of 26-02).

Confinement in the theory on R^4 follows from the area law of the arrow from the container estimate to the area law or of the arrow from the two uniformities to the area law, together with the limit to $\mathbb{R}^4$ Assumption .

04

Tying the two roads together — the open arrow tying the two roads together, and the statement of the road from the direction of time

The arrow tying the two roads together (open). The gap road of § 02 and the confinement road of § 03 both reach $\mathbb{R}^4$ through assumptions that cross the band (the uniform slab gap, or the lateral-widening inequality and the uniform slab tension). To state both conclusions on the same theory on $\mathbb{R}^4$, we need an arrow saying that the two roads give the same limiting theory and that both hold in that theory. This is tying the two roads together (a difference outside the ledger). Its label is Assumption, but unlike the other assumption rows, there is not yet a sentence saying what it suffices to assume.

Since there is no known road going directly from the area law to the mass gap, the arrow tying the two roads together cannot be written as "an extension of the confinement road". At the level of physical expectation the two are linked (excitations on a string of tension $\sigma > 0$ are heavy, 17-03), but that is not an arrow Reading (a physical estimate). The gap is derived by the road of § 02 (carrying the gap of the small-T^2 gap stage through the band), confinement by the road of § 03, and the arrow tying the two roads together is limited to the role of saying "the two are statements about the same theory".

The statement of the road from the direction of time. The conditional statement of the road of Part 23 has a different form. From the upper side $\xi^2\uparrow$ ($C_P \le K\xi_{\mathrm{RG}}^2$) of the diffusive-relaxation-time assumption and the one-sided bridge (the One-Sided Bridge Proposition, $C_P \ge \kappa\xi^2$), a lower bound on the gap in the physical units of the lattice, $m_{\mathrm{phys}} \ge (\kappa/K)^{1/2}$, follows at each β Proved here (algebra on top of the assumptions, 23-01 § 06). Saying this uniformly as $\beta \to \infty$ is the four-dimensional goal of Part 23 (the ledger row "uniformity of the relaxation-time upper bound and the one-sided bridge"; the physical-unit target level of 23-15 Table 5), and this goal too is a statement that crosses the band. The uniform slab gap of the road from the direction of space and the "$\xi^2\uparrow$ uniform in β, and the bridge" of the road from

the direction of time are uniformity statements of the same type, and neither has been shown inside the band (26-07).

05

What cannot be said, and the differences that remain even when the ledger is empty

None of the arrows of this chapter shows the mass gap or confinement. The only things whose paper proof could be placed in the book are the Doubling-Iteration Theorem (algebra), the arrow of slab confinement at fixed lattice spacing, and the chessboard arrow with T^2 fixed. The arrow of slab confinement says nothing about the continuum limit, and the arrow of the fractional-instanton rate (the Confinement Lower Bound by Fractional Instantons) has no proof in the book (the label is Assumption; a proof with citations is in the paper) and is not uniform in N. The arrow of the small-T^2 gap and the arrow of the small-T^2 area law for the theory on a small T^2 are propositions of the research programme, at the stage of an outline. The band forms, the lateral-widening inequality and the uniform slab tension, contain the quantities of the conclusion (bias, tension) in the form "uniform in L", and the uniform slab gap states decay of correlations in a form uniform in L. The band statement itself carries the content of the conclusion. The statement of this chapter is a conditional statement only insofar as the band is placed among the assumptions.

Even if every row of the ledger disappears, a difference from what the problem statement requires remains: all compact simple groups (for groups without a centre the vortex tools cannot be used), the OS axioms on $\mathbb{R}^4$ with the recovery of rotations and non-triviality, and the arrow from the area law to the mass gap. These are in the separate frame "the differences that remain outside the ledger" of 27-02 § 05 (the limit to R^4 and tying the two roads together of Table 1 also go there). Nor is the ledger a table that only shrinks: as research advances, rows can split and new rows can appear.

06

The label of each arrow, and the dependency graph

We list the arrows in the format of the five grades (23-00 § 01). The label is the label of the arrow, not of its premises. Even for an arrow whose premise is Assumption, the label is Proved here if the inference from the premises to the conclusion is written on paper, and Assumption if it is at the stage of an outline.

Table 2 The label of each arrow ("—" marks rows without machine checking; the Lean column gives only the names of bundles re-checked by the main session)

Arrow	Premises ⟹ conclusion	Label	Grounds	Conditions written in the same row	Machine checking
Arrow of the small-T^2 gap	$1 \wedge 5 \Longrightarrow$ existence of the theory on a small T^2 and the gap $m \geq c/L$	Assumption	Proposition of the research programme for the theory on a small T^2 (outline). The transfer-matrix step is an abstract lemma of the vessel	Decay of block observables (form with L fixed) contains the quantity m of the conclusion. Uniform in a; L is small	—

Arrow	Premises ⟹ conclusion	Label	Grounds	Conditions written in the same row	Machine checking
Arrow of the R^4 gap	Arrow of the small-T^2 gap $\wedge$ 8 $\wedge$ 9 $\Longrightarrow$ the gap on $\mathbb{R}^4$	Assumption	Outline	The uniform slab gap (the ledger row of uniform decay of block observables) is uniform decay of block observables; what the arrow of the R^4 gap adds is the transfer to the limiting theory	—
Arrow of slab confinement	Lattice spacing and N fixed $\Longrightarrow$ area law for every β, $\sigma \geq -\ln \tanh(\beta N^2)$	Proved here	25-04	In the continuum limit the tension is 0. Comparison with earlier arguments (Borgs, Tomboulis–Yaffe type) remains	The Lean column of 25-04
Arrow of the fractional-instanton rate	Fixed $N \geq 2$, $\beta \geq 1 \Longrightarrow -\ln \theta \geq c\,\beta^{-a} e^{-\beta(S_* + \varepsilon(\beta))_M 2}$	Assumption	Confinement Lower Bound by Fractional Instantons (no proof placed in the book; a proof with citations is in the paper. 25-02 § 07 (e))	Not uniform in N. Says nothing about the continuum limit. The paper is a draft	—
Arrow of the small-T^2 area law	1 $\wedge$ 2 $\Longrightarrow$ area law for the theory on a small T^2 (uniform in a)	Assumption	Proposition of the research programme (outline). The parts of the insertion are Proved here in 25-05 and 25-06	The form of the tension $e^{-F/g^2(L)/L^2}$ is an expectation	The Lean column of 25-05 (finite version)
Arrow of the reduction of the band	3 $\wedge$ 4 $\wedge$ 6 $\Longrightarrow \theta(R; T_R^2) \leq e^{-cR^2}$	Assumption	Conditional theorem of the paper on the reduction of the band (the proof is a sketch)	Stated at $L \geq L_{\min}(a)$, where there are no lattice artefacts	—
Doubling-Iteration Theorem	(1) $\wedge$ $K^{1/3} t_0 < 1 \Longrightarrow$ (2)	Proved here	The proof in § 03	Algebra independent of the content of θ	Doubling (`Doubling.iterate`, `Doubling.decay`) (assumptions in § 03)
Arrow from the container estimate to the area law	Arrow of the reduction of the band $\wedge$ 4 $\Longrightarrow$ area law with tension uniform in L	Assumption	The Container Identity Cited (25-03) and frame decorrelation	The global version uses Tomboulis–Yaffe Cited and a global base point	—

Arrow	Premises ⟹ conclusion	Label	Grounds	Conditions written in the same row	Machine checking
Chessboard arrow	Reflection positivity of $z \Longrightarrow$ with T^2 fixed, $\lvert\langle W(C)\rangle\rvert \le \kappa_{\mathrm{cb}}^{\eta(C)}$	Proved here	The proposition of the paper on the reduction of the band and the Chessboard Estimate Cited (26-05)	A statement with L fixed. Transverse reflections are not positive because of the twist	ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`) (algebra of the core)
Arrow from the two uniformities to the area law	Chessboard arrow $\wedge$ 7 $\wedge$ 8 $\Longrightarrow$ area law with tension uniform in L	Assumption	Outline	The uniform slab tension contains the quantity of the conclusion	—
Arrow of the R^4 area law	(Arrow from the container estimate to the area law, or arrow from the two uniformities to the area law) $\wedge$ 9 $\Longrightarrow$ area law on $\mathbb{R}^4$	Assumption	Outline	—	—
Arrow tying the two roads together	Arrow of the R^4 gap $\wedge$ arrow of the R^4 area law $\wedge$ 10 $\Longrightarrow$ the mass gap and confinement on the same theory on $\mathbb{R}^4$	Assumption	Open arrow. The statement of tying the two roads together is not settled	The area law alone does not give the gap	—
Arrow of the road from the direction of time	$\xi^2\uparrow \wedge$ one-sided bridge $\Longrightarrow m_{\mathrm{phys}} \ge (\kappa/K)^{1/2}$ at each β	Proved here	23-01 § 06 (algebra on top of the assumptions)	A statement at each β. Making it uniform in β is a statement that crosses the band	The Lean column of 23-01

Dependency graph (the numbers of the premises are smaller than the number of the conclusion; 1–10 are the assumptions of Table 1):

The cycle check only looks at whether, for every "⟸", the numbers on the right are smaller than the number on the left. Among the assumption rows, those that contain the quantity of the conclusion are decay of block observables (form with L fixed) (the rate m, in a form uniform in a) and the lateral-widening inequality and the uniform slab tension in the form of positivity of the 't Hooft tension (bias, tension, in a form uniform in L). This is not circular, but it shows that what the arrow of the small-T^2 gap, the arrow of the reduction of the band and the arrow from the two uniformities to the area law add is only a restatement of uniformity and algebra, and that the content lies on the side of these assumptions. The ledger (27-02 § 04) writes its rows in forms that do not contain the quantity of the conclusion. Decay of block observables (form with L fixed), the lateral-widening inequality and the uniform slab tension, which do contain it, are "restatements" of ledger rows rewritten to fit the arrows of this chapter, not the ledger rows themselves. The content of the arrow of the R^4 gap also lies on the side of the uniform decay of correlations in the uniform slab gap. The arrow of slab confinement and the arrow of the fractional-instanton rate are nodes that are not among the ancestors of the arrow tying the two roads together; they record what can be said on paper at the stage of fixed lattice spacing. The arrow of the small-T^2 area law writes the same content as the base point at small T^2 in the language of the theory on a small T^2, and in the graph we kept the base point at small T^2 as a leaf.

What this chapter can say

What is said	What is not said
The doubling iteration (the Doubling-Iteration Theorem): if nesting and lateral widening are assumed in the form of the numerical inequalities (1), then $\theta(R_k;T^2_{R_k}) \le K^{-1/3}e^{-cR_k^2}$ Proved here	The two inequalities of (1) themselves (frame decorrelation and the lateral-widening inequality)

What is said	What is not said
The area law with the lattice spacing and the T^2 fixed (slab confinement) Proved here	Showing, inside this book, the bound on the fractional-instanton rate at fixed N (the Confinement Lower Bound by Fractional Instantons) (the label is Assumption; a proof with citations is in the paper). A bound uniform in N. The tension in the continuum limit
The chessboard estimate with T^2 fixed, $\lvert\langle W(C)\rangle\rvert \le \kappa_{\mathrm{cb}}^{n(C)}$ Proved here	Comparing κ_{cb} across scales (the uniform slab gap)
That the statement has been split into arrows, with a label on each arrow. That the gap and confinement come out of different bundles of arrows	Any of the two gap arrows, the arrow of the small-T^2 area law, the arrows from the reduction of the band to the R^4 area law, and the arrow tying the two roads together (outlines on top of assumptions, or an open arrow). The mass gap, confinement, the continuum limit
That the arrow of the road from the direction of time (a lower bound on the gap at each β) is algebra on top of the assumptions Proved here	The form uniform in β (a statement that crosses the band)

Sources and reproduction

Item	Kind	Source / tools
Names and contents of the assumptions in Table 1	This book	A-06 § 06, 27-02
The form of the arrow of the small-T^2 gap and the arrow of the small-T^2 area law (the research programme for the theory on a small T^2)	Assumption	The research programme as rewritten in this book's study (SU(2) on $\mathbb{R}^2\times$ a small twisted T^2). The propositions are at the stage of an outline
Arrow of slab confinement	Proved here	25-04
Arrow of the fractional-instanton rate	Assumption	Theorem A (the Confinement Lower Bound by Fractional Instantons) and Theorem B (the Reverse Estimate at a Fixed Plane) of the paper on lattice fractional instantons (draft) "Fractional instantons confine on the lattice: a rigorous semiclassical bound for SU(2) gauge theory on a twisted small torus" (A-07). No proof is placed in the book (a proof with citations is in the paper)
Arrow of the reduction of the band, chessboard arrow, the definition of the lateral-widening inequality	Assumption, Proved here	The conditional theorem, the proposition on reflection positivity and the chessboard corollary of the paper on the reduction of the band (draft) "Where the twisted-slab route to confinement stops: a corrected window target, a reduction to transverse widening, and SU(2) versus U(1) numerics" (A-07)
Doubling-Iteration Theorem	Proved here	The proof in the text. The algebra is the Lean bundle `Doubling`
Container Identity	Cited	G. Mack, V. B. Petkova (1980). Checked in the source table of 25-03
The Tomboulis–Yaffe inequality	Cited	E. T. Tomboulis, L. G. Yaffe, Commun. Math. Phys. 100 (1985). Checked in the source table of 26-01
Arrow of the road from the direction of time	Proved here	23-01 § 06

Terms used in this chapter — the conditional statement, arrow, the theory on a small T^2 and the theory on R^4, ultraviolet control, uniform acceptance of insertion, the base point at small T^2, frame decorrelation, the lateral-widening inequality, the uniform slab tension, the uniform slab gap, tying the two roads together, the doubling iteration, the chessboard density κ_{cb}, the open arrow. Their meanings are in the A-02 Glossary and A-06 § 06.

Next chapter to read: 27-02 The ledger of conditions — the present state of each assumption, and what is needed for it to disappear.

The ledger of conditions

This chapter is a map of open questions. § 01, § 02 and § 06 are guide material.

What this chapter shows — A ledger that lists, one row at a time, the conditions placed by the conditional statement of Part 27 (27-01). For each row: the mark of its state in the record, its label in the book, what is needed for it to disappear, the rows it presupposes, and the chapters that treat it. A diagram of the dependencies between rows. And, in a frame separate from the ledger, what remains as a difference from the problem statement even when every row of the ledger has disappeared.

Prerequisite chapters — 16-09 (the table of the seven stages a proof must contain, and the figure of the two roads). The rows of the first road are taken from 23-15 Table 1 and 23-15 § 07.

Said first — The ledger is a list of conditions, not a gauge of progress. We do not count its rows and read off "this much left". This chapter adds no new results. The proofs and counterexamples for the contents of the rows are in the chapters in the right-hand column (including chapters still being written).

Order of this chapter

1. The definition of "a row disappears" — the rule placed at the head of the ledger
2. A copy of the table of stages — the marks of 16-09 Table 1, and the rows of the ledger (Table 1)
3. The ledger — twelve rows and their breakdown (Table 2)
4. The diagram of dependencies between rows — the numbers of premises are smaller than those of conclusions
5. The differences that remain outside the ledger — what remains even when every row has disappeared (Table 3)
6. The day rows increase — the ledger is not a table that only shrinks

---

01

The definition of "a row disappears" — the rule placed at the head of the ledger

Rule

A row of the ledger disappears when, and only when, the following two are both in place. (1) A paper proof of the statement of the row has been placed in some chapter of this book (a proof existing in the record is not enough). (2) If the row has a Lean entry, the theorems written in that entry have passed a re-check on the side of this book that reads the axioms again.

The point of this rule is to separate the state of the record from the state of the book. Even a row that is closed in the record (mark ■) is not removed from the ledger until its paper proof has been placed in a chapter of the book. For example, reflection positivity of z was a row closed in the record, and its proof has been placed in 26-04 § 03. The algebra of the last step is also closed in Lean (ReflPos). This row is closed.

One more thing. When a row disappears, the rows that use it as a premise do not disappear automatically. For example, even if the base point at small T^2, frame decorrelation and the renormalisation comparison all disappear, positivity of the 't Hooft tension disappears only when the paper for the reduction from the base point at small T^2, frame decorrelation and the renormalisation comparison to positivity of the 't Hooft tension has been placed in the book (26-02). And even if positivity of the 't Hooft tension disappears, not one of the differences outside the ledger (§ 05) moves.

02

A copy of the table of stages — the marks of 16-09 Table 1, and the rows of the ledger

Table 1 copies the column of marks of 16-09 Table 1 and lists which rows of the ledger bear on each stage. The marks mean the same as in 16-09: they mark the state in the record, and are not a gauge of how far things are proved (16-09 § 02). The contents of the stages and the column of what is known are kept only in 16-09 and are not repeated here.

Table 1 The marks of the seven stages a proof must contain (a copy of 16-09 Table 1) and the rows of the ledger (■ closed in the record / ◐ partial / □ open)

Stage	Mark	Ledger rows
Vessel stage	◐	Reflection positivity of z (writing out the assembly of the vessel is not set up as a row. § 06)

Stage	Mark	Ledger rows
Ultraviolet-control stage	◐	Ultraviolet control (the continuum limit in a periodic cubic box was shown by the published construction; the form needed by this book's road is open)
Small-T^2 gap stage	◐	Small-T^2 gap
Small-T^2 confinement stage	◐	Uniform acceptance of insertion, base point at small T^2 (and the form of frame decorrelation with L fixed)
Band stage	□	In the language of confinement: frame decorrelation, renormalisation comparison, positivity of the 't Hooft tension; in the language of the gap: band comparison (in the language of the gap), uniform decay of block observables. In the language of the time side: uniform gap of the double well (in miniature), uniformity of the relaxation-time upper bound and the one-sided bridge
R^4 stage	◐	Outside the ledger: the four parts of the limit to R^4, tying the two roads together (infinite volume from a sequence of periodic boxes, and the reconstruction, were shown by the published construction)
General-group stage	□	Outside the ledger: general groups (existence was shown by the published construction for every compact simple group)

03

The ledger — twelve rows and their breakdown

Table 2 is the ledger. Rows 1–10 are the rows of the second road (from the direction of space), and the uniform gap of the double well and the uniformity of the relaxation-time upper bound and the one-sided bridge are the rows of the first road (from the direction of time). The rows of the band are set up in two languages. Frame decorrelation, the renormalisation comparison and positivity of the 't Hooft tension are rows in the language of confinement (the vortex free energy, the charged sector with electric flux), and the band comparison (in the language of the gap) and uniform decay of block observables are rows in the language of the mass gap (the neutral sector without electric flux). We put the ledgers of the two roads into one because both roads stop at the same band (16-09 Figure 1). The rows are numbered in an order in which premises come before conclusions (§ 04). We write for the case of the group SU(2), the Wilson action on the lattice, and the 't Hooft twist $n_{12} = 1$ put on T^2.

Table 2 The ledger of conditions (to the right of the row name is the mark = the state in the record. The label is the label in the book, for each claim within the row. "What is needed for it to disappear" is what is needed in addition to (1)(2) of the rule in § 01. The six rows under the renormalisation comparison are its breakdown)

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
1 **Ultraviolet control** ◐	A multiscale analysis uniform in a from the lattice spacing a up to a small physical scale L_0 (locality and analyticity of the small-field effective action, rarity of large fields, the effective coupling staying small). On a small T^2	Assessment The continuum limit in a periodic cubic box was shown by the published construction (at the level of the committee's assessment; Volume 2) / Assumption A construction with twisted boundary conditions or in an elongated box, and a statement in a form uniform in the lattice spacing, are not in the published construction (within the range searched). The ultraviolet control of this row is a condition that is still open: that the same construction stands under twisted boundary conditions	Extending the published construction to the form this book's road needs (twisted boundary conditions, elongated boxes, a form uniform in the lattice spacing) (Volume 2, 16-03, the seam in Table 2 of A-08). On the side of this book's road (Part 15), completing the written-out steps of Bałaban (including the steps the original sources call unpublished), and verifying them. An assumption that depends on asymptotic freedom, which does not apply to U(1) or $\mathbb{Z}_2$ Premises: — Chapters: 7-07, 25-00, 26-11 (summary) → Part 15 (15-00–15-09; the decomposition statement is in 15-03, the four rows that do not close in 15-08) Tables that split this row into small questions: 15-09 Table 1 (the table of ultraviolet questions, with the current state of the answers), 15-08 Table 1 (the four rows that do not close) The small-field contribution to the coupling holds, under conditions, in the same form on the group as in the sources for flat fields; what the sources lack is the explicit quadratic term between blocks and the group version of its local cancellation (15-08 § 06)
2 **Small-T^2 gap** ◐	The twist removes the zero modes, and the gap of the transfer matrix $\geq c/L$ is uniform in a	Proved here the twist part (uniqueness of the vacuum, the gap $4\sin^2(\pi/2N)$ of the two-dimensional lattice Laplacian, $S_{\min} > 0$ in the (1,1) sector; N fixed) / Assumption the form uniform in a	Under ultraviolet control, writing the lower bound on the gap uniformly in a Premises: ultraviolet control Chapters: 25-01

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
3 **Uniform acceptance of insertion** ◐	Under the small-field frame, the Barker-type acceptance rate $b_F = (1 - \mathbb{E}[\tanh(W/2)])/2$ of the vortex insertion dynamically driven by a procedure of length $m(a)$ is at least $\delta/2$, uniformly in a. Said in terms of the mean, the mean of $\tanh(W/2)$ is at most $1 - \delta$ (W is the work of the insertion). "Uniform in the lattice spacing" becomes false unless the length of the procedure $m(a) \propto (L/a)^2 (r/a)^2$ is put into the statement (with the length fixed, the dissipation grows like $(L/a)^2/m$)	Paper the sandwich of acceptance rates: for the Metropolis type $e^{-\Delta F} O \le a_F \le \min(e^{-\Delta F}, O)$, for the Barker type $\frac{1}{2} a_F \le b_F \le \min(a_F, 1/(1+e^{\Delta F}))$. O is the overlap of the path measures of the forward and reverse paths, and $O \ge \frac{1}{2} e^{-D}$ (D is the dissipation). As a corollary, uniform acceptance of insertion is, up to constants, the same as boundedness of the insertion free energy (ΔF bounded uniformly in a) $\wedge$ the uniform lower bound on the path overlap (O bounded below uniformly in a). Uniform acceptance of insertion $\Rightarrow$ base point at small T^2 is one line ($b_F \le 1/(1+e^{\Delta F})$), and uniform acceptance of insertion contains the base point at small T^2 (Lean LatticeGaugeAcceptanceSandwich (`barker_le_of_crooks`, `overlap_sandwich`). The algebra of inequalities with a Crooks-type identity placed as an assumption; the Bretagnolle–Huber step is outside Lean) / Cited linear response of the dissipation (Sivak–Crooks 2012) / Assumption an estimate of the friction $\zeta \le \mathrm{Var}/\mathrm{gap}$ uniform in a, and the remainder of linear response / Reading making the procedure longer lowers the work, and $m \cdot D$ approaches a constant for $m = 64$–256 (the computation record (2026-10-22). The acceptance rates in 25-08 Tables 1 and 2 are Barker-type values. Measurement conditions in 25-08)	A lower bound uniform in a for the uniform lower bound on the path overlap: an estimate of the friction (boundedness of the fluctuation per plaquette of the face, and the gap of the heat bath of the container $\gtrsim (a/r)^2$; on the side of ultraviolet control and the small-T^2 gap, not on the side of frame decorrelation and the renormalisation comparison) and an estimate of the remainder of linear response. Boundedness of the insertion free energy is the content of the base point at small T^2, so removing uniform acceptance of insertion also means attaching a measurable certificate to the base point at small T^2 Premises: ultraviolet control, small-T^2 gap Chapters: 25-06, 25-08

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
4 **Base point at small T^2** ◐	At a small physical length L_0, in the symmetric container $(D_{L_0} \times T^2_{L_0}$, twist $n_{12} = 1)$, $\theta(L_0) \le 1 - \varepsilon_0$ uniformly in a, $\varepsilon_0 \propto (L_0\Lambda)^{11/3}$	Cited the form of the string tension (Tanizaki–Ünsal, arXiv:2201.06166 eq. (2.37), dilute regime, one loop) and the numerics of fractional instantons on the twisted lattice (Bergner–González-Arroyo–Soler, arXiv:2505.10396) / Paper Lemma on the Upper Bound for the Minimal Action of a Symmetric Box: the minimal action of the symmetric box satisfies $S_{\min}(N,N) \le 2N^4(1-\cos(\pi/N^2)) < \pi^2$ for every N (a lattice version of 't Hooft's constant-curvature solution; an abelian configuration is placed explicitly. Lean LatticeGaugeAbelianTwistAction (`totalAction_eq`, `totalAction_lt_pi_sq`). That the minimal action of sector (1,1) is at most the action of this configuration is outside Lean). With the lattice fixed, the rate as $\beta \to \infty$ is $S_{\min}(N,N)$ (the Laplace principle) / Assumption the form uniform in a. It splits into two conditional rows: ultraviolet control around a vortex background (a background of constant curvature, including the extension to non-flat backgrounds) and insertion acceptance in a symmetric container (uniform acceptance of insertion in a symmetric container of size L_0)	The two rows, ultraviolet control around a vortex background and insertion acceptance in a symmetric container. The one-loop estimate of the work in insertion acceptance in a symmetric container becomes a ratio of determinants of the lattice fluctuation operator (explicitly writable) around the constant-curvature background. A lower bound on the action (the lattice BPS bound) is not needed for the base point at small T^2 (it is needed on the upper side of the dilute regime, in the converse direction of the upper end of the renormalisation comparison). Finite volume does not appear in the base point at small T^2 (it is on the side of the upper end of the renormalisation comparison and positivity of the 't Hooft tension). The lattice version is the same semiclassical picture as the upper end of the renormalisation comparison Premises: ultraviolet control, uniform acceptance of insertion Chapters: 25-02
5 **Reflection positivity of z** ■	The ensemble summed over twists is positive under reflections through lattice points in directions 3 and 4. As a corollary, the Chessboard Estimate	Proved here / Lean: ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`) (the algebra of the core on non-negative weights)	— (the proof has been placed in 26-04 § 03, and the same section has the fact that transverse reflections are not positive because of the twist. The algebra of the last step is also closed in Lean (ReflPos). This row is closed) Premises: — Chapters: 26-04, 26-05
6 **Frame decorrelation (the confinement side)** ◐	The correlations between the frames of containers decay uniformly in L. Taking the container to be the whole interior of a block, on a fixed T^2_L the nested inequality $\kappa_{\mathrm{cb}}(sR;L) \le \kappa_{\mathrm{cb}}(R;L)^{s^2}$ holds with constant 1 for all L, R, s	Paper Nested Supermultiplicativity Lemma (nested supermultiplicativity. It uses only the Markov property and the nested form of Mack–Petkova, and does not use reflection positivity. Lean LatticeGaugeNestedBlocks (`nested_supermultiplicative`) is an abstract form on a finite probability space; the Markov property is outside Lean). With L fixed, reflection positivity of z and the chessboard replace it by a single density κ_{cb} (Proved here, L fixed). The chessboard is used only in the step that descends from κ_{cb} to a single container and Wilson loops / Assumption the comparison across L (lateral comparison of the chessboard density)	Writing the reduction of 26-02 with $\kappa_{\mathrm{cb}}(L)$ instead of θ gives $C_D = 1$, and the part uniform in L does not remain as an independent assumption Paper. What remains is the comparison across L (lateral comparison of the chessboard density) $\kappa_{\mathrm{cb}}(R;L') \le C(L'/L)^2\kappa_{\mathrm{cb}}(R;L)$, which is the lateral-widening inequality read in terms of κ_{cb}. There is no nesting sideways (tiling T^2_{2L} with four copies of T^2_L makes the twist even, and transverse reflections are not positive because of the twist), so this comparison sits in the same place as the renormalisation comparison. Split into columns, it becomes the same problem as one of the faces of the middle of the renormalisation comparison (twist cost of a column). If the base point at small T^2 is kept in terms of θ, a one-scale row $1 - \kappa_{\mathrm{cb}}(L_0;L_0) \ge \eta(1 - \theta(L_0;L_0))$ is needed. Placing the paper (the Nested Supermultiplicativity Lemma, and the reduction written with κ_{cb}) in the book Premises: reflection positivity of z (only the descending step) Chapters: 26-02, 26-05

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
7 **Renormalisation comparison** (the core of the band) □	The vortex free energy at side $2N$ and coupling β is at most a constant times that at side N and coupling β', with $\beta' < \beta$. Non-perturbatively, for every β	Six rows of breakdown	An estimate with the error kept within a constant factor, for every β. An argument that closes the band must be able to distinguish U(1) (U(1) has a transition inside the band, at $\beta_c \approx 1.01$). The construction published on 2026-11-10 gives no handle inside the band (it carries every step at weak coupling and stops at the lattice of spacing 1). At the weak end there is a non-perturbative input that "the finer the step, the weaker the coupling", but it is a statement about the coefficients of the effective action, and it works only where the coefficients are very large (coefficients of about 9×10^5 or more, at very weak coupling). It is not the "input that distinguishes U(1)" needed in the middle of the band (Volume 2) Premises: reflection positivity of z, frame decorrelation Chapters: 26-06
Strong-coupling end of the renormalisation comparison ■	The range $\beta \lesssim 10^{-79}$	Assumption (there is a proof in the record. The constants are crude and the bookkeeping is a sketch, so it stays Assumption until the paper is placed in the book)	Writing out the steps, and improving the constants. In the strong-coupling window (β about 10^{-3} or less), this book's Lean has the area law and a vortex floor whose rate per area does not depend on the transverse size (20-06; the lattice spacing is fixed and the prefactor remains; it is not the renormalisation comparison itself) Chapters: 26-06
Lower end of the renormalisation comparison □	Pushing confinement and the comparison up to $\beta \approx 0.3$–1	Assumption	A finite-size criterion by mixing of box magnetic flux, and computer assistance (a certificate with interval arithmetic) The computer-assisted chain for the hierarchical model is a theorem about the Migdal–Kadanoff image itself, and Tomboulis's representative (the image shrunk uniformly) is pushed up in the transverse coordinate by at least (5/3)(1−α) in one step and leaves the tube, so it cannot be used as it stands as a tool for the lower end of the renormalisation comparison either Proved here (the note in 15-04 § 05) Chapters: 26-06, 15-04

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
Middle of the renormalisation comparison □	One inequality that uses non-commutativity. Any one of the four faces (softness in the twist direction, mixing of box magnetic flux, twist cost of a column, pressure margin), uniformly in the scale	Assumption (none of the faces is proved)	A proof in a form that fails for U(1) What is proved in Tomboulis's sandwich (arXiv:0707.2179) is an upper and lower inequality for a single number, the partition function; the step needed for the form of the renormalisation comparison, "representing the partition functions with and without a twist by the same representative (a common interpolation parameter)", is not proved (K. R. Ito and E. Seiler). This step must become false for U(1), and sits in the same place as the middle of the renormalisation comparison Cited Proved here Reading A candidate for the fifth face (the proposal of a one-step inequality with a fixed partner of comparison): the string tension of the one-step Migdal–Kadanoff image does not exceed the string tension of the genuine coarse theory, $\sigma[T_{\mathrm{MK}}w] \le 4\sigma[w]$. In the leading strong-coupling term and in the one-loop asymptotics the directions agree, and it has a form that fails for U(1) at the step where the MK image enters confinement first. Inside the band it is unknown, and it has not been shown at any β Assumption (an idea) On finite boxes the threshold of the proposal of a one-step inequality with a fixed partner of comparison is 1 ($R := \Delta F(\mathrm{coarse}; T_{\mathrm{MK}}w)/\Delta F(\mathrm{fine}; w) \ge 1$. ΔF is dual to σ, and the genuine one step preserves ΔF) Proved here . Over one step of the orbit, $4^4/2^4$ is $R = 1.34(7)$ and $6^4/3^4$ is $R = 1.17(20)$, within the resolution, so no verdict is given. There is neither evidence of failure nor numerical support for the side where it holds. It is a weak test that even the do-nothing map passes, and the failure for U(1) does not appear in a one-step box Reading (15-04 § 05) Chapters: 26-06, 26-10, 15-04
Upper end of the renormalisation comparison ◐	Semiclassics at fixed N and large β	Assumption the confinement direction (the Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3) of the draft paper: at fixed N, $-\ln\theta \ge c\beta - a_e - \beta(S_*+\varepsilon)M^2$. No proof is placed in this book. A proof with citations is in the paper: the general chessboard theorem and the Morse–Bott argument are cited) / Assumption the converse uniform in M, and $S_* = S_{\min}$	A uniform bound in the converse direction (already reduced to a single positivity lemma), and agreement of the minimal actions Chapters: 25-02, 26-06
One-loop end of the renormalisation comparison ■	With the comparison that reshapes the fluctuations, $\beta - \beta' = 0.258$. With the comparison that keeps the shape of the fluctuations, $\beta' \ge \beta + 0.023$ (the anti-asymptotically-free direction)	Proved here (at the one-loop level; not a non-perturbative claim) / Reading the direction of the numbers (SU(2) has $\beta' < \beta$ throughout the band; for U(1) the sign flips at $\beta_c \approx 1.01$. Lattices, seeds and errors in 26-09)	Making it non-perturbative is ultraviolet control and the middle of the renormalisation comparison Chapters: 25-07, 26-09

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
Band in the language of the coupling (mixed derivative) ☐	In a box of side L with a uniform background holonomy (angles α, γ) at the two ends in time (the Schrödinger functional box), the mixed derivative $M = \partial^2 \ln Z / \partial\alpha\,\partial\gamma$, normalised to β at tree level as M_R, satisfies $M_R(2L) \le (M_R(L) - \delta)_+$ on the interval of the band, or $-\Delta \ln M_R / \Delta L^2 \ge \sigma_0 > 0$ (δ, σ_0 independent of the lattice spacing). M drops exactly the terms that depend on one boundary only, and measures the free energy of the electric flux running through from bottom to top (the dual of the vortex of the middle of the renormalisation comparison) Reading . What is measured is the difference D_R over two values of γ. The difference $h := \beta_R - D_R$ from the coupling of the same box, $\beta_R = 4/\bar{g}^2$ (the derivative at the single point $\eta = \pi/4$), is the marker of the one-sided terms Ultraviolet: M_R has the same one-loop running $-8b_0 \ln(L/a)$ as β_R (at one loop on the lattice the coefficient is 1.009 times), and its doubling step is 0.2575, the same as for β_R. Only the constant differs, $M_R - \beta_R = +0.21$; this difference comes entirely from the charged fluctuations and is 0 for $U(1)$ Cited Computed Band: h has the form of a function of $\bar{g}^2$; it turns positive at $\bar{g}^2 \approx 4.5$, has its maximum 0.14–0.18 at 5–10, falls to 0 at 60–140, and is slightly negative (-0.01–-0.03) on the strong-coupling side. All 36 points with $L/a = 3$–8 lie on one curve, pointwise within 2σ Computed Strong coupling: for fixed $L \ge 4$, below the convergence region of the expansion ($\beta < \beta_0(L)$), $h < 0$. The leading term is the one-sided band term $-(8/s)u^{3L} \approx -(16/\pi)L^2 u^{3L}$ ($u = I_2(\beta)/I_1(\beta)$, $s = \sin(\pi/2L^2)$); it does not enter D_R), and the term of the tube joining top and bottom is also negative Paper Lean (StrongCouplingOneSidedTerm, 9 theorems. Assumptions: the remainder $\lvert R\rvert \le C_L u^{3L+1}$, $\sin x > x - x^3/4$, the tree normalisation $\hat{D} \le 3$ of D_R, the coefficients on paper). Convergence of the expansion is Cited (Osterwalder–Seiler). A β_0 uniform in L is not yet done	Assumption (the band inequality is not shown at any β) / ultraviolet Cited Computed / band Computed / strong coupling Paper Lean (convergence Cited)	A non-perturbative proof of the inequality on the interval of the band. Distinguishing $U(1)$ takes the shape of $h(\bar{g}^2)$, not the size of h: for $U(1)$, $h \approx 0$ deep in the Coulomb phase and in the confined phase ($\lvert h\rvert \le 0.023$ at 11 of 12 points), with a peak only at one point inside the width of the transition of the finite box (0.35 at $L/a = 4$, still 0.29(4) at $L/a = 8$); for $SU(2)$ the peak lies on a band of width $\bar{g}^2 \approx 5$–10 Computed Reading . The one-loop ultraviolet difference +0.21 is also 0 for $U(1)$ Computed (the computation record (2026-10-23 to 10-28)) The Schrödinger functional box and the coupling $\bar{g}^2$ are as defined by Lüscher–Narayanan–Weisz–Wolff (hep-lat/9207009) Cited Premises: ultraviolet control (the coupling at the ultraviolet end) Chapters: 26-06, 26-09
8 **Band comparison (in the language of the gap)** ☐	For the dimensionless quantity $x(L) = L\,m_0(L)$, the lowest mass $m_0(L)$ of the neutral sector of the box measured by the size of the box, the doubling map has no fixed point on the interval of the band: $x(2L) \ge x(L) + \delta$, with δ independent of the lattice spacing	Assumption / Paper In the Coulomb phase of U(1), x stays at the photon value $x^* \approx 2\pi$, so the band comparison (in the language of the gap) fails. The ratio-of-rates form $m_0(2L) \ge (\frac{1}{2} - \varepsilon) m_0(L)$ ends up holding on periodic boxes for U(1) ($m_0(2L)/m_0(L) = 1/(2\cos(\pi/2L)) > \frac{1}{2}$), so it is not a form that distinguishes the groups	A proof in a form that fails for U(1). Of the four faces of the middle of the renormalisation comparison, the two that also work in the language of the gap are κ_w (softness in the twist direction) and $\delta(L_0)$ (the total-variation distance inside when the centre flux on the boundary of the box is changed), extended to all boundary conditions; as a new face, one step function of x is added. The phases to be excluded are a massless phase and first-order coexistence; the non-confining phase of $\mathbb{Z}_2$ (which also has a gap) need not be excluded. The Tomboulis–Yaffe inequality holds for U(1) by the same proof and is a tool that descends to the charged sector, so it is not a tool for the band comparison (in the language of the gap) Reading . Since it can be written in a language that does not use the centre, it can be defined even for the groups without a centre among general groups Premises: ultraviolet control (the coupling at the ultraviolet end is placed at the finite value that ultraviolet control hands over) Chapters: 26-06

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
9 **Uniform decay of block observables (the gap side)** ☐	For block observables F, G with vacuum expectation 0 (their supports a distance t apart), $\lvert\langle FG\rangle_{a,L}\rvert \le C_F C_G\, e^{-mt}$, with $m > 0$ independent of a and L. The form of the gap of the small-T^2 gap uniform in L (the task of a uniform gap in 16-07)	Assumption / Paper Uniform decay of block observables gives the mass gap under the limit to R^4 (the content that the arrow of the R^4 gap in 27-01 asks of the uniform slab gap has this form, and frame decorrelation is not enough) / Cited uniform exponential decay under arbitrary boundary conditions gives the area law (Chatterjee 2021, CMP 385, Theorem from Uniform Decay to the Area Law (Theorem 2.4 of Chatterjee 2021); on the lattice)	The band comparison (in the language of the gap), and carrying the small-T^2 gap uniformly in L. Positivity of the 't Hooft tension is the band in the language of confinement, and even if the base point at small T^2, frame decorrelation and the renormalisation comparison disappear, uniform decay of block observables does not move. On the side of time, uniformity of the relaxation-time upper bound and the one-sided bridge is a row of the same type Premises: ultraviolet control, small-T^2 gap, band comparison (in the language of the gap) Chapters: 27-01, 16-07
10 **Positivity of the 't Hooft tension** (the band in the language of confinement) ☐	$\ln(1/\theta(L,L)) \ge cL^2$, with c independent of L (the 't Hooft string tension is positive)	Proved here the reduction from the base point at small T^2, frame decorrelation and the renormalisation comparison (the algebra of the iteration in Lean: Doubling (`Doubling.iterate`)). In the form written with κ_{cb}, the chessboard-density base point and the lateral comparison of the chessboard density, the same iteration goes through with $K = 4C$ (Lean: LatticeGaugeNestedBlocks (`doubling_iterate`)) / Assumption the band itself	The base point at small T^2, frame decorrelation and the renormalisation comparison disappearing, and the paper for the reduction being placed in the book. Positivity of the 't Hooft tension is the band in the language of confinement; the mass gap needs uniform decay of block observables separately. Intermediate milestones: (a) exclusion of a deconfined phase, (b) $\ln(1/\theta) \ge cL^2/\ln L$ Premises: base point at small T^2, frame decorrelation, renormalisation comparison Chapters: 26-01, 26-02
11 **Uniform gap of the double well** (what remains of the first step) ☐	For the path measure of the 0+1-dimensional double well, a gap uniform in k and $\hbar$ for chain length $k \ge 8$ (a uniform logarithmic Sobolev inequality for a measure with non-convex regions). The band in miniature	Assumption . The convex side (length ≤ 7) and the uniqueness of the minimum are closed in the record (the section that places them in the book is a supplement to 23-15)	Closing the rows of 23-15 Table 1 in a form uniform as $\hbar \to 0$, or stitching finite blocks together with strong mixing The side $\hbar \to 0$ (the small-ħ remaining item) reduces to showing, as $\hbar \to 0$, one margin among the inputs of the Six-Node In-Phase Poincaré Proposition, $\hbar\rho - 2\hbar\kappa \ge 0.067$ Paper . The two limiting conditions (the bridge landscape: the global minimum is unique and interior, with $\lambda_{\min} \ge 0.2$ and $\kappa_0 \le 0.1282$; the coarse landscape: $U_0''(t^*) \ge 1.943$) are checked with interval arithmetic, and the limit of the margin is at least 0.758 Computer-assisted (the action gap is in floating point Reading). To overlap with the range of the record ($\hbar \ge 0.005$), the quantitative uniform Laplace method and a lemma on one-dimensional Muckenhoupt asymptotics on the side of $\hbar\rho$ are newly needed Assumption . The value of $\hbar_0$ expected from the quantitative uniform Laplace method is 4×10^{-4}–8×10^{-4} Reading (the computation record (2026-10-22)) For $\hbar \in [0.001949, 0.005]$, the margin of the lattice target level $\hbar\rho - 2\hbar\kappa \ge 0.067$ holds by interval arithmetic on six subintervals Computer-assisted (the arithmetic on the subintervals and the logic of the covering are Lean : LatticeGaugeH1HbarInterval, 15 theorems). The gap to the $\hbar_0$ of the quantitative uniform Laplace method is not yet done; from the next subinterval on, the estimate of the corner tail does not close with this computing machinery, and the machinery has to be replaced (keeping the weights as logarithms, or revisiting the estimate of the corner tail) Reading (the computation record (2026-10-24 to 10-28)) Premises: — Chapters: 23-09 § 06, 23-15, 26-07

Row	What is to be shown (with its conditions in the same row)	Label	What is needed for it to disappear, premises, chapters
12 **Uniformity of the relaxation-time upper bound and the one-sided bridge** (the four-dimensional goal, side of time) □	The upper side of the diffusive-relaxation-time assumption (the relaxation-time upper-bound assumption, $CP \le K\xi^2$) and the one-sided bridge, uniform as $\beta \to \infty$ (the physical-unit target level of 23-15 Table 5)	Assumption	Crossing the band in the language of time. Even if the uniform gap of the double well disappears, the uniformity of the relaxation-time upper bound and the one-sided bridge does not move (the uniform gap of the double well is a miniature, not an implication) Premises: ultraviolet control Chapters: 23-01, 23-15 § 07, 26-07

What to read from Table 2. (a) The rows marked ■ in the record are only reflection positivity of z and two rows of the breakdown of the renormalisation comparison (the strong-coupling end and one loop). For reflection positivity of z the proof has been placed in 26-04 § 03, and the algebra of the last step is also closed in Lean (ReflPos), so this row is closed. The two rows of the breakdown have not yet disappeared by the rule of § 01. (b) Non-abelian dynamics enters at the middle of the renormalisation comparison (and at frame decorrelation and positivity of the 't Hooft tension, which gather into it), and this row has a form that correctly fails for U(1) and $\mathbb{Z}_2$. The other rows are structural facts, or rows that depend on ultraviolet control. (c) The weak form of positivity of the 't Hooft tension (the weak form of the lateral-widening inequality, the uniform slab tension) has almost the same content as the band. We read the reduction not as having made the problem easier but as having pinned down the middle of the renormalisation comparison as the place where the non-abelian input is needed. (d) Uniform acceptance of insertion, the base point at small T^2 and frame decorrelation are conditional (◐) rows, but their content has not disappeared; it has moved to other rows. Uniform acceptance of insertion is the same as the conjunction of boundedness of the insertion free energy and the uniform lower bound on the path overlap, and contains the base point at small T^2; the base point at small T^2 splits into the two rows ultraviolet control around a vortex background and insertion acceptance in a symmetric container; and the part of frame decorrelation uniform in L moves, as the lateral comparison of the chessboard density, to the same place as the renormalisation comparison. (e) Even if positivity of the 't Hooft tension, the band in the language of confinement, disappears, uniform decay of block observables remains for the mass gap. That the two roads stop at the same band is right as a type, but they arrive at different sectors.

04

The diagram of dependencies between rows — the numbers of premises are smaller than those of conclusions

Figure 1 writes the dependencies between the rows of the ledger and the rows outside it, split into layers. Arrows point from premise to conclusion, and every row has a larger number than its premise rows. The rows of the ledger are written in forms whose statements do not contain the quantities of the conclusion (the gap on $\mathbb{R}^4$, the area law on $\mathbb{R}^4$) (the assumption rows ultraviolet control, uniform acceptance of insertion, frame decorrelation, the middle of the renormalisation comparison, the band comparison (in the language of the gap), uniform decay of block observables, and uniformity of the relaxation-time upper bound and the one-sided bridge). The assumptions in forms that contain the quantities of the conclusion (the assumption of the arrow of the small-T^2 gap and the forms of the band) are marked explicitly as "restatements" in 27-01 (assumptions of arrows that restate uniform decay of correlations as a gap, and uniform bias and tension as an area law). Positivity of the 't Hooft tension is the band itself and contains a quantity close to the conclusion of the conditional statement. We put positivity of the 't Hooft tension in the ledger to show, in one row, the road to removing it once the reduction (from the base point at small T^2, frame decorrelation and the renormalisation comparison to positivity of the 't Hooft tension) is on paper. There are no exceptions to the numbering rule.

```
Layer 0   1 ultraviolet control ◂                5 reflection positivity of z ■

ultraviolet control in arbitrary volume = ultraviolet control + extensive extension to arbitrary volume + continuity in
(the rows outside the ledger include parts that the published construction showed, in the form from a sequence of period

First road   12 uniformity of the relaxation-time upper bound and the one-sided bridge □ (← 1). The row of the same type
             11 uniform gap of the double well □ is 12 in miniature (not an arrow of implication)
```

Figure 1 Dependencies between the rows (to the right of ← are the premises). The base point at small T^2 and the upper end of the renormalisation comparison stand on the same semiclassical picture, but this is not an arrow of implication, so it is not in the figure. Uniform acceptance of insertion ⇒ base point at small T^2 follows in one line, but the relation is that uniform acceptance of insertion contains the base point at small T^2, so the figure only puts uniform acceptance of insertion among the premises of the base point at small T^2. The premises of uniqueness and non-triviality of the limit are, as written in 16-07, positivity of the 't Hooft tension and tying the two roads together; since the gap side of tying the two roads together has been moved to uniform decay of block observables, we write positivity of the 't Hooft tension and uniform decay of block observables Reading . "Area law ⇒ mass gap" is not set up as an arrow (§ 05).

05

The differences that remain outside the ledger — what remains even when every row has disappeared

Separate frame

Even if all twelve rows of the ledger disappear, four differences from the requirements of the problem statement (Jaffe–Witten 2000, 0-03) remain (the limit to R^4 [split into four rows in Table 3], tying the two roads together, general groups, verification and peer review; seven rows with the breakdown). An empty ledger does not mean that the problem is solved.

Table 3 The differences that remain outside the ledger (the correspondence with the tasks of 16-07 is this book's arrangement)

Row	Difference	Mark	Present state	16-07
Limiting measure on R^4 and its positivity	Of the limit to $\mathbb{R}^4$, the limiting measure, translations, preservation of reflection positivity, the Hilbert space and $H \geq 0$	◐	Assessment Infinite volume from a sequence of periodic boxes (along a subsequence) and the reconstruction were shown by the published construction (the Wightman axioms phase by phase; there is no convergence or uniqueness of the limit; Volume 2) / Assumption The reduction from the family of twisted slabs of this book's road is open. Its conditions are ultraviolet control in arbitrary volume (ultraviolet control extended to arbitrary volume with extensive constants) and continuity in the sources uniform in the lattice spacing and the volume. The rest is known argument (compactness, preservation of inequalities under weak limits, a symmetric contraction semigroup) Cited . The statement of ultraviolet control alone is not enough: no source derives, as a theorem, boundedness uniform in a of the expectations of gauge-invariant observables Cited	Task toward infinite volume
Rotation invariance	Recovery of rotation invariance	☐	It is present within the reconstruction of the published construction (Volume 2). From the family of twisted slabs of this book: it does not follow from invariance under the hypercubic group and continuity. What is needed is a lemma that the limits of regularisations with rotated lattice orientations agree, or a direct estimate that the breaking vanishes as $a \to 0$; neither ultraviolet control nor positivity of the 't Hooft tension promises it. The reflections of reflection positivity of z are positive only in directions 3 and 4, and reflection positivity in directions 1 and 2 comes only from rotation invariance Reading	Task of the remaining axioms
Local fields and OS regularity	Local fields and OS regularity, the linear-growth condition (Osterwalder–Schrader axiom E0′) (Wightman fields)	☐	It is present within the reconstruction of the published construction (Volume 2). From the family of twisted slabs of this book: renormalisation of composite operators and their uniform estimates	Task of the remaining axioms, task of local fields and short distances
Uniqueness and non-triviality of the limit	Uniqueness of the limit, non-triviality, clustering	☐	The published construction has no convergence or uniqueness of the limit. Clustering and a unique vacuum are on the side of decay uniform in the volume (uniform decay of block observables) and of positivity of the 't Hooft tension. Uniqueness is not required on our reading of the problem statement, but it is needed on the road that derives the recovery of rotation invariance from uniqueness. That the two roads give the same theory is also included here	Task of non-triviality
Tying the two roads together	Tying the two roads together: stating both the mass gap and confinement on the same theory on $\mathbb{R}^4$	☐	The area law alone does not give the gap (16-09 § 03). The gap side (the form "carry the gap of the small-T^2 gap through the band to $\mathbb{R}^4$ with the same constants") has been moved to uniform decay of block observables in the ledger, and "the same theory" is included in uniqueness and non-triviality of the limit. What substantively remains is the consistency of scales $0 < \inf m/\sqrt{\sigma} \leq \sup m/\sqrt{\sigma} < \infty$ (along the same sequence $\beta \to \infty$); this is a condition for stating confinement in physical units, and lies outside the requirements of the problem statement (what the problem statement asks for is the mass gap Cited). In three-dimensional U(1) there is an example in which both hold on the lattice and yet the ratio goes to 0, so the condition is not empty Cited (summary)	Task of one scale

Row	Difference	Mark	Present state	16-07
General groups	All compact simple groups	☐	Existence was shown by the published construction for every compact simple group (Volume 2). The vortex tools cannot be used for groups without a centre. On the mass gap: for SU(N), it is expected that the rows can be turned into conditional ones Reading . The places specific to SU(2) are of four kinds, of which two need redoing: the properties of SU(2) = S^3 (the conditional law of one link being one-parameter, the explicit formula of the heat kernel, the Heat-Kernel Fluctuation Rarity Lemma), and -1 lying in the Weyl group (a cubic treatment replacing the evenness of class functions). On top of these comes redoing the numerics of 26-09 for SU(3) (on top of ultraviolet control and the renormalisation comparison, which are open for SU(2)). What gets filled: the twist by the centre $\mathbb{Z}_N$ (for primitive twists the clock-and-shift pair is unique up to conjugation Cited (González-Arroyo, arXiv:hep-th/9807108 § 4.2); the adjoint gap is $4\sin^2(\pi/(NL))$, agreeing with the numerics for SU(3) at $L = 3$–6 Reading (the computation record (2026-10-22)); one loop gives $\beta - \beta' = 11N^2 \ln 2/(12\pi^2)$ Paper), the n-colour version of the colour lemma (Lean ColorAverageN (`colorAverage` , `design_identity`); no assumptions, including the existence of the weighted quartic design; the application to su(N) is on paper), and the SU(N) version of the Tomboulis–Yaffe inequality Cited (Kanazawa, arXiv:0808.3442 Theorem 2; its application to the slabs of this book is not done). All compact simple groups remain open: for groups without a centre (G_2, F_4, E_8), neither the vortex tools nor the arrows that use the centre can be used Cited (16-07 § 07), and for Sp(n) ($n \geq 2$) the centraliser of the pair that absorbs the twist is continuous, so a single twist on T^2 does not remove the zero modes Reading	16-07 § 07
Verification and peer review	Verification	☐	Writing out the whole, Lean (as far as it reaches), expert refereeing, publication. The rules of the prize require refereed publication followed by a period of acceptance	—

The differences outside the ledger are not put in the ledger because they are not conditions of the conditional statement (27-01) but the distance between the conclusion of the statement and the requirements of the problem statement. The rows of the ledger are "work of removing assumptions"; the rows outside are "work of carrying the conclusion as far as the problem statement". If the two were mixed in one table, then on the day the ledger became empty it would read as if the problem had been solved. The gap side of tying the two roads together (crossing the band in the language of the gap) is a condition of the same type as the assumption of the arrow of the R^4 gap in 27-01, so it has been placed inside the ledger as uniform decay of block observables.

What is not set up as an arrow. "Area law ⇒ mass gap" is kept as a physical expectation, read as Reading , and is not made an arrow of Figure 1. From reflection positivity and the area law alone it is false (the direct product of a lattice measure with an area law and U(1) in the Coulomb phase keeps reflection positivity and the area law and has no gap Paper ; no counterexample within simple groups is known). The theorem known on the lattice goes the other way: uniform exponential decay under arbitrary boundary conditions gives the area law Cited (Chatterjee 2021 Theorem from Uniform Decay to the Area Law, Durhuus–Fröhlich 1980). In the language of the transfer matrix, the area law is the gap of the charged sector with electric flux, and the mass gap is the gap of the neutral sector without electric flux.

06

The day rows increase — the ledger is not a table that only shrinks

As research advances, rows disappear, but they can also increase. For example, when the reduction of the band was worked out, the lateral-widening inequality split into two rows, a strong form and a weak form, and it turned out that the strong form is stronger than confinement (it contains monotonicity of the slab tension). When the renormalisation comparison was worked out, two new rows appeared, the strong-coupling end and the one-loop end, and the middle row split into four faces. When tying the two roads together was reviewed, two rows that cross the band in the language of the gap, the band comparison (in the language of the gap) and uniform decay of block observables, appeared inside the ledger, the row of frame decorrelation became the row on the confinement side, frame decorrelation, and the limit to R^4 split into four rows. Writing out the assembly of the vessel (the vessel stage) has no row for now, but a row may appear at the stage of writing it out.

So the number of rows of this ledger, laid out over time, is not a gauge of progress. What to read is the content of each row, and what is needed to remove it.

The current list of premises is in 28-04.

What this chapter can say

What is said	What is not said
The list of conditions of the conditional statement, and for each row its state in the record, its label, and what is needed for it to disappear (Table 2)	The proof of any row. This chapter adds no new results

What is said	What is not said
Proved here the reduction to positivity of the 't Hooft tension, reflection positivity of z, the twist part of the small-T^2 gap, the confinement direction of the upper end of the renormalisation comparison, the one-loop level of the one-loop end of the renormalisation comparison (within the conditions written in the rows)	Positivity of the 't Hooft tension itself, the non-perturbative form of the renormalisation comparison, ultraviolet control, the uniform lower bound on the path overlap, the lateral comparison of the chessboard density, the band comparison (in the language of the gap), uniform decay of block observables
Paper the sandwich of acceptance rates in uniform acceptance of insertion, the Lemma on the Upper Bound for the Minimal Action of a Symmetric Box in the base point at small T^2, the Nested Supermultiplicativity Lemma in frame decorrelation, the reduction of the small-ħ remaining item in the uniform gap of the double well (in the computation record; the paper proofs are not yet placed in the chapters of the book)	That these rows disappear by the rule of § 01
That there are four differences that remain even when every row of the ledger has disappeared (the limit to R^4 [split into four rows in Table 3], tying the two roads together, general groups, verification and peer review; seven rows with the breakdown) (Table 3)	That an empty ledger would mean the problem is solved (this cannot be said; the differences outside the ledger remain)
That, of the limit to R^4, only the limiting measure and its positivity are connected by known arguments, on the condition of ultraviolet control in arbitrary volume	That ultraviolet control in arbitrary volume holds; rotation invariance; local fields and OS regularity; uniqueness and non-triviality of the limit
The arithmetic of the theorem names in the Lean column (the algebra of finite sums and the inequality of the iteration, the inequality of the sandwich of acceptance rates, the action of the abelian twisted configuration, the inequality of nested averages, the identity of the quartic design)	That the Lean column checks the statement of the row itself

Terms used in this chapter — the ledger, a row disappears, the marks of the state in the record (■◐□), the differences that remain outside the ledger, the renormalisation comparison, the four faces, the band in miniature, the diffusive-relaxation-time assumption. Their meanings are in the A-02 Glossary and the A-06 Index of names.

Next chapter to read: 27-03 The table of questions. The conditional statement itself is in 27-01.

The table of questions (a cross-index)

> This chapter is an index; it points to the relevant sections of each chapter.

What this chapter shows — The questions that the parts of this book left open, gathered into one index. The seventeen questions of Part 23, and the nineteen questions and six candidate rules of Part 24, are looked up by chapter and item number, without moving the items. The questions left by the text of Parts 25 and 26 are given running numbers per table on this page, listed with the section of the chapter they come from and the rows of the ledger of conditions they concern (the rows of 27-02 Table 2, and the differences outside the ledger). The two tables of "the next move" listed by the record of the study are also looked up in the language of the ledger rows.

Prerequisite chapters — 27-02 (the ledger of conditions; the numbers and names of the rows are fixed there). The content of the questions is in the chapters in the right-hand column of each row.

Said first — This chapter adds no new results. Questions are questions, not claims. The status of a question (done, partly done, not yet, new) and "what does not move even if settled" are kept only in the tables of the chapters they come from, and are not copied here. Whichever question is settled, the problem of the mass gap does not move. What moves is one row of the ledger, or one label in one chapter.

Order of this chapter

1. How to read the index — the five sources, the numbering convention, and the correspondence with the ledger rows (Table 1)
2. The questions of Part 23 (Table 2)
3. The questions and candidate rules of Part 24 (Tables 3 and 4)
4. Questions from Part 25 (Table 5)
5. Questions from Part 26 — the assumptions of the reduction of the band, criteria, β-monotonicity and more (Table 6)
6. The next moves listed by the record of the study — two tables looked up by ledger row (Table 7)
7. Looking up from the ledger rows — for each row, the questions that concern it (Table 8)

01

How to read the index — the five sources and the numbering convention

The questions have five sources. Table 1 gives, for each source, how the numbers are assigned and the table that the numbers point to. The numbers are those of the source chapter, used as they are and not renumbered on this page. Parts 25 and 26 do not yet have a chapter gathering their questions, so we pick up sentences in the form of questions from the sections "what cannot be said", "what remains" and "what is lacking" of the text of those parts, and number them on this page. The numbers are plain running numbers per table, without letters, and in the text questions are referred to by short names.

Table 1 The five sources of the questions

Source	Numbers	Count	Table to look in	How the size of a question is written
Part 23 (the first road, first half)	Running numbers 1–17	17	23-17 Table 3	Tools (SAT, paper, python3, interval arithmetic, Lean, literature) and the form of settlement
Part 24 (the first road, second half)	Running numbers 1–19, candidate rules 1–6 and three combinations	19 + 9	24-08 Table 1, Table 2	Kind of work (paper, reading, computation, Lean) and status
Parts 25 and 26 (the second road and the band)	Running numbers 1–16 of Tables 5 and 6	16 + 16	Tables 5 and 6 of this page	As in the sentences of the source sections. No estimate of size is written
Part 15 (ultraviolet control)	Running numbers 1–31	31	15-09 Table 1	As in the sentences of the source chapter (the conditions are in the tables of the source chapter)
"The next move" of the record of the study	Order 1–7 of the record's table, and order of work 1–4	7 + 4	Table 7 of this page	Looked up after replacing them with the language of the ledger rows

The names of the ledger rows are as in 27-02 Table 2 (the twelve rows from ultraviolet control to uniformity of the relaxation-time upper bound and the one-sided bridge, and the six rows of the breakdown of the renormalisation comparison). The differences outside the ledger are the limit to R^{4}, tying the two roads together, general groups, and verification and peer review (27-02 Table 3). The "rows concerned" column of the tables is written with row names.

The column "rows concerned" of the tables gives, as this book's arrangement, which ledger rows' content a question would touch if it were settled. Settling a question does not necessarily make a row disappear. A row disappears only when its paper proof has been placed in the book and, if it has a Lean entry, the re-check is done (27-02 § 01).

02

The questions of Part 23

The questions of Part 23 are "small questions" expected to be settled at the size of an undergraduate thesis. Table 2 lists only a one-line summary and where to look. The form of settlement and "what does not move when settled" are in each row of 23-17 Table 3. The assumption around which the questions of Part 23 turned is the diffusive-relaxation-time assumption (the upper side is the relaxation-time upper-bound assumption, the lower side the relaxation-time lower-bound assumption).

Table 2 The questions of Part 23 (summaries; the full text of each row is in 23-17 Table 3)

Q.	Summary	Tools	Rows concerned	Where to look
1	Does a complete family of $k = 3$ cells exist in $d = 9$?	SAT, Lean	— (the combinatorics of one-link integration)	23-17 Table 3, 23-02 § 02
2	The largest dimension in which a complete family exists, $d_{\max}(k)$	Exhaustive search, paper	— (same as above)	23-17 Table 3
3	The constants of $1 - \lambda_k$ for the Hermite family	Paper, python3	— (worked example)	23-17 § 05
4	The $SU(N)$ version, and the Lean statement, of the saturation of the ratio of functions on the forest	Paper, Lean	Uniformity of the relaxation-time upper bound and the one-sided bridge	23-17 Table 3
5	$CP(\beta)$ in the link variables of two-dimensional lattice Yang–Mills	Paper, python3	Uniformity of the relaxation-time upper bound and the one-sided bridge (control)	23-17 Table 3

Q.	Summary	Tools	Rows concerned	Where to look
6	The best constant of the curvature after one-link integration, $c^{*} \in [21, 27]$	Global optimisation, interval arithmetic	— (the strong-coupling side)	23-17 Table 3, 5-11
7	The coefficient of N^{-3} in the column model, analytically	Paper, python3	Uniform gap of the double well	23-17 Table 3
8	In the column model, the sign of $1/P$ at finite u	python3	Uniform gap of the double well	23-17 Table 3
9	How much does the shortfall c_{2} change with the choice of gauge in the block transformation?	python3	Uniformity of the relaxation-time upper bound and the one-sided bridge	23-17 Table 3
10	C_{P} and ξ^{2} of the two-dimensional $O(3)$ sigma model	python3, literature	Uniformity of the relaxation-time upper bound and the one-sided bridge (an asymptotically free control)	23-17 Table 3
11	C_{P}/ξ^{2} of the three-dimensional $\mathbb{Z}_{2}$ gauge theory	python3	Uniformity of the relaxation-time upper bound and the one-sided bridge (control)	23-17 Table 3
12	Monotonicity in volume of $C_{P}(V)$, and boundary conditions	python3	Uniformity of the relaxation-time upper bound and the one-sided bridge	23-17 Table 3
13	Collect the primary sources on the dynamical exponent of local algorithms for four-dimensional $SU(2)$	Literature	Uniformity of the relaxation-time upper bound and the one-sided bridge	23-17 Table 3
14	Bound from above, by interval arithmetic, the two-point maximal correlation of the medium-core step ($8 \le k \le 14$)	Interval arithmetic, paper	Uniform gap of the double well	23-17 Table 3, 23-15 Table 1
15	Read the power of the prefactor $\hbar^{-p}$ of C_{P} for the core by the capacity of the degenerate point	python3, paper	Uniform gap of the double well	23-17 Table 3
16	A comparison theorem showing the alternating maximal correlation between boxes $c_{\mathrm{alt}} < 1$	Paper	Uniform gap of the double well	23-17 Table 3
17	When a small term that breaks the conservation is added to a dynamics with conservation, the length at which the gap departs from the square of the side	Paper, python3	Uniformity of the relaxation-time upper bound and the one-sided bridge (the smallest model of Part 24)	23-17 Table 3

Reading Table 2. The questions that concern the row of the uniform gap of the double well (what remains of the first step) are the question "the N^{−3} coefficient of the column model", the question "sign of 1/P in the column model", the question "interval arithmetic for the maximal correlation of the core", the question "power of the prefactor for the core and window" and the question "comparison for the alternating maximal correlation of boxes"; the questions opened by "the road of blocks and mixing" in the supplement to Part 23 (the road of blocks and mixing in 23-15) are gathered in Table 6 of Part 26 as the question "two-sided area laws inside the band". The questions concerning uniformity of the relaxation-time upper bound and the one-sided bridge are questions of how to set up the statement of the diffusive-relaxation-time assumption on the side of the four-dimensional lattice; whichever of them is settled, uniformity of the relaxation-time upper bound and the one-sided bridge itself (the upper-bound assumption and the bridge, uniform as $\beta \to \infty$) does not move.

```

The questions and candidate rules of Part 24

The questions of Part 24 came out of the study that repairs the form of the statement of the relaxation-time assumption (the length at which conservation breaks, the sector and local versions, the form the one-sided bridge needs, the vacuum measure). Table 3 gives only summaries and where to look; the status (done, partly done, not yet, new) and "what moves and what does not move if settled" are in 24-08 Table 1.

Table 3 The questions of Part 24 (summaries; the full text of each row and its status are in 24-08 Table 1)

Q.	Summary	Size	Where to look (the section the question came from)
1	For the free field, compare the excitation energies of observables supported in the box	Paper	24-04 § 05
2	Monotonicity of the factor that cuts off times, $\varphi(x)/x^2$	Elementary, Lean	24-04 § 03
3	Whether the static ratio catches the slowness, for the sign of the Polyakov loop on a small periodic box	Small computation	24-01 § 02
4	For $U(1)$ on a two-dimensional layer, how the gap decreases as the strip-shaped region is lengthened	Computation	24-02 § 03
5	Primary sources on the autocorrelation of the topological charge in pure $SU(2)$ gauge theory	Reading, computation	24-07 § 07
6	A many-family version of the Two-Projection Lemma, and its condition on maximal correlation	Paper	24-03 § 06
7	$\inf \operatorname{Hess} V_t$ of the one-link Wilson weight convolved with the heat kernel, and the flow of the weight of the bad set	Paper + small computation	24-06 § 07
8	For Wilson's transfer operator, show the time-step comparison assumption ((D) in the paper "one-sided bridge") restricted to functions cut off at low energy	Paper	24-04 § 08
9	For finite-state reversible Markov chains, close in Lean $\tau_{\mathrm{int}} \le C_P$ and the identity of the ground-state transformation	Lean	24-05 § 01
10	Reread the autocorrelations of local modes and topological modes in two-dimensional CP^{N-1} through the eyes of the local version	Reading, computation	24-02 § 07
11	For two-dimensional $SU(2)$, find λ_W and Γ of families of loops at finite β	Computation	24-04 § 06
12	On a four-dimensional box, the values for families of loops the size of the span	Computation	24-04 § 06
13	For the 0+1 double well, sandwich the local ratio by a reduction to one dimension with the position of the kink as coordinate	Paper + small computation	24-04 § 07
14	Add one point $\beta = 7$ for the two-dimensional strip-shaped region, and see whether the slope settles	Computation	24-02 § 05
15	For fields whose ratio lies between the threshold and 1, another argument that sees the mass while staying in the ratio form	Paper	24-04 § 06
16	On Wilson's lattice with discretised time, write the version of the bridge that cuts off times (the In-Window Supremum Proposition and the lower bound in finite volume) under the time-step comparison assumption	Paper	24-04 § 03

Q.	Summary	Size	Where to look (the section the question came from)
17	Whether the Kogut–Susskind Hamiltonian becomes frustration-free when it is split with terms grouped by sector	Paper	24-05 § 04
18	On the CP^{N-1} test bed, add seeds and pairs of N, and read the exponent of the slowness of the topological mode	Computation	24-02 § 07
19	Measure the definition (2) of the length at which conservation breaks with the charge of a four-dimensional subregion	Computation	24-02 § 01

The summaries of Table 3 are shortened from the sentences of the source table. The terms of Part 24 "window factor" and "window version of the bridge" are restated here as "the factor that cuts off times" and "the version of the bridge that cuts off times", so that they are not confused with the band of Part 26 (note on terms: 26-00 § 02). The "strip-shaped region" of the question "U(1) gap on two-dimensional layers" and the question "the single point β=7 of the band" is a width-2 region of a two-dimensional lattice, a different thing from the crossover band. In terms of ledger rows, only the question "reduction to kink positions" touches the uniform gap of the double well; the others are questions that repair the form of the statement of uniformity of the relaxation-time upper bound and the one-sided bridge.

The candidate rules are candidates for the question "if we were to make new mathematics, what would we put as rules?", and each has one question attached (24-08 Table 2). Table 4 lists only the symbol, the name of the rule and where to look. The relation to the three roots of the third step is in 24-08 Table 3.

Table 4 The candidate rules (the one-line candidate and its question are in 24-08 Table 2)

Symbol	Name of the rule	Section where the candidate came from
1	Axiomatising scale	24-07 § 06
2	The algebra of loops	24-07 § 06
3	Conserved quantities and sectors	24-03 § 04
4	The class of measures that pay with rarity	24-06 § 07
5	An axiom of asymptotic freedom	24-07 § 06
6	Curvature rule (Bakry–Émery on the space of orbits)	24-07 § 06
1+4, 3+4, 2+3	Three combinations	The three rows at the bottom of 24-08 Table 2

Seen from the study of Parts 25 and 26, among the candidates the axiom of asymptotic freedom and axiomatising scale sit closest to the problem of the band. In the statements that cross the band, the place where asymptotic freedom enters is narrowed to one (the $\beta' < \beta$ of the renormalisation comparison, 26-06 § 01), and the question of the axiom of asymptotic freedom (what follows from the rule of approaching a free field in the ultraviolet) becomes a question of restating that one place in the language of rules. This is an estimate of position; none of the candidates promises a prospect of crossing the band Reading (a physical estimate).

04

Questions from Part 25

These are the questions that the text of Part 25 (the second road: from the direction of space) left open. The sentence in each row is the sentence of the source section shortened into the form of a question, with its conditions kept in the same row. The group is $SU(2)$, and the small T² carries the 't Hooft twist $n_{12} = 1$. The questions from the three chapters 25-06 to 25-08 (driven insertion, fixed maps, the measured record)

are the five rows at the bottom of the table (from the question "kernels with flip probability near 1" to the question "extending the measurements and their errors").

Table 5 Questions from Part 25 (the rows concerned are rows of the ledger of 27-02; this book's arrangement)

Q.	Question (with its conditions in the same row)	Rows concerned	What does not move even if settled	Source
1 Reverse direction of the fractional-instanton lower bound	The converse of the Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3): at fixed N, an upper bound by a dilute gas uniform in M (a bound on the string tension from above). In the draft it is reduced to a single positivity lemma	Upper end of the renormalisation comparison	A bound uniform in N, the continuum limit	25-02 § 06, A-07 § 06
2 Agreement of the minimal actions	Agreement of the minimal actions $S_*(N,\ell) \to S_{\min}(N,\infty)$ (the minimal action of a column with its frame frozen to the vacuum, and the minimal action of a free fractional instanton). The numbers agree to five digits (a reading)	Upper end of the renormalisation comparison	Same as above	25-02 § 06
3 Existence of fractional instantons	On the twisted $T^2 \times \mathbb{R}^2$, existence of a solution of topological charge $\frac{1}{2}$ attaining the lower bound $4\pi^2/g^2$ of the action (at present an outline with assumptions)	Base point at small T^2	The rate on the lattice, the band	25-02 § 02, § 07 (c)
4 SU(N) versions of the three facts	The $SU(N)$ version of uniqueness of the vacuum that absorbs the twist, the gap of the adjoint field, and the absence of flat configurations in the (1,1) sector	General groups	Groups without a centre	25-01 § 09 (c)
5 Bias of the outer container	The second term when moving to a fixed sector: that the bias of the outer container is typically small (0 as $M \to \infty$)	Frame decorrelation	A uniform estimate of the container free energy	25-03 § 04, § 08 (b)
6 Estimating the container free energy	Estimate the container free energy ΔF_j uniformly over good frames and uniformly in the lattice spacing (needs a multiscale analysis of the conditional measure with the frame held fixed)	Ultraviolet control, frame decorrelation	The band (the stage of widening sideways)	25-03 § 08 (e)
7 Cost of inserting a thick vortex	With the map of a thick vortex, bound the cost of the insertion independently of N (an improvement of the Slab Confinement Theorem towards the continuum limit; at present an outline, Assumption)	Ultraviolet control, uniform acceptance of insertion	The band	25-04 § 04, § 07 (c)
8 Gap from insertion to the area law	The three things lacking between the insertion estimates and the area law: (i) that the event that insertions are refused simultaneously in all cells is exponentially rare in the number of cells, (ii) that the lower bound on the acceptance rate is uniform in the lattice spacing, (iii) an upper bound on the variance of the insertion ratio	Uniform acceptance of insertion	The band	25-05 § 07
9 U(1) negative control	A negative control that applies the insertion estimates to four-dimensional $U(1)$ (not confining at weak coupling) and checks where they stop working	Middle of the renormalisation comparison (the condition that distinguishes groups)	The estimate for $SU(2)$	25-05 § 07, § 08 (f)

Q.	Question (with its conditions in the same row)	Rows concerned	What does not move even if settled	Source
10 Oddness of composed insertions	That the map composing insertions in separate cells satisfies the identity "odd under insertion" (at present an assumption of the Many-Cell Second-Moment Estimate, and an assumption in Lean too)	Uniform acceptance of insertion	The identity for one cell	25-05 § 08 (c)
11 Literature check for slab confinement	Comparing the Slab Confinement Theorem with arguments of Tomboulis–Yaffe type and with the area law for spatial Wilson loops at high temperature (Borgs 1985)	— (a question about the label)	The content of the theorem	25-04 § 06
12 Kernels with flip probability near 1	Constructing a kernel whose flip probability a is close to 1. The Flow Lemma $\theta \le 1 - a$ gives only a naive form, because for a one-step kernel a saturates around $\frac{1}{2}$ (a judgement from measurement and the record)	Positivity of the 't Hooft tension (a form usable for testing the band)	Ultraviolet control	25-06 § 06, § 08 (d)
13 Quasi-static limit	The quasi-static limit: that the work W approaches the conditional free energy of the container as the number of driving steps $m \to \infty$ (a proof including an estimate of how the kernel mixes)	Uniform acceptance of insertion	The band	25-06 § 04, § 08 (b)
14 Error of the shaping map	Bound the error of the map that reshapes the fluctuations (the local relative entropy near the vortex surface, and higher loops) at intermediate coupling and for large fields. At one loop it reproduces $\beta - \beta' = 0.258$	Renormalisation comparison (from one loop to non-perturbative)	The statement that crosses the band itself (the middle of the renormalisation comparison)	25-07 § 08 (a)
15 Ultraviolet cost of a fixed map	Whether the extra ultraviolet cost of fixed maps grows in the same way in four-dimensional gauge theory (whether cancellation by Ward identities occurs). The present numbers are three points in a two-dimensional model	Ultraviolet control	The band	25-07 § 06, § 08 (d)
16 Extending the measurements and their errors	Measurements that widen the T^2 beyond the sizes measured (up to about $L\sqrt{\sigma} \approx 2$), and an estimate of the errors of driven insertion and replica exchange (the treatment of autocorrelation)	— (a question about a reading)	Any ledger row (numbers are not proofs)	(b)(c) of 25-08 § 07

Reading Table 5. The reverse direction of the fractional-instanton lower bound and the agreement of the minimal actions are exactly what remains of the upper end of the renormalisation comparison in the ledger; if they are settled, both sides of the rate match on the lattice at fixed N, but the direction of increasing N is the same problem as the middle of the renormalisation comparison. The question "estimating the container free energy" and the question "cost of inserting a thick vortex" are questions that touch the content of ultraviolet control, a wall separate from the band (25-00 § 02). (ii) of the question "gap from insertion to the area law" is a restatement of the row uniform acceptance of insertion.

05

Questions from Part 26 — the assumptions of the reduction of the band, criteria, β-monotonicity and more

These are the questions that the text of Part 26 (the crossover band) left open. The first three rows put into question form the three assumptions of the reduction of the band (26-02 § 02), and the difficulty of the band is concentrated in the third row, the lateral-widening inequality (26-02 § 08). An argument that

closes the band must be able to distinguish $U(1)$ (the criterion "distinguish from the U(1) transition", 26-06 § 08). This condition applies to every row of Table 6.

Table 6 Questions from Part 26 (the rows concerned are rows of the ledger of 27-02; this book's arrangement)

Q.	Question (with its conditions in the same row)	Rows concerned	What does not move even if settled	Source
1 Non-perturbative proof of the lateral-widening inequality	Show the lateral-widening inequality (strong form $\theta(R;T_{L'}^2) \le C(L'/L)^2\theta(R;T_L^2)$, or the weak form in which the total loss is finite) non-perturbatively across $L \sim 1/\Lambda$, between the dilute regime and the confining regime. It does not follow from structural inputs alone (reflection positivity, duality, the transfer matrix)	Positivity of the 't Hooft tension (the place of the input to the reduction is the renormalisation comparison)	From the limit to R^4 to verification and peer review	26-02 § 02, § 08
2 Uniformity of frame decorrelation	Show frame decorrelation $\theta(sR;T_L^2) \le C_{\mathrm{D}}\,\theta(R;T_L^2)^{s^2}$ uniformly in L. With L fixed it is replaced by the chessboard density κ_{cb}, so the question becomes a comparison of $\kappa_{\mathrm{cb}}(L)$ across scales	Frame decorrelation	The non-abelian input to the band (non-perturbative proof of the lateral-widening inequality)	26-02 § 02, 27-02 Table 2, frame decorrelation
3 Proof of the base point at small T^2	Show the base point at small T^2, $\theta(L_0;T_{L_0}^2) \le 1-\varepsilon_0$, under ultraviolet control and uniform acceptance of insertion (the expected size $\varepsilon_0 \propto (L_0\Lambda)^{11/3}$ is a one-loop estimate)	Base point at small T^2 (premises: ultraviolet control, uniform acceptance of insertion)	The band	26-02 § 02, 27-01 Table 1, base point at small T^2
4 Excluding a deconfined phase	Exclusion of a deconfined phase: $\Delta F(L,L) \to 0$ (at any speed). It rules out the known non-confining phases, but gives no uniform lower bound on the tension	Partway to positivity of the 't Hooft tension	The mass gap, a uniform tension for the area law	26-01 § 06, 26-06 § 08
5 Almost-area-law question	Almost area law: $\ln(1/\theta(L,L)) \ge cL^2/\ln L$ (almost area law; by the Tomboulis–Yaffe inequality, decay faster than the perimeter law)	Partway to positivity of the 't Hooft tension	A uniform tension	26-01 § 06
6 β-monotonicity question	β-monotonicity: $\partial_\beta \Delta F \ge 0$ with the lattice geometry held fixed. Rewritten in terms of electric flux, it is a problem of the same weight as β-monotonicity of the string tension in lattice units, and as far as we searched, not even β-monotonicity of Wilson-loop expectation values has been shown. In the chain of the band it is not needed if the renormalisation comparison is shown directly	Renormalisation comparison (an auxiliary role)	The renormalisation comparison itself	26-06 § 02
7 Z_2 and U(1) on twisted slabs	Checking that, on a slab with twist n_{12}, β-monotonicity for $\mathbb{Z}_2$ and $U(1)$ does not follow from Ginibre's inequality (without the twist it does)	Renormalisation comparison	β-monotonicity for $SU(2)$	26-06 § 01

Q.	Question (with its conditions in the same row)	Rows concerned	What does not move even if settled	Source
8 Criterion at the lower end	The criterion at the lower end: push confinement and the comparison up to $\beta \approx 0.3$–1, by a finite-size criterion of Dobrushin–Shlosman type using the influence $\delta(L_0, \beta)$ on the inside when the centre flux on the boundary of the box is changed, and by a computer-assisted count of the growth constant of admissible surfaces	Lower end of the renormalisation comparison	Above $\beta \approx 1$ (the middle)	26-06 § 04
9 Bookkeeping at the strong-coupling end	Write out the bookkeeping of the Strong-Coupling-End Expansion Proposition (the interaction of volume polyhedra and surface contours), and make the constant $u_0 \approx 10^{-80}$ larger	Strong-coupling end of the renormalisation comparison	Beyond roughening ($\beta_R \approx 1.9$)	26-06 § 03
10 Four faces of the middle	Show any one of the four faces of the middle (softness in the twist direction κ_w, mixing of box magnetic flux $\delta(L_0)$, twist cost of a column $f(\ell)$, pressure margin) uniformly in the scale, in a form that fails for $U(1)$. As a preliminary step, test κ_w and $\delta(L_0)$ numerically with $U(1)$ as the control	Middle of the renormalisation comparison	Ultraviolet control	26-06 § 07
11 Two-sided area laws inside the band	At each β in the band, the area law on both sides at fixed β (with errors of the order of the perimeter; the assumption of two-sided area laws inside the band). If this can be said, the comparison inside the band shrinks to finitely many steps (the Lemma Reducing the Comparison inside the Band)	Renormalisation comparison	The seam between the upper end of the band and ultraviolet control	26-06 § 06
12 What remains of the road of blocks and mixing	What remains of the road of blocks and mixing for the first step: the second and third stages of strong mixing (the Laplace method with constraints), checking against the original sources the Varadhan-type limit, Witten's Morse theory (corners of the Neumann box) and the standard theorem for one-dimensional chains, and interval arithmetic for the curvature at the minimum $\lambda_*(12)$ and the reach of the optimal path	Uniform gap of the double well	Uniformity of the relaxation-time upper bound and the one-sided bridge (the uniform gap of the double well is a miniature, not an implication)	the road of blocks and mixing in 23-15, 26-07 § 06
13 Convexity threshold and mixing length	Why, in the first step, the convexity threshold (the first conjugate point at the top, ≈ 7.84) and the mixing length (about 9) are numerically close	Uniform gap of the double well	Uniformity of the relaxation-time upper bound and the one-sided bridge	26-07 § 07 (c)
14 Touchstone of the smallest band	Whether the smallest band can be crossed: test a tool claimed to cross the band first on two-dimensional asymptotically free models (the $O(N)$ model at large N, the Gross–Neveu model), with the ultraviolet cutoff still removed (the screening criterion "crosses the smallest band". Exponential decay at all temperatures for the two-dimensional $O(3)$ model is also said to be unsolved; not yet checked)	Positivity of the 't Hooft tension (a touchstone)	The four-dimensional band	26-08 § 07, the question "C_P and ξ^2 of the O(3) σ model"

Q.	Question (with its conditions in the same row)	Rows concerned	What does not move even if settled	Source
15 Comparison principle for large loops	The asymptotic form of the comparison principle for large loops only, $\sigma_{\mathrm{tw}}(L) \le \sigma_{\infty}$. The form for small loops was broken numerically, but this form has not been refuted (there is no mechanism to show it)	Positivity of the 't Hooft tension	The comparison principle for small loops (broken numerically)	26-08 § 04
16 Testing the three new candidates	Put each of the three new candidates (reduction by compactness of the band, log-concavity of the Weyl measure and a height/azimuth decomposition, local step function of a column) through the tests of the screening criteria	Middle of the renormalisation comparison	None of the candidates closes the band	26-10 § 05, § 07

Reading Table 6. Items 1–3 of Table 6 are the three assumptions of the reduction theorem (26-02 § 03); if all three are in place, the correct form of the band follows. But the three differ in character, and non-abelian dynamics enters only in the question "non-perturbative proof of the lateral-widening inequality" (uniformity of frame decorrelation is replaced by a structural fact once L is fixed, and the question "proof of the base point at small T^{2}" is a statement on the weak-coupling side). From the question "β-monotonicity" to the question "two-sided area laws inside the band" is the breakdown of the renormalisation comparison: the question "criterion at the lower end" is the lower end, the question "four faces of the middle" the middle, and the question "bookkeeping at the strong-coupling end" the strong-coupling end. From the question "touchstone of the smallest band" to the question "testing the three new candidates" are questions coming from the chapters on the roads tried and stopped and on new candidates (26-08, 26-10). The question "what remains of the road of blocks and mixing" and the question "convexity threshold and mixing length" are questions about the first step on the side of time (the first road); even if they are settled, the band does not move (26-07 § 04). The questions of ultraviolet control (the ultraviolet questions) are in Part 15, and 15-09 Table 1 is their index (the fifth source in Table 1).

06

The next moves listed by the record of the study — two tables looked up by ledger row

Among the material of Parts 25 and 26 there are two tables of "the next move", kept as a record of the study. One lists seven rows in decreasing order of the prospect of closing; the other lists four rows in the order of work. Both are tables in the record, not chapters of the book. Table 7 looks up each of their rows in the language of the ledger rows and the chapters of the book. The "amount of work" scale of the record's tables is a number of prospects, not a number with grounds, so it is not copied.

Table 7 The rows of the record's two tables, with the ledger rows and the chapters of the book (the sentences for the content of each row are on the side of the chapters of the book)

Record's table	Order	Content (in the language of the book)	Ledger row	Chapter of the book, question on this page

Record's table	Order	Content (in the language of the book)	Ledger row	Chapter of the book, question on this page
Order of the prospect of closing	1	What remains of strong mixing for the first step (checking the Varadhan-type limit, a uniform form of the Laplace method with constraints)	Uniform gap of the double well	the road of blocks and mixing in 23-15, what remains of the road of blocks and mixing
	2	The logarithmic Sobolev inequality for blocks in the first step (checking Witten's Morse theory and the decomposition against the original sources, interval arithmetic for λ_*)	Uniform gap of the double well	Same as above, what remains of the road of blocks and mixing
	3	Stitching 1 and 2 together (the standard theorem for one-dimensional chains)	Uniform gap of the double well	Same as above, what remains of the road of blocks and mixing
	4	The positivity lemma needed for the converse bound of the paper on lattice fractional instantons (by a low-temperature cluster expansion at one scale)	Upper end of the renormalisation comparison	Reverse direction of the fractional-instanton lower bound, A-07 § 06
	5	Agreement of the minimal actions in the paper on lattice fractional instantons (exponential decay of the minimisers, and cutting off)	Upper end of the renormalisation comparison	The question "agreement of the minimal actions"
	6	Writing out the bookkeeping of the strong-coupling end, and improving the constant u_0	Strong-coupling end of the renormalisation comparison	The question "bookkeeping at the strong-coupling end"
	7	The middle: show the comparison between scales by one of the four faces	Middle of the renormalisation comparison	The question "four faces of the middle"
Order of work	1	Of the faces of the middle, test κ_W and $\delta(L_0)$ numerically with $U(1)$ as the control	Middle of the renormalisation comparison	The question "four faces of the middle"
	2	The upper end: writing out the semiclassical theorem at fixed N	Upper end of the renormalisation comparison	Reverse direction of the fractional-instanton lower bound, agreement of the minimal actions, 25-02 § 06
	3	The lower end: a computer-assisted estimate of the growth constant of surfaces, and formulating the criterion by mixing of box magnetic flux	Lower end of the renormalisation comparison	The question "criterion at the lower end"
	4	Add to the paper on the reduction of the band the scan with step functions and the $U(1)$ control	— (a revision of the paper)	A-07 § 05

None of the rows of the two tables touches the differences outside the ledger. Questions aimed at the differences outside the ledger are in the table of tasks of Part 16 (16-07) and in the unknown column of the table of the seven stages a proof must contain (16-09 Table 1).

07

Looking up from the ledger rows — for each row, the questions that concern it

Table 8 looks up Tables 2–7 again from the side of the ledger rows. The content of each row, its label and what is needed for it to disappear are in 27-02 Table 2; here we list only the numbers of the questions

concerned. A row without questions is a row in which no step small enough to be shrunk into the form of a question is yet in sight.

Table 8 The ledger rows and the questions concerned (this book's arrangement)

Row	Questions concerned
Ultraviolet control	Estimating the container free energy, cost of inserting a thick vortex, the question "ultraviolet cost of a fixed map" (in part), the ultraviolet questions (15-09 Table 1, with the current state of the answers). 15-08 Table 1 (the four rows that do not close) and 15-09 Table 1 are the tables that split this row
Small-T^2 gap	— (the twist part is on paper in 25-01; the form uniform in a depends on ultraviolet control)
Uniform acceptance of insertion	Cost of inserting a thick vortex, gap from insertion to the area law, the question "oddness of composed insertions", the question "quasi-static limit"
Base point at small T^2	The question "existence of fractional instantons", proof of the base point at small T^2
Reflection positivity of z	— (the proof has been placed in 26-04 § 03; this row is closed)
Frame decorrelation	The question "bias of the outer container", estimating the container free energy, uniformity of frame decorrelation
Renormalisation comparison	Strong-coupling end: bookkeeping at the strong-coupling end / lower end of the renormalisation comparison: criterion at the lower end / upper end of the renormalisation comparison: reverse direction of the fractional-instanton lower bound, agreement of the minimal actions / middle of the renormalisation comparison: the question "U(1) negative control", four faces of the middle / testing candidates for the middle of the renormalisation comparison: the question "testing the three new candidates" / outside the breakdown: the question "error of the shaping map", the question "β-monotonicity", the question "Z_2 and U(1) on twisted slabs", two-sided area laws inside the band
Positivity of the 't Hooft tension (the band)	Non-perturbative proof of the lateral-widening inequality (the content), the question "excluding a deconfined phase", the question "almost area law" (intermediate milestones), the question "kernels with flip probability near 1", the question "comparison principle for large loops" (forms usable for testing the band), the question "touchstone of the smallest band" (a touchstone)
Uniform gap of the double well (what remains of the first step)	The question "the N^{−3} coefficient of the column model", the question "sign of 1/P in the column model", the question "interval arithmetic for the maximal correlation of the core", the question "power of the prefactor for the core and window", the question "comparison for the alternating maximal correlation of boxes", the question "reduction to kink positions", what remains of the road of blocks and mixing, convexity threshold and mixing length
Uniformity of the relaxation-time upper bound and the one-sided bridge (the four-dimensional goal, side of time)	Items 4, 5, 9–13 and 17 of Table 2, and items 1–12 and 14–19 of Table 3 (all are questions that repair the form of the statement of this row, not this row itself)
Limit to R^4	—
Tying the two roads together	— (even the statement of what it suffices to assume is not settled, 27-01 § 04)
General groups	The question "SU(N) versions of the three facts" (only the $SU(N)$ part)
Verification and peer review	—

What to read from Table 8. The rows with many questions are the renormalisation comparison, and the uniform gap of the double well and uniformity of the relaxation-time upper bound and the one-sided bridge; the questions on the band itself (positivity of the 't Hooft tension) gather in the non-perturbative proof of the lateral-widening inequality. The questions on excluding a deconfined phase and the almost area law are intermediate milestones weaker than positivity of the 't Hooft tension, and settling them does not make positivity of the 't Hooft tension disappear. The differences outside the ledger have almost no steps that can be shrunk into the form of a question. Tying the two roads together starts, before any question is set, from making a statement of what needs to be shown.

What this chapter can say

What is said	What is not said
Which section of which chapter the questions and candidate rules of Parts 23 and 24 came from (Tables 2–4)	The answer to any question. The status and the full text of "what does not move even if settled" are in the source tables
A list of the questions that the text of Parts 25 and 26 left open, with their source sections (Tables 5 and 6)	Estimates of the size of the questions. Of the sentences of chapters 26-03 to 26-05 and 26-09, only those that overlap with rows of Table 6 have been picked up
The correspondence between questions and ledger rows (Table 8, this book's arrangement)	That settling a question makes a row disappear (the rule for rows disappearing is 27-02 § 01)

Sources and reproduction

Item	Kind	Source / tools
The questions of Table 2	This book	23-17 Table 3
The questions and candidate rules of Tables 3 and 4	This book	24-08 Table 1, Table 2
The questions of Tables 5 and 6	This book	The sections of the chapters in the right-hand column ("what cannot be said", "what remains", "what is lacking", "map")
The record's two tables in Table 7	This book	From the material of Parts 25 and 26, the table of next moves (seven rows in order of the prospect of closing) and the "order of the next work" in the list of tasks up to a proof (four rows). The content of the rows has been replaced with the language of the chapters of the book
Numbers and names of the ledger rows	This book	27-02 Table 2, Table 3

Terms used in this chapter — ledger row, the differences outside the ledger, what does not move even if settled, intermediate milestone, the lateral-widening inequality, frame decorrelation, the base point at small T^2, β-monotonicity, the renormalisation comparison, the four faces, candidate rules, the diffusive-relaxation-time assumption. Their meanings are in the A-02 Glossary and the A-06 Index of names.

Next chapter to read: 27-04 What is not claimed (a cross-index) — the reverse side of the questions: what this book does not show, does not read strongly, and does not call false either.

2026-10-15 · chapter Yang–Mills and the mass gap Part 27 Closing — conditional statements not shown, not read strongly, not called false · Kiichi, Shiori and Rin

What is not claimed (a cross-index)

> This chapter is an index; it points to the relevant sections of each chapter.

What this chapter shows — What this book does not claim, gathered across the parts into one index. The fourteen items of Part 23 (23-16 Table 2) and the sixteen items of Part 24 (24-08 Table 4) are looked up by chapter and item number, without moving the items. From the sections "what cannot be said" of the text of Parts 25, 26 and 27 we pick up items, give them running numbers per table on this page (items 1 onwards of Tables 4 to 6), and list them with the places in the text that support them. Finally, a table of examples in which sentences of Parts 25 to 27 lose their conditions in a one-line summary.

Prerequisite chapters — None. You can start reading anywhere. The three meanings (not shown, not read strongly, not called false) are used as in 23-16 § 01. The numbers of the ledger rows are those of 27-02 Table 2.

Said first — This book does not solve the problem of Yang–Mills existence and the mass gap. This book's study does not construct the continuum limit (the continuum limit in a periodic box, and the reconstruction phase by phase, were shown by the construction published on 2026-11-10; at the level of the committee's assessment; Volume 2). There is no proof of the mass gap, and no proof of confinement in the continuum limit. This chapter only writes that fact out, split into items, and adds no new results.

The order of this chapter

1. How to read the index — the three meanings, and the number of items per part (Table 1)
2. The fourteen items of Part 23 — looking up 23-16 Table 2 (Table 2)
3. The sixteen items of Part 24 — looking up 24-08 Table 4 (Table 3)
4. The items of Part 25 — on the tools of the second road (Table 4)
5. The items of Part 26 — on the band (Table 5)
6. The items of Part 27 — on the conditional statement and the ledger (Table 6)

7. Conditions drop out in summaries — sentences of Parts 25 to 27 and one-line summaries (Table 7)

01

How to read the index — the three meanings, and the number of items per part

"Not claimed" has three meanings (23-16 § 01). Not shown: on that proposition this book shows nothing. Not read strongly: what has been shown carries conditions or assumptions, and read in a form with the conditions removed it becomes a sentence that has not been shown. Not called false: that a method did not reach something is a property of that method, not a claim that the proposition it did not reach is false. Besides these, there are items of "not judged, not counted": rederivations of known results are not counted as results, and the correctness of other documents is not judged.

The third becomes clearer when written in logical form. Writing "P is claimed" as $\vdash P$, $\neg(\vdash P)$ and $\vdash \neg P$ are different sentences, and the "not claimed" of this chapter always has the meaning on the left. The items of Part 26 have one more direction: cases in which a numerical reading points to the opposite of a proposition (the measurement of the comparison principle, item 4 of Table 5). There too, the book does not claim the opposite proposition as a theorem, but places it as a "reading".

Table 1 The items per part (how they are numbered, and how many)

Part	Numbers	Count	Table or section to look in
Part 23 (the first road, first half)	Items 1–14	14	23-16 Table 2
Part 24 (the first road, second half)	Items 1–16	16	24-08 Table 4 (the five items on the candidate rules are at the end of 24-08 § 02)
Part 25 (the second road)	Running numbers 1–13	13	Table 4 of this page (the "what cannot be said" of each chapter)
Part 26 (the crossover band)	Running numbers 1–12	12	Table 5 of this page
Part 27 (closing)	Running numbers 1–6	6	Table 6 of this page

The items of Part 23 apply as they are to Part 24 (24-08 § 04), and in the same way the items of Parts 23 and 24 apply as they are to Parts 25 to 27. In particular, "not reaching something is not evidence that it is false" (items 8 and 12 of 23-16) and "conditions drop out in summaries" (23-16 § 06) are common to all parts.

02

The fourteen items of Part 23 — looking up 23-16 Table 2

Table 2 lists only the gist of each item, its kind, and the main places in the text that support it. The full text of the items and all the supporting text are in 23-16 Table 2. The assumption named by the items of Part 23 is the diffusive-relaxation-time assumption (the upper side is the relaxation-time upper-bound assumption, the lower side the relaxation-time lower-bound assumption), and the gists in Table 2 use this name.

Table 2 The items of Part 23 (gist; full text in 23-16 Table 2)

Item	Gist	Kind	Supporting text (main places)
1	The solution of the problem of existence and the mass gap; a construction of the continuum limit	Not shown	23-01 § 08
2	Even for the first step, the double-well relaxation-time power statement has not been shown. The First-Step Upper-Bound Proposition is algebra on top of four conditions	Not shown	23-05 § 08
3	There is not yet a single $\hbar$ at which all rows of the four conditions hold at once	Not shown	23-12 § 06
4	Computer-assisted results are inequalities inside the range that was computed	Not read strongly	23-08 § 10
5	Readings are used neither as upper bounds nor as proofs of lower bounds	Not read strongly	23-00 Table 1
6	A Lean theorem checks the algebra from assumptions to conclusion	Not read strongly	23-13 § 05
7	From the first step to the second step on, only the prospect that the form of the sentences and the form of the tools lift	Not read strongly	23-03 § 06
8	That a tool did not reach something is a property of that tool	Not called false	the table of scope in 23-10
9	Rederivations of known results are not counted as results. The correctness of other documents is not judged	Not judged	23-14 § 03
10	The record on the side of the four-dimensional lattice also remains assumption	Not shown	23-01 § 05
11	Under the assumption of the one-sided bridge, the upper-bound assumption implies a lower bound on the gap, but the converse is false in general. The diffusive-relaxation-time assumption is not the mass gap itself	Not read strongly	23-01 § 06

Item	Gist	Kind	Supporting text (main places)
12	The "death" of a detour plan does not mean that the remaining proposition is false	Not called false	23-10 § 03
13	The reading that the upper-bound assumption fails in the periodic box is a conditional reading, resting on numbers from the literature and on a conjecture	Not called false	23-01 § 05
14	A proposition with assumption rows left is not put out as a result	Not counted	23-12 § 08

03

The sixteen items of Part 24 — looking up 24-08 Table 4

Table 3 gives the gist of the items of Part 24, their kind, and the main places in the text that support them. The full text is in 24-08 Table 4. What is not claimed about the candidate rules (neither consistency nor a prospect towards the third step is shown, the Boolean-algebra comparison is a metaphor, and five others) is at the end of 24-08 § 02; here we only point to it.

Table 3 The items of Part 24 (gist; full text in 24-08 Table 4)

Item	Gist	Kind	Supporting text (main places)
1	The solution of the problem of existence and the mass gap. The continuum limit, recovery of rotations, the OS axioms and non-triviality are not touched	Not shown	24-00 § 05
2	That the relaxation-time assumption is false (the reading for the periodic box extends the numbers of the originals and a conjecture)	Not called false	24-01 § 06
3	The sector and local versions are candidate definitions, not shown at any β	Not shown	24-03 § 07
4	The one-sided bridge is an inequality on a lattice with continuous time. On Wilson's lattice with discretised time, the time-step comparison assumption ((D) in the paper "one-sided bridge") remains	Not read strongly	24-04 § 08
5	"The gap = the Poincaré constant of the vacuum measure" is an identity, and we do not say it has made the problem easier	Not read strongly	24-05 § 07
6	The definition of the length at which conservation breaks, and the restatement of what to compare with, are candidates	Not read strongly	24-02 § 08
7	The results for hierarchical models and two-dimensional models imply nothing for four dimensions	Not read strongly	24-06 § 09

Item	Gist	Kind	Supporting text (main places)
8	The non-perturbative mechanisms of physics (confinement, instantons, centre vortices, duality) are not used as tools of proof in Part 24	Not shown	24-07 § 08
9	The two points of "because it is four dimensions" are estimates as properties of the critical dimension	Not read strongly	24-07 § 01
10	The "what is not claimed" of Part 23 applies to Part 24 as it is	—	23-16 § 02
11	The local version goes only as far as the definition and the ratio form. The local diffusive-relaxation-time assumption has not been shown for the target gauge theory	Not shown	24-03 § 03
12	The thresholds of the local bridge depend on the choice of reference and on the family of test observables	Not read strongly	24-04 § 06
13	For the 0+1 double well, the local ratio is not 1. Taking it to approach 1 at short distances in four dimensions is an assumption that depends on asymptotic freedom	Not read strongly	24-04 § 07
14	The length at which conservation breaks was measured only on the width-2 region of two-dimensional $U(1)$	Not read strongly	24-02 § 03
15	For $SU(2)$, it is undecided whether the freezing of the topological charge breaks the relaxation-time assumption	Not called false	24-07 § 07
16	The results of the two-dimensional CP^{N-1} test bed imply nothing for four dimensions	Not read strongly	24-02 § 07

Item 8 of Part 24 needs care in reading when set beside Parts 25 and 26. Part 24 did not use centre vortices or instantons as tools of proof, but Part 25 puts vortex surfaces and fractional instantons at the centre of its tools. What it uses, however, are only finite identities on the lattice, estimates at fixed lattice spacing and conditional sentences; it does not bring the physical mechanisms into proofs as they are (items 2, 4 and 5 of Table 4).

04

The items of Part 25 — on the tools of the second road

These items are picked up from the sections "what cannot be said" of the chapters of Part 25 (from the direction of space). The group is $SU(2)$, and the small T^2 carries the twist $n_{12} = 1$. The kind column gives the three meanings (and "not judged, not counted").

Table 4 What Part 25 does not claim, and the sentences of the text that support it

Item	What is not claimed	Kind	Supporting sentence of the text (gist)
1	"Weak coupling persists up to the size of the small T^2" is not a theorem. It is a physical estimate made on the assumption of ultraviolet control, and an estimate uniform in the lattice spacing is nowhere in this book. That the small T^2 and $\mathbb{R}^4$ are connected without a phase transition (adiabatic continuity) is a conjecture and is not used	Not shown	(a)(b) of 25-00 § 08
2	The Slab Confinement Theorem is a statement with the lattice spacing and the size N of the T^2 fixed. The lower bound $-\ln\tanh(\beta N^2) \approx 2e^{-2\beta N^2}$ goes to 0 in the continuum limit, and also vanishes as $N \to \infty$. It says nothing about a tension uniform in the lattice spacing, nor about four-dimensional confinement	Not read strongly	(a)(b) of 25-04 § 07, § 04
3	The Container Identity is a rewriting of the Mack–Petkova identity, and is known. The rewriting in the summed ensemble, the way of moving to a fixed sector, nesting, the insertion identities and the Slab Confinement Theorem are also elementary, and have not been checked against the earlier literature. No novelty is claimed for the results of this part	Not counted	25-03 § 08 (a), 25-04 § 06, 25-05 § 08 (d)
4	None of the insertion identities and inequalities derives confinement. The large-deviation step, the ultraviolet step and the upper bound on the second moment remain	Not shown	25-05 § 08 (a), § 07
5	The count for a dilute gas of fractional instantons (string tension $\propto \Lambda^2(\Lambda L)^{5/3}$, margin $5/3 = 11/3 - 2$) is a physical estimate in the dilute regime $\Lambda L \ll 1$, at the one-loop level. The action values obtained by cooling are upper bounds on the minimal action, not lower bounds	Not read strongly	(a)(b) of 25-02 § 07
6	The Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3) is a statement of a draft, and its label in this book is Assumption. It is not uniform in N, and says nothing about the continuum limit or about the mass gap. The converse bound (uniform in M) is open	Not read strongly	25-02 § 06, § 07 (e)

Item	What is not claimed	Kind	Supporting sentence of the text (gist)
7	The count that, in four dimensions, independent containers give only up to $R/\ln R$ is a count on top of the assumption of the original source (that the free energy of thick containers takes a form uniform in the boundary values), not a four-dimensional theorem. Neither that assumption nor its negation has been shown	Not read strongly	25-03 § 08 (d)
8	The three facts about the twisted T^2 (uniqueness of the vacuum, the gap of the adjoint field $4\sin^2(\pi/2N)$, the absence of flat configurations in the (1,1) sector) say nothing about the lattice spacing $a \to 0$. The gap of the adjoint field is a lower bound on classical fluctuations, not a gap of the quantum effective action	Not read strongly	25-01 § 09 (a)
9	The Lean column covers only finite sums and real algebra. The Haar measure of $SU(2)$, the co-closed sign field, the topology and projections of sectors, and that θ is the bias of a sector are outside Lean	Not read strongly	25-03 § 08 (f), 25-04 § 07 (e), 25-05 § 08 (b)
10	No sentence of this part says anything about widening the T^2 beyond $1/\Lambda$. That stage is the crossover band, and the second road stops there	Not shown	25-02 § 07 (d), 25-09
11	The Driven Insertion Identity and the Flow Lemma do not derive confinement. "For a one-step kernel the flip probability saturates around $\frac{1}{2}$" is a judgement from measurement and the record, not a theorem. The Crooks Relation and the Jarzynski Equality are known	Not read strongly	(a)(d)(e) of 25-06 § 08
12	The comparison of isometric maps and reshaping maps is a statement at the one-loop (Gaussian) level. "Upper bounds come only from variation and explicit construction" is a judgement about this book's list of tools, not a theorem. That the leftover relative entropy is proportional to the area is an estimate for general maps	Not read strongly	(a)(c)(e) of 25-07 § 08
13	The measured numbers of Part 25 are not proofs. The trend from widening the T^2 does not show the band numerically (it goes only up to about $L\sqrt{\sigma} \approx 2$), and reading the measurement of simultaneous flips as a numerical picture of the band has been withdrawn	Not read strongly	(a)(b)(f) of 25-08 § 07

05

The items of Part 26 — on the band

These items are picked up from the chapters of Part 26 (the crossover band). The band is the interval around the scale $L \sim 1/\Lambda$ at which weak coupling turns into strong coupling; it is a different thing from the "window" of Parts 23 and 24 (26-00 § 02).

Table 5 What Part 26 does not claim, and the sentences of the text that support it

Item	What is not claimed	Kind	Supporting sentence of the text (gist)
1	The band is unsolved. This book does not show, in any form, a statement that crosses the band ($\ln(1/\theta(L,L)) \geq cL^2$ uniformly in L, or an intermediate milestone towards it). Neither the renormalisation comparison nor β-monotonicity has been shown at any β of the band	Not shown	26-01 § 06, 26-02 § 08, 26-06 § 09 (a)
2	The reduction did not make the problem easier. The reduction theorem is a statement on top of three assumptions, and the strong form of the lateral-widening inequality is stronger than confinement (it contains monotonicity of the slab tension). The lemma that shrinks the comparison inside the band to the area law at fixed β is also a reduction, and its assumption contains an unsolved problem	Not read strongly	26-02 § 05, 26-06 § 09 (c), 27-02 § 03
3	Do not read "the renormalisation comparison holds at both ends" with the conditions removed. The strong-coupling end is an outline in the range $u \leq u_0 \approx 10^{-80}$ with part of the bookkeeping only sketched, and the weak-coupling end is a computation at the one-loop level. A non-perturbative weak-coupling comparison has not been shown at any β	Not read strongly	26-06 § 09 (b), § 03
4	The comparison principle (in the form that Wilson loops on $\mathbb{R}^4$ are bounded by loops on the twisted slab) is a statement at the one-loop level and is not used as a non-perturbative tool. With $SU(2)$, the Wilson action and $\beta = 2.1$, the plaquette on the twisted slab $16 \times 16 \times 2 \times 2$ is lower than on 16^4 (7σ with errors taken from both sides, 5.5σ in an independent rerun), so it is broken for small loops. The book places this as a reading that refutes it Reading (not a theorem)	Not read strongly	26-08 § 04

Item	What is not claimed	Kind	Supporting sentence of the text (gist)
5	The numbers of the lattice-doubling test (small lattices up to 8^4, few values of β, 1–3 seeds) are a reading of direction, not evidence that $SU(2)$ has no phase transition to a non-confining phase	Not read strongly	26-06 § 09 (d), 26-00 § 03 (ii)
6	We do not say that β-monotonicity is false (no counterexample has been found; a reading). The four faces of the middle are candidates, and none has an estimate uniform in the scale	Not called false	26-06 § 09 (e)(f)
7	The wall of the first step, the "summit-curvature shortfall wall", is the band in miniature, not the band. We do not say that the results of the first step imply anything in four dimensions. That four dimensions have no "finite block beyond the crossover length" is not a claim that the road of blocks is impossible in four dimensions	Not read strongly / Not called false	(b)(f) of 26-07 § 07, 26-00 § 05
8	We do not say that the road of blocks and mixing closes the first step. Apart from the Hidden-Convexity Proposition, its rows are Assumption and Reading	Not shown	26-07 § 07 (d), the road of blocks and mixing in 23-15
9	"The only place where non-abelian enters" is a phrase with the restriction "within this reduction". The margin $5/3 = 11/3 - 2$ is a physical estimate in the dilute regime at the one-loop level	Not read strongly	26-02 § 08, 26-00 Table 1
10	The negative lemma, that the lateral-widening inequality does not follow from structural inputs alone (reflection positivity, the identities of centre and duality, positivity of the transfer matrix), is a statement of the form "from this set of inputs alone", not a claim that the band cannot be crossed	Not called false	26-00 Table 1, 26-04 § 04
11	None of the candidate new viewpoints closes the band. The reduction by compactness of the band is a reduction, and we do not say it has made the band easier. Nor do we say that the candidates are not combinations of known facts	Not shown	(a)(b)(g) of 26-10 § 07
12	"Stopped" for a road tried and stopped means that its tool could not cross the band, not that the proposition aimed at by the road is false. Roads stopped for reasons of estimate can be reopened if a new input appears	Not called false	26-08 § 01

06

The items of Part 27 — on the conditional statement and the ledger

Table 6 What Part 27 does not claim, and the sentences of the text that support it

Item	What is not claimed	Kind	Supporting sentence of the text (gist)
1	Confinement (the area law) is not the mass gap. There is no known road that gets the mass gap from the area law, and the arrow joining the two on the same theory is open (even the statement of what it suffices to assume is not settled)	Not shown	16-09 § 03, 27-01 § 04, 25-00 § 08 (c)
2	The conditional statement is a statement only insofar as the band is placed among the assumptions. Only the arrows whose paper proof has been placed in the book are called "theorems", and the assumptions in the form of the band (the lateral-widening inequality, the uniform slab tension, the uniform slab gap) carry the content of the conclusion	Not read strongly	27-01 § 05
3	The propositions of the research programme on $\mathbb{R}^2\times$ a small twisted T^2 (the arrow of the small-T^2 gap on the gap side, the arrow of the small-T^2 area law on the confinement side) are conditional and at the stage of an outline. The assumption of the arrow of the small-T^2 gap (block correlations decay at rate $m \geq c/L$) contains the quantity of the conclusion	Not read strongly	27-01 § 02, § 03
4	Even if every row of the ledger disappears, that does not mean the problem is solved. Four things remain: the limit to $\mathbb{R}^4$ (split into four rows in Table 3 of 27-02), tying the two roads together, general groups, and verification and peer review (seven rows with the breakdown)	Not shown	27-02 § 05, 27-00 § 01
5	A row closed in the record (mark ■) does not mean it has disappeared from the book's ledger. A row disappears only when its paper proof has been placed in the book and, if it has a Lean entry, the re-check is done	Not read strongly	27-02 § 01
6	The number of rows of the ledger is not a gauge of progress. Rows can also split and increase	Not counted	27-02 § 06

07

Conditions drop out in summaries — sentences of Parts 25 to 27 and one-line summaries

The error of reading a claim strongly arises, in most cases, at the stage of shrinking a sentence of the text into one line (23-16 § 06). Table 7 sets the conditional sentences of the text of Parts 25 to 27 beside one-liners from which the conditions have been dropped entirely. Every sentence in the right-hand column is a sentence this book has not shown.

Table 7 Sentences of the text (with conditions) and one-liners with the conditions dropped (everything on the right is wrong, or not shown)

Topic	Sentence of the text	One-liner with the conditions dropped
Slab confinement	With the lattice spacing and the side N of the T^2 fixed, $\sigma \geq -\ln\tanh(\beta N^2)$ for every β Proved here (25-04 § 02)	Confinement in lattice gauge theory has been shown
Confinement Lower Bound by Fractional Instantons	At fixed $N \geq 2$, $\ell \geq 2$, $\beta \geq 1$, $M \in 2\ell\mathbb{N}$, a lower bound on the area law with rate $S_*(N,\ell)$ (a statement of the draft; the book's label is Assumption , 25-02 § 06)	It has been shown that fractional instantons cause confinement
The one-loop comparison	With the comparison that reshapes the fluctuations, $\beta - \beta' = 0.258$ (per doubling) Proved here (at the one-loop level, 26-06 § 03)	The renormalisation comparison holds
The doubling test	For $SU(2)$, the $\beta - \beta'$ read off is $+0.13$–$+0.25$ ($4^4 \to 8^4$ and others, $\beta = 2.5$–3.0, 1–3 seeds) Reading	$SU(2)$ has no phase transition inside the band
The reduction theorem	Under the three assumptions of the base point, frame decorrelation and the lateral-widening inequality, the correct form of the band follows Proved here (conditional, 26-02 § 03)	The band has been reduced to a single inequality and become easier
The comparison inside the band	Under the area law on both sides at each β of the band (the assumption of two-sided area laws inside the band), the comparison inside the band shrinks to finitely many steps Proved here (26-06 § 06)	The renormalisation comparison inside the band has been shown
The iteration in Lean	`Doubling.iterate` (assumptions: $c \geq 0$, $t_k \geq 0$, $t_{k+1} \leq c^3 t_k^4$; conclusion: $c\,t_k \leq (c\,t_0)^{4^k}$) is algebra of a sequence of real numbers	The reduction of the band has been checked in Lean

Topic	Sentence of the text	One-liner with the conditions dropped
Reflection positivity of z	The proof is placed in 26-04 § 03. The algebra of the last step is also closed in Lean (ReflPos). This row is closed (27-02 § 01)	The whole proof of reflection positivity of z has been checked in Lean

The error types in Table 7 are the same two as in Table 5 of Part 23. One drops the scope (fixed lattice spacing, fixed N, the one-loop level, small lattices); the other drops the grade (Reading, Assumption, the reach of Lean). In Parts 25 to 27 one more type is added: reading "reduced" as "made easier". A reduction gathers the difficulty into one place; it does not reduce the difficulty.

What this chapter can say

What is said	What is not said
That this book shows nothing about the existence and the mass gap of the problem statement (0-03). Which sentences of which chapters support the items of Parts 23 and 24 (Tables 2 and 3)	The truth or falsity of the claims of the problem statement. Existence of the continuum limit (on the side of this book's study; the published construction showed it in a periodic box). A gap uniform in the volume
The items of Parts 25, 26 and 27, and the places in the text that support them (Tables 4–6)	The truth or falsity of the proposition of each item. Of the sentences of chapters 26-03 to 26-05 and 26-09, only those that overlap with rows of Table 5 have been picked up
Pairs of conditional sentences of Parts 25 to 27 and one-liners with the conditions dropped (Table 7)	That the sentences in the right-hand column of Table 7 are false (only that they have not been shown)

Terms used in this chapter — not shown, not read strongly, not called false, not judged / not counted, the conditions that drop out in a summary, the crossover band, reduction, the differences that remain outside the ledger, the diffusive-relaxation-time assumption. Their meanings are in the A-02 Glossary and the A-06 Index of names.

Next chapter: 28-00 Entrance — the statements to be shown, and sufficient conditions through a representation. To read alongside it, A-07 Papers that came out of this book — the main theorem of each paper, with its label and conditions. To go back to the entrance of Part 27, 27-00.

Entrance — the statements to be shown, and sufficient conditions through a representation

> This chapter is a guide.

What this chapter shows — Part 28 lays out "what would suffice" as a tree of the root and its sufficient conditions. This entrance shows the distinction between the root and the sufficient conditions, how to read the premise labels, and the order of the chapters in this part.

Prerequisite chapters — 19-07 Statements to be shown. The firm theorems are in Parts 20–22 (20-00, 21-00, 22-00).

Said first — This part is a list of premises and implications, and it shows none of the roots. Of the roots, the four on the ultraviolet side (matching, convergence of the full sequence, non-degeneracy, equicontinuity) and the tree of premises that supports them are statements about this book's design (measures pushed forward by a fixed block map). The existence of four-dimensional Yang–Mills theory was shown by the construction published on 2026-11-10, with a different design, and the committee's assessment is that it is proved in Lean (Volume 2; the two designs are compared in Part 14, and the record of this book's ultraviolet attempt is in Part 15). So the roots and the tree on the ultraviolet side are kept as a record of the statements to be shown and the sufficient conditions within this book's design. The roots on the infrared side (uniform decay and the mass gap that follows from it, and the band) remain open, and these are the main subject of Volume 3. The premise labels are as of 2026-11-13; they are updated in A-08 A map to the mass gap.

The order of this chapter

1. The root, and sufficient conditions through a representation (Table 1)
2. Key to the premise labels (Table 2)
3. Symbols for why a form is not fixed (Table 3)
4. The chapters of this part

01

The root, and sufficient conditions through a representation

In this part we call the statements to be shown the "roots" of the tree, and their sufficient conditions the "leaves".

The **roots** are the six statements to be shown, written only with the objects defined in Part 19 (the Wilson measure, the push-forward measure, the vortex ratio, the vessel of reconstruction) (19-07).

The **sufficient conditions** are the premises we place in order to derive the root on the present road. Many of them are statements made through quantities used to write down the theory at coarse scales — effective couplings, large-field activities, background fields, classes — and this book calls such a description a **representation**. Many of the quantities of a representation are not yet defined from the lattice.

Table 1 The root, and the sufficient conditions on the present road

Root (19-07)	Language of the root	Sufficient conditions on the present road (names of rows in 28-04)	Language of the sufficient co
Matching	Expectations under the push-forward measure, β_n	One-step bracket of the coupling and recursion of the activity (definition and continuity of the effective coupling, net one-step bracket of the coupling, large-field contribution to the coupling, recursion of the activity, rarity of supply, moving invariant interval and margin)	Effective coupling u_k, activ supply w_k
Convergence of the full sequence	Push-forward measure $\nu_{n,m}$	Contraction of the one-step map and matching at the endpoint, the estimates of the premise of ultraviolet stability	Coordinates of the one-step class, background field
Non-degeneracy	$\nu_{n,m}$ and the set of small fields	Rarity of two-step events (the plaquette part, the background-invariant part)	The plaquette part in the sa language as the root; the background-invariant part background fields
Equicontinuity	$\nu_{n,m}$ and the family of observables	Equicontinuity of observables	Same language as the root
Uniform decay	Covariances under $\nu_{n,m}$, the vessel	Uniform decay of block observables, of the same form as the root; the seam to the vessel of the mass gap; the rows for fine observables, infinite volume, rotation and non-triviality (from approximation of flowed observables by block variables to the limit is not a free field); band comparison (in the language of the gap) and from the area law to the gap	Flowed observables, rotate lattices, box masses
Band	Vortex ratio θ	Base point, nesting and widening (non-negativity of θ, base point at small T^2, single-scale criterion, question of the cost of a twist-inserting map, frame decorrelation, lateral-widening inequality (strong form)), tension doubling (tension-doubling inequality, monotonicity of the vortex free energy and renormalisation comparison)	θ, sheet tension

The root is read for the sequence fixed by matching. If it is read in a form where the sequence of couplings can be chosen freely, $\beta_n \equiv 0$ alone makes the mass-gap and band parts of the root stand (19-07 § 01). The "Matching" row of Table 1 is not one row alongside the other five; it is the row that fixes how the other five are quantified.

The root does not depend on the representation. If the representation is changed (a different definition of the background, a different norm, and so on), the sufficient conditions change, but the root does not. The list (28-04) writes the root at the top and the sufficient conditions below it, as those "on the present road".

02

Key to the premise labels

A premise label is written as one column of a table. It is separate from the labels used in the text (Proved here, Cited, Computer-assisted, Reading, Assumption — the system of 23-00). When the text writes out the statement of a premise itself, its label in the text is Assumption .

Table 2 Premise labels

Label	Meaning	What it does not guarantee
Theorem	Machine-checked in Lean, and a check that compares the definitions and the statement with a separate pair of eyes has confirmed the content of the statement	That it is the premise in exactly its stated form (the scope is written in the same column)
Theorem (weak form)	The same, but only up to a form weaker than the premise. We say separately whether it pays the column as it stands or is a similar but different statement	That it reaches the form of the premise

Label	Meaning	What it does not guarantee
On paper	There is an argument on paper	That it is free of errors (the check comparing definitions and statement with a separate pair of eyes has not been done)
Form fixed, unproved	The form of the statement is settled. "Conditional" means: for the sequence fixed by matching, and only when the restrictions on threshold and period are imposed	That it holds
Form not fixed	The form of the statement is not yet settled. The reason is given by a symbol (Table 3)	—
Depends on design	Determined by a design choice (28-05)	That the choice is determined uniquely
Literature	Depends on a result in the literature	That this book has re-derived it

03

Symbols for why a form is not fixed

Table 3　Reason symbols

Symbol	Meaning
(a)	Too light: it stands for a trivial object, or because a quantity can be chosen freely
(b)	Too strong: it is false, or there are examples where it is false
(c)	Object undefined: a quantity in the statement is not defined from the lattice
(d)	There are numerical signs against the present form
(e)	There is a form at one scale, but no form across steps
(f)	The order of quantifiers is not fixed

A list sorted by origin is in 28-06.

04

The chapters of this part

Chapter	Contents
28-01 Subsequential limits, and the properties that pass to the limit	The parts that stand without premises, and the parts where premises do the work
28-02 Convergence of the full sequence	Convergence of the full sequence through matching at the endpoint
28-03 From decay to the mass gap, and the reduction of the band	From uniform decay to the mass gap of the vessel; from base point, nesting and widening to the area exponent
28-04 The list of premises — tree and labels	The root and the tree of 57 rows of premises, tables by stage, counts by label, a dictionary of other names
28-05 What depends on design choices	Nine choices, and which theorems and premises depend on which
28-06 Open places, and places where the object does not yet exist	Where the 24 rows whose form is not fixed come from, and what would fix their form. What is not claimed

The three chapters on implications are theorems that write "what follows if the premises hold", with all the assumptions shown. What follows can be weaker than the root (28-01 reaches only subsequential limits), and there are also implications that go beyond the root (28-03 goes from uniform decay to the mass gap of the vessel).

What this chapter can say

Can say	Cannot say
The distinction between the root and the sufficient conditions; the meaning of the premise labels and the reason symbols	None of the root is shown

Sources and reproduction

Item	Type	Source, tools
The tree of the root and sufficient conditions, the labels	Assumption	The inventory of premises in this book's study (2026-11-13). The full text is in 28-04

Words used in this chapter — root, sufficient condition, representation, premise label, reason symbol. Their meanings are in A-02 Glossary.

Next chapter: 28-01 Subsequential limits, and the properties that pass to the limit — reads what follows from the premises, with all the assumptions shown. To start from the list, read 28-04.

Subsequential limits, and the properties that pass to the limit

This chapter is this book's study.

What this chapter shows — Let $\nu_{n,m}$ be the measure obtained by pushing the fine measure μ_n on a box of side $2^n L$ forward to the coarse level m by the block map. For it we read, with all the assumptions shown, the conditional theorem "if many assumption fields hold, then a subsequential limit exists, and the limit has reflection positivity, symmetry and a non-degeneracy lower bound" (Lean: `BoxWalk.chain_end_to_end_box`). The content of this theorem splits in two. (a) Properties that hold uniformly on finite lattices pass to subsequential limits. (b) From the one-step structure for the coupling, the matching point can be taken inside an explicit bracket.

Prerequisites — 19-04 The block map and the push-forward measure, 19-01 The Wilson measure, 19-03 Reflection, 19-07 The statements to be shown.

Said first — This is an implication, and none of its assumptions has been shown on the four-dimensional lattice. The existence of a subsequential limit holds, without assumptions, for any family of probability measures. The reading that joins (a) and (b) ("the fine measure is the Wilson measure at the coupling fixed by the matching point") lies outside the theorem. The quantities put into the assumptions (effective coupling, activity, supply, remainders, background invariants, the sequence of observables) are not defined from the lattice. So the fact that this theorem is closed does not mean that the content of the continuum limit has been shown. The existence of four-dimensional Yang–Mills theory was shown by the construction published on 2026-11-10, with a different design (Volume 2). The implication of this chapter is a record of what this book's design (measures pushed forward by a fixed block map) placed as premises (§ 08).

The order of this chapter

1. The form of the theorem — what is fixed and what is left free — only the block map and the push-forward are fixed by definition

2. The table of assumption fields — Lean names, mathematical wording, and whether they are paid by concrete objects (Tables 1 and 2)
3. The first conclusion — the matching point lies in a bracket — a statement about the family of functions u alone, not connected to the measure
4. The second conclusion — convergence along a subsequence — from compactness, it holds for any family of measures
5. Properties that pass to the limit — reflection positivity, invariance, lower bounds on the mass of closed sets, the modulus of continuity of observables (Table 3)
6. The version with the Wilson measure as the fine measure — the scope in which two fields disappear, and the fields that remain
7. The reading that joins the two lies outside the theorem — joining the sequence of bare couplings to the effective coupling needs a definition of the effective coupling
8. Relation to the conditional implication assembled earlier — its assumptions are statements written with the push-forward measure

---

01

The form of the theorem — what is fixed and what is left free

One road to building a continuum limit goes as follows. On boxes whose lattice spacing is halved step by step (periodic boxes of side $2^n L$, $n = 0, 1, 2, \ldots$) we place fine measures μ_n, and push them forward by the block map to the coarse box of side $2^m L$ (19-04). The limit $n \to \infty$ with the coarse level m fixed is the candidate for "the distribution of the block variables of the continuum limit" on a box of fixed physical size.

We fix notation. $\mathbb{B}$ is the closed unit ball of the quaternions, and E_m is the space of configurations that put a value in $\mathbb{B}$ on each link of the box of side $2^m L$. Since E_m is a finite product of balls, it is a compact metric space. $B_m : E_{m+1} \to E_m$ is the block map, $\mathrm{down}_{n \to m}$ its $n - m$-fold composite, and the push-forward measure is

$$\nu_{n,m} = (\mathrm{down}_{n \to m})_* \, \mu_n \qquad (m \le n) \quad (1)$$

(Lean: `ChainBlockMap.blockMap`, `down`, `vP`). The block map includes a retract that returns the average of path products to the ball with threshold $r_0 > 0$ (19-04). r_0 is a free argument of the theorem (field `hr : 0 < r₀`), and the limit may depend on r_0. In

the box version the family of paths and the weights are also fixed (weights $(1/8, 3/4, 1/8)$, six orderings; Lean: `BoxWalk.boxPaths`, `boxW`).

This much is fixed by definition. Inside the theorem, the fine measure μ_n is an arbitrary family of probability measures. Besides this, the coupling functions u_k, activities z_k, supplies w_k, remainders $r_k^{\S}, r_k^{]}$, plaquette variables $Y_{m,p}$, background invariants $f_{m,x}$, the sequence of observables s_n, the reflection Θ_m, the symmetry actions, the set of small fields C_m and so on all enter as free variables. The assumption fields are conditions on these free quantities.

Assumptions	First conclusion	Second conclusion
The one-step structure for the coupling, rarity, splitting of observables, reflection positivity, symmetry, representation, and others (§ 02) All Assumption . The quantities are not defined from the lattice	For any target value t and step n, a point x with $u_n(x) = t$ lies in an explicit bracket (§ 03) A statement about u alone	Along some subsequence, $\nu_{n,m}$ converges at every level m, and the limit inherits the assumed properties (§ 04, § 05) The convergence itself holds without assumptions

Lean: `ChainBlockMap.chain_end_to_end_blockMap` (version with a general family of paths and weights), `BoxWalk.chain_end_to_end_box` (box version) — machine-checked as an implication (assumptions as in the tables). The two conclusions sit side by side, joined by "and", in a single statement.

02

The table of assumption fields

We list all the assumption fields. The column "Paid?" says whether the field is shown for concrete objects (measures or maps with a definition), or remains an assumption about abstract quantities. In the box version, the continuity of the block map and the consistency of the push-forward ($(B_m)_*\nu_{n,m+1} = \nu_{n,m}$) are paid from the definitions inside the theorem and do not appear as fields (Lean: `ChainBlockMap.continuous_blockMap`, `hcons_blockMap`).

Table 1 Fields on the side of measures and observables ($\nu_{n,m}$ is as in (1). "For large n" means "there is n_0 such that for $n \geq n_0$")

Lean field	Mathematical wording	Paid?

Lean field	Mathematical wording	Paid?
`rarity`	Assumption For each level m, large n and each block i of the region R_m: $\nu_{n,m}$(the plaquette variable $Y_{m,p}$ of block i exceeds the threshold $y_h(m)$, or the background invariant $f_{m,x}$ exceeds the threshold $f_h(m)$ (in Lean this threshold is named `θ`, which has nothing to do with the vortex ratio))$\le n_p(m)P_1(m) + n_{pt}(m)S(m)$. Rarity	Abstract. $Y_{m,p}$ and $f_{m,x}$ are free functions, and the event itself is not defined
`hCc`, `hgood`	Assumption C_m is a closed set and contains the event "in every block, plaquette variable $\le y_h$ and invariant $\le f_h$"	Abstract
`hθc`, `hθp`	Assumption Θ_m is continuous. For large n and F in the class $\mathcal{A}_m$, $\int F(\Theta_m\omega)F(\omega)\,d\nu_{n,m} \ge 0$. Reflection positivity	**There is a version paid with the Wilson measure** (§ 06; the class is a strip of fixed width)
`hsc`, `hsym`	Assumption The symmetry action g is continuous. For large n, $\nu_{n,m}$ is invariant under g	Abstract (remains in the Wilson version too)
`split`, `lattice_vanishing`, `shift_vanishing`	Assumption $\lvert s_n(d) - s_n(d')\rvert \le \tau_n + \Omega(\mathrm{dist}(d,d'))$, $\tau_n \to 0$, $\Omega(r) \to 0$ $(r \downarrow 0)$. Splitting of observables (a split form of equicontinuity)	Abstract. s_n is free
`hcount`, `hdense`, `hbd`	Assumption The set D in the space X of observable placements is countable and dense, and $\lvert s_n(d)\rvert \le K$ (K is one number independent of d and n; its Lean name is `Bd`)	Abstract
`hac`, `ham`, `hbr`, `hbv`	Assumption The symmetry action on X is continuous and preserves D, and the breaking $\lvert s_n(gd) - s_n(d)\rvert \le \varepsilon_b(g,n,d) \to 0$	Abstract
`hpos`	Assumption For large n, $\sum_{a,b} c_a c_b\, s_n(x_{ab}) \ge 0$ (the matrix form of reflection positivity)	Abstract
`HR`	Assumption For each $d \in D$ and large n, $s_n(d) = \int F_d\,d\nu_{n,\mathrm{lev}(d)}$ (F_d is a bounded continuous function at level $\mathrm{lev}(d)$). Representation	Abstract (holds trivially if s_n is *defined* as the expectation under ν)

Table 2 Fields on the side of the coupling (the structure `TransientChainError.CouplingStepsTransientE` and two outside it. The domain is $\{x : u_j(x) \ge u_\star\ (j \le k)\}$)

Lean field	Mathematical wording	Paid?

Lean field	Mathematical wording	Paid?
`flow`	Assumption $u_{k+1} = u_k - b + r^{\mathrm{s}}_k + r^{\mathrm{l}}_k$ (the one-step decrease of the coupling)	Abstract. $u, z, w, r^{\mathrm{s}}, r^{\mathrm{l}}$ are free functions $\mathbb{N} \times \mathbb{R} \to \mathbb{R}$, and $W, \Phi, \mathcal{D}, e$ are free functions $\mathbb{R} \to \mathbb{R}$
`small_net`, `transient`	Assumption $b_{\mathrm{inf}} + \delta_k - e(u_k) \le b - r^{\mathrm{s}}_k \le b_{\mathrm{p}} + e(u_k)$, $\sum_{k<n} \max(-\delta_k, 0) \le D_0$ (the net bracket for small fields, and the sum of transients)	
`large_rem`	Assumption $\lvert r^{\mathrm{l}}_k \rvert \le \mathcal{D}(u_k)\, z_k$ (the large-field remainder)	
`act_rec`, `act_nonneg`, `act_init`, `supply`	Assumption $z_{k+1} \le \rho z_k + A w_k + B z_k^2$, $z_k \ge 0$, $z_0 \le W(u_0)$, $w_k \le \Phi(u_k)$ (the recursion of activities, and the supply)	
`fix_shift`, `DW`, `margin`	Assumption $\rho W(s) + A\Phi(s) + B W(s)^2 \le W(s')$ ($u_\star \le s$, $u_\star \le s' \le s + D_0$), $\mathcal{D}(s) W(s) \le Y$, $e(u_\star) + Y \le b_{\mathrm{inf}}$ (a moving invariant interval, and the margin)	
`ustar_pos`, `he`, `hD`, `hρ`, `hA`, `hB`	Assumption $u_\star > 0$, e is decreasing on $[u_\star, \infty)$, $\mathcal{D} \ge 0$, $\rho, A, B \ge 0$	
`h0`, `hCu`	Assumption $u_0(x) = x$. $x \mapsto u_{k+1}(x)$ is continuous on the domain	Abstract

The fields of the two tables can be satisfied simultaneously Proved here . For example, take the region R_m, the class $\mathcal{A}_m$, P and the index sets of the two symmetry actions to be empty, $C_m = E_m$, X a single point, $s_n(d) = \int F_d \, d\nu_{n,\mathrm{lev}(d)}$, $u_k(x) = x - k$, $b = b_{\mathrm{inf}} = b_{\mathrm{p}} = 1$, the remainders, activities and supplies and $W, \Phi, \mathcal{D}, e, \delta, D_0, Y, \rho, A, B$ all 0, and $u_\star = 1$. With this choice, however, the corresponding conclusions are also trivial. No choice that pays the fields with quantities of real content is known.

Detour: what the one-step structure for the coupling actually says

May be skipped. The structure in Table 2 has seventeen fields, but the content that matters for the first conclusion is that "the one-step decrease $u_k - u_{k+1}$ of u lies in the bracket $[\, b_{\mathrm{inf}} + \delta_k - e(u_k),\ b_{\mathrm{p}} + e(u_k) \,]$", together with numerical conditions on $u_\star, e, \delta, D_0$ alone Proved here . Indeed, if an arbitrary u satisfies this bracket, then setting $r^{\mathrm{s}}_k := u_{k+1} - u_k + b$, $r^{\mathrm{l}} = z = w = 0$, $W = \Phi = \mathcal{D} = 0$, $Y = \rho = A = B = 0$ makes `flow`, `small_net`, `large_rem`, the four on activities and supply, `fix_shift`, `DW`, `hD`, `hρ`, `hA` and `hB` hold. The remaining four — $u_\star > 0$ (`ustar_pos`), e decreasing on $[u_\star, \infty)$ (`he`), the sum of transients $\sum_{k<n} \max(-\delta_k, 0) \le D_0$ (`transient`), and $e(u_\star) \le b_{\mathrm{inf}}$ (the $Y = 0$ form of `margin`) — do not follow from this choice, and remain as conditions on the choice of $u_\star, e, \delta, D_0$. The fields for the large-field remainder, activity and supply give a name to one "way of splitting" that produces the bracket; as long as the quantity that fixes the splitting (the decomposition of the effective action) is not defined from the lattice, they add no content by themselves. Which splitting carries meaning is the subject of the list of premises (28-04) and of the open places (28-06).

03

The first conclusion — the matching point lies in a bracket

The first conclusion has the following form.

$$\forall t \geq u_\star + D_0,\ \forall n,\ \exists x: \quad \begin{cases} t + (b_{\mathrm{inf}} - e(u_\star) - Y)\, n - D_0 \ \leq\ x \ \leq\ t + (b_{\mathrm{p}} + e(u_\star) + Y)\, n, \\ u_n(x) = t, \qquad u_k(x) \geq t - D_0 \ \ (k \leq n). \end{cases}$$

In the intended reading, x is the bare inverse coupling of the fine lattice, $u_k(x)$ the effective inverse coupling after k steps of renormalisation, and t the target value matched at the coarse end. Formula (2) reads: "the bare value x that becomes exactly t after n steps lies in an explicit bracket linear in n, and does not leave the domain at intermediate steps." The bracket closes around the one-loop decrease b because the one-step decrease lies in $[b_{\mathrm{inf}} - e,\ b_{\mathrm{p}} + e]$.

Formula (2) is a statement about the family of functions u and the constants of Table 2 alone. The fine measure μ_n, the push-forward measure $\nu_{n,m}$ and the observables s_n appear neither in (2) nor in the fields used to derive (2) (Table 2). Inside the theorem there is not a single field joining u and μ.

The proof runs in two steps. (i) On the domain, induct on k for the activity and the coupling together, and derive that the one-step decrease lies in the bracket (the large-field remainder is bounded by $\mathcal{D}W \leq Y$ and absorbed into the bracket by `margin`). (ii) From $u_0(x) = x$ and the continuity of u_{k+1}, take x with $u_n(x) = t$ inside the bracket by the intermediate value theorem Proved here . Both are arguments about real functions; the lattice does not appear.

04

The second conclusion — convergence along a subsequence

The second conclusion begins with the following existence statement.

$$\exists\, \varphi \text{ strictly increasing},\ \exists\, (\nu_m)_{m \geq 0} \text{ probability measures}: \qquad \nu_{\varphi(k),m} \xrightarrow[k \to \infty]{} \nu_m \quad (\text{wea}$$

Formula (3) **holds for any family of probability measures μ_n, without using a single assumption field**. The reason is that E_m is a compact metric space, and the space of probability measures on it is compact (and metrisable) in the topology of weak convergence Cited (Prokhorov's theorem, in the case of a compact space). Since the product over countably many levels m is also compact, one subsequence φ common to all m can be taken (Lean: `WeakUltravioletExistence.exists_common_subseq`).

So formula (3) by itself says nothing about what the limit is. The limit may depend on the choice of the subsequence φ. The limit has content reflecting the choice of the fine measure only through the "properties that pass to the limit" of the next section. Convergence of the full sequence (not a subsequence) is not among the conclusions of this theorem. It is the subject of the next chapter, 28-02, and one of the statements to be shown (convergence of the full sequence in 19-07, stated for the sequence of couplings fixed by matching).

The consistency of the push-forward $(B_m)_*\nu_{n,m+1} = \nu_{n,m}$ holds by definition, and since B_m is continuous it passes to the limit: $(B_m)_*\nu_{m+1} = \nu_m$ (Lean: `WeakUltravioletExistence.limit_consistent`). The family of limits is a projective system consistent with the block maps.

05

Properties that pass to the limit

The rest of the second conclusion is that the fields of Table 1 pass to the subsequential limit. All are of one type: "a closed condition that holds uniformly at finite n (for large n) is preserved in the weak limit."

Table 3 Properties for large n, and properties in the limit (the Lean conclusion structures `WeakUltravioletExistence.BlockConclusion` and `ObservableConclusion`)

Assumption (for large n)	Conclusion (in the limit)	Tool that carries it over
`h0c`, `h0p`	`reflection_positive`: for $F \in \mathcal{A}_m$, $\int F(\Theta_m\omega)F(\omega)\,d\nu_m \geq 0$	$F \circ \Theta_m \cdot F$ is bounded and continuous, so the integral converges, and ≥ 0 is a closed condition Proved here
`hsc`, `hsym`	`symmetric`: ν_m is invariant under the symmetry action	The same (an equality of integrals of bounded continuous functions) Proved here
`rarity`, `hgood`, `hCc`	`small_field_mass`: $\nu_m(C_m) \geq c_m$, $c_m = 1 - \lvert R_m\rvert\,(n_p P_1 + n_{pt} S)$	A union bound gives $\nu_{n,m}(C_m) \geq c_m$ for large n. The mass of a closed set does not drop in the weak limit: $\limsup_n \nu_n(C) \leq \nu(C)$ Cited
`HR`	For $d \in D$, $S(d) = \int F_d\,d\nu_{\mathrm{lev}(d)}$ and $s_{\varphi(k)}(d) \to S(d)$	The definition of weak convergence itself Proved here
`hbd`	`bounded`: $\lvert S(x)\rvert \leq K$ for all $x \in X$	A closed condition Proved here
`split`, `lattice_vanishing`, `shift_vanishing`, `hcount`, `hdense`	`continuous`, `modulus`: S extends uniformly continuously to all of X, with a modulus of continuity coming from Ω	Equicontinuity by an $\varepsilon/2$ argument; the limit on the countable dense D is extended to X Proved here

Assumption (for large n)	Conclusion (in the limit)	Tool that carries it over
`hac`, `ham`, `hbr`, `hbv`	`invariant`: $S(gx) = S(x)$	The breaking goes to 0, so equality on D; extended to X by continuity Proved here
`hpos`	`positive`: $\sum_{a,b} c_a c_b S(x_{ab}) \geq 0$	A closed condition Proved here

In Lean the non-degeneracy lower bound c_m is written as a subtraction of values in $[0, \infty]$, and when $|R_m|(n_p P_1 + n_{pt} S) \geq 1$ it is read as $c_m = 0$ (a lower bound without content). The lower bound has content only when the right-hand side of the rarity field is small compared with the size $|R_m|$ of the region.

This whole section shows that the implication on the side of measures goes only as far as "properties that hold uniformly at finite n pass to the weak limit". The properties themselves (rarity, reflection positivity, symmetry, equicontinuity of observables) all sit on the side of the assumptions. Of these, only the two fields in the next section are shown for concrete objects.

06

The version with the Wilson measure as the fine measure

There is a version in which the fine measure is the normalised SU(2) Wilson measure (coupling β_n, 19-01) on the box $(\mathbb{Z}/2^n L)^4$ of side $2^n L$. Here $\beta : \mathbb{N} \to \mathbb{R}$ is an *arbitrary sequence*. In addition, the reflection Θ_m is fixed to be the time reflection $x_0 \mapsto -x_0$ in a plane of lattice sites, and the class $\mathcal{A}_m$ is fixed to be the following $\mathcal{A}_m^{(c)}$.

$$\mathcal{A}_m^{(c)} = \{F \text{ bounded continuous} : \ F \text{ depends only on coarse links with base time in } \{1, \dots, 1$$

Then the reflection-positivity field `h0p` and the reflection-continuity field `h0c` are proved inside Lean and disappear (Lean: `BoxWalk.wilson_h0p`, `continuous_reflCfg`; the former is the assumption-free statement "for any sequence of couplings β and large n, the pushed-forward Wilson measure is reflection positive for the class of strip (4)"). The resulting statement is `BoxWalk.chain_end_to_end_box_wilson2` — machine-checked as an implication (the assumptions are those of Tables 1 and 2 minus `h0p` and `h0c`).

We state the scope of this version precisely.

- **Within the scope in which the two fields disappear, it is confirmed.** The class (4) is non-empty where m is large enough (it contains the function $\cos(\mathrm{Re}\, U_{\ell_0})$ of one link; Lean: `BoxWalk.stripSet_witness`), and the reflection positivity of the limit has content.

- **Read as "the chain has been closed with the Wilson measure", it is conditional.** The one-step structure for the coupling, rarity, the symmetry `hsym`, the representation and the observable fields all remain assumptions.
- The class (4) is a narrow class. The strip width c is one and the same number at every level m, does not widen as m grows, and does not include links in the time-0 plane. It is smaller than the positive-time class $\mathcal{A}_m(P)$ (the whole positive half) of the conditional implication assembled earlier (§ 08). That class is defined by reflection in a symmetric plane of the coarse lattice (for example a plane between lattice sites) and by pull-back to supports on the positive side of the fine lattice, and the reflection itself differs from $x_0 \mapsto -x_0$ in a plane of lattice sites. Moreover the conclusion is "some subsequence, and some limit" for each c, so "one limit is reflection positive for the strips of all c" does not follow from this one statement.

Even in the Wilson-measure version, β_n is an arbitrary sequence, and no relation at all is placed between it and u. This is the subject of the next section.

07

The reading that joins the two lies outside the theorem

So far, the content of the theorem has split in two.

(a) The side of measures	(b) The side of the coupling
Properties that hold uniformly on finite lattices (reflection positivity, symmetry, lower bounds on the mass of closed sets, equicontinuity of observables) pass to subsequential limits. The subsequential limit itself exists without premises.	From the one-step structure for the coupling, a matching point x with $u_n(x) = t$ can be taken inside an explicit bracket linear in n.

The intended reading joins the two by one sentence: "the fine measure μ_n is the Wilson measure at the coupling $\beta_n = 4x_n$ fixed by the matching point x_n (the point taken in (2) for the target t)." This sentence is **not in the theorem**. The Wilson version (§ 06) takes an arbitrary sequence β and places no relation between β_n and x_n. So all that can be read from the theorem is that (a) and (b) hold separately.

In the conditional implication assembled earlier (§ 08), this sentence is placed as a definition of the setting (the fine measure is defined to be the Wilson measure at the β_n chosen by the matching bracket for the bare coupling). Even in that implication,

however, the effective coupling u_k is defined not from the push-forward measure $\nu_{n,m}$ but as a quantity built from the Gibbs expectations (or ratios of partition functions) of separate finite lattices fixed for each step k, and the quantities on the side of the coupling and those on the side of the measure (for example a threshold on the coupling side, and the threshold $y_h(m)$ of the rarity event) are not joined inside the theorem. In the Lean chain theorem this definition is not placed either, and the fine measure is an arbitrary family.

To join them, the effective coupling u_k has to be defined from the lattice. For example, if u_k is defined as a function of some expectation under the Wilson measure at bare coupling x, then $u_n(x) = t$ in (2) becomes a statement about defined objects only: "match the fine Wilson measure so that some quantity at the coarse level takes a fixed value." That form is in 19-07 as one of the statements to be shown, "Matching" (19-07 states all the statements other than matching for the sequence of couplings fixed by matching). A choice remains as to which quantity to match by, and that belongs to the design choices (28-05).

In addition, the other quantities of Tables 1 and 2 are not defined from the lattice either. The effective coupling and the remainders (quantities that come from a decomposition of the effective action), the large-field activity and supply, the background field and its invariants, and the sequence of observables and its representation are all free variables inside the theorem. The fact that this theorem is "closed" is no substitute for defining these quantities from the lattice and showing the fields.

08

Relation to the conditional implication assembled earlier

This theorem rewrites an implication of the same type as the chain theorem of the conditional implication that this book's study assembled earlier (a form that derives weak ultraviolet existence of four-dimensional SU(2) lattice Yang–Mills theory in a small box by a machine-checked chain from per-step premises; 2026-10-30), with the coupling fields later put in a different form (the width of the bracket written with an error function e and transient terms δ_k) and the block map replaced by a concrete map on the box. The Lean of the earlier implication is a statement over an abstract block map. In the earlier implication, the fine measure is defined to be the Wilson measure at the β_n chosen by the matching bracket for the bare coupling (§ 07). Among the assumptions of the earlier implication, the small-field set assumption (at each level there is a closed set C_m with $\nu_{n,m}(C_m) \geq 1 - \eta_m$ for large n), equicontinuity of observables (equicontinuity of the expectations s_n) and the summability-of-increments assumption ($|s_{n+1}(x) - s_n(x)|$ is summable) are, once the fine measure is

given, statements written only with the push-forward measure and its expectations. The remaining assumption (the one-step bracket assumption for the coupling) is a statement about the effective inverse coupling u_k; the definition of u_k is on paper, and in Lean it is a free function. None of these assumptions has been shown in four dimensions, and the main theorem is an implication. The existence of four-dimensional Yang–Mills theory itself was shown by the construction published on 2026-11-10, with a different design (Volume 2; the two designs are compared in Part 14). In this book we first set out the statements that can be written with the push-forward measure alone as "statements to be shown" (19-07), and read the theorem of this chapter as the implication that takes charge of the part about subsequential limits and the properties that pass to the limit.

What this chapter can say

Can say	Cannot say
Implication: if all the fields of Tables 1 and 2 hold, then (2) holds, and the properties of Table 3 hold for the subsequential limit of (3). Lean: `BoxWalk.chain_end_to_end_box` (the box version of `ChainBlockMap.chain_end_to_end_blockMap`) — machine-checked as an implication (assumptions as in the tables)	None of the fields is shown for concrete quantities on the four-dimensional lattice (except the two of § 06). The quantities put into the assumptions are not defined from the lattice
Cited The subsequential limit of (3) exists for any family of probability measures (compactness). Lean: `WeakUltravioletExistence.exists_common_subseq`	That the limit does not depend on the subsequence (convergence of the full sequence; 28-02)
Proved here Formula (2) is a statement about u and the constants of Table 2 alone, and is not connected to the measure	That μ_n is the Wilson measure fixed by the matching point (a reading outside the theorem)
Wilson version: when the fine measure is the Wilson measure (an arbitrary sequence of couplings), `h0p` and `h0c` disappear. Lean: `BoxWalk.chain_end_to_end_box_wilson2`, `wilson_h0p` — confirmed within the scope in which the two fields disappear	That the chain has been closed with the Wilson measure (the remaining fields are assumptions). The class is the fixed-width strip (4), not the whole positive half
Proved here The fields of Tables 1 and 2 can be satisfied simultaneously (by trivial objects)	A choice that satisfies the fields simultaneously with objects of real content

Assumptions of the conditional implication assembled earlier (small-field set assumption, equicontinuity of observables, summability-of-increments assumption, one-step bracket assumption for the coupling; § 08)	—	Record of this book's study (2026-10-30)

Words used in this chapter — implication, push-forward measure, subsequence, weak convergence, projective system, one-step structure for the coupling, matching point, bracket, rarity, set of small fields, non-degeneracy lower bound, equicontinuity, representation, strip class. Their meanings are in A-02 Glossary.

Next chapter: 28-02 Convergence of the full sequence — reads conditions sufficient to remove the subsequence, in the form of a Lipschitz contraction of the one-step map and matching at the endpoint.

Convergence of the full sequence

> This chapter is this book's study.

What this chapter shows — The theorem of the previous chapter gives only subsequential limits. To remove the subsequence, it suffices that the differences of coarse-scale quantities when the lattice is made one step finer be summable. In this chapter we read, with all the assumptions shown, one sufficient condition that bounds those differences — a Lipschitz contraction of the one-step renormalisation map, and matching of the coupling at the coarse end — as the convergence of skew-product orbits matched at the endpoint (Lean: `SkewOrbit.coarse_tendsto` and others). Lean examples also show that the conditions $\varepsilon + \tau < 1$ and $4cc' < (1-\varepsilon-\tau)^2$ are necessary and sufficient for this method, and that matching at the endpoint cannot be removed.

Prerequisite chapters — 28-01 Implication of subsequential limits, 19-04 The block map, 19-07 Statements to be shown (convergence of the full sequence).

Said first — This is an implication. The theorem is a statement about orbits of points in a metric space, and no measure appears in it. The assumed one-step map (a map on the marginal coordinate u and the irrelevant coordinate v) is not defined from the lattice. So convergence of the full sequence for the continuum limit of the lattice does not follow from this theorem. What follows is only a conclusion of the form "if one step of renormalisation has this form and this contraction". The existence of four-dimensional Yang–Mills theory was shown by the construction published on 2026-11-10, with a different design (Volume 2). The implication of this chapter is a record within this book's design (measures pushed forward by a fixed block map) (28-00).

The order of this chapter

1. From a subsequence to the full sequence — what is missing — if the increments are summable, the full sequence converges
2. The form of the one-step map — the marginal direction and the irrelevant directions — the skew-product map, and families of orbits matched at the endpoint
3. The table of assumption fields — Lipschitz contraction, diameter, matching at the endpoint (Table 1)

4. The statement — the Cauchy property at the coarse end and uniqueness of the limit — difference $\leq D\theta^n$; the limit does not depend on the bare values
5. The route of the proof — a two-point boundary-value problem — differences in u propagate from the coarse side, differences in v from the fine side
6. Conditions and rate — necessary and sufficient for this method — eigenvalues of a linear model, and a rate that cannot be improved
7. Matching at the endpoint cannot be removed — an example where, for the same map, removing the matching gives a non-Cauchy sequence
8. The assumed map is not defined from the lattice — what must be defined for the statement to become a statement about the lattice

---

01

From a subsequence to the full sequence — what is missing

The subsequential limit of the previous chapter (28-01 § 04) exists for any family of probability measures. Since the limit may depend on the choice of subsequence, that alone does not allow us to say "one continuum limit has been determined". We need convergence of the full sequence (the sequence without passing to a subsequence).

There is an easy sufficient condition for convergence of the full sequence. For a sequence s_n of one coarse-scale quantity (for example the expectation of an observable at level m), if

$$|s_{n+1} - s_n| \leq \delta_n, \qquad \sum_n \delta_n < \infty \quad (1)$$

then s_n is a Cauchy sequence and converges, and every subsequential limit equals that limit Proved here (Lean: `WeakUltravioletExistence.tendsto_of_summable_increments`, `subseq_limit_eq`; the form for a family of observables is `WeakUltravioletExistence.weak_uv_observable_full`). In the conditional implication that this book's study assembled earlier (28-01 § 08), a condition of the form (1) is placed as an assumption (the summability-of-increments assumption). The summability-of-increments assumption assumes that, on a countable dense family of gauge-invariant functions, the step-by-step increments of the values of observables are summable. It is not the same statement as weak convergence of the full sequence of push-forward measures (convergence of the full sequence in 19-07, stated for the sequence of couplings fixed by matching): it is stronger by the summability, and the family of functions is different. The step from that family to all bounded continuous functions is an argument on paper.

The question is where to get the δ_n of (1). We push the two fine measures on lattice $n+1$ and lattice n forward to the same coarse level m and compare them. Since renormalisation maps compose, the side of lattice $n+1$ can be seen as "renormalise once, then follow the same road as lattice n". If the effective action after one step differs only a little from the bare action of lattice n, and that difference contracts over the remaining steps, then the difference at the coarse end becomes small. The theorem of this chapter writes the "contracts" part of this line of argument as a statement about orbits of points.

02

The form of the one-step map — the marginal direction and the irrelevant directions

We think of the effective action as described by two coordinates: the marginal coordinate $u \in \mathbb{R}$ (the inverse coupling) and the irrelevant coordinate v (everything else; a point of a metric space X). The one-step map from scale k ($k = n$ is the fine end, $k = 0$ the coarse end) to $k-1$ is

$$\Phi_k(u, v) = \big(u - b_k + r_k(u, v),\ T_k(u, v)\big) \quad (2)$$

(Lean: `SkewOrbit.step`). b_k is the one-step decrease of the coupling (a number near the one-loop value), r_k its correction, and T_k the map on the irrelevant coordinate. The map depends only on the step k, not on the lattice n one started from.

Why a skew product. If a map contracted in every direction, convergence of orbits would follow in the manner of the contraction mapping principle. The renormalisation map does not contract in the direction u of the coupling (under asymptotic freedom, u just decreases by roughly b at each step). Only the irrelevant direction v contracts, and the two directions affect each other through r_k and T_k. A map of this form is called a skew product.

The orbit of lattice n is the sequence of points that starts from the bare value $w_n(n)$ at scale n and goes down to the coarse end $w_n(0)$ by $w_n(k-1) = \Phi_k(w_n(k))$ (Lean: `SkewOrbit.IsOrbit`). For a family of orbits $(w_n)_n$, we call the following three together "admissible" (Lean: `SkewOrbit.Admissible`).

- Each w_n is an orbit from scale n to 0.
- **Matching at the endpoint**: for all n, the marginal coordinate at the coarse end takes the same value $\bar{u}$: $w_n(0)_u = \bar{u}$.
- The irrelevant coordinate stays, at every step, in a set $\mathcal{B} \subset X$ of diameter at most D.

Matching at the endpoint plays the same role as the first conclusion of the previous chapter (28-01 § 03: there is a bare value that becomes exactly the target value after n steps). The two theorems, however, do not refer to each other's quantities.

03

The table of assumption fields

Table 1 Assumptions for the convergence of skew-product orbits matched at the endpoint (fields of the midpoint version `SkewOrbit.coarse_tendsto_mid`; $v, v' \in \mathcal{B}$, u, u' all real numbers)

Lean field	Mathematical wording	Paid?
`hr`	Assumption $\lvert r_k(u,v) - r_k(u',v')\rvert \le \varepsilon \lvert u-u'\rvert + c\, d(v,v')$	Abstract. r_k, T_k, X are free and not defined from the lattice
`hT`	Assumption $d(T_k(u,v), T_k(u',v')) \le c' \lvert u-u'\rvert + \tau\, d(v,v')$	
`hB`	Assumption The diameter of $\mathcal{B}$ is $\le D$	Abstract
`hε`, `hc`, `hc'`, `hτ`, `hD`	Assumption $\varepsilon, c, c', \tau, D \ge 0$	Numerical conditions
`hετ`, `h4`	Assumption $\varepsilon + \tau < 1$, $4cc' < (1-\varepsilon-\tau)^2$	Numerical conditions (necessary and sufficient for this method, § 06)
`hw` (`Admissible`)	Assumption The family of orbits is admissible (being orbits, matching at the endpoint, staying in $\mathcal{B}$)	Abstract
`[CompleteSpace X]`	Assumption X is complete	Abstract

The general version (`SkewOrbit.coarse_step`, `coarse_cauchy` and others) is given one θ and assumes $\tau < \theta < 1 - \varepsilon$ and

$$q := \frac{cc'/(1-\varepsilon-\theta) + \tau}{\theta} < 1 \quad (3)$$

The θ of this chapter is the contraction rate, and has nothing to do with the vortex ratio θ_M (19-02). Taking the midpoint $\theta = (1-\varepsilon+\tau)/2$, (3) follows from $4cc' < (1-\varepsilon-\tau)^2$ (Lean: `SkewOrbit.midpoint_admissible`).

The Lipschitz fields are assumed for all values of u, but this is not a restriction. If the fields are assumed only on a window $u, u' \ge a$, and we add that the orbits stay in the window ($w_n(k)u \ge a$ for all n, k), the same conclusion follows (Lean: `SkewOrbitProbe.coarse_tendsto_window`, `limit_independent_window`; the original theorem is applied to the map cut off by $u \mapsto \max(u, a)$). This suits situations in which only estimates on the weak-coupling window $u \ge u_\star$ are used.

The assumptions can be satisfied simultaneously, and not only in trivial cases. With $X = \mathbb{R}$, $\mathcal{B} = [-1, 1]$ ($D = 2$), $b = 0$, $r(u, v) = \frac{7}{20}v$, $T(u, v) = \frac{7}{10}v + \frac{1}{20}u$ ($\varepsilon = 0$, $c = 7/20$, $c' = 1/20$, $\tau = 7/10$, $4cc' = 0.07 < 0.09$), one can build an admissible family in which the bare irrelevant coordinate oscillates near $\pm\frac{1}{2}$ and does not converge, while the coarse end converges (Lean: `SkewOrbitProbe.Ex.admissible`, `Ex.coarse_converges`, `Ex.bare_not_cauchy`).

04

The statement — the Cauchy property at the coarse end and uniqueness of the limit

Under the assumptions of Table 1, with $\theta = (1 - \varepsilon + \tau)/2$, the following holds.

$$d\big(w_{n+1}(0)_v,\ w_n(0)_v\big) \le D\,\theta^n \qquad (\text{all } n). \ (4)$$

So the irrelevant coordinate $w_n(0)_v$ at the coarse end is a Cauchy sequence; if X is complete it converges **along the full sequence**, and its limit v_∞ satisfies $d(w_n(0)_v, v_\infty) \le D\theta^n/(1-\theta)$. Moreover, the limits of two admissible families matched at the same $\bar{u}$ coincide. The limit does not depend on the choice of the bare irrelevant coordinates $w_n(n)_v$. A continuous function Ψ of the coarse-end point (u, v) converges along the full sequence to $\Psi(\bar{u}, v_\infty)$.

Lean: `SkewOrbit.coarse_step` (formula (4)), `coarse_cauchy`, `coarse_tendsto`, `coarse_rate`, `limit_independent`, `observable_tendsto`, and the midpoint versions `coarse_step_mid`, `coarse_tendsto_mid`, `limit_independent_mid` — machine-checked as an implication (assumptions as in Table 1).

Let us check what (4) compares. Cutting the orbit of lattice $n+1$ to scales n and below gives an orbit that starts at scale n from "the bare value with one step Φ_{n+1} applied" (Lean: `SkewOrbitProbe.one_step_after`). The orbit of lattice n starts from the bare value at scale n. Both are matched to $\bar{u}$ at the coarse end, so this is a comparison of two admissible orbits of the same length n.

Read in the language of the continuum limit, the statement becomes: "if a coarse-scale observable is a continuous function of (u_0, v_0), the sequence of its expectations converges without passing to a subsequence, and the limit does not depend on the choice of the irrelevant part of the bare action." This reading lies outside the theorem (§ 08).

05

The route of the proof — a two-point boundary-value problem

Compare two admissible orbits w, w' of the same length n, and set $x_k = |w(k)_u - w'(k)_u|$, $y_k = d(w(k)_v, w'(k)_v)$.

Step 1: the one-step inequalities. Taking the difference of the first components of (2) and using `hr` of Table 1 gives $x_k \le x_{k-1} + \varepsilon x_k + c\, y_k$, that is,

$$(1-\varepsilon)\, x_k \le x_{k-1} + c\, y_k, \qquad y_{k-1} \le c' x_k + \tau\, y_k \qquad (1 \le k \le n) \ (5)$$

(the latter is `hT`) Proved here . The boundary values are $x_0 = 0$ (matching at the endpoint) and $y_n \le D$ (the diameter of $\mathcal{B}$). x propagates from the coarse side ($k = 0$) towards the fine side, and y from the fine side ($k = n$) towards the coarse side.

Step 2: a weighted maximum. Set $M := \max_{k \le n} y_k\, \theta^{-(n-k)}$. Accumulating the first half of (5) from $x_0 = 0$, induction gives $x_k \le cM\theta^{n-k}/(1-\varepsilon-\theta)$ (it closes exactly because $\theta/(1-\varepsilon-\theta) + 1 = (1-\varepsilon)/(1-\varepsilon-\theta)$) Proved here .

Step 3: tightening. Putting this into the second half of (5) gives, for $k - 1 < n$, $y_{k-1}\theta^{-(n-k+1)} \le qM$ (q as in (3)). At $k = n$, $y_n \le D$. So $M \le \max(D, qM)$, and from $q < 1$ we get $M \le D$, in particular $y_0 \le D\theta^n$ Proved here (Lean: `SkewOrbit.two_point_bound`, `orbit_compare`).

The use of $q < 1$ in Step 3 is where the contraction condition does its work. Since the u direction does not contract, bounding the difference in u by the difference in v requires the difference in u to be 0 at the coarse end (matching at the endpoint).

06

Conditions and rate — necessary and sufficient for this method

Three facts about the choice of θ have been checked in Lean.

- **Necessary and sufficient**: the existence of a θ satisfying $\tau < \theta < 1 - \varepsilon$ and (3) is equivalent to $\varepsilon + \tau < 1$ and $4cc' < (1-\varepsilon-\tau)^2$ (Lean: `SkewOrbitProbe.theta_exists_iff`). Taking the midpoint loses nothing in the conditions.
- **The window of rates**: with $s = \sqrt{(1-\varepsilon-\tau)^2 - 4cc'}$ and $\theta_\pm = \big((1-\varepsilon+\tau) \pm s\big)/2$, every θ with $\theta_- < \theta < \theta_+$ can be used (Lean: `SkewOrbitProbe.rate_window`). The rate can be improved to just above θ_-.
- **A rate that cannot be improved**: with $\varepsilon = 0$, $c = 1/6$, $c' = 1/3$, $\tau = 1/2$ ($\theta_- = 2/3$, $\theta_+ = 5/6$), there are sequences satisfying (5) and the boundary values with $y_0 \ge (2/3)^n$

$/2$. So no decrease faster than θ_- follows from (5) (Lean: `SkewOrbitProbe.Sharp.sharp`).

$\theta_\pm$ are the eigenvalues of the matrix $\begin{pmatrix} 1-\varepsilon & -c \\ c' & \tau \end{pmatrix}$ of the linear model with the sign of the cross term reversed Proved here (the roots of the characteristic polynomial $\lambda^2 - (1 - \varepsilon + \tau)\lambda + (1-\varepsilon)\tau + cc'$). $4cc' \le (1-\varepsilon-\tau)^2$ is the condition for them to be real.

"Necessary and sufficient" here is **relative to this method of proof (the two-point estimate from (5))**. It is not a claim that convergence of the full sequence itself becomes false when the conditions fail. Formula (5) looks only at the sizes of differences and does not use the sign of the cross terms, so for maps where the sign is known there is room for better estimates.

07

Matching at the endpoint cannot be removed

With the same map as in the example of § 03 ($\varepsilon = 0$, $c = 7/20$, $c' = 1/20$, $\tau = 7/10$, $\mathcal{B} = [-1, 1]$), one can build a family in which every member is an orbit and the irrelevant coordinate stays in $\mathcal{B}$, but the marginal coordinates at the coarse end are not aligned. In that family the irrelevant coordinate at the coarse end is not Cauchy (Lean: `SkewOrbitProbe.Ex.matching_needed`).

What lies behind this is that the matrix of the map $\begin{pmatrix} 1 & c \\ c' & \tau \end{pmatrix}$ has a direction with eigenvalue $21/20 > 1$ (a direction close to the marginal direction). In this example, if u at the coarse end is not aligned, the orbits have a component in this direction, and its size alternates from one n to the next. Matching at the endpoint is the operation that fixes the component in this expanding direction afresh for each n.

So convergence of the full sequence does not follow from "contraction" alone. **How the bare coupling is chosen for each n (matching) is part of the statement.** In the language of the lattice this corresponds to "Matching" among the statements to be shown (19-07). The first conclusion of the previous chapter gives an existence of the same type (a bare value that becomes exactly the target value after n steps) for a different quantity, but the u of the two theorems is not set to be the same thing. There too, u is not defined from the lattice (28-01 § 07). Nor has it been shown, for general maps, that an admissible family exists (including that the irrelevant coordinate stays in $\mathcal{B}$).

08

The assumed map is not defined from the lattice

This theorem is a statement about orbits of points in the metric space $\mathbb{R} \times X$. Measures, lattices and block maps appear nowhere in the statement. To read it as convergence of the full sequence for the continuum limit of the lattice, the following must be fixed outside the theorem.

1. **Coordinates**: describe the effective action at step k by (u, v) — in particular the irrelevant coordinate v and its metric. The effective action (the effective measure at step k) itself is not yet defined from the lattice.
2. **The map**: write one step of renormalisation as a map Φ_k on those coordinates (that it takes the form (2), and that b_k is common to the two orbits).
3. **Contraction**: that the map has the Lipschitz estimates of Table 1 with constants satisfying $4cc' < (1 - \varepsilon - \tau)^2$.
4. **Observables**: that expectations of coarse-scale observables are continuous functions of the coarse-end coordinates (u_0, v_0).

All four are at present on the side of the assumptions. In the list of premises (28-04), the row for the Lipschitz contraction of the one-step map and matching at the endpoint carries the label "Form not fixed (object undefined)", and below it hang premises at the level of the representation, such as an induction uniform in the step and one-step renormalisation of small fields. Which coordinates and norm to choose is a design choice (28-05).

We have not checked whether the Lipschitz contraction follows from existing renormalisation-group estimates (estimates of analytic form in the fields and parameters). This chapter makes no claim about that prospect.

What this chapter can say

Can say	Cannot say
Proved here If the increments are summable, the full sequence converges, and subsequential limits equal its limit. Lean: `WeakUltravioletExistence.tendsto_of_summable_increments`, `weak_uv_observable_full`	That the increments of lattice expectations are summable (the assumption of the conditional implication assembled earlier, the summability-of-increments assumption)

Can say	Cannot say
Implication: under the assumptions of Table 1, the irrelevant coordinate at the coarse end converges along the full sequence, the differences are at most $D\theta^n$, and the limit does not depend on the bare values. Lean: `SkewOrbit.coarse_step`, `coarse_tendsto`, `limit_independent`, `observable_tendsto` — machine-checked as an implication (assumptions as in the table)	That the assumed maps r_k, T_k and coordinates X are defined from the lattice. Convergence of the full sequence for the continuum limit of the lattice
The existence of a usable θ is equivalent to $\varepsilon + \tau < 1$ and $4cc' < (1-\varepsilon-\tau)^2$. Lean: `SkewOrbitProbe.theta_exists_iff`, `rate_window`, `Sharp.sharp`	That convergence of the full sequence is false when the conditions fail (this is a limit of the method, not a negation of the statement)
Removing matching at the endpoint, there is a non-Cauchy family for the same map. Lean: `SkewOrbitProbe.Ex.matching_needed`	How to match on the lattice (which quantity, at which step)
Proved here The u of this chapter and the coupling function u of the previous chapter are separate variables of separate theorems	Setting the two to be the same. That an admissible family (orbits with matching that stay in $\mathcal{B}$) exists for the actual maps
The assumptions can be satisfied simultaneously by a non-trivial example. Lean: `SkewOrbitProbe.Ex.admissible`, `Ex.bare_not_cauchy`	That the actual renormalisation maps satisfy the assumptions

Words used in this chapter — convergence of the full sequence, summability of increments, skew product, marginal coordinate, irrelevant coordinate, one-step map, orbit, matching at the endpoint, admissible family, Lipschitz contraction, two-point boundary-value problem, window of rates. Their meanings are in A-02 Glossary.

Next chapter: 28-03 From decay to the mass gap, and the reduction of the band — reads the two implications on the infrared side, and the fact that there is no arrow between them.

From decay to the mass gap, and the reduction of the band

> This chapter is this book's study.

What this chapter shows — We read two implications on the infrared side. (i) If a sequence of measures has uniform exponential decay, the theory reconstructed from the limit measure has a mass gap (Lean: `OSGap.massGap_of_measures_sub`). Inside the strong-coupling window, these assumptions are all paid by concrete Wilson measures. (ii) If base point, nesting and widening hold for the vortex ratio θ, then $\ln(1/\theta)$ grows in proportion to the area (Lean: `BandReduction.band_reduction` and others). Finally we write down that there is no arrow from the conclusion of (ii) to the assumptions of (i).

Prerequisites — 19-03 The vessel of reconstruction and the definition of the mass gap, 20-04 Reconstruction and the mass gap, 19-02 The vortex ratio θ, 26-02 Reduction to one inequality.

Said first — Both are implications. Outside the window, (i) remains an assumption, and there is no concrete sequence of measures (a sequence in which the lattice spacing moves) that pays the assumptions. Also, the conclusion alone cannot exclude the trivial case in which the Hilbert space contains only the vacuum. (ii) is a statement of inequalities about a real function $\theta(R, L)$; neither lattice nor measure appears in it. That the actual vortex ratio satisfies the three assumptions has not been shown. There is no arrow, either in Lean or on paper, that derives the mass gap from the area exponent. Exponential decay uniform in the lattice spacing is not in the construction published on 2026-11-10 either; what it has goes only as far as estimates of polynomial speed at long distances (16-03). The two implications of this chapter are shaped towards the open question on the infrared side.

The order of this chapter

1. The two implications, and what lies between them — decay ⇒ gap; the three assumptions ⇒ area exponent; area ⇒ gap is absent
2. From decay to the mass gap — the statement — reconstruction over the limit measure, and ‖ T − P_Ω ‖ ≤ e^{−m}

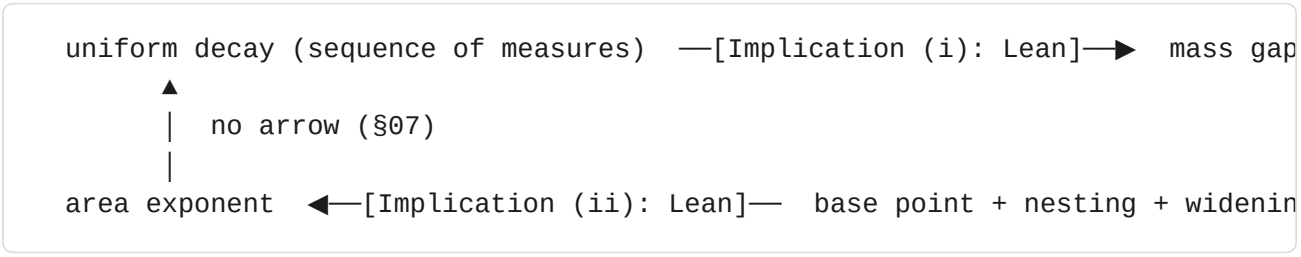
3. From decay to the gap — the table of assumption fields — reflection positivity, symmetry, translation, decay (Table 1)
4. Inside the strong-coupling window, everything is paid — relation to the theorem of 20-04, and outside the window
5. The reduction of the band — the statement — at scales doubling each time, the bias shrinks by a fourth power
6. The reduction of the band — the table of assumption fields — base point, nesting, widening (Table 2)
7. There is no arrow from the area exponent to the mass gap — the two roads exist separately

---

01

The two implications, and what lies between them

On the infrared side (the side of long distances) there are two goals. One is the mass gap (contraction of the transfer operator away from the vacuum); the other is confinement (the vortex ratio and loop expectations decreasing in proportion to the area). The two implications of this chapter take charge of the last step towards each goal.



Both arrows are machine-checked in Lean in the form "if ..., then ...". The assumption sides (uniform decay, the three inequalities) correspond to "mass gap (uniform decay)" and "band" among the statements to be shown (uniform decay and band in 19-07, both stated for the sequence of couplings fixed by matching), and neither has been shown in a form in which the lattice spacing moves. The vertical arrow of the figure, as § 07 explains, does not exist.

02

From decay to the mass gap — the statement

We fix the setting. X is the space of configurations and Y the space of configurations on the positive side. The continuous maps $r, \Theta_r : X \to Y$ are the map that restricts a

configuration to the positive side, and the map that reflects in the mirror and then restricts. $\mathrm{sh} : Y \to Y$ is the translation by one time unit. Observables are bounded continuous functions on Y; among them we use a subspace W that contains the constant 1 and is closed under translation (for example functions that depend only on finitely many time slices). For a measure ν, the pairing and the translation are

$$\langle F, G\rangle_\nu = \int F(\Theta_r x)\, G(rx)\, d\nu(x), \qquad (\tau F)(y) = F(\mathrm{sh}\, y) \quad (1)$$

If the pairing is positive semidefinite and symmetric, and τ is symmetric with respect to the pairing, one can build the Hilbert space obtained by quotienting W by the pairing and completing, the transfer operator T coming from τ, and the vacuum Ω coming from the constant 1 (the vessel of reconstruction; 19-03). A mass gap m means $\|T - P_\Omega\| \le e^{-m}$ (P_Ω is the projection onto the vacuum; 19-03).

Implication (i). Suppose a sequence of probability measures μ_n converges weakly to ν, and the fields of Table 1 hold. Then there is a vessel of reconstruction D over W whose pairing is the pairing (1) of ν, whose translation is τ and whose constant is 1, and D has mass gap m.

Lean: `OSGap.massGap_of_measures_sub` — machine-checked as an implication (assumptions as in Table 1). The conclusion ties the pairing, translation and constant of the vessel to the quantities of ν; it is not a form in which the vessel can be chosen at will.

The route of the proof has three steps. (1) Reflection positivity, symmetry and the symmetry of translation pass to the weak limit because $F \circ \Theta_r \cdot G \circ r$ is bounded and continuous (the same type as 28-01 § 05) Proved here . (2) With these, the vessel over ν can be built. (3) The decay field also passes to the limit, and $\langle \tau^k F, \tau^k F\rangle_\nu - \langle 1, F\rangle_\nu^2 \le C_F e^{-2mk}$ holds for all $F \in W$. Translated into the language of Hilbert space, this says that T^k contracts by e^{-mk} on vectors orthogonal to the vacuum, which gives $\|T - P_\Omega\| \le e^{-m}$ (Lean: `OSGap.Datum.hasMassGap_of_decay`).

03

From decay to the gap — the table of assumption fields

Table 1 Assumptions of `OSGap.massGap_of_measures_sub` ("for large n" means "there is n_0 such that for $n \ge n_0$"; $F, G \in W$)

Lean field	Mathematical wording	Inside the strong-coupling window	Outside the window

Lean field	Mathematical wording	Inside the strong-coupling window	Outside the window
`h`	Assumption $\mu_n \to \nu$ (weak convergence)	All paid by the Wilson measure (§ 04, 20-04)	Abstract (convergence of a sequence in which the lattice spacing moves has not been shown)
`h1`, `hW`	Assumption $1 \in W$, and W is closed under translation		A choice of the class of observables
`hRP`	Assumption For large n, $\int F(\Theta_r x)F(rx)\,d\mu_n \geq 0$ (reflection positivity)		A theorem for measures on the fine lattice (20-01). For pushed-forward measures it depends on the class
`hsym`, `hshift`	Assumption For large n, the pairing is symmetric, and translation is symmetric with respect to the pairing		Abstract
`hdec`	Assumption For each F there is a constant C_F such that for each k and large n, $\int F(\mathrm{sh}^k\Theta_r x)F(\mathrm{sh}^k rx)\,d\mu_n - \left(\int F(rx)\,d\mu_n\right)^2 \leq C_F e^{-2mk}$ (uniform decay)		Form fixed, not shown (needs an m uniform in the lattice spacing)

In the decay field `hdec`, m and C_F do not depend on n. The mass m of the limit theory is a number in units of one time step of the lattice on which the measures μ_n live. To speak of a physical mass in the continuum limit, block observables at coarse scales must decay at a rate independent of the lattice spacing and the box size. That is "mass gap" among the statements to be shown (uniform decay in 19-07, stated for the sequence of couplings fixed by matching), and paying the assumption `hdec` of this implication in that form is open outside the window. The field `h` also assumes weak convergence of the sequence μ_n. When there is only a subsequential limit, as in the previous chapter (28-01 § 04), applying it to that subsequence gives a conclusion "about that limit point", and the limit itself is not determined uniquely.

The conclusion alone cannot exclude the trivial case. If the space obtained by quotienting W by the pairing is only the vacuum (one-dimensional), then $T - P\Omega = 0$ and a mass gap holds for any m. The assumption fields can also be satisfied simultaneously on a one-point space Proved here . A mass gap with content requires saying separately that there are states outside the vacuum (non-degeneracy). The theorem for the strong-coupling window includes non-degeneracy in its statement (20-04).

> 04

Inside the strong-coupling window, everything is paid

In the strong-coupling window $18\tanh|\beta|<1$ ($|\beta|<0.0556$ Reading), the sequence obtained by lifting the normalised Wilson measures on the periodic boxes $(\mathbb{Z}/2(n+1))^4$ periodically to $\mathbb{Z}^4$ converges weakly, without a subsequence, to a single measure ν_β. On top of that, the properties corresponding to the fields of Table 1 (reflection positivity, symmetry, translation, decay) are all shown for concrete measures, the vessel of reconstruction satisfies $\|T-P_\Omega\|\le(18\tanh\beta)^{1/2}$, and there are states outside the vacuum ($0<\beta$; Lean: `InfMain2.wilson_infvol_main2`; the statement gathered into one in 20-04). This is a formalisation of a result of a known type from the strong-coupling expansion Cited (of the type of Osterwalder–Seiler, Ann. Phys. 110 (1978) 440).

Here is what the theorem inside the window does not say. The lattice spacing is fixed at 1. The window is only $|\beta|<0.0556$, and does not reach the side of the continuum limit ($\beta\to\infty$). The mass figure $-\frac{1}{2}\log(18\tanh\beta)$ is only a lower bound.

So the position of implication (i) is as follows. **Inside the window, all the assumptions of the implication are paid, and the conclusion stands as a theorem about concrete Wilson measures. Outside the window, they remain assumptions.** To use it for the mass gap of the continuum limit, one needs to show the fields of Table 1 for a sequence of measures in which the lattice spacing moves (the sequence of fine-lattice measures pushed forward to a coarse level, 28-01), and none of them has been shown.

05

The reduction of the band — the statement

The goal on the side of confinement is that the vortex ratio becomes small in proportion to the area. In the intended reading, $\theta(R,L)$ is the sector bias at a typical frame, for a container of size R in the directions of the plane and a transverse torus of side L, with lengths measured in physical units (26-02 § 01; the definition of the vortex ratio on the lattice is in 19-02). The goal is $\ln(1/\theta(R,R))\ge cR^2$ for a $c>0$ uniform in physical units.

Implication (ii). Let $\theta:\mathbb{N}\times\mathbb{N}\to\mathbb{R}$ be an arbitrary function, and assume the structure `Hyp` of Table 2 (non-negativity, base point, nesting, widening). The assumptions outside the structure are $L_0>0$, $s\ge1$, $C\ge0$, $C_D\ge0$, $c\ge0$, $c^3=4CC_D$. Taking doubling scales $R_k=2^k sL_0$, for all k

$$c\,\theta(R_k,R_k)\;\le\;\big(c\,t_0\big)^{4^k},\qquad t_0:=Cs^2\,C_D\,(1-\varepsilon_0)^{s^2}\quad(2)$$

holds. Moreover, if $c \geq 1$ and $0 < c\,t_0 < 1$, then when $\theta(R_k, R_k) > 0$ (the assumptions of `area_exponent` are these three and (2))

$$4^k \ln \frac{1}{c\,t_0} \;\leq\; \ln \frac{1}{\theta(R_k, R_k)} \quad (3)$$

and since $4^k = R_k^2/(sL_0)^2$, this is the form of the area exponent, $\ln(1/\theta(R_k, R_k)) \geq c' R_k^2$.

Lean: `BandReduction.band_reduction` (formula (2)), `area_exponent` (formula (3)), and the parts `BandReduction.jump` (from the base point, one nesting and one widening give $\theta(sL_0, sL_0) \leq t_0$) and `step` (one doubling step, $\theta(2R, 2R) \leq 4CC_D\,\theta(R, R)^4$) — machine-checked as an implication (assumptions as in Table 2).

The core of the proof is `step`. Using nesting with $n = 2$ gives $\theta(2R, R) \leq C_D \theta(R, R)^4$, and using widening with $L = R$, $L' = 2R$ gives $\theta(2R, 2R) \leq 4C\,\theta(2R, R)$; together, $t_{k+1} \leq 4CC_D\,t_k^4$. Setting $c^3 = 4CC_D$ gives $c\,t_{k+1} \leq (c\,t_k)^4$, and induction gives (2) Proved here .

There is also a version that, instead of the base point, puts in a number at one size, $\theta(R_0, R_0) \leq t_0$, and uses widening only "at doubling steps where the bias is already small" (Lean: `BandFiniteSize.doubling`; the assumptions are three in the structure — non-negativity, the $n = 2$ case of nesting, and widening when $\theta(2L, L) \leq \delta$ — and $R_0 > 0$, $C \geq 0$, $C_D \geq 0$, $c \geq 1$, $c^3 = 4CC_D$, $\theta(R_0, R_0) \leq t_0$, $c\,t_0 \leq 1$, $C_D t_0^4 \leq \delta$). The conclusion has the same form as (2).

06

The reduction of the band — the table of assumption fields

Table 2 Fields of the structure `BandReduction.Hyp` (θ is an arbitrary function $\mathbb{N} \times \mathbb{N} \to \mathbb{R}$)

Lean field	Mathematical wording	For the intended θ
`nonneg`	Assumption $\theta(R, L) \geq 0$ for all R, L	For the vortex ratio at fixed lattice spacing, a theorem for all real β when the longitudinal size is even (21-06). The correspondence with the container bias is on paper
`base`	Assumption $\theta(L_0, L_0) \leq 1 - \varepsilon_0$ (base point)	In the form with fixed lattice spacing, the thin-vortex floor $\lvert\theta_M\rvert \leq \tanh(N^2\lvert\beta\rvert)^{M^2}$ is a theorem (21-02). A form uniform in the lattice spacing has not been shown
`nest`	Assumption $\theta(nR, L) \leq C_D\,\theta(R, L)^{n^2}$ for all R, L, n (nesting)	Input on paper (the nesting argument of 26-02). The correspondence with the Lean field is also on paper
`widen`	Assumption For $0 < L \leq L' \leq R$, $\theta(R, L') \leq C\,(L'/L)^2\,\theta(R, L)$ (widening)	Not shown. There is one sufficient condition (direction-wise subadditivity of the vortex free energy) (28-04), but whether it holds is open

This implication is a statement about real inequalities. θ is an arbitrary function, and lattice, measure and lattice spacing do not appear in the statement. That the intended θ (the container bias) satisfies the three assumptions is placed as input on paper and has not been shown. In particular, in the intended reading all lengths are in physical units, and the assumptions must be uniform in the lattice spacing. The floor theorems at fixed lattice spacing (21-02, 21-03) do not give this uniformity.

The assumptions can be satisfied simultaneously Proved here . With $\theta(R, L) = e^{-R^2}$, $C_D = C = 1$ and ε_0 small, nesting holds with equality and widening holds because $(L'/L)^2 \geq 1$. In this example the conclusion is of a form known from the start, and the example only shows that the assumptions are not contradictory. Also, using nesting with $n = 1$ forces $C_D \geq 1$ when $\theta > 0$.

The forms of other statements about the band — the doubling inequality for the tension, monotonicity, one-scale criteria and so on — are laid out with labels in the list of premises (28-04). This chapter does not give them chapters of their own.

07

There is no arrow from the area exponent to the mass gap

There is no arrow, either in Lean or on paper, from the conclusion of implication (ii) (the area exponent) to the assumption of implication (i) (uniform decay of block observables).

"Area law ⇒ mass gap" in its naive form is false in general Proved here . For example, on a two-dimensional lattice, take a gauge theory with an area law and add to it, as a direct product, a decoupled model without a mass gap (for example the critical two-dimensional Ising model; that the gap of the transfer matrix closes at the critical point is in 2-09 § 07). The expectation of a Wilson loop is determined by the gauge part alone, so the area law remains, but the correlations of the Ising part do not decay exponentially, so the theory as a whole has no mass gap (the gap of the transfer matrix of a direct product is the smaller of the two gaps). So deriving decay from the area exponent requires a separate argument that uses the absence of such decoupled parts.

In the opposite direction there is the following result Cited (Chatterjee, Comm. Math. Phys. 385 (2021) 1007, arXiv:2006.16229; 17-02). If centre symmetry is not broken, Wilson loops satisfy $|\langle W(R \times T)\rangle| \leq e^{-V(R)T}$ with $V(R) \to \infty$ (this stops short of saying that the string tension is positive), and if moreover one assumes a strong form of gap — uniform exponential decay under arbitrary boundary conditions — the area law follows. This strong form of decay is not the same as the assumption of implication (i) of this chapter, nor as the mass gap in the Clay sense. The two implications of this book have no arrow in that direction in Lean either.

So on the present map the two roads exist separately.

- **The road of the mass gap**: uniform decay ⇒ mass gap (implication (i)). The assumed uniform decay is shown inside the window and open outside it.
- **The road of confinement**: base point, nesting, widening ⇒ area exponent (implication (ii)). The three assumptions have not been shown in a form uniform in the lattice spacing.

By which road the last arrow to the mass gap is to be drawn (whether, for example, to use the comparison rows that write band quantities in the language of the mass gap) is the subject of the list of premises (28-04) and of the open places (28-06). This chapter does not claim which road goes through.

What this chapter can say

Can say	Cannot say
Implication (i): if a sequence of measures converges weakly and the fields of Table 1 hold, the vessel of reconstruction over the limit measure has mass gap m. Lean: `OSGap.massGap_of_measures_sub` — machine-checked as an implication (assumptions as in the table)	Showing the fields outside the window, for sequences in which the lattice spacing moves. The conclusion alone does not give non-degeneracy (states outside the vacuum)
In the strong-coupling window $18 \tanh \lvert\beta\rvert < 1$, $0 < \beta$, the fields are all paid by concrete Wilson measures, and a mass gap with non-degeneracy holds. Lean: `InfMain2.wilson_infvol_main2` (20-04)	Moving the lattice spacing, outside the window, an upper bound on the mass (only a lower bound)
Implication (ii): from base point, nesting and widening, $\ln(1/\theta)$ grows in proportion to the area at doubling scales. Lean: `BandReduction.band_reduction`, `area_exponent`, `jump`, `step`, `BandFiniteSize.doubling` — machine-checked as an implication (assumptions as in the table)	That the intended θ satisfies the three assumptions (input on paper). Base point and widening uniform in the lattice spacing
Proved here The naive "area law ⇒ mass gap" is false when there is a decoupled part without a mass gap	An arrow deriving uniform decay from the area exponent (neither in Lean nor on paper)

The reduction of the band (§ 05, § 06)	Lean	`BandReduction.Hyp`, `band_reduction`, `area_exponent`, `jump`, `step`, `iterate`, `BandFiniteSize.Hyp`, `doubling`. The statements were copied by reading the source text. The reduction on paper is in 26-02
Examples in which the assumptions are satisfied simultaneously (§ 03, § 06)	Proved here	The choices given in the text
A result in the direction from the gap to confinement (§ 07)	Cited	S. Chatterjee, Comm. Math. Phys. 385 (2021) 1007, arXiv:2006.16229

Words used in this chapter — implication, vessel of reconstruction, transfer operator, projection onto the vacuum, mass gap, uniform decay, non-degeneracy, strong-coupling window, vortex ratio, sector bias, base point, nesting, widening, area exponent. Their meanings are in A-02 Glossary.

Next chapter: 28-04 The list of premises — tree and labels — lays out, with labels, the tree whose root is the statements to be shown and whose leaves are the sufficient conditions on the present road, including the assumptions of the three implications.

The list of premises — tree and labels

This chapter is this book's study. The dictionary of § 09 is a guide.

What this chapter shows — A tree with the six statements of 19-07 (the roots) at the top and the 57 rows of sufficient conditions that support them on the present road below, and a table of the 57 rows. For each row we give the name of its content, a one-line statement, the object the statement is about, the label, and, if the form is not fixed, the reason symbol. We also give counts by label, and a table matching these names to the names in the conditional implication assembled earlier and to the names in the ledger of Part 27.

Prerequisite chapters — 28-00 Entrance (key to the labels), 19-07 The statements to be shown. The definitions of the objects are in Part 19 (19-01–19-04).

Said first — This list is as of 2026-11-13, and the labels move. Updates are made in A-08 A map to the mass gap. Many statements in the tables use quantities not yet defined from the lattice (effective coupling, activity, background field and so on). Those rows are marked "Form not fixed" or "Object: no definition", and do not claim that the statement has a meaning. The rows supporting the roots on the ultraviolet side (most of Tables 2 and 3) are a record of sufficient conditions in this book's design (the measure pushed forward by a fixed block map). The existence of four-dimensional Yang–Mills theory was shown, with a different design, by the construction published on 2026-11-10 (Volume 2; the two designs are compared in Part 14). The rows on the infrared side (uniform decay in Table 4, and the band in Table 5) are aimed at questions that remain open.

The order of this chapter

1. How to read the stages and labels — the order of the tables, and seven labels
2. The tree — the root, and sufficient conditions through a representation (Figure 1)
3. Counts by label, and what they tell us (Table 1)
4. Premise of the box continuum limit — the continuum limit in a fixed box (Table 2, 17 rows)
5. Premise of ultraviolet stability — estimates of ultraviolet stability (Table 3, 21 rows)

6. Premises of full-sequence convergence, observables, infinite volume, rotation and non-triviality (Table 4, 7 rows)
7. The band — rows on the vortex free energy (Table 5, 12 rows)
8. Five rows added outside the 57 (Table 6)
9. A dictionary of other names (short version, Table 7)

01

How to read the stages and labels — the order of the tables, and seven labels

The order of the tables. The rows are arranged in four tables, in the order of the stages into which the road to a proof is divided. The number in the left column of each table is a running number within that table. In the text, rows are referred to by the name of their content.

Stage	Table	Rows
Premise of the box continuum limit: the continuum limit in a box of fixed size (premises of the chain of block maps)	Table 2	17
Premise of ultraviolet stability: estimates of ultraviolet stability (step-by-step estimates; the kinds of estimate, in order, are free-field input, constrained Green's functions, background field, small-field expansion, large fields, and induction across steps)	Table 3	21
Premises of full-sequence convergence, fine observables, infinite volume, rotation and non-triviality	Table 4	7
The band (crossover of the vortex free energy; the rows around the band in the ledger of conditions, 27-02)	Table 5	12

The free-field premise (absolute conditions on the free field) is a reference to rows of the premise of ultraviolet stability (bracketing of the propagator, contraction of irrelevant terms, coefficient of the one-step decrease of the coupling, contraction of the background map, geometry of many-body sums (correlation norm), large-field estimate), so it has no rows of its own. The fermion premise is outside the scope of this list.

Labels. A premise label is one column of a table, and is separate from the labels of the text (Proved here, Cited, Computer-assisted, Reading, Assumption) (key in 28-00).

Label	Meaning
Theorem	Machine-checked in Lean, and a check that compares the definitions and the statement with a separate pair of eyes has confirmed the content of the statement

Label	Meaning
Theorem (weak form)	The same, but only up to a form weaker than the premise. The same column says whether it **pays the premise's column as it stands** or is a **similar but different statement** (a different object, a subfamily, a linearisation and so on)
On paper	There is an argument on paper. The check comparing definitions and statement with a separate pair of eyes has not been done
Form fixed, unproved	The form of the statement is settled. There is no proof. "Conditional" means: only when, for the sequence fixed by matching, the restrictions on threshold and period are put into the statement
Form not fixed	The form of the statement is not yet settled. The reason is given by a symbol
Depends on design	A row determined by a design choice (28-05)
Literature	Depends on a result in the literature. Not re-derived in this book

Reason symbols (for rows whose form is not fixed): (a) too light (stands for trivial objects), (b) too strong (false, or there are examples where it is false), (c) object undefined, (d) there are numerical signs against the present form, (e) there is a form at one scale but no form across steps, (f) the order of quantifiers is not fixed.

The "Object" column of the tables says which object the statement is about. Objects with a definition in Part 19 are linked by anchor; those without are marked "no definition".

02

The tree — the root, and sufficient conditions through a representation

The root of the tree is the six statements of 19-07. The root is written with defined objects only. Below it hang the premises (leaves) we place in order to derive the root on the present road. Many of the leaves are statements made through a **representation** (quantities used to write down the theory at coarse scales): effective couplings, activities, background fields, classes.

Figure 1 The tree of the root and sufficient conditions (as of 2026-11-13; labels in parentheses)

```
Matching (19-07 §02)
  └─ sufficient conditions through the effective coupling
       │  · definition and continuity of the effective coupling (design)
       │  · net one-step bracket of the coupling (not fixed)
       │  · large-field contribution to the coupling (not fixed)
       │  · recursion of the activity (not fixed)
       │  · rarity of supply (not fixed)
       │  · moving invariant interval and margin (not fixed)

        · gap of a small twisted box and uniform acceptance of insertion (not
        · from the vortex area exponent to the Wilson-loop area law (lit.)
```

Three things can be read from the tree.

1. **At the level of the root, the forms of the statements are settled** (except for the choice of matching). The root, however, has content only when read for the sequence fixed by matching (if the sequence is taken freely, $\beta_n \equiv 0$ makes the uniform-decay and band parts of the root stand; 19-07 § 01). Of the 24 rows whose form is not fixed, 13 sit at the level of the representation below the root, 8 are rows whose object does not yet exist or which are settled after something upstream, and 3 concern the quantification and truth of band statements (28-06). Changing the representation changes the leaves, not the root.
2. **The plaquette part of non-degeneracy (rarity of two-step events: plaquette part) and equicontinuity (equicontinuity of observables) are premises whose form is, as it stands, a statement about defined objects only**; they do not go through a representation.
3. **The open forms on the side of the band come not from the representation but from the order of quantifiers and from truth** (tension-doubling inequality, monotonicity of the vortex free energy and renormalisation comparison, from the area law to the gap). Their origin differs from the ultraviolet side.

Inside the chain theorem of the present road (28-01), the sequence of bare couplings β_n and the effective coupling are not connected. The Lean theorem takes the sequence of bare couplings arbitrarily. The conditional implication assembled earlier (28-01

§ 08) joins the two by defining the fine measure to be "the Wilson measure at the β_n chosen by the matching bracket for the bare coupling", but the proof itself splits into the coupling side and the measure side. The candidate place in the chain where the two could be joined is linking the thresholds.

03

Counts by label, and what they tell us

Table 1 Counts by label (as of 2026-11-13, 57 rows; the 5 rows added in § 08 are not counted)

Label	Count	Rows
Theorem	3	Continuity, composition and push-forward consistency of the block map, reflection positivity of the fine lattice, constrained inverse identity
Theorem (weak form)	10	Gauge covariance and locality, commuting with the lattice symmetries, reflection positivity at the coarse level, single-scale rarity on the fine lattice, bracketing of the propagator, contraction of irrelevant terms, coefficient of the one-step decrease of the coupling, contraction of the background map, geometry of many-body sums (correlation norm), non-negativity of θ
On paper	8	Symmetries of the measure, family of observables and small-field set, one-step background-field lemma, multistep background field, single-scale expansion tools, gauge fixing step by step, class and localisation, frame decorrelation
Form fixed, unproved	7	Rarity of two-step events: plaquette part, equicontinuity of observables, Constrained Decay Theorem, uniform decay of block observables, base point at small T^2, single-scale criterion, lateral-widening inequality (strong form) (the Constrained Decay Theorem in the version around the vacuum; the other 6 rows conditional)
Form not fixed	24	Net one-step bracket of the coupling, large-field contribution to the coupling, recursion of the activity, rarity of supply, moving invariant interval and margin, rarity of two-step events: background-invariant part, positivity with background, zero-order transport of the background, small-field one-step renormalisation theorem, large-field estimate, large-field gas, induction uniform in the step, contraction of the one-step map and matching at the endpoint, approximation of flowed observables by block variables, ultraviolet estimate uniform in the box size, one-step ultraviolet estimate for the bridge, independence of the infinite-volume limit from the box shape, the limit is not a free field, question of the cost of a twist-inserting map, tension-doubling inequality, monotonicity and renormalisation comparison, gap of a small twisted box and uniform acceptance of insertion, band comparison (in the language of the gap), from the area law to the gap
Depends on design	2	Definition and continuity of the effective coupling, row sums of the lift uniform in the step
Literature	3	Value of the one-loop coefficient, from the vortex area exponent to the Wilson-loop area law, forest interpolation formula

The objects that rows with a theorem label speak about. The 13 rows labelled "Theorem" or "Theorem (weak form)" are statements about one of the following: the Wilson measure on the fine lattice (reflection positivity of the fine lattice, single-scale rarity on the fine lattice, non-negativity of θ), the block map itself (continuity, composition and push-forward consistency of the block map, gauge covariance and locality, commuting with the lattice symmetries), structural properties of the push-forward measure (reflection positivity at the coarse level, for the strip class), the free field, the vacuum background and the linearised blocking (bracketing of the propagator, contraction of irrelevant terms, coefficient of the one-step decrease of the coupling, contraction of the background map, geometry of many-body sums (correlation norm)), or an abstract identity (constrained inverse identity). **There is no theorem giving quantitative estimates for measures at renormalised scales (the push-forward measure $\nu_{n,m}$ or the effective measure at step $k \geq 1$).** For the push-forward measure, what exists is only structural properties carried over from the fine measure by the push-forward.

Rows that pay a column as it stands. Of the 10 rows labelled "Theorem (weak form)", only reflection positivity at the coarse level (for the strip class) pays a premise column of the present road as it stands. The others are similar but different statements — a different object, a subfamily, a linearisation, a one-step form, and so on (distinguished in the label column of the tables).

Where the rows whose form is not fixed come from. Of the 24 rows, 20 include (c) (object undefined) or (e) (no form across steps) among their reasons. The 4 that do not (zero-order transport of the background, tension-doubling inequality, monotonicity and renormalisation comparison, from the area law to the gap) are on the side of "too strong, or there are false examples"; for zero-order transport of the background there is an argument on paper that its present form is false (not yet checked by another pair of eyes).

Rows whose form is fixed but unproved, and choices that make them stand trivially. Of the 7 rows, 6 (rarity of two-step events: plaquette part, equicontinuity of observables, uniform decay of block observables, base point at small T^2, single-scale criterion, lateral-widening inequality (strong form)) have a "fixed form" only for the sequence fixed by matching, with the restrictions on threshold and period put into the statement. If the sequence is taken freely, uniform decay of block observables, base point at small T^2, single-scale criterion and lateral-widening inequality (strong form) stand trivially with $\beta_n \equiv 0$ ($\theta = 0$, and variables separated in time are independent) Proved here . The theorem of uniform decay of block observables in the strong-coupling window (20-04) lies in this direction: it is an example in which the statement can be satisfied, not a check of its content. Non-degenerate small examples exist for the version of the Constrained Decay Theorem around the vacuum (one-dimensional,

scalar, for two of the inputs) and for the form of base point at small T^2 with fixed lattice spacing (the thin-vortex floor, 21-02).

04

Premise of the box continuum limit — the continuum limit in a fixed box

These are the premises for the chain of block maps, in a box of fixed size, to give subsequential limits and the properties that pass to the limit. The implication that uses them is in 28-01. Notation: B is the block map, $\nu_{n,m}$ the push-forward measure, u_k the effective coupling at step k (its definition from the lattice is not fixed), z_k the large-field activity, w_k the supply.

Table 2　Premise of the box continuum limit (as of 2026-11-13)

Number	Name	Statement	Object	Label	Reason
1	Continuity, composition and push-forward consistency of the block map	B is continuous. The map from step n to m is the composite of single steps. $(B_m)_*\nu_{n,m+1} = \nu_{n,m}$	19-04, push-forward	Theorem: for every family of paths, weights and family of measures	—
2	Gauge covariance and locality	$B(U^g) = B(U)$ $g\|_{\text{coarse sites}}$. $B(U)_b$ depends only on fine links within a finite distance of b	19-04	Theorem (weak form, a similar but different statement): the form for the one-step map. The extension to composites and the reach distance are on paper	—
3	Commuting with the lattice symmetries	Translations, reflections and the hypercubic group commute with B	19-04	Theorem (weak form, groundwork): translations checked; reflection in the time direction in Lean (content not yet checked); reflections in the other axes and the hypercubic group on paper	—
4	Reflection positivity of the fine lattice	For bounded measurable f depending only on links on the positive side, $\int f(\Theta U)\, f(U)\, d\mu_W \geq 0$	19-01, reflection	Theorem: even side length. For the plane of lattice sites, all real β; for the plane through the middle of links, $\beta \geq 0$ and gauge-invariant f (20-01)	—

Number	Name	Statement	Object	Label	Reason
5	Reflection positivity at the coarse level	For F in the positive-time class, $\int (F \circ \Theta)\, F\, d\nu_{n,m} \geq 0$; matrix form $\sum c_a c_b\, s_n(x_{ab}) \geq 0$	19-04, positive side	Theorem (weak form, pays the column as it stands): for the class whose positive side is taken as a strip. The matrix form is on paper. The form taking the whole coarse half as the positive side is not placed (28-05)	—
6	Symmetries of the measure	$\nu_{n,m}$ is invariant under lattice symmetries. The breaking of symmetry of observables $\to 0$	19-04	On paper: the symmetry fields for the pure gauge theory are not in Lean. What Lean has is a version for families of measures with fermions (global gauge transformations and unit translations in the four directions)	—
7	Family of observables and small-field set	D is countable and dense, $\lvert s_n\rvert \leq B_d$, $s_n(x) = \int G_x\, d\nu_{n,\mathrm{lev}(x)}$, C_m is closed and contains the two-step event	19-07	On paper: the inclusion (two-step event $\subseteq$ small-field set) depends on how the background invariants are extended (choice of the small-field set and extension of the background invariants)	—
8	Definition and continuity of the effective coupling	$u_0(x) = x$. $x \mapsto u_{k+1}(x)$ is continuous on $\{u_j \geq u_\star\ (j \leq k)\}$	No definition (u_k)	Depends on design	—
9	Net one-step bracket of the coupling	$u_{k+1} = u_k - b + r_k^s + r_k^l$, $b_{\inf} + \delta_k - e(u_k) \leq b - r_k^s \leq b_p + e(u_k)$, $\sum_k \max(-\delta_k, 0) \leq D_0$	No definition (u_k, small- and large-field remainders r_k^s, r_k^l)	Form not fixed	(c)(e)
10	Large-field contribution to the coupling	$\lvert r_k^l\rvert \leq D(u_k)\, z_k$	No definition (r_k^l, z_k)	Form not fixed	(a)(c)
11	Recursion of the activity	$z_{k+1} \leq \rho z_k + A w_k + B z_k^2$, $z_k \geq 0$, $z_0 \leq W(u_0)$	No definition (z_k, w_k)	Form not fixed	(a)(c)(e)

Number	Name	Statement	Object	Label	Reason
12	Rarity of supply	$w_k \le \Phi(u_k)$ (from an exponential moment of the plaquette variable uniform in the step, $\mathbb{E}\, e^{\sigma Y} \le m_1(\sigma)$)	No definition (w_k, plaquette variables at step k)	Form not fixed	(c)(e)
13	Single-scale rarity on the fine lattice	For $\beta \ge 81$, the probability that all plaquettes of X have $\operatorname{Re} U_p < 0$ is $\le q_1^{\lfloor \lvert X\rvert/6 \rfloor}$, with $q_1 < 1$ independent of the volume	19-01	Theorem (weak form, a similar but different statement, not connected to any column): one scale, $\beta \ge 81$, a ratio to the full partition function (22-01)	—
14	Moving invariant interval and margin	$\rho W(s) + A\Phi(s) + BW(s)^2 \le W(s')$ $(u_\star \le s,\ s' \le s + D_0)$, $D(s)W(s) \le Y$, $e(u_\star) + Y \le b$ inf	Real functions W, Φ, D, e	Form not fixed: W, Φ, D, e are free, and taking them all 0 makes it hold	(a)(c)
15	Rarity of two-step events: plaquette part	For large n, $\nu_{n,m}\big(\beta_m(1 - \operatorname{Re} U_p) > y_h(m)\big) \le P_1(m)$	19-04	Form fixed, unproved (conditional: for the sequence fixed by matching, with the threshold floor and $\eta_m < 1$ put into the statement)	—
16	Rarity of two-step events: background-invariant part	For large n, $\nu_{n,m}\big(f_{m,x} > f_h(m)\big) \le S(m)$	No definition (the background-field invariant f)	Form not fixed	(c)
17	Equicontinuity of observables	$\lvert s_n(d) - s_n(d')\rvert \le \tau_n + \Omega(\operatorname{dist}(d, d'))$, $\tau_n \to 0$, $\Omega(r) \to 0$	19-04 (the family of observables is the one in family of observables and small-field set)	Form fixed, unproved (conditional: for the sequence fixed by matching)	—

Premise of ultraviolet stability

These are the premises for deriving the representation-level premises of the premise of the box continuum limit (net one-step bracket of the coupling, large-field contribution to the coupling, recursion of the activity, rarity of supply) from step-by-step estimates. Notation: G_k is the family of free-field propagators at step k, P/ω the free propagator (19-04 § 07), $\mathcal{M}$ the one-step map.

Table 3 Premise of ultraviolet stability (as of 2026-11-13)

Number	Name	Statement	Object	Label	Reason
1	Bracketing of the propagator	For every step k and momentum, $c_0\,P/\omega \preceq G_k \preceq P/\omega$, $c_0 = 3/100$	19-04	Theorem (weak form, a similar but different statement): both the upper and lower sides checked. The object is the symbol recursion (a family of matrices for each momentum): free field, vacuum background, linearisation, weights $(1/8, 3/4, 1/8)$ (15-12)	—
2	Positivity with background	$\lambda_{\min}(H_c(B)) \geq \lambda_0(1 - f_1/f_\star)$	Definition on paper (background field B, constrained Hessian H_c)	Form not fixed: the background field and constrained Hessian are definitions on paper, and three forms stand side by side	(c)
3	Contraction of irrelevant terms	$\mathcal{M}^{17}(\omega G_k) \preceq \tau\,\omega G_{k+17}$, $\tau < 1/170$, uniform in k	19-04	Theorem (weak form, a similar but different statement): the τ of the quadratic form, different from the τ_k of the induction. The one-step estimate at step 0 is conditional (15-12)	—

Number	Name	Statement	Object	Label	Reason
4	Coefficient of the one-step decrease of the coupling	The free-field coefficient b_k converges at rate $(3/5)^k$, and the sum of transients is finite	19-04	Theorem (weak form, a similar but different statement): quadratic functionals of arbitrary data on the constrained covariance of the free field converge at rate $(3/5)^k$. That b_k is such a functional is on paper	—
5	Value of the one-loop coefficient	$b_\infty = 2b_0 \ln 2$	—	Literature: not re-derived for this map	—
6	Contraction of the background map	The sum of one-unit displacements $\sum_j \Delta_j < \infty$ (the free-field part is of the type $\|\psi_l\|^2 \le 0.608^l$)	19-04	Theorem (weak form, a similar but different statement): the free-field part	—
7	Geometry of many-body sums (correlation norm)	Correlation norm of the plaquette field $\Lambda \le 640/9$	19-04	Theorem (weak form, a similar but different statement): free field, linearisation, torus (15-12). The reach constant is in geometry of many-body sums (reach constant)	—
8	Constrained inverse identity	$C = G - GT^*(TGT^*)^{-1}TG$, with upper and lower estimates	Abstract linear maps	Theorem: a finite-dimensional abstract identity and estimates	—
9	Constrained Decay Theorem	The one-step constrained Green's function at step k satisfies, for an exponential weight W, $\|Wx\| \le \frac{11}{2}\|Ww\|/r^2$, with constants uniform in k	Abstract (Lean). The concrete objects are on paper	Form fixed, unproved (the version around the vacuum). The version for a general background has form not fixed (c)	—

Number	Name	Statement	Object	Label	Reason
10	Zero-order transport of the background	$\sup_n 4^n\theta_n < \infty$, $\sum_n 4^n\theta_n^{3/2} < \infty$ (θ_n: the ratio of the sup of background plaquettes in units of step j, divided by coarse units)	Definition on paper (the background as minimiser of the action)	Form not fixed: in its present form, it diverges numerically for the background that minimises the action Reading (the argument on paper that it is false has not yet been checked)	(b)(d)
11	One-step background-field lemma	For small fields, the minimum of the constrained action is unique, analytic, exponentially local, and commutes with coarse gauge transformations	Definition on paper (background field)	On paper	—
12	Multistep background field	Unique and regular on nested small-field regions. The inverse of the linearisation is at most 1 in the action norm, independent of the number of steps	Definition on paper (background field)	On paper	—
13	Row sums of the lift uniform in the step	$\sup \lvert Eg\rvert \le R \sup \lvert g\rvert$, with R uniform in k	Definition on paper (the linear lift)	Depends on design: the choice of gauge and norm. The one-dimensional scalar case is a theorem	—
14	Single-scale expansion tools	Cluster expansion on product white-noise measures, and its convergence	Abstract	On paper	—
15	Forest interpolation formula	—	—	Literature: the formula itself is not in Lean	—
16	Small-field one-step renormalisation theorem	Coarse action = β_{k+1} S_W(background) + local expansion + many-body terms. The many-body terms are exponentially small in distance	No definition (the effective action at step k)	Form not fixed	(c)(e)

Number	Name	Statement	Object	Label	Reason
17	Gauge fixing step by step	Landau gauge at each step. The determinant is block lower-triangular. Estimate of the Haar Jacobian	Definition on paper	On paper	—
18	Large-field estimate	For each step t and each hole γ, $\lvert z_t(\gamma)\rvert \le \exp(-\gamma E\, \beta\, S^\flat(\gamma))$, $S^\flat(\gamma) \ge s_* \lvert\gamma\rvert$, with $s_* > 0$ uniform in step and volume	No definition (activities, coarse class)	Form not fixed	(c)(d)(e)
19	Large-field gas	$\sum_{X \ni x} \lvert z(X)\rvert\, e^{2\lvert X\rvert} \le 1$, and that the partition function of the gas equals the corresponding ratio	No definition (activities)	Form not fixed	(a)(b)(e)
20	Class and localisation	The only local gauge-invariant terms of dimension at most 4 are the constant and $\sum \operatorname{tr} F^2$	Definition on paper (class)	On paper: the algebra of localisation is in Lean; identification with the class is on paper	—
21	Induction uniform in the step	$r_{k+1} \le \tau_k r_k + a_k w_k + s_k$, $w_{k+1} \le b_k r_k + \sigma_k w_k + s'_k$; if the product of the coefficients is below $1/4$, it stays in the ball	No definition (r_k, w_k are real sequences with no definition as coordinates of the class)	Form not fixed	(c)(e)

06

Premises of full-sequence convergence, observables, infinite volume, rotation and non-triviality

These rows have their forms fixed after the forms of the premise of the box continuum limit and the premise of ultraviolet stability are settled. For the rows on fine observables and rotation, the objects needed to write the statements are not yet defined (28-06).

Table 4　Premises of full-sequence convergence, fine observables, infinite volume, rotation and non-triviality (as of 2026-11-13)

Number	Name	Statement	Object	Label	Reason
1	Contraction of the one-step map and matching at the endpoint	$\lvert r_k(u,v)-r_k(u',v')\rvert \le \varepsilon\lvert u-u'\rvert + c\lVert v-v'\rVert$, $\lVert T_k(u,v)-T_k(u',v')\rVert \le c'\lvert u-u'\rvert + \tau\lVert v-v'\rVert$, $4cc' < (1-\varepsilon-\tau)^2$	No definition (the coordinates u, v of the one-step map)	Form not fixed	(c)
2	Approximation of flowed observables by block variables	Approximate an observable at flow time t by a Lipschitz function of the block variables at step m, with an error $\varepsilon_m(t) \to 0$ uniform in the lattice	No object (flowed observables)	Form not fixed: flowed observables are undefined	(c)
3	Ultraviolet estimate uniform in the box size	The premise of the box continuum limit and the premise of ultraviolet stability hold with constants independent of the box size L	All of those two premises	Form not fixed	(e)
4	Uniform decay of block observables	$\lvert\langle F\cdot G\circ\tau_t\rangle - \langle F\rangle\langle G\rangle\rvert \le C_F C_G\, e^{-mt}$, with m independent of the lattice spacing and the box (exact form in 19-07 § 06)	19-04, 19-03	Form fixed, unproved (conditional: for the sequence fixed by matching, with time differences up to half the period). A theorem in the strong-coupling window (20-04), but in the direction where it stands trivially	—
5	One-step ultraviolet estimate for the bridge	The one-step image from a rotated fine lattice to the standard coarse lattice lies in the ball of the chain	No object (the block map from a rotated lattice)	Form not fixed	(c)
6	Independence of the infinite-volume limit from the box shape	The limits of sequences of tori of different shapes coincide	No definition (the infinite-volume limit)	Form not fixed	(c)
7	The limit is not a free field	(by which quantity to say it is not fixed)	—	Form not fixed	(c)

07

The band — rows on the vortex free energy

In this stage many rows can be written with the vortex ratio θ (19-02) alone. The statements are written in the notation $\theta(R;T_L^2)$ of 26-02 (longitudinal size R, size L of the transverse torus). $m_0(L)$ is the box mass of the box of size L (the gap of the transfer operator), and $\sigma_N(\beta)=\liminf_M(-\ln\theta_{N,M})/M^2$ is the slab tension.

Table 5 Premises of the band (as of 2026-11-13)

Number	Name	Statement	Object	Label	Reason
1	Non-negativity of θ	If M is even, $0\le\theta_{N,M}(\beta)$ for all real β	19-02	Theorem (weak form, a similar but different statement): the subfamily with M even. The column needs all sizes (21-06)	—
2	Base point at a small box	$\theta(L_0;T_{L_0}^2)\le 1-\varepsilon_0$, uniform in the lattice spacing	19-02	Form fixed, unproved (conditional: for the sequence fixed by matching). The form with fixed lattice spacing is the thin-vortex floor (21-02)	—
3	Single-scale criterion	At a physical size L_*, $\theta(L_*;T_{L_*}^2)<(s^2)^{-1/(s^2-1)}$ (0.63 for $s=2$, 0.7598 for $s=3$)	19-02	Form fixed, unproved (conditional: for the sequence fixed by matching)	—
4	Question of the cost of a twist-inserting map	For a gauge-covariant smooth map T, $\mathbb{E}_+[S\circ T-S-\ln J_T]\le 2\,\mathrm{artanh}(0.7598)$, uniform in the lattice spacing	No object (the map T)	Form not fixed	(c)
5	Nesting (frame decorrelation)	$\theta(nR;T_L^2)\le C_D\,\theta(R;T_L^2)^{n^2}$	19-02	On paper	—
6	Lateral widening for doubling	$\theta(R;T_{L'}^2)\le C\,(L'/L)^2\,\theta(R;T_L^2)$ $(L\le L'\le R)$	19-02	Form fixed, unproved (conditional: for the sequence fixed by matching)	—
7	Tension-doubling inequality	For some $\delta_0>0$ and N_1, $4\sigma_{2N}(\beta)\ge e^{\delta_0}\sigma_N(\beta)$ for all $N\ge N_1$	Definition on paper (slab tension σ_N)	Form not fixed: (d) only for the form uniform in β	(b)(f)

Number	Name	Statement	Object	Label	Reason
8	Monotonicity of the vortex free energy and renormalisation comparison	The free energy of a twist insertion is monotone in β. $s(N,\beta') \le s(2N,\beta)$	19-02	Form not fixed	(b)
9	Gap of a small twisted box and uniform acceptance of insertion	Gap $\ge c/L$ uniform in the lattice spacing. The acceptance rate of driven vortex insertions uniform in the lattice spacing	19-02, 19-03	Form not fixed: the gap operator of small twisted boxes and the insertion map are undefined	(c)
10	Band comparison (in the language of the gap)	For $x(L) := L\,m_0(L)$, $x(2L) \ge x(L) + \delta$, together with stability above the threshold	19-03 (box mass)	Form not fixed: the box mass $m_0(L)$ of the box used (with spatial planes) is undefined	(c)
11	From the area law to the gap	From the band (area exponent) to uniform decay of block observables	—	Form not fixed: the naive form is false in two dimensions	(b)
12	From the vortex area exponent to the Wilson-loop area law	—	—	Literature: the typical-frame version has not been re-derived	—

Among the band rows, the tension-doubling inequality and monotonicity and renormalisation comparison still have a choice of how to quantify the form of the statement (uniformly in β, or at fixed physical size). From the area law to the gap is the arrow joining the side of the mass gap and the side of confinement, and this book does not have it (28-03).

08

Five rows added outside the 57

There are five premises that do not fall under any of the 57 rows. So as not to change the counting, they are kept outside the counts of Table 1. The labels of these 5 rows have not yet passed a check at the same level as the 57.

Table 6　Added premises (as of 2026-11-13)

Number	Name	Statement	Object	Label	Reason
1	Linking the thresholds	Tie the scale factor β_m of the plaquette variable and the threshold $y_h(m)$ of the two-step event to u_m and the threshold $y_s(u_m)$ on the coupling side (for example under $\beta_m = 4u_m$, $y_h(m) = y_s(u_m)$, or the analytic floor $y_h(m) \le \beta_m(1-\cos\varphi_c)$ (φ_c is a fixed angle that sets the small-field threshold))	No definition (u_m)	Form not fixed: in the conditional implication assembled earlier, too, the theorem does not tie these two together	(c)
2	Choice of the small-field set and extension of the background invariants	That the two-step event is contained in the small-field set. It holds when the background invariants are extended outside $SU(2)$ by values larger than the threshold f_h, and is false when they are extended by 0	Definition on paper (background field)	Depends on design	—
3	Constant of the quadratic form of the background	The three constants of the premise "background estimate" of the implication assembled earlier (constants of the quadratic forms that make up the Lipschitz constant of the background map)	Definition on paper (background field)	On paper	—
4	Geometry of many-body sums (reach constant)	The row sum R of correlations of the plaquette field is finite	19-04	Form fixed, unproved	—
5	Seam to the vessel of the mass gap	The vessel implication (28-03) assumes weak convergence of the full sequence of measures, and that the subspace of observables is closed under time translation. When used along a subsequence, it takes the form "at every limit point"	19-03	Form fixed, unproved (conditional: for the sequence fixed by matching; the same form as the root of full-sequence convergence)	—

Lateral widening for doubling (lateral-widening inequality (strong form))	—	Lateral-widening inequality (strong form) in 26-02, and the same row in 27-01	—
Monotonicity of the vortex free energy and renormalisation comparison	—	β-monotonicity, renormalisation comparison (26-06)	—

Name of the content	Name in the conditional implication assembled earlier	Ledger (27-02)	Lean
Gap of a small twisted box and acceptance (small-box gap and acceptance)	—	Small-T^2 gap, uniform acceptance of insertion	—
Band comparison (in the language of the gap)	—	Band comparison (in the language of the gap) in the ledger	—

The summability-of-increments assumption is the assumption that, for a countable dense family of gauge-invariant functions, the step-by-step increments of the values of observables are summable. It is not the same as full-sequence convergence in 19-07 § 03: it is stronger by the summability, and the family of functions is different. Also, the implication assembled earlier defines the fine measure to be the Wilson measure at the β_n chosen by the matching bracket for the bare coupling, whereas the Lean theorem takes the sequence of bare couplings arbitrarily.

Among the ten premises of the implication assembled earlier, support of reflection positivity is reflection positivity. The other nine are the premises other than reflection positivity. The existence of four-dimensional Yang–Mills theory itself was shown, with a different design, by the construction published on 2026-11-10 (Volume 2).

What this chapter can say

Can say	Cannot say
The six roots and the 57 rows of premises are laid out as a tree and in tables by stage, with labels and reason symbols (as of 2026-11-13)	None of the premises is shown in this chapter. The labels follow the record of the checks of that date
The 13 rows with theorem labels are statements about the Wilson measure on the fine lattice, the block map itself, structural properties of the push-forward measure, the free field and linearisation, or an abstract identity	There is no theorem giving quantitative estimates for measures at renormalised scales
Of the 24 rows whose form is not fixed, 20 owe this to an undefined object or to the absence of a form across steps	Answers to the questions that would fix the forms of the open rows (only the questions are in 28-06)
Of the 7 rows whose form is fixed but unproved, 6 are conditional on the sequence fixed by matching	If the sequence is taken freely, 4 of them stand trivially with $\beta_n \equiv 0$. Non-degenerate small examples exist for only 2 rows

Sources and reproduction

Item	Type	Source, tools
The 57 rows of premises, labels, reason symbols, the tree	Assumption	The inventory of premises in this book's study (2026-11-13). The labels come from the Lean sources and from the record of the check that compared definitions and statements with a separate pair of eyes

Words used in this chapter — premise, root, sufficient condition, representation, effective coupling, activity, supply, background field, class, push-forward measure, two-step event, vortex ratio, slab tension, ledger of conditions. Their meanings are in A-02 Glossary.

Next chapter: 28-05 What depends on design choices — tabulates the rows labelled "Depends on design", and which choices the constants of the other rows depend on.

What depends on design choices

> This chapter is this book's study.

What this chapter shows — One step of renormalisation and the statements of the premises contain places that are not decided by mathematics but chosen and fixed by us. For nine such choices we tabulate the present values and the theorems and premises that would have to be redone if the choice changed. We also confirm here that the theorems of Parts 20 and 21 and the rarity of large plaquettes (22-01) do not depend on the choice of block map.

Prerequisites — 19-04 § 08 Weights as a design choice, 28-04 The list of premises.

Said first — This chapter does not claim which choice makes the premises easier to satisfy. The table of constants for other weights, and the computation of whether overlapping block averages preserve reflection positivity of the push-forward measure, have not yet passed a check and are not included. We only write that there is an issue there. The choices here are choices within this book's design (the measure pushed forward by a fixed block map), and are separate from the design of the published construction that showed the existence of four-dimensional Yang–Mills theory (the two designs are compared in Part 14).

The order of this chapter

1. What a design choice is — fixing things so that a definition is unique
2. The nine choices and their present values (Table 1)
3. Transverse weights, scale factor, pull-back radius — choices in the block map itself
4. Overlap of block averages — the issue with reflection positivity
5. Norm, gauge, definition of the background — choices of representation
6. The way of matching, and the definition of compatibility in the gas
7. Which theorems and premises depend on which choices (Table 2)
8. Other fixings (Table 3)

01

What a design choice is — fixing things so that a definition is unique

To define one step of renormalisation (19-04), one has to settle on one choice of the weights of the family of paths, the scale factor of the blocks, the procedure that returns the average to the group, and so on. The statements of the premises (28-04) also involve decisions such as which norm to measure with and around which background to expand.

These are not determined uniquely by mathematics; we choose and fix them. If a choice changes, the constants and certificates of the theorems that depend on it must be redone, and the statements of the premises themselves change. Among the statements to be shown (19-07), the band can be written with the vortex ratio θ alone and does not depend on the choice of block map. The other five depend, through the push-forward measure $\nu_{n,m}$, on the choice of block map (weights, scale factor, radius), and matching, non-degeneracy and equicontinuity depend further on the choice of observables and sets.

This chapter is a table that makes visible, in one place, which choice affects what.

02

The nine choices and their present values

Table 1　Design choices (as of 2026-11-13)

Choice	Present value	Premises that depend on it (names of rows in 28-04)
Transverse weights of blocking $(\alpha, 1-2\alpha, \alpha)$	$\alpha = 1/8$	The free-field inputs (bracketing of the propagator, contraction of irrelevant terms, coefficient of the one-step decrease of the coupling, contraction of the background map, geometry of many-body sums (correlation norm)), the Constrained Decay Theorem, zero-order transport of the background, row sums of the lift uniform in the step, large-field estimate
Block scale factor	2	The matching bracket, rarity of two-step events: plaquette part, the free-field inputs (from bracketing of the propagator to geometry of many-body sums), zero-order transport of the background, band doubling (single-scale criterion, lateral-widening inequality (strong form), tension-doubling inequality)
Radius r_0 of the radial pull-back	A free parameter $(0 < r_0 \le 1)$	The range of linearisation, large-field estimate

Choice	Present value	Premises that depend on it (names of rows in 28-04)
Overlap of block averages	Overlapping (an average over paths shifted transversely with $(1/8, 3/4, 1/8)$)	Reflection positivity at the coarse level, recursion of the activity, rarity of supply, uniform decay of block observables
Norm	The sup norm and the sum-of-squares norm are mixed from place to place	The Constrained Decay Theorem, zero-order transport of the background, multistep background field, row sums of the lift uniform in the step, induction uniform in the step
Gauge	Landau slice at each step / axial gauge / tree gauge	The Constrained Decay Theorem, row sums of the lift uniform in the step, gauge fixing step by step
Definition of the background	The minimiser of the constrained action	Rarity of two-step events: background-invariant part, positivity with background, zero-order transport of the background, one-step background-field lemma, multistep background field
Way of matching (definition of the effective coupling)	Not fixed (observable, step, target value, choice of solution; two proposed definitions of u_k on paper)	Definition and continuity of the effective coupling, net one-step bracket of the coupling, the domain of every row of the premise of the box continuum limit
Definition of compatibility in the gas	The conditional implication assembled earlier: not adjacent / Lean: not overlapping	Large-field contribution to the coupling, large-field gas

03

Transverse weights, scale factor, pull-back radius — choices in the block map itself

Transverse weights. The paths that build a coarse link are shifted by $-1, 0, +1$ units in a transverse direction, with weights $(\alpha, 1-2\alpha, \alpha)$ (19-04 § 03). At present $\alpha = 1/8$. The constants of the one-step free-field theorem (15-12) were all computed for this value and cannot be used as they stand for other weights: the lower constant $c_0 = 3/100$ of the sandwich on the propagator, the 17-step contraction $\tau < 1/170$, the correlation norm $\Lambda \le 640/9$ of the plaquette field, and so on.

There is an issue as to what becomes better and what worse when the weights change (whether the plaquette field measured in coarse units grows with the step, and how the properties of the constraint change with the weights).

Scale factor. One step halves the lattice spacing. The matching bracket (19-07 § 02) is written in terms of the step number $n = \log_2(1/a_n)$, and the threshold of the single-scale criterion on the band side differs for each scale factor s (0.63 for $s = 2$, 0.7598 for $s = 3$).

Pull-back radius. This is the threshold r_0 of the procedure that returns the average of path products to the unit ball. The linearisation theorem for the block map (15-13) has $0 < r_0 \le 1$ among its assumptions.

Theorems that do not depend on the choices. The theorems of Part 20 (reflection positivity, strong coupling) and Part 21 (vortex floors, Polyakov loops), and the rarity of large plaquettes (22-01), use only the Wilson measure on the fine lattice and twisted partition functions, and do not use the block map. So they depend on none of these three choices (nor on the overlap of § 04) Proved here .

04

Overlap of block averages — the issue with reflection positivity

In the present family of paths, the paths that build a coarse link are shifted transversely, so neighbouring blocks share fine links (an overlapping average).

Reflection positivity (20-01) is a theorem for the Wilson measure on the fine lattice. Whether reflection positivity is preserved for the pushed-forward coarse measure $\nu_{n,m}$ is expected to depend on whether blocks straddle the reflection plane, that is, on whether there is overlap, and **there is an issue here.** The computation has not yet passed a check and is not included.

In the present list of premises, reflection positivity at the coarse level (the row on reflection positivity at the coarse level) is placed in the form of the class whose positive side is taken as a strip (coarse observables depending only on links in the positive half of the fine lattice). In this form it is paid as a statement about the Wilson measure on the fine lattice. The form that takes the whole coarse half as the positive side is not placed among the premises.

Besides reflection positivity at the coarse level, what depends on this choice is rarity across steps (recursion of the activity and rarity of supply; the road that uses the Chessboard Estimate from reflection positivity) and the vessel used to go from uniform decay to the mass gap (uniform decay of block observables).

05

Norm, gauge, definition of the background — choices of representation

These three are choices made not in the block map but in writing down (representing) the theory at coarse scales. They do not appear in the root (19-07), only on the side of the sufficient conditions.

- **Norm.** Whether to measure the plaquette field in the sup norm or in the action (sum-of-squares) norm. The present form of zero-order transport of the background (the row in 28-04) is written in the sup norm, and the reasons (b)(d) for its form not being fixed are tied to this choice. The Constrained Decay Theorem and the multistep background field are written in the sum-of-squares or action norm.
- **Gauge.** Landau slice at each step, axial gauge, tree gauge. Whether the row sums of the lift are uniform in the step (row sums of the lift uniform in the step) changes with the choice of gauge. For the one-dimensional scalar lift, the row sums are a theorem.
- **Definition of the background.** We use the background that minimises the action under the block constraint. The rarity of the background invariants (rarity of two-step events: background-invariant part), positivity with background, and the background-field lemmas (one-step background-field lemma, multistep background field) are written on top of this definition. There is also the road of switching to a different background that can be written by an explicit formula.

06

The way of matching, and the definition of compatibility in the gas

The way of matching. The sequence of bare couplings β_n is fixed by matching the expectation of a coarse observable Y_0 at step m_0 to a target value κ_0 (19-07 § 02). What is chosen is Y_0, m_0, κ_0, and how to pick a solution when there are several. In the language of the premises, one possible road is to make this correspond to the definition of the effective coupling u_k (definition and continuity of the effective coupling). There are two proposed definitions of u_k on paper (read as a renormalised coupling, or as a coefficient of the blocked action). Which is taken changes the meaning of the domain $u_m \geq u_\star$ of every row of the premise of the box continuum limit. The conditional implication that this book's study assembled earlier (28-01 § 08) defines the fine measure to be the Wilson measure at the β_n chosen by the matching bracket for the bare coupling, and the Lean theorem takes the sequence of bare couplings arbitrarily. The premise that ties the threshold on the measure side to the threshold on the coupling side (linking the thresholds) is also settled together with this choice.

The definition of compatibility in the gas. This is the definition of what it means, in the large-field gas, for two large-field regions to be "compatible". The conditional implication that this book's study assembled earlier (28-01 § 08) uses "not adjacent", the Lean form uses "not overlapping", and the two are different. What depends on it is the large-field contribution to the coupling and the large-field gas, both of which have forms not fixed.

07

Which theorems and premises depend on which choices

Table 2 Table of dependencies (● means depends). The top 5 rows are theorems, the rest premises (as of 2026-11-13)

Theorem or premise	Weights	Scale factor	Radius	Overlap	Norm	Gauge	Background	Matchin
Part 20 (reflection positivity, strong coupling)								
Part 21 (vortex floors, Polyakov loops)								
15-12 One step of the free field	●	●

Large-field gas								
Induction uniform in the step					●			

Theorem or premise	Weights	Scale factor	Radius	Overlap	Norm	Gauge	Background	Matchin
Uniform decay of block observables (vessel)				●				
Band doubling (single-scale criterion, lateral-widening inequality (strong form), tension-doubling inequality)		●						

Of the top 5 rows of Table 2, only the two chapters on the free field and linearisation depend on the choices. On the side of the premises, rows that depend on the weights gather in the premise of ultraviolet stability, and rows that depend on the background, norm and gauge gather around the background field and the constrained estimates.

08

Other fixings

These are not choices in the block map or the representation, but fixings that determine the scope of theorems and premises.

Table 3 Other fixings

Fixing	Present value	What depends on it
Threshold for large plaquettes	The rarity theorem uses $\operatorname{Re} U_p < 0$. The premise side uses a threshold $y_h(m)$ for each step	22-01, rarity of supply, single-scale rarity on the fine lattice, rarity of two-step events: plaquette part
Range of β	Strong-coupling windows $18 \tanh \lvert\beta\rvert < 1$ and $24(1 - e^{-4\lvert\beta\rvert}) < 1$; rarity for $\beta \geq 81$	Part 20, 22-01, single-scale rarity on the fine lattice
Reflection plane and positive side	Plane of lattice sites (all real β) / plane through the middle of links ($\beta \geq 0$). At the coarse level the positive side is taken as a strip	20-01, reflection positivity of the fine lattice, reflection positivity at the coarse level
Extension of the background invariants	How values outside $SU(2)$ are set (whether to extend by values larger than the threshold)	The inclusion in the family of observables and small-field set, rarity of two-step events: background-invariant part, choice of the small-field set and extension of the background invariants
Class of observables	Flowed observables (no definition yet)	Approximation of flowed observables by block variables, the rotation premise

Fixing	Present value	What depends on it
Geometry of the twist	Background twist $n_{12} = 1$, transverse size N held fixed	Part 21, every row of the band

What this chapter can say

Can say	Cannot say
The present values of the nine choices and the premises that depend on them are tabulated	Which choice makes the premises easier to satisfy
Proved here The theorems of Parts 20 and 21 and 22-01 do not use the block map, so they do not depend on the choice of block map	—
The constants of the one-step free-field theorem in Part 15 were computed with weight 1/8 and scale factor 2	The constants for other weights (the table has not been checked and is not included)
There is an issue between the overlap of block averages and reflection positivity of the push-forward measure	The answer to that issue (the computation has not been checked and is not included)

Sources and reproduction

Item	Type	Source, tools
The list of choices and the dependencies	Assumption	The inventory of premises in this book's study (2026-11-13)
Definition of the block map and the weights	Lean	Source table of 19-04
Constants of the one-step free-field theorem	Lean	Source table of 15-12
The two definitions of compatibility in the gas	—	The conditional implication that this book's study assembled earlier (28-01 § 08) and this book's Lean bundle

Words used in this chapter — design choice, transverse weights, scale factor, pull-back radius, overlap of block averages, norm, gauge, background field, matching, compatibility in the gas. Their meanings are in A-02 Glossary.

Next chapter: 28-06 Open places, and places where the object does not yet exist — lists the premises whose form is not fixed, sorted by origin.

Open places, and places where the object does not yet exist

> This chapter is a map of open questions.

What this chapter shows — A list that divides into three the 24 rows labelled "Form not fixed" in 28-04, according to where the openness comes from. For each row we write whether what would fix its form is an argument on paper, a small numerical experiment, or a design choice. At the end we place the stages for which the objects needed to write the statements do not yet exist (fine observables, rotation), and what this book does not claim.

Prerequisite chapters — 28-04 The list of premises (row names and labels), 19-07 The statements to be shown.

Said first — This chapter is a list and answers none of the questions. The column "What would fix it" records the kind of question, and does not claim that the question will be settled soon. The content moves, so updates are made in A-08 A map to the mass gap.

The order of this chapter

1. Three origins — Table 1
2. Objects of the representation undefined — 13 rows on the ultraviolet side (Table 2)
3. No object at all, or downstream — 8 rows (Table 3)
4. Order of quantifiers and truth — 3 rows of the band (Table 4)
5. The order of the questions that would fix the forms
6. Stages whose objects are not yet defined
7. What this book does not claim

01

Three origins

There are 24 premises whose form is not fixed (28-04 Table 1). Looking only at the reason symbols ((a) too light, (b) too strong, (c) object undefined, (d) numerical signs against the present form, (e) no form across steps, (f) order of quantifiers not fixed) they look scattered, but divided by origin there are three groups.

Table 1 Origins of the 24 rows whose form is not fixed (as of 2026-11-13)

Origin	Rows	Which rows	Relation to the root
The object of the expression is undefined	13	Net one-step bracket of the coupling, large-field contribution to the coupling, recursion of the activity, rarity of supply, moving invariant interval and margin, rarity of two-step events: background-invariant part, positivity with background, zero-order transport of the background, small-field one-step renormalisation theorem, large-field estimate, large-field gas, induction uniform in the step, contraction of the one-step map and matching at the endpoint	The root (19-07) can be written. Below it, the form of the sufficient conditions passing through the effective coupling, the activity, the background field and the class is not fixed
No object at all, or downstream	8	Approximation of flowed observables by block variables, ultraviolet estimate uniform in the box size, one-step ultraviolet estimate for the bridge, independence of the infinite-volume limit from the box shape, the limit is not a free field, question of the cost of a twist-inserting map, gap of a small twisted box and uniform acceptance of insertion, band comparison (in the language of the gap)	Rows for which an object needed in the statement (flowed observables, the map from a rotated lattice, a map that inserts a twist, the vessel of a small twisted box, and so on) does not exist, or whose form is fixed after the upstream forms are settled
Order of quantifiers and truth	3	Tension-doubling inequality, monotonicity of the vortex free energy and renormalisation comparison, from the area law to the gap	The root for the band can be written. Candidate sufficient conditions have false examples, or the order of quantification is not fixed

The 13 rows of the representation sit at the level of the representation below the root. Changing the representation (a different definition of the background, a different norm, and so on) changes the leaves, but not the root. The openness on the side of the band comes not from the representation but from the quantification and truth of the statements.

```
02
```

Objects of the representation undefined — 13 rows on the ultraviolet side

Inside the chain theorem of the present road, the effective coupling u, activity z, supply w, remainders, plaquette variables, background invariants and observables are all free variables. Only the block map and the push-forward measure are defined from the lattice (19-04). So the following rows need definitions of their objects before any proof.

Table 2 The 13 rows at the level of the representation, and what would fix their form

Row	Reason	What would fix it	The smallest question
Net one-step bracket of the coupling	(c)(e)	Paper (design)	Define the effective coupling uniquely. If restated in the language of matching (19-07 § 02): which coarse observable to match at which step. Whether the domain $u_m \geq u_\star$ of the other rows can then be written in the same language
Large-field contribution to the coupling	(a)(c)	Small numerical experiment, and design	The present form holds if the activity is chosen freely (light). When a form uniform in volume and step is put into the statement, does that uniformity hold numerically on small lattices for the plain Wilson measure?
Recursion of the activity	(a)(c) (e)	Paper and small numerical experiment	For the measure $\nu_{n,n-1}$ pushed forward by one step only, does pulling back the event "a coarse plaquette is large" to an event on the fine lattice give a form to which the Chessboard Estimate (22-01) applies?
Rarity of supply	(c)(e)	Design	Can the supply be defined as the probability of an event under the push-forward measure (the fine-side image is small, the coarse plaquette is large)? If so, it merges with rarity of two-step events: plaquette part
Moving invariant interval and margin	(a)(c)	Paper, after the definitions of the large-field contribution to the coupling and of rarity of supply	The real functions W, Φ, D, e are free, and it holds if they are all taken to be 0. Do the actual gas coefficients take this form, with the margin numbers holding?
Rarity of two-step events: background-invariant part	(c)	Design (definition of the background)	Whether to make it an event in plaquette variables alone, without background invariants, or to switch to a background that can be written by an explicit formula
Positivity with background	(c)	Design (definition of the background), and paper	Fix the definitions of the background field and the constrained Hessian, and decide which of the three forms standing side by side to take as the premise

Row	Reason	What would fix it	The smallest question
Zero-order transport of the background	(b)(d)	Paper (design)	The present form (measured by the sup over plaquettes) diverges numerically for the background that minimises the action Reading (the argument on paper that it is false has not yet been checked). If the zeroth-order term is written in the action norm, does it close under the same assumptions as the multistep background field?
Small-field one-step renormalisation theorem	(c)(e)	Paper	Is the background field the only undefined object needed to write down the step-0 statement whose input is the Wilson action itself?
Large-field estimate	(c)(d) (e)	Small numerical experiment	Does the lower bound over steps of the action of each hole stay at a positive value proportional to the number of plaquettes as the steps go deeper?
Large-field gas	(a)(b) (e)	Small numerical experiment, and design	The literal form always holds on a fixed lattice (light), while the form with equality on all regions does not hold numerically on small lattices Reading (strong). Fix a form in between that includes uniformity. The choice of the definition of compatibility in the gas (not adjacent / not overlapping) also remains (28-05)
Induction uniform in the step	(c)(e)	Design (the norm of the induction), and paper	When the induction coordinate r_k is defined by coordinates of the class, does the free-field contraction (contraction of irrelevant terms) become a coefficient of the recursion for r_k?
Contraction of the one-step map and matching at the endpoint	(c)	Paper, after the forms of the small-field one-step renormalisation theorem and of induction uniform in the step are settled	In the language of the coordinates of induction uniform in the step, does the contraction condition become a statement in the same coordinates?

Of the 13 rows, 5 (large-field contribution to the coupling, recursion of the activity, rarity of supply, large-field estimate, large-field gas) gather around the treatment of large fields (activities and the gas). Their content (the form of the estimates and the premises on the gas) will not be given chapters in this book until the forms of the statements are settled.

> 03

No object at all, or downstream — 8 rows

Table 3 Rows with no object, or whose form is fixed after the upstream is settled

Row	Reason	What would fix it
Approximation of flowed observables by block variables	(c)	Definitions of the lattice gradient flow and of flowed observables (§ 06)
Ultraviolet estimate uniform in the box size	(e)	Fixed as the uniform version of the premise of the box continuum limit and the premise of ultraviolet stability, after their forms are settled
One-step ultraviolet estimate for the bridge	(c)	Definition of the block map from a rotated fine lattice to the standard coarse lattice (only a sketch on paper)
Independence of the infinite-volume limit from the box shape	(c)	After the definition of the infinite-volume limit (the limit of large boxes)
The limit is not a free field	(c)	The choice of the quantity by which to say it (for example, the limiting value of the same observable at another step m_1, when matched at step m_0)
Question of the cost of a twist-inserting map	(c)	Definition of the map T (the method is not fixed). This row is a sufficient condition for the single-scale criterion, so there is also the road of checking the single-scale criterion directly
Gap of a small twisted box and uniform acceptance of insertion	(c)	Definitions of the operator that measures the gap of small twisted boxes, and of the map for driven vortex insertion
Band comparison (in the language of the gap)	(c)	Definitions of the vessel for boxes with spatial planes, and of the box mass $m_0(L)$

04

Order of quantifiers and truth — 3 rows of the band

Table 4 Rows on the band side whose form is not fixed

Row	Reason	What would fix it
Tension-doubling inequality	(b)(f). (d) only for the form uniform in β	Small numerical experiment. With the transverse size N held fixed and $\beta \to \infty$, there are numbers in which the minimal action of a vortex (21-05) increases with N, a sign pointing against the form uniform in β Reading . Either state it on a sequence at fixed physical size ($N = L_*/a$, $\beta = \beta(a)$), or fix the order of quantifiers

Row	Reason	What would fix it
Monotonicity of the vortex free energy and renormalisation comparison	(b)	On lattices with finite non-abelian groups there are examples where monotonicity fails Reading . Decide what to place as an assumption for $SU(2)$ (the form in 26-06)
From the area law to the gap	(b)	Paper (choice of road). The naive form is false in two dimensions. Whether to fix the last arrow on the side of the mass gap as the single route from band comparison (in the language of the gap) and stability above the threshold, via a uniform lower bound on the box mass, to uniform decay

05

The order of the questions that would fix the forms

Putting first what is settled cheaply (on paper or with small numerics), and, at equal cost, what has more downstream, gives the following order. Items 1–3 are independent of each other.

1. Fix the matching observable Y_0 and step m_0, and define the effective coupling uniquely (definition and continuity of the effective coupling, net one-step bracket of the coupling; paper).
2. Put numbers on the plaquette part of the rarity of two-step events (rarity of two-step events: plaquette part) under the push-forward measure (small numerical experiment). It is a premise written with defined objects only, yet there is no check on small examples.
3. Decide with which background and which norm to state zero-order transport of the background (paper). The definition of the background for rarity of two-step events: background-invariant part is settled at the same time.
4. Whether the recursion of the activity can be stated for the measure pushed forward by one step only (paper and small numerics; after 2).
5. Run the Constrained Decay Theorem through in one dimension from input to output, and check whether the assumptions can be satisfied simultaneously (Lean).
6. Look at the uniformity of the large-field gas in numbers (small numerical experiment).
7. Look at how the large-field estimate depends on the depth of steps (numerics).
8. Run the quadratic part of the induction uniform in the step through in one line (paper; after 1).
9. Look at the shape of the region where the tension-doubling inequality can hold (numerics).

10. Fix the last arrow on the side of the mass gap as a single route (from the area law to the gap; paper).

06

Stages whose objects are not yet defined

For two of the requirements of the problem statement, objects to write the statements about are needed before the forms of the premises can be discussed (19-07 § 08).

Stage	Statement we want to write	Missing object
Fine observables	Convergence in the continuum limit of expectations of point fields and flowed observables	The lattice gradient flow and the definition of flowed observables (not in this book's Lean). The approximation row (approximation of flowed observables by block variables) also has its form not fixed because this definition is missing
Rotation	Agreement of expectations of rotated observables (invariance under the Euclidean group)	Observables on which rotations finer than the hypercubic group act (the fine-observables stage), or one step from a rotated lattice to the standard lattice (the object of the one-step ultraviolet estimate for the bridge)
Infinite volume	Convergence, on windows, of push-forward measures as the box grows	Can be written by adding one definition (restriction to a window in box coordinates, or periodic extension). In the strong-coupling window it can be written by periodic lifting and is a theorem (20-03)
Non-triviality	That the limit differs from the limit of the free field	Can be written, but by which observable to say it is not fixed (the limit is not a free field)

07

What this book does not claim

- **The mass gap itself.** This book shows nothing about the existence of a mass gap for four-dimensional $SU(2)$ Yang–Mills theory (or for any compact simple group). The lower bound on the mass in the strong-coupling window (20-04) is a theorem at one scale with the lattice spacing fixed.
- **Construction of the continuum limit.** This book does not construct the limiting theory as the lattice spacing goes to 0. The existence of four-dimensional Yang–Mills theory was shown, with a different design, by the construction published on 2026-11-10, and the committee's assessment is that it is proved in Lean (Volume 2). The conclusion of the conditional implication that this book's study assembled earlier (weak ultraviolet existence in small boxes in this book's design) goes only as far as

subsequential limits under its premises and the passage of properties of finite lattices to the limit, and many of those premises have forms not fixed (28-01).

- **The band.** This book shows nothing about the statement that spans the strong-coupling side and the weak-coupling side with one constant (19-07 § 07). The vortex floors (21-02, 21-03) are in a form with the lattice spacing and transverse size fixed. The upper bound on the vortex free energy inside the strong-coupling window (20-06) has a rate that does not depend on the transverse size (the prefactor remains), but it does not extend outside the window.
- **Confinement.** Neither a four-dimensional area law outside the strong-coupling window nor a re-derivation of the passage from the vortex area exponent to the area law of Wilson loops (from the vortex area exponent to the Wilson-loop area law) is in this book. The lattice area law inside the strong-coupling window is in 20-06 (a formalisation of a known type; continuum Wilson loops are in neither this book nor the published construction).
- **Non-triviality and rotation invariance.** For these two items of the problem statement, this book has not even fixed the forms of the statements (for rotation, the object does not yet exist; 19-07 § 08).
- **The position of the theorem in the strong-coupling window.** The lower bound on the mass in the strong-coupling window is an example on the side where the statements to be shown stand trivially, not a check of the content of the statements (19-07 § 01).

An index of "what is not claimed" for the earlier parts is in 27-04.

What this chapter can say

Can say	Cannot say
The 24 rows whose form is not fixed are divided into three by origin (representation level 13; no object or downstream 8; quantification and truth 3)	The form of any row is not fixed here
For each row, whether paper, numerics or design would fix its form, and the smallest question, are written down	Answers to the questions. The order of the questions is by cost and amount downstream, not by the prospect of an answer
For the stages of fine observables and rotation, the objects to write the statements about do not yet exist	Definitions of those objects
This book shows nothing about the mass gap itself, the construction of the continuum limit, or the band	—

Sources and reproduction

Item	Type	Source, tools
The division of the 24 rows, the smallest questions, the order of the questions	Assumption	The inventory of premises in this book's study (2026-11-13)
Examples with finite non-abelian groups where monotonicity fails	Reading	Numerical record of this book's study (direct sums on lattices with finite groups). The description in 26-06
That the naive form of "area law to gap" is false in two dimensions	Proved here	The counterexample of 28-03 § 07 (the direct product of a two-dimensional gauge theory with an area law and the critical two-dimensional Ising model; that the gap closes at the critical point is in 2-09 § 07)
Index of what is not claimed	—	27-04

Words used in this chapter — form not fixed, representation, effective coupling, activity, gas, background field, class, order of quantifiers, gradient flow, flowed observable, what is not claimed. Their meanings are in A-02 Glossary.

Next chapter to read: A-01 Table of notation. To read alongside: A-08 A map to the mass gap — updates to this list and progress on the questions are followed there.

Table of notation — one convention for each letter, two meanings separated by name

> This chapter is a guide to notation and terms.

What this chapter shows — The symbols of this book can be looked up by "meaning, chapter of definition, note". The three ways of writing the gauge field, the six ways of writing the coupling, and the normalisation of CP are set out with conversion formulas, tables and moving figures. Different meanings of the same letter (β, Δ, η, σ, Ω and others) are told apart in one table.

Prerequisite chapters — None. As a dictionary, it can be opened from any chapter. The "Chapter" column of each row is the chapter that defined the symbol.

Said first — This chapter is a list of conventions and contains no claims of content. The correctness of formulas is shown in each chapter; here only the arithmetic of conversions and the normalisation of generators were checked on this machine. The names of assumptions are kept separately in A-06 Index of names. This chapter shows nothing about the mass gap.

The order of this chapter

1. How to use this table — the common conventions, and three choices of convention
2. Spacetime and indices — the signature $(-,+,+,+)$ and imaginary time (Table 1)
3. Groups and Lie algebras — normalisation of generators and structure constants (Tables 2 and 3)
4. Three ways of writing the gauge field — where g and i go (Table 4). Detour: why physics likes to attach i
5. Lattice symbols — links, plaquettes, link angles (Table 5)
6. Six ways of writing the coupling — conversions and one-loop coefficients (Table 6, Figure 1, Table 7)
7. Scales, lengths, masses — lattice units and physical units, the symbol $\asymp$ (Table 8)

8. Probability, spectrum, relaxation — three CP and two η (Figure 2, Tables 9 and 10)
9. Different meanings of the same letter — a list for telling them apart (Table 11). Detour: can symbol collisions be eliminated?

01

How to use this table — one convention for each letter

This chapter is a dictionary to look things up in; it need not be read from the front. The tables have four columns, "symbol, meaning, chapter, note", and "chapter" is the chapter that defined the symbol. Check the correctness of formulas in that chapter.

There are four conventions common to all chapters. From Part 3 on, $\hbar = c = 1$. An index appearing twice in the same term is summed. Both $\ln$ and $\log$ are the natural logarithm. When the same letter has two meanings, this is declared at the start of the chapter (the list is in § 09). Beyond that, the appearance of the symbols changes with the following three choices.

$$\underbrace{\text{way of writing the gauge field}}_{\S 04\ \text{three ways}} \times \underbrace{\text{way of writing the coupling}}_{\S 06\ \text{six ways}} \times \underbrace{CP\ \text{normalisation}}_{\S 08\ \text{two ways}} \tag{1}$$

The choices in (1) do not change the physical content, only coefficients and signs. But the same condition looks like a different number. Example. The strong-coupling condition of Shen–Zhu–Zhu, $|\beta_{\mathrm{SZZ}}| < 1/(16(d-1))$, becomes $\beta_{\mathrm{SZZ}} < 1/48$ in four dimensions ($d = 4$), and in this book's Wilson β it is $\beta < 0.0833$ for SU(2) and $\beta < 0.1875$ for SU(3) (§ 06) Computed . The names of assumptions (the diffusive-relaxation-time assumption, the relaxation-time upper-bound assumption, the eight statements of construction and others) are in A-06 Index of names, and the legend of the labels is in 0-01.

02

Spacetime and indices — the signature is $(-,+,+,+)$, and in imaginary time everything becomes $+$

Physical spacetime is Minkowski spacetime, where only the time direction carries a negative sign in the squared distance (2-04, and the existing article One sign is different). Constructive field theory and lattice arguments work in Euclidean space $\mathbb{R}^4$, with time rotated to imaginary values (4-02).

$$\eta_{\mu\nu} = \mathrm{diag}(-1,1,1,1), \qquad t = -i\tau, \qquad A_0 = iA_4, \qquad F_{\mu\nu}F^{\mu\nu} \longmapsto \sum_{\mu,\nu=1}^{4} F_{\mu\nu}F_{\mu\nu} \tag{2}$$

(2) gives, from the left, the metric, the rotation (Wick rotation), and the result of rotating. In Euclidean signature the metric is the identity matrix, so upper and lower indices are not distinguished. Example. The light path $-t^2 + |\mathbf{x}|^2 = 0$ becomes $\tau^2 + |\mathbf{x}|^2$ when rotated, positive except at the origin.

Table 1 Spacetime and indices

Symbol	Meaning	Chapter	Note
$x^\mu,\ \mu = 0,\dots,3$	Minkowski coordinates ($x^0 = t$)	2-04	Some textbooks use the opposite signature $(+,-,-,-)$
$x_4 = \tau,\ \mu = 1,\dots,4$	Imaginary time and Euclidean indices	4-02	$\tau = it$
$i,j,k = 1,2,3$	Spatial indices	3-02	Do not mix with the colour indices a,b,c
$E_i,\ B_i$	Colour electric and magnetic fields	3-02	$B_i = \tfrac{1}{2}\varepsilon_{ijk}F_{jk}$; in Euclidean signature $E_{E,j} = F_{4j}$
d	Dimension of (Euclideanised) spacetime	0-03	The problem statement has $d = 4$
$\mathbb{Z}^d,\ a\mathbb{Z}^d$	The integer lattice, the lattice with spacing a	5-01	§ 05

03

Groups and Lie algebras — generators are normalised by $\mathrm{tr}(T^aT^b) = \tfrac{1}{2}\delta^{ab}$

The gauge group G is a compact simple Lie group, and in almost all examples it is $\mathrm{SU}(N)$ (1-04). For generators we take Hermitian T^a in the physics style. Unless the normalisation is fixed, both the structure constants and the coupling constant are off by constant factors.

$$[T^a, T^b] = i\,f^{abc}\,T^c, \qquad \mathrm{tr}(T^aT^b) = \tfrac{1}{2}\,\delta^{ab}, \qquad a,b,c = 1,\dots,N^2-1 \tag{3}$$

In the mathematics style one takes anti-Hermitian $X^a = -iT^a$, giving the form $[X^a, X^b] = f^{abc}X^c$ without i. It is the same f^{abc}. Example. For SU(2), $T^a = \sigma^a/2$ and $f^{abc} = \varepsilon^{abc}$; for SU(3), $T^a = \lambda^a/2$ (half the Gell-Mann matrices). The adjoint Casimir C_A ($f^{acd}f^{bcd} = C_A\delta^{ab}$) is N, the fundamental Casimir C_F ($\sum_a T^aT^a = C_F\mathbf{1}$) is $(N^2-1)/2N$, and the index of the representation $T(R)$ ($\mathrm{tr}_R\,T^aT^b = T(R)\delta^{ab}$) is $\tfrac{1}{2}$ for the

fundamental representation. What enters the one-loop coefficient (4-06) is C_A and $T(R)$.

Table 2 Numerical check of the normalisation of generators Computed

Group	$\max \lvert \operatorname{tr} T^a T^b - \frac{1}{2}\delta^{ab} \rvert$	C_F	C_A	Independent non-zero f^{abc} ($a<b<c$)
SU(2)	0	0.75	2	$f^{123} = 1$
SU(3)	1.1×10^{-16}	1.333333	3	$f^{123}=1$; $f^{147}=f^{246}=f^{257}=f^{345}=\frac{1}{2}$; $f^{156}=f^{367}=-\frac{1}{2}$; $f^{458}=f^{678}=\frac{\sqrt{3}}{2}$

Table 2 was obtained by writing out the matrices, computing $f^{abc} = -2i \operatorname{tr}([T^a, T^b]T^c)$, and checking the residual on substituting back into (3) (at most 1.1×10^{-16}) and that the Casimir is a constant multiple of the identity matrix.

Table 3 Symbols for groups and Lie algebras

Symbol	Meaning	Chapter	Note
G, $\mathfrak{g}$, N	Gauge group, Lie algebra, the size of $\mathrm{SU}(N)$	1-03	Large N is in 17-04
T^a, f^{abc}	Hermitian generators, structure constants	1-04, 3-02	Normalisation is (3)
σ^a, λ^a	Pauli matrices, Gell-Mann matrices	1-04	σ is also used in other meanings (§ 09)
C_A, C_F, $T(R)$	Casimirs and the index of a representation	4-06	Values in the text
χ_r, d_r	Character and dimension of the representation r	5-02	$\chi_r(U) = \operatorname{tr}_r U$
$\Omega(x)$	Gauge transformation (a group element at each point)	3-01	The letter g is kept for the coupling

04

Three ways of writing the gauge field — where to put g, and where to attach i

The same gauge field is written in three ways. The physics chapters "separate Hermitian A from the coupling g", the path-integral and dictionary chapters "absorb g into the field and put $1/g^2$ in front of the action", and the geometry chapters use "an anti-Hermitian 1-form $\mathcal{A}$". The translation is one line.

$$\hat{A} = g\,A, \qquad \mathcal{A} = -i\hat{A} = -ig\,A, \qquad \hat{F} = g\,F, \qquad \mathcal{F} = -i\hat{F} = -ig\,F \tag{4}$$

"Absorbing" is just multiplying by g, and "geometry" is just multiplying further by $-i$. But $-i$ changes the sign of $\operatorname{tr} F^2$. For Hermitian X, $\operatorname{tr} X^2 \geq 0$, while for anti-Hermitian $-iX$ it is ≤ 0, so the geometric action carries a minus sign.

Table 4 Three ways of writing the gauge field (Euclidean action)

	Physics (g placed in D)	**Physics (g absorbed)**	**Geometry (anti-Hermitian)**
Covariant derivative	$\partial_\mu - igA_\mu$	$\partial_\mu - i\hat{A}_\mu$	$d + \mathcal{A}$
Field strength	$\partial_\mu A_\nu - \partial_\nu A_\mu - ig[A_\mu, A_\nu]$	$\partial_\mu \hat{A}_\nu - \partial_\nu \hat{A}_\mu - i[\hat{A}_\mu, \hat{A}_\nu]$	$d\mathcal{A} + \mathcal{A} \wedge \mathcal{A}$
Gauge transformation	$\Omega A \Omega^{-1} - \frac{i}{g}(\partial\Omega)\Omega^{-1}$	$\Omega \hat{A} \Omega^{-1} - i(\partial\Omega)\Omega^{-1}$	$\Omega \mathcal{A} \Omega^{-1} - (d\Omega)\Omega^{-1}$
Action S_E	$\frac{1}{2}\int \operatorname{tr} F_{\mu\nu}F_{\mu\nu} = \frac{1}{4}\int F^a_{\mu\nu}F^a_{\mu\nu}$	$\frac{1}{2g^2}\int \operatorname{tr} \hat{F}_{\mu\nu}\hat{F}_{\mu\nu}$	$-\frac{1}{g^2}\int \operatorname{tr} \mathcal{F} \wedge *\mathcal{F}$
Chapters that use it	3-02, 3-03, Part 4 (except 4-02; 4-03 uses both)	0-01, 4-02, 18-04	1-07, 3-04, 3-05

The topological charge Q is related to the second Chern number $c_2 = \frac{1}{8\pi^2}\int \operatorname{tr} \mathcal{F} \wedge \mathcal{F}$ by $Q = -c_2$ ((2) of 3-05; the difference in sign is $(-i)^2 = -1$, coming from $\mathcal{F} = -igF$), and the action has the lower bound $S_E \geq 8\pi^2|Q|/g^2$ Known . Example. For SU(2) with $g^2 = 1$ ($\beta = 4$), the action of one instanton is $8\pi^2 = 78.96$, and the weight e^{-S_E} is about 5×10^{-35} Computed .

Detour: why physics likes to attach i

You may skip this. In quantum mechanics observables are Hermitian operators, with real eigenvalues (2-05). Colour charge is an observable, so physics takes Hermitian generators and puts i in the exponent, $e^{i\theta^a T^a}$. On the geometric side, the Lie algebra is the space of tangent vectors at the identity of the group, and $\mathfrak{su}(N)$ is just the anti-Hermitian matrices. One can write e^X, and neither i nor g appears in the curvature. Precisely, the two styles differ only by changing the basis by a factor i, and represent the same connection on the same group. The differences are only the sign of $\operatorname{tr} F^2$ and the i in front of f^{abc}.

05

Lattice symbols — links, plaquettes, Wilson loops

Lattice gauge theory replaces spacetime by a lattice of spacing a and places a group element on each edge (link) (5-01). The key symbols are the Wilson action and its coefficient β.

$$S_W(U) = \beta \sum_P \Big(1 - \frac{1}{N}\operatorname{Re}\operatorname{tr} U_P\Big), \qquad \beta = \frac{2N}{g^2}, \qquad U_P = U_{x,\mu}U_{x+a\hat{\mu},\nu}U^{-1}_{x+a\hat{\nu},\mu}U^{-1}_{x,\nu} \tag{5}$$

(5) sums the deviations from the identity of the product U_P around every small square (plaquette P). $\beta = 2N/g^2$ is the value for which it matches the continuum action, coefficient included, for smooth fields as $a \to 0$ (5-01 § 05) Known . Unless stated

otherwise, this book's β is this Wilson β. $\beta = 4/g^2$ in the SU(2) chapters (23-01, 23-02, 18-05) is the same formula with $N = 2$. A link sees the field only in the form $U_{x,\mu} \approx e^{-iga A_\mu}$. The parallel transport of 1-07 is its inverse, which is why the sign of the exponent of the plaquette is opposite to 1-07 (the trace does not change).

SU(2) links are also written with angles. The study in Part 23 writes $U = e^{i\vartheta\cdot\sigma}$, while the book's (3) gives $U = e^{i\theta^a T^a}$, so they are related by $\theta = 2\vartheta$.

$$U = e^{i\vartheta\cdot\sigma} = e^{i\theta^a T^a} \quad (\theta^a = 2\vartheta^a), \qquad \tfrac{1}{2}\operatorname{tr} U = \cos|\vartheta| \tag{6}$$

Example. For $\vartheta = (0.3, -0.2, 0.5)$, $\frac{1}{2}\operatorname{tr} U$ computed with the matrix exponential and $\cos|\vartheta|$ are both 0.815941 Computed. The difference in how the angle is taken acts as a constant factor on C_P in § 08.

Table 5 Lattice symbols

Symbol	Meaning	Chapter	Note
$a,\ L$	Lattice spacing, number of points on a side of the periodic lattice	5-01	$4L^4$ links, $6L^4$ plaquettes
$U_\ell = U_{x,\mu}$	Group element on the link ℓ	5-01	$U_{x+a\hat{\mu},-\mu} = U_{x,\mu}^{-1}$
$P,\ U_P$	Plaquette and the product around it	5-01	$1 - \frac{1}{N}\operatorname{Re}\operatorname{tr} U_P \in [0, 2]$
μ_β	Wilson measure $Z^{-1} e^{-S_W} \prod dU_\ell$	5-01	dU is the Haar measure
$W(C),\ W_{R\times T}$	Wilson loop $\frac{1}{N}\operatorname{tr} U_C$, rectangle	5-02	T is the length in time
σ	String tension: $\langle W_{R\times T}\rangle \approx e^{-\sigma RT}$	5-02, 5-08	Lattice units. In physical units $\sqrt{\sigma}$
$\vartheta,\ \theta$	SU(2) link angle, $\theta = 2\vartheta$	(6), 23-13	Different from θ of the θ term
$b,\ k,\ \delta(b)$	Factor per step, number of steps, the shortfall of the bookkeeping	23-02	Definitions of the study in Part 23

06

Six ways of writing the coupling — β, β_{Ch}, β_{SZZ}, λ, g^2, α

The same coupling g^2 is written with different letters and different normalisations in different literature. Comparing term by term with the action (5) fixes the conversions (repeated from (8a) of 5-01).

$$\beta = \frac{2N}{g^2}, \qquad \beta_{\mathrm{Ch}} = \frac{\beta}{N}, \qquad \beta_{\mathrm{SZZ}} = \frac{\beta}{N^2}, \qquad \lambda = g^2 N = \frac{2N^2}{\beta}, \qquad \alpha = \frac{g^2}{4\pi} \tag{7}$$

β_{Ch} is Chatterjee's form, writing the action as $\beta_{\mathrm{Ch}} \sum_P \mathrm{Re}\,\mathrm{tr}(I - U_P)$; β_{SZZ} is 't Hooft's convention, writing the inverse coupling as $N\beta_{\mathrm{SZZ}}$ (Shen–Zhu–Zhu, 5-04); λ is the 't Hooft coupling; α is what physics calls the strength of the coupling. The running coefficients also have a way of being written for each variable (Table 1 of 4-06); in this book b_0 is the coefficient for g, and κ that for the Wilson β.

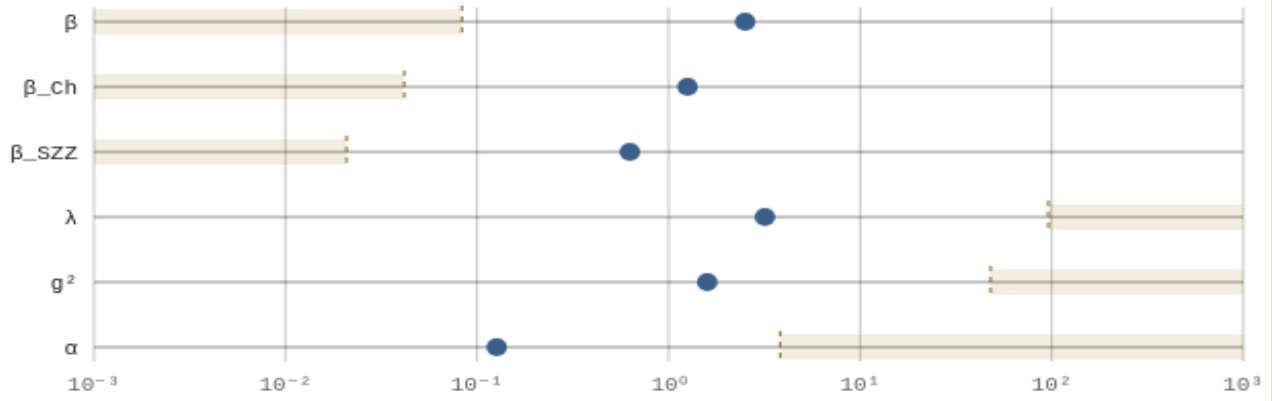
$$\mu \frac{dg}{d\mu} = -b_0 g^3 + \cdots, \qquad b_0 = \frac{11N}{48\pi^2}, \qquad \frac{d\beta}{d\ln\mu} = \kappa = 4N b_0 = \frac{11N^2}{12\pi^2} \quad (8)$$

The right of (8) is the one-loop prediction that the same physics is kept if β is raised by $\kappa \ln 2$ each time a is halved Known . $\kappa = 11/(3\pi^2)$ for SU(2) is the same number as "the slope of the step formula" of the study in Part 23, and also the same number as the value at SU(2) (C_g = 8) of the one-loop slope s = 11C_g/(24π²) of Volume 2 (10-01). Each of them is the known coefficient written in the lattice convention (23-14).

Table 6 Constants for each group (pure SU(N)) Computed

N	dim G	b_0	$2b_0$	κ	$\kappa \ln 2$	$b_0^{(\alpha)} = 11N/12\pi$ (μ² dα/dμ² = −b₀^(α) α², Table 1
2	3	0.04644	0.09288	0.3715	0.2575	
3	8	0.06966	0.13932	0.8359	0.5794	

Figure 1 Coupling converter. Moving the Wilson β with the knob moves the values of the six ways of writing (●) together on logarithmic scales. The vertical dashed line is the edge of the Shen–Zhu–Zhu condition in four dimensions ($d = 4$), $\beta_{\mathrm{SZZ}} = 1/(16(d-1)) = 1/48$, and the coloured band is the side where the condition holds. Switching SU(2) / SU(3) moves the position of the edge.



SU(2), β = 2.512: β_Ch = 1.256, β_SZZ = 0.6280, λ = 3.185, g² = 1.592, α = 0.1267. Outside the condition (edge at β = 0.08333). One-loop increment for halving a: κ ln2 = 0.2575

Computed The numbers in this figure were computed on this machine. The figure computes (7) on the spot (the same formulas as Table 7).

Table 7 Numerical examples of the conversion, and the edge of the strong-coupling condition in four dimensions ($d = 4$) Computed

Case	β	β_{Ch}	β_{SZZ}	λ	g^2	α

Case	β	β_{Ch}	β_{SZZ}	λ	g^2	α
SU(2), $\beta = 2.5$	2.5	1.25	0.625	3.2	1.6	0.12732
SU(3), $\beta = 6.0$	6	2	0.66667	3	1	0.07958
SU(2), edge of the condition	0.08333	0.04167	0.02083	96	48	3.81972
SU(3), edge of the condition	0.1875	0.0625	0.02083	96	32	2.54648

In 't Hooft's convention, β_{SZZ} and λ, the edge of the condition does not depend on N. The SU(2) $\beta = 2.5$ often used in numerical computation and the edge of the condition are about 30 times apart in α. The conditions are to be read in the normalisation of each paper; the conversion here is this book's arithmetic.

07

Scales, lengths, masses — separating lattice units from physical units

The symbols for length and mass come double, in lattice units (numbers with the lattice spacing as 1) and in physical units. If they are confused, "there is a gap on the lattice" and "there is a gap in the continuum" look like the same sentence (4-11).

$$m_{\mathrm{lat}} = \frac{1}{\xi}, \qquad \Delta = m_{\mathrm{phys}} = \frac{m_{\mathrm{lat}}}{a}, \qquad \xi_{\mathrm{phys}} = a\,\xi \tag{9}$$

ξ is the correlation length in lattice units, fixed by the rate of exponential decay of two-point correlations ((6) of 2-08). In the continuum limit, $a \to 0$ and $\xi \to \infty$ are taken together so that the product $a\xi$ stays constant. Example. If $\xi = 20$ and $a = 0.05$, then $\xi_{\mathrm{phys}} = 1$. Halving a needs $\xi = 40$, which at one loop corresponds to raising β by $\kappa \ln 2$. That two quantities are the same up to constant factors is written with the following symbol.

$$A \asymp B \quad \Longleftrightarrow \quad \exists\, 0 < c \le C : \;\; c \le A/B \le C \quad \text{(throughout the range considered)} \tag{10}$$

(10) says that the ratio goes neither to 0 nor to infinity; it is stronger than $\ln A / \ln B \to 1$, which compares only power exponents, and tells apart differences in logarithmic factors (Figure 2 of § 08).

Table 8 Symbols for scales, lengths and masses

Symbol	Meaning	Chapter	Note
H, Ω, $\mathcal{H}$	Hamiltonian, vacuum, Hilbert space	4-11	$H\Omega = 0$
Δ, m	Δ: the constant in the problem statement that bounds the energy of excitations from below. m: the largest value that can be taken as Δ (the lower end of the spectrum)	0-03, 4-11	$m = \inf \sigma(H\|_{\Omega^\perp})$. There is a gap $\Longleftrightarrow m > 0$

Symbol	Meaning	Chapter	Note
ξ, m_{lat}, m_{phys}	Correlation length (lattice units), $1/\xi$, m_{lat}/a	2-08, 18-03	(9)
μ	Renormalisation scale (momentum)	4-06	Same letter as indices and measures (§ 09)
Λ	The scale of dimensional transmutation ($\mu e^{-1/(2b_0 g^2)}$ at one loop)	4-07	Its value depends on the scheme. The ratio $m/\sqrt{\sigma}$ does not
ξ_{RG}, $a := 1/\xi_{\mathrm{RG}}$	The bookkeeping length $b^{k(\beta)}$, and the lattice spacing fixed by it	23-01	Definition of the study in Part 23. Agrees with a of Part 5 under the bookkeeping-length chain

08

Probability, spectrum, relaxation — three C_P and two η

In the second half of the book, the Poincaré constant C_P, which expresses how fast fluctuations are smoothed out, comes to the centre (1-10). It is the supremum of the ratio of the variance to the mean square of the gradient.

$$C_P = \sup_f \frac{\mathrm{Var}_\mu(f)}{\mathcal{E}(f)}, \qquad \mathcal{E}(f) = \mathbb{E}_\mu\Big[\sum_\ell |\nabla_\ell f|^2\Big], \qquad \lambda_1 = \frac{1}{C_P} \tag{11}$$

λ_1 is the gap of the Langevin dynamics that preserves μ. The same letter C_P is used for three quantities. The vacuum C_P is C_P of the vacuum measure at one time ($\Delta = 1/(2C_P^{(\alpha)})$; convention with kinetic term $\frac{1}{2}p^2$, exact for finitely many degrees of freedom; 2-05 § 08, A-06 Table 4); the path C_P is C_P of the path measure (Wilson measure) (C_P of the record of this book's study); and the path C_P measured in a graduation names the normalisation, according to whether the gradient of the path C_P is measured in the link angle ϑ or in the field $A = \sqrt{\beta}\,\vartheta$ (23-01 The line of construction and the diffusive-relaxation-time assumption).

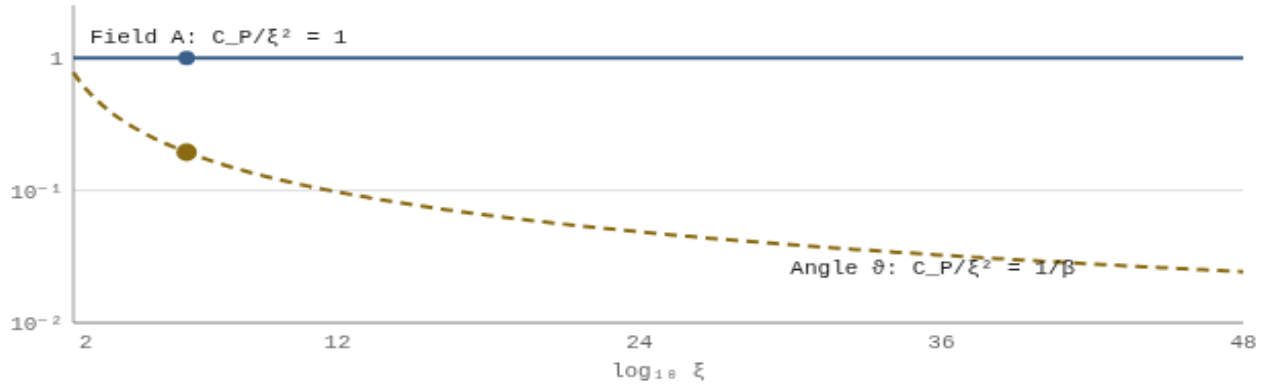
$$\mathcal{E}_A = \frac{\mathcal{E}_\vartheta}{\beta}, \qquad C_P[\mathcal{E}_A] = \beta\, C_P[\mathcal{E}_\vartheta], \qquad \text{in the free approximation } C_P^{(A)} = \xi^2,\ C_P^{(\vartheta)} = \frac{\xi^2}{\beta}$$

The free approximation is the approximation that regards the action as a Gaussian free field keeping only the quadratic terms, and gives $C_P^{(A)} = 1/m^2 = \xi^2$ (m in lattice units). A in (12) is A of § 04 measured in lattice units ($\sqrt{\beta}\,\vartheta^a = -aA^a$; the same field up to sign).

(12) shows that writing "$C_P \asymp \xi^2$" without naming the normalisation can change whether the sentence is true. A sentence comparing power exponents (the relaxation-

time assumption) moves only by the logarithm of β, and is the same sentence in both normalisations. A band statement, that the ratio stays within constant bounds, changes truth value with the normalisation. That is why this book writes band statements with the normalisation, as $(\xi^2)_{\mathrm{band}}[\mathcal{E}_\vartheta]$ (23-01 The line of construction and the diffusive-relaxation-time assumption).

Figure 2 Why the normalisation is named (SU(2), free approximation). Horizontal axis $\log_{10}\xi$, vertical axis C_P/ξ^2 (logarithmic). The solid line is the field normalisation 1, the dashed line the angle normalisation $1/\beta$. β is linked by replacing ξ with the one-loop formula for the bookkeeping length, $\xi \approx e^{3\pi^2\beta/11}$ (up to a constant factor) (asymptotic scaling assumed Physics). Moving ξ with the knob shows the local power exponent $\ln C_P/\ln\xi$ in the readout.



ξ = 10^6.0: β = 5.133, C_P^(ϑ)/ξ² = 0.1948, power exponent 1.8816 (angle) / 2 (field)

Computed The numbers in this figure were computed on this machine. The figure computes (12) and the one-loop formula on the spot (the same formulas as Table 9).

Table 9 C_P/ξ^2 in the angle normalisation and the local power exponent (SU(2), free approximation, replacing ξ by the one-loop formula for the bookkeeping length, $\beta = \frac{11}{3\pi^2}\ln\xi$. Asymptotic scaling assumed Physics)

Computed

ξ	β	$C_P^{(\vartheta)}/\xi^2$	$\ln C_P^{(\vartheta)}/\ln\xi$	$\ln C_P^{(A)}/\ln\xi$
10^2	1.7109	0.5845	1.8834	2
10^6	5.1326	0.1948	1.8816	2
10^{12}	10.2652	0.0974	1.9157	2
10^{48}	41.0609	0.0244	1.9664	2

The ratio in the angle normalisation goes to 0, so $(\xi^2)_{\mathrm{band}}[\mathcal{E}_\vartheta]$ fails in this free approximation. The power exponent $2 - \ln\beta/\ln\xi$ is still 1.97 at $\xi = 10^{48}$, but it goes to 2. This is an example showing a convention of notation, and shows nothing about C_P of the Yang–Mills measure.

There are also two exponents. The dynamical exponent z is the power in $C_P \asymp \xi^z$, and η without qualification is $\eta_{\mathrm{dyn}} = 2 - z$ (18-05 § 02, 2-10). The static $\eta_s = 2\Delta_O - (d-2)$ is the power of correlations fixed by the scaling dimension Δ_O of the operator O, and the two are equal only when the relation $z = 2 - \eta_s$ holds. Example. For Glauber

dynamics of the two-dimensional Ising model, $\eta_s = 1/4$ and $\eta_{\mathrm{dyn}} = -0.1665$ (18-03) Physics .

Table 10 Symbols for probability, spectrum and relaxation

Symbol	Meaning	Chapter	Note
$\mathbb{E}_\mu$, Var_μ, $\langle\cdot\rangle$	Expectation, variance, physical expectation	1-08	$\langle\psi,\phi\rangle$ is the inner product
$\sigma(H)$	Spectrum of an operator	1-10	Different from the string tension σ
CP, λ_1, $\mathcal{E}\vartheta$, $\mathcal{E}_A$	(11)(12)	1-10, 23-01	The three CP: the vacuum C_P, the path C_P, the path C_P measured in a graduation
τ_{exp}, τ_{int}	Exponential and integrated autocorrelation times	2-10, 5-07	For continuous-time Langevin, $\tau_{\mathrm{exp}} = CP$
z, η_{dyn}, η_s	Dynamical exponent, $2-z$, static power	2-10, 18-05	Different from the metric $\eta_{\mu\nu}$

09

Different meanings of the same letter — a list for telling them apart by context

The conventions of mathematics and physics have assigned the same letters to different things, so collisions within one book cannot be avoided. This book keeps the strong conventions as they are and declares the meaning at the start of the chapter. The guide for telling them apart is "subscripts and arguments". Example. $\beta(ba) = \beta(a) - \kappa \ln b + \cdots$ in 18-04 is the Wilson inverse coupling taking the lattice spacing as argument, not the β function $\beta(g)$.

Table 11 Different meanings of the same letter

Letter	Meaning (chapter)	How to tell apart
β	Wilson inverse coupling (5-01; the converted β_{Ch} and β_{SZZ} are in § 06) / inverse temperature $1/k_BT$ (2-08; in 2-07 the length of the loop $\beta\hbar$) / the critical exponent β (2-08 § 06, $1/8$ for the two-dimensional Ising model) / the β function (4-06) / (β) of the three CP (23-01)	Without qualification, the Wilson inverse coupling. The β function carries the argument g. The exponent is written alongside α, γ, ν
Δ	Mass gap (4-11) / Laplacian Δ_{lat} (1-08) / scaling dimension Δ_O (18-05; the scaling dimension of 17-08 is the same) / the decrease per step $\Delta(b)$ and the MCRG shift $\Delta\beta$ (18-04) / coproduct $\Delta(\Gamma)$ (4-05) / the group quantity Δ_G (Adhikari–Cao in 16-01; Δ_G in 16-05 and 16-08 is the mass gap) / difference Δx (2-04)	The scaling dimension carries an operator subscript, the Laplacian carries lat, the coproduct takes a diagram as argument. For Δ_G, see the chapter's declaration
η	Metric $\eta_{\mu\nu}$ (2-04) / $\eta_{\mathrm{dyn}}, \eta_s$ (18-05)	With two indices, the metric

Letter	Meaning (chapter)	How to tell apart
κ	One-loop slope (4-06) / decay rate of the Gaussian chain $1/\xi$ (2-08)	Decay rate only within 2-08
λ	Gell-Mann matrices (1-04) / 't Hooft coupling (17-04) / eigenvalue λ_1 (1-10)	With a colour index, a matrix; with a numeral subscript, an eigenvalue
σ	Pauli matrices (1-04) / string tension (5-02) / spin σ_x (2-08) / spectrum $\sigma(H)$ (1-10)	If the argument is an operator, the spectrum
Ω	Gauge transformation $\Omega(x)$ (3-01) / vacuum (4-11)	With an argument point x, a gauge transformation
θ	Angle of the θ term (3-05) / link angle 2ϑ (§ 05) / gac of the plaquette (5-01)	Multiplied by Q, the θ term
Λ	Lorentz transformation (2-04) / scale of dimensional transmutation (4-07)	If a matrix, the transformation
μ	Spacetime index / renormalisation scale (4-06) / measure μ_β	In subscript position, an index
a	Lattice spacing (5-01) / spacing fixed by bookkeeping $1/\xi_{\mathrm{RG}}$ (23-01) / starting point of a path (sections 01–06 of 2-07; from section 07, the step width) / colour index (3-02)	Superscript, colour. In 2-07 it switches by section
δ	Kronecker δ^{ab} (1-04) / shortfall of the bookkeeping $\delta(b)$ (23-02)	With two indices, Kronecker; with the factor b as argument, the shortfall
P	Plaquette P (5-01) / subscript of the Poincaré constant C_P (1-10)	As a subscript of C, the Poincaré constant
H	Hamiltonian (4-11) / Ising energy function (2-08)	An assumption is the name of a sentence
I	Identity matrix ($\mathrm{tr}(I-U_P)$ in 5-01) / modified Bessel function $I_k(J)=\frac{1}{2\pi}\int_0^{2\pi} e^{J\cos\theta}\cos k\theta\, d\theta$ (sections 06 and 07 of 0-04)	With a subscript k and an argument, the Bessel function
Ghost	The anticommuting Faddeev–Popov fields $c^a, \bar{c}^a$ (4-08 § 03) / states of negative weight in Pauli–Villars regularisation (4-10)	If a field, Faddeev–Popov; if a state of negative inner product, Pauli–Villars
Orientation of links	Parallel transport carries from the start point to the end point (1-07) / the lattice link $U_{x,\mu}$ is its inverse, carrying from $x+a\hat{\mu}$ to x, $U\approx e^{-igaA}$ (5-01 § 02) / numbering of chains: 3-01 uses $U_j=U(j{+}1,j)$, 3-02 uses $U_n=U(n,n{+}1)$	The value of the trace does not depend on the orientation. When comparing signs of exponents, see each chapter's declaration (the correspondence with 1-07 in 5-01 § 05)
T	Generators T^a, index $T(R)$ / length in time (5-02) / temperature (2-08) / transfer matrix T (2-08, 4-11; $T=e^{-aH}$)	Superscript, a generator. Inside a matrix power or a trace, the transfer matrix

Detour: can symbol collisions be eliminated?

You may skip this. Assigning a different letter to every quantity would eliminate collisions, but we do not, for two reasons. One is distance from the literature: writing the string tension with anything other than σ would make the tables of lattice papers unreadable as they are. The other is the number of letters: the number of quantities is far larger than the number of letters in commonly used typefaces. Precisely, a collision does harm only when two meanings stand in the same formula or the same table. For example, the three C_P in Table 3 of 23-01 stand in the same table as the Wilson β, so they are distinguished by name (the vacuum C_P, the path C_P, the path C_P measured in a graduation), rather than by a superscript such as (β) alone.

Table 12 The κ's compared (a copy of 26-05 Table 2): quantities that use the letter κ

Symbol	Meaning	Chapter
κ_{cb}	Chessboard density: the geometric mean, per block, of the product of the container biases of all blocks ((4) of 26-05)	26-05, 26-00 Table 1
κ (the one-sided bridge)	The comparison constant of the One-Sided Bridge Proposition (Theorem 3.1 of the paper) (in the form $CP \geq \kappa \xi^2$)	23-01 § 06
κ_{BE}	The lower bound on the Bakry–Émery curvature	24-09
$\hbar\kappa$, κ_f	An upper bound on the strength of the coupling to neighbouring sites; the crossing strength of Brascamp–Lieb	23-06
$\kappa = 3/1000$	The lower bound outside the defects in the Barta row	23-09
κ (Part 24)	The comparison constant between the Langevin metric and the metric of the kinetic term	24-09
$\kappa_{\mathrm{C7}}(k)$	The convexity constant of a chain of length k (the same quantity as $\kappa(k)$ in 23-11)	26-07
κ_w	Adapted stiffness: the variance of the force along the generator of the twist (width w; one of the candidate quantities for the band)	26-10

Table 13 Other meanings of θ and of "band" (a copy of 26-00 Table 0)

Word	Meaning	Chapters that use it	Relation to the band of Part 26
"Band" in Parts 23 and 24	The "band statement" of 23-01 § 05 and 23-15 (5) (the statement that a quantity lies within a width of constant multiples of the square of a length); ℓ_{band} of 23-09 (a length tied to the band at the summit); the "two-dimensional strip" (a narrow, strip-shaped lattice) of 24-02 § 03, § 05 and 24-09. The "twisted strip" of the two-dimensional model in 25-07 § 06 also has the meaning of a strip-shaped lattice	23-01, 23-09, 23-15, 24-02, 24-09, 25-07	Words with another meaning. Not the band of this part (an interval of scales)

Word	Meaning	Chapters that use it	Relation to the band of Part 26
Three meanings of θ	The threshold θ of 23-09 (θ_B, θ_σ and others; the value that divides configurations into the valley side and the summit side); the sector bias $\theta(R;T^2_L)$ of this part ((4) of 25-01); the vacuum angle θ of Tanizaki–Ünsal (set as $\theta = 0$ in 25-02)	23-09, 25-01, 25-02	Only the sector bias is a quantity of this part. The other two are different quantities

What this chapter can say

Matter	What is said	What is not said
Conventions of notation (Tables 1, 3, 5, 8, 10, 11)	A list collecting in one place the conventions used by the chapters of this book. The definitions are as in the linked chapters	Properties of the quantities each symbol refers to (existence, positivity and so on). These can be said only within the range of the labels in each chapter
Normalisation of generators (3) and structure constants (Table 2)	Checked numerically for SU(2) and SU(3) Computed . Standard convention Known	General G (the list in 1-04)
Three ways of writing the gauge field (Table 4)	That they translate into one another by the substitutions (4). $Q = -c_2$ ((2) of 3-05) Known	—
Conversion of couplings (7) and constants (Tables 6 and 7, Figure 1)	Conversions as this book's arithmetic Computed . b_0 and κ rewrite known one-loop coefficients Known	The content of each paper's conditions (conditions are read in the normalisation of the paper)
Normalisation of C_P ((12), Table 9, Figure 2)	Arithmetic under the free approximation and the one-loop formula (up to constants) Computed	The size of C_P for the lattice Yang–Mills measure. Whether the relaxation-time assumption holds
The mass gap	—	This chapter is only conventions of notation, and shows nothing, on the lattice or in the continuum

Sources and reproduction

Item	Kind	Source / tools
Definition of each symbol (the "Chapter" column of each table)	Chapters of this book	The linked chapters. Primary sources are as in the source tables of those chapters
Definitions of Δ and m in the problem statement	Primary source (text checked)	A. Jaffe, E. Witten, “Quantum Yang–Mills Theory” (the official Clay problem description) § 4. As in the source table of 4-11
The Wilson action and $\beta = 2N/g^2$	Known	K. G. Wilson, Phys. Rev. D 10 (1974) 2445–2459. As in the source table of 5-01
The convention for β Ch	Primary source (text checked)	S. Chatterjee, “Yang–Mills for probabilists”, arXiv:1803.01950 (2018) § 3. As in the source table of 5-01
The convention for β SZZ and the condition $1/(16(d-1))$	(1.2)(1.3) of the text checked (the reading of the normalisation is in 5-04)	H. Shen, R. Zhu, X. Zhu, Comm. Math. Phys. 400 (2023) 805–851, arXiv:2204.12737. As in the source table of 5-04
The one-loop coefficient b_0 and its four ways of writing	Known	D. J. Gross, F. Wilczek (1973), H. D. Politzer (1973), D. Tong's lecture notes § 2.4, the QCD chapter of the PDG. As in the source table of 4-06
The three CP, $\mathcal{E}_\vartheta$, $\mathcal{E}_A$, the bookkeeping length	Definitions of the study in Part 23	Source tables of 23-01 and 23-13

Next chapter to read: A-02 Glossary (look up the meaning of a term in one to three lines, and jump to the chapter). The names of assumptions are in A-06 Index of assumptions.

Glossary — looking up the words of this book in one line, and jumping to the chapter of definition

This chapter is a glossary; each entry points to the chapter that defines it.

What this chapter shows — The meaning of the main words in this book, in 1–3 lines each. Which word is defined in which chapter, and in what order they build up to reach "the mass gap". How to tell apart words that name different quantities under the same name (β, Δ, η, C_P, "gap").

Prerequisite chapters — None. You may look things up from anywhere, and read the details in the linked chapters. The conventions for symbols are in A-01 Table of notation, the list of assumptions in A-06 Index of names, and the literature in A-03 Guide to the literature.

Said first — The explanations here are summaries; the master copy of each definition is the linked chapter. Some conditions were dropped to fit a single line, so check the hypotheses of theorems in the linked chapters. The mass gap has not been shown (for existence in four dimensions, the committee's assessment is that it is proved in Lean in the construction published in 2026; 6-00). This book does not claim to solve the problem.

Order of this chapter

1. How to use this, and the single road of words — the form of an entry, filtering, twelve words from the group to the mass gap (Figure 1), a table of frequent words
2. Mathematical preparation (1): groups, Lie algebras, geometry — group, SU(2), compact simple group, Lie groups and Lie algebras, connection, holonomy, curvature, gauge transformation
3. Mathematical preparation (2): analysis and probability — Gaussian measure, Lebesgue measure in infinite dimensions, self-adjoint operators and spectrum, variational principle, Poincaré constant
4. Physical preparation — action, states and the Hamiltonian, path integral, imaginary time, correlation length, phase transition, transfer matrix, Langevin and z (Figure 2)

5. Yang–Mills theory: classical, quantisation, axioms — field strength, instanton, orbit space, renormalisation, asymptotic freedom, Λ, gauge fixing and BRST, Gribov, Schwinger functions, OS axioms, mass gap
6. Lattice gauge theory — link variable, plaquette, Wilson action, Elitzur's theorem, Wilson loop, area law and string tension, strong-coupling expansion, continuum limit, lattice correlation-length problem (Chatterjee's Problem 5.1)
7. Constructive field theory — constructive field theory, triviality, cluster expansion, blocking, ultraviolet stability, stochastic quantisation
8. Words for reading the published construction (Parts 6–14) — published construction, assessment, probability kernel, representation, forced activity, shooting, calendar, induction hypothesis, seed, chessboard root, phase measure and others
9. Physical pictures — dual superconductivity, centre vortex, effective string, large N, holography, one scale
10. The words of this book (Parts 16, 18, 23 and 24) — the two columns of settledness, seams, the study with the diffusive-relaxation-time assumption at its axis (the side of the four-dimensional lattice, the model of the first step, the assembly of the first step, computation and checking), the words of Part 24
11. Different quantities under the same name — β, Δ, η, b_0, three C_P, three "gaps", Detour: four uses of the word "dimension"

01

How to use this, and the single road of words

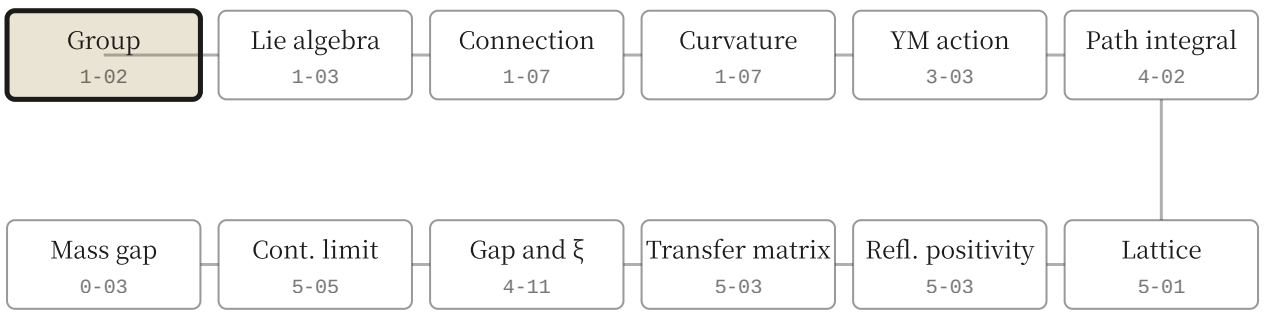
Each entry consists of "the headword", "a meaning in 1–3 lines" and "→ the chapter where it is defined". The order is not alphabetical but follows the parts of the book, so the words needed to read an entry are usually a little above it. To search by word, you can filter with the box below (without JavaScript, use in-page search).

The backbone of this book is one formula. Set the energy of the vacuum of the Hamiltonian H to 0; the distance from it to the next part of the spectrum is called the mass gap (4-11 § 01).

$$\Delta \;=\; \inf\big(\operatorname{spec} H \setminus \{0\}\big) \;>\; 0 \quad (1)$$

To read this formula you need "spectrum", "Hamiltonian" and "vacuum", and to give it meaning for four-dimensional Yang–Mills theory you need everything from groups to lattices and reflection positivity. Figure 1 is that single road.

Figure 1 The single road of words — moving the knob advances a step and shows that word and its chapter of definition below. "Play in order" advances one step at a time. The number in each box is the chapter that uses the word on this single road (the chapters of definition are the links in the entries below)



1. Group — a collection of symmetries (1-02)

Without JavaScript, the twelve boxes of the figure and their chapter numbers can still be read as they are.

Table 1 counts how many chapters the main words appear in. "First chapter" is the chapter where the name first appears, not necessarily the chapter of definition.

Table 1 Number of chapters in which the main words appear (the body text of the 105 chapters other than the appendices; counted excluding script, style, the whole-book contents and the meta line)

Word	Chapters	First chapter
Mass gap	101	0-01
Confinement	56	0-01
Correlation length	54	0-02
Gauge transformation	48	0-01
Asymptotic freedom	47	0-01
Plaquette	46	0-03
Refl. positivity	43	0-02
Wilson loop	43	0-01
String tension	40	0-02
Transfer matrix	38	0-04
diffusive-relaxation-time assumption	26	0-02
Poincaré constant	20	1-10
Dynamical exponent	14	2-08

Computed The numbers in this table were counted on this machine (a small script that counts words in the body text of the drafts; the numbers move as chapters are revised). Of the 26 words counted, we list the top 10 by number of chapters (excluding

"connection", which overlaps with ordinary Japanese) and the 3 words central to Part 23 of this book (relaxation-time assumption, Poincaré constant, dynamical exponent).

02

Mathematical preparation (1): groups, Lie algebras, geometry

Yang–Mills theory is the theory of a mechanism for comparing the orientation of a group from place to place (the connection) and of the mismatch in that comparison (the curvature). The first half of Part 1 prepares the words for this. The key formula is the one line that makes the curvature F from the connection A (in the geometric way of writing; for conversion to the physical way, see A-01).

$$F = dA + A \wedge A \quad (2)$$

Example: if the group is $U(1)$ (complex numbers of absolute value 1), then $A \wedge A = 0$ and $F = dA$, and we are back to the field strength of electromagnetism (2-03). For $SU(2)$, $A \wedge A \neq 0$, and this is where the interaction of the field with itself comes from.

Group

A set with a product, an identity and inverses, whose product is associative. An abstraction of a collection of symmetries (operations that preserve a shape). → 1-02

SU(2), double cover

The group of 2×2 unitary matrices with determinant 1. The same as the quaternions of length 1; its shape is the three-dimensional sphere. It maps two-to-one onto the rotation group SO(3). → 1-02

Compact simple group

A bounded, closed, connected matrix group (a compact connected Lie group) whose Lie algebra is non-abelian and has no ideals other than 0 and the whole (simple in the sense of Lie groups; a finite centre, as in $SU(N)$, is allowed). The problem statement lets the gauge group be chosen arbitrarily from among these. → 0-03

Lie group, Lie algebra

A group whose product can be taken smoothly, and its tangent space at the identity equipped with the commutator $[X, Y]$. The Lie algebra is the "infinitesimal directions" of the group. → 1-03

Connection

A rule for comparing vectors at neighbouring points. The gauge field A is a connection. → 1-07

Parallel transport, holonomy

Carrying a vector along a connection. The change (an element of the group) after going once round a closed path and returning is the holonomy. The prototype of the link variables of the lattice and of Wilson loops. → 1-07

Curvature

The leading part, proportional to the area, of the holonomy of a small loop. Formula (2). The field strength of gauge theory. → 1-07

Gauge transformation (geometry)

Changing the basis at each point by an element of the group. The connection changes as $A \mapsto gAg^{-1} - (dg)g^{-1}$ and the curvature as $F \mapsto gFg^{-1}$. → 1-07

03

Mathematical preparation (2): analysis and probability

Quantised Yang–Mills theory can be written, in imaginary time, as "a probability measure on configurations of the field". A configuration is infinitely many numbers, so we need probability in infinite dimensions and the language of the spectrum of operators. The inequality used most in this book is the Poincaré inequality, which bounds the variance by "how much the value changes when you shake things".

$$\mathrm{Var}_\mu(f) \;\le\; C_P\, \mathcal{E}(f), \qquad \mathcal{E}(f) = \mathbb{E}_\mu\big[|\nabla f|^2\big] \quad (3)$$

Example: if μ is the standard Gaussian distribution on the real line, then $C_P = 1$, with equality for $f(x) = x$ (variance 1, expected squared derivative 1). Known The reciprocal of the best C_P is the gap of the diffusion that has μ as its equilibrium (1-10).

Gaussian measure

A measure determined by its mean and covariance alone. The most basic measure that can be built even in infinite dimensions; constructive field theory often starts from here. → 1-08

There is no Lebesgue measure in infinite dimensions

On an infinite-dimensional separable Hilbert (Banach) space such as ℓ^2, the only measure that is invariant under translations and gives finite values to bounded sets is 0. The reason why the "$\mathcal{D}A$" of the path integral has no literal meaning. → 1-09

Self-adjoint operator, spectrum

The infinite-dimensional version of a Hermitian matrix, and the set of its "eigenvalues" (including continuous parts). The Hamiltonian is self-adjoint and its spectrum is real. → 1-10

Variational principle (Rayleigh–Ritz)

The bottom of the spectrum (the smallest eigenvalue, if there is one) is the infimum of $\langle \psi, H\psi\rangle / \langle \psi, \psi\rangle$. However many trial functions you put in, you only get upper bounds. → 1-10

Poincaré inequality, Poincaré constant C_P

Formula (3), and the best constant that goes in it. Its value depends on the normalisation of $\mathcal{E}$ (what you differentiate by), so each chapter states its normalisation. → 1-10

04

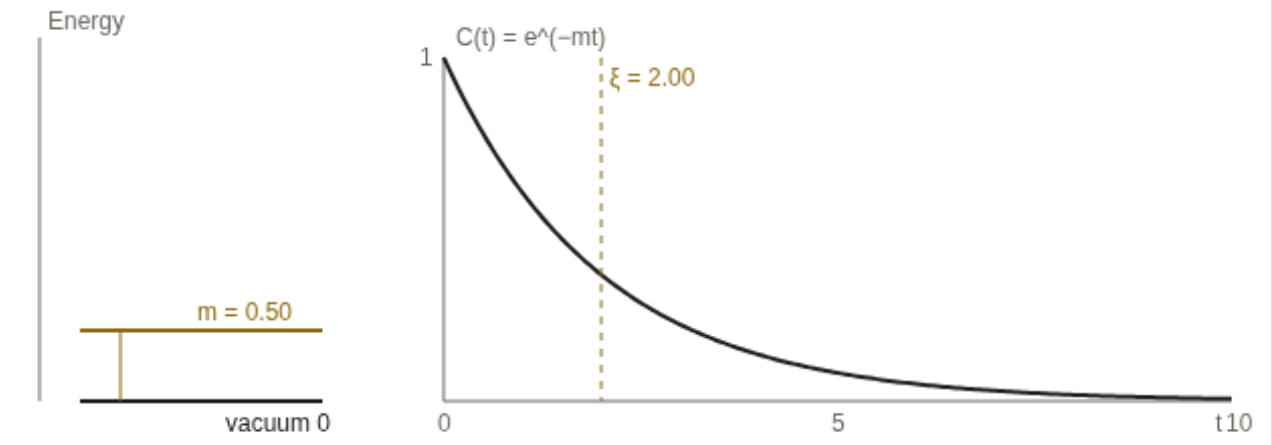
Physical preparation

The words of Part 2 have two faces, quantum mechanics and statistical mechanics. What quantum mechanics calls "the energy gap" and statistical mechanics calls "the length over which correlations decrease" become the same quantity through imaginary time. This is the rereading that runs through the whole book; as a formula, it is the following expansion using the vacuum $|0\rangle$ and the excitations $|n\rangle$ (4-11 § 02).

$$\langle O(t)\,O(0)\rangle - \langle O\rangle^2 \;=\; \sum_{n\geq 1} |\langle n|O|0\rangle|^2\, e^{-(E_n - E_0)t} \;\approx\; C\, e^{-mt}, \qquad \xi = \frac{1}{m} \quad (4)$$

Example: if $m = 0.5$ then $\xi = 2$, and the correlation at a separation of $t = 10$ decreases by a factor of $e^{-5} \approx 0.0067$. Moving the gap m with the knob in Figure 2 changes the spacing of the levels on the left and the rate of decrease on the right together.

Figure 2 Gap and correlation length — changing the gap m with the knob changes at the same time the height of the first excitation on the left and the rate at which the correlation e^{-mt} on the right decreases. The vertical dashed line is t = ξ = 1/m



```
m = 0.50, ξ = 2.00, C(5) = 0.0821, C(10) = 0.0067
```

Table 2 The gap m and the correlation $C(t) = e^{-mt}$ (with the constant C = 1)

m	ξ = 1/m	C(1)	C(5)	C(10)
2.00	0.50	0.1353	0.0000	0.00000
0.50	2.00	0.6065	0.0821	0.00674
0.10	10.00	0.9048	0.6065	0.36788

Computed The numbers in this figure and table were computed on this machine (values of the exponential function; the figure draws the same formula on the spot). The smaller the gap, the farther the correlation persists, and as $m \to 0$ the correlation length becomes infinite. This is what "critical" looks like.

Action, Euler–Lagrange equation

A functional S that assigns one number to a whole path. The classical motion is the path that makes S stationary, and that condition is the Euler–Lagrange equation. → 2-01

State, Hamiltonian

A state is a unit vector in a Hilbert space; the Hamiltonian H is the self-adjoint operator that generates the time evolution e^{-itH} and represents the energy. → 2-05

Path integral

The way of writing quantum theory in which all paths are summed with weight $e^{iS/\hbar}$ (in imaginary time, e^{-S}). → 2-07

Imaginary time, Wick rotation

Substituting $t = -i\tau$. The oscillation e^{iS} becomes the damping e^{-S}, and quantum theory becomes the probability of statistical mechanics. → 2-07

Correlation function, correlation length

The tie between the values at two distant points, and the length ξ when it decreases as $e^{-r/\xi}$. In formula (4), the reciprocal of the gap. → 2-08

Phase transition, critical point, universality

When a parameter is moved, the free energy and other quantities change in a non-smooth (non-analytic) way. If a quantity jumps, it is a first-order transition; if nothing jumps but the correlation length becomes infinite, it is a continuous transition, and that point is a critical point. At a critical point, behaviour that does not depend on the details (universality) appears. → 2-08, 16-11 § 04, 26-12

Transfer matrix

The weight of one step of imaginary time made into a matrix (an operator) $T = e^{-H}$. The ratio of the largest eigenvalue to the next determines how correlations decrease. → 2-07

Langevin dynamics, Glauber dynamics

A noisy gradient flow that has a given measure as its equilibrium (the continuous case), and a stochastic dynamics that rewrites one point at a time (the discrete case). Not the time of the theory but a provisional time for producing samples. → 2-10

Dynamical exponent z, critical slowing down

The exponent when the relaxation time grows as a power of the correlation length, $\tau \sim \xi^{z}$. The phenomenon that the dynamics becomes slower the closer one is to criticality is critical slowing down. → 2-10

05

Yang–Mills theory: classical, quantisation, axioms

These are the words of Parts 3 and 4. The classical theory is the theory of "connections that minimise the square of the curvature", and when it is quantised, one length scale that the classical theory does not have is born. That scale is expressed by Λ, and at one loop it has the following form (4-07).

$$\Lambda = \mu \exp\!\left(-\frac{1}{2b_0\, g^2(\mu)}\right), \qquad b_0 = \frac{11N}{3}\cdot\frac{1}{16\pi^2} \quad (\text{pure } SU(N)) \tag{5}$$

Example: for $SU(3)$, $11N/3 = 11$. As g^2 is made small, Λ approaches 0 in the form e^{-1/g^2}, and does not show up in any power series in g^2. Known

Classical

Field strength

$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - ig[A_\mu, A_\nu]$. The last commutator is the mark of non-commutativity: the field interacts with itself. → 3-02

Yang–Mills action

$S = \frac{1}{2g^2} \int \operatorname{tr} F_{\mu\nu} F_{\mu\nu}\, d^4x$ (Euclidean, written with g absorbed into A). In four dimensions its value does not change when the scale is changed. → 3-03

Self-dual, instanton

A connection satisfying $F = \pm * F$ (+ is self-dual and − anti-self-dual; the signs of the topological charge are opposite). A finite-action solution that brings the action all the way down to a constant times the absolute value of the topological charge. The representative is the BPST solution (a solution of topological charge 1 with a size around one point). → 3-03

Second Chern number, topological charge

$\frac{1}{8\pi^2} \int \operatorname{tr} F \wedge F$ (in the anti-Hermitian way of writing). An integer that does not change when the connection is changed continuously. → 3-05

Gauge orbit space, Singer's theorem

The space in which connections related by gauge transformations are identified. In the non-abelian case, there is no global way to choose one connection from each orbit continuously. → 3-04

Quantisation

Divergence, regularisation, renormalisation

That loop integrals become infinite at short distances; the cutoff that makes them temporarily finite; and readjusting the couplings so that observables remain finite when the cutoff is removed. → 4-04

Renormalisation group, β function

The rule for how the effective coupling flows when the scale at which one looks is changed. The speed of the flow is the β function $\mu\, dg/d\mu$. → 4-04

Asymptotic freedom

That the β function is negative and the coupling becomes weaker at shorter distances. For pure $SU(N)$, the one-loop coefficient $\mathbf{11}N/\mathbf{3}$ is what matters. → 4-06

Dimensional transmutation, Λ

That in a theory with only a dimensionless coupling, one length scale Λ appears through quantisation. Formula (5). → 4-07

Gauge fixing, Faddeev–Popov, ghost

A condition that narrows the connections representing the same physics down to one, and the determinant that then appears in the integral. The determinant written in terms of fields is the ghost. → 4-08

BRST symmetry

A symmetry, involving the ghosts, that remains in the action after gauge fixing. It is used to check that physical quantities do not depend on the choice of gauge. → 4-08

Gribov copy, Gribov region

That one orbit contains several connections satisfying the gauge condition (a manifestation of Singer's theorem), and the region where the Faddeev–Popov operator is positive. → 4-08

Axioms and definitions

The Wightman axioms, Haag's theorem

The set of conditions that a quantum field theory on Minkowski spacetime should satisfy, and the theorem showing that an interacting field cannot be placed in the same representation as the free field (if the fields at time 0 are unitarily related to a free field and the vacuum is unique and invariant under spatial translations and rotations, then the field is a free field). → 4-09 axioms, Haag

Refl. positivity

The property that the correlation with the time-reflected function is non-negative. With it, a state space with a positive inner product can be built from the Euclidean measure. → 4-10

Schwinger functions

The correlation functions of the field in Euclidean (imaginary) time, $\langle \phi(x1) \cdots \phi(x_n) \rangle$. The Wightman functions continued to imaginary time. → 4-10

The Osterwalder–Schrader axioms, reconstruction

The set of conditions that the Schwinger functions (just above) should satisfy, and the theorem that if they are satisfied, a Hilbert space and a Hamiltonian can be built. → 4-10

Mass gap

Formula (1). That the spectrum above the vacuum is separated by $\Delta > 0$. It can be rephrased as the mass of the lightest particle, but this is a separate condition from the existence of particles. → 4-11

Non-trivial

That the constructed theory is not a free field (Gaussian). One of the requirements of the problem statement. → 0-03

06

Lattice gauge theory

These are the words of Part 5. A lattice replaces spacetime by a mesh of spacing a, and represents the gauge field by elements of the group placed on the edges (links) of the mesh. That gauge invariance is kept exactly is the strength of the lattice. The action is a sum over the small squares (plaquettes), one by one.

$$S_W = \beta \sum_P \Big(1 - \tfrac{1}{N} \operatorname{Re} \operatorname{tr} U_P\Big), \qquad \beta = \frac{2N}{g^2} \quad (6)$$

Example: for $SU(2)$ ($N = 2$) with $\beta = 2.4$, $g^2 = 4/\beta \approx 1.67$. Making β larger makes g smaller, and by asymptotic freedom the lattice spacing a measured in physical units is expected to approach 0 (the one-loop running, 4-07) Physics . Some references use a different normalisation; for conversion, see 5-01.

Link variable, lattice spacing

The element of the group U_ℓ placed on the edge joining neighbouring lattice points (the lattice version of the parallel transport of a connection), and the width of the mesh a. → 5-01

Plaquette, staple

The product U_P of the four edges of a unit square (the holonomy of a small loop), and the product of the three edges with one edge removed. → 5-01

Wilson action

Formula (6). The lattice action that adds $1 - \frac{1}{N} \operatorname{Re} \operatorname{tr} U_P$ for each plaquette; in the naive limit $a \to 0$ it returns to the Yang–Mills action. → 5-01

Elitzur's theorem

On the lattice, the expectation value of a quantity that changes under gauge transformations (such as a component of a single link) is 0 in every volume and every limit. Local gauge symmetry does not break spontaneously. → 5-04

Wilson loop

The trace of the product of links along a closed path. Gauge invariant; it represents the weight for carrying a pair of heavy charges. → 5-02

Area law, perimeter law, string tension

The area law is that the expectation value of a Wilson loop decreases as the exponential of the enclosed area, $e^{-\sigma \cdot \mathrm{area}}$; the perimeter law is that it decreases with the length of the perimeter. The coefficient σ is the string tension. → 5-02

Confinement

That a colour charge cannot be taken out on its own. On the lattice it is often judged by the area law (the static potential growing in proportion to the distance), but there are several formulations. → 5-02

Strong-coupling expansion, character expansion

A method of expanding the weight in characters of the group when β is small. Here the area law and a positive gap can be shown Known (Osterwalder–Seiler 1978). → 5-02

Continuum limit, scaling

The limit $\beta \to \infty$ ($a \to 0$) that keeps quantities in physical units fixed. Scaling is when dimensionless ratios stop depending on a. → 5-05

Glueball

The lightest excitation of pure Yang–Mills regarded as a particle. On the lattice its mass is measured from how correlations decrease. → 5-08

The lattice correlation-length problem, the direction of the lattice version of the mass gap

Chatterjee's (2018) problem. For four-dimensional lattice gauge theory, show that for each β the correlation length $\xi(\beta)$ exists and is finite, and that $\xi(\beta) \to \infty$ as $\beta \to \infty$. If the gap in lattice units stayed uniformly positive, the mass would become infinite in the continuum limit, so the question is posed in this direction. That the gap in physical units is kept is the step beyond (the physical-unit gap statement). → 5-09

07

Constructive field theory

These are the words of Part 7. Constructive field theory is the field that builds interacting field theories as probability measures and proves that they satisfy the axioms. Which dimensions are easy, and where things stop, can be estimated from the "dimension" of the coupling. The Yang–Mills coupling has a power of length.

$$g^2 \sim (\mathrm{length})^{d-4} \quad (7)$$

Example: for $d = 2$, g^2 has the dimension of mass squared, and for $d = 3$ of mass to the first power, and it stops mattering at short distances (super-renormalisable). For $d = 4$ it is dimensionless; it does not weaken by a power of the scale, and moves only logarithmically under the renormalisation group (marginal). In Yang–Mills, by asymptotic freedom, it weakens logarithmically at short distances (4-06). Known Where things stand in each dimension is in 16-01.

Constructive field theory

The field that builds field theories as mathematical objects (measures, operators) and checks the axioms. This book reads it divided into six stages. → 7-01

Triviality

That only a Gaussian (free field) remains when the continuum limit is taken. A result of the type shown for ϕ^4 in four dimensions. → 7-08

Cluster expansion

A technique that splits the measure into a sum of contributions from small lumps far from each other, and shows convergence. Effective at strong coupling and large mass. → 7-04

Blocking, renormalisation group step

One step that coarsens the lattice by a factor b and integrates out the fine fluctuations to get a new action. Repeating it controls the continuum limit. → 7-05

Ultraviolet stability

That, in finite volume, the upper and lower bounds of the final action after repeated blocking do not depend on the lattice spacing. A theorem in three dimensions, a theorem with a hypothesis in four. There are three readings of different strength. → 7-06, 7-07 three readings

Stochastic quantisation, regularity structures

A method of building the measure as the equilibrium of a Langevin equation, and the theory that gives meaning to singular stochastic partial differential equations. → 7-09

08

Words for reading the published construction (Parts 6–14)

These are the words of Volume 2. Volume 2 reads the construction of the existence of four-dimensional Yang–Mills theory published on 2026-11-10 (the Lean code and the committee's assessment). The objects of the published construction are called by

names that carry their meaning, and the identifiers in the code are added as sources. The list of names and symbols is in A-06 § 02, and the conventions for the labels are in 6-00.

Statements and checks

Published construction

The Lean 4 code submitted on 2026-10-28 (yang-mills-group/OpenAI-YM-20261028), and the assessment of the committee that examined it (2026-11-10). This book cites its theorem at the level of "the committee's assessment is that it is proved in Lean". → 6-00

Assessment

The committee's assessment (docs/assessment-1.pdf in yang-mills-group/YM). Part I compares the result of the construction with the problem statement; Part II is the record of the checks. → 6-00

Public theorem, construction theorem, the committee's combined target

The statement in the form of the published question (whose only assumption is that the Lie algebra is simple), a stronger statement that contains it as a projection, and a statement on top of that in which the committee bundled its independent checks into one family. They differ in how much they say. → 6-02

Headline theorems, outside the dependencies

The 17 headline theorems listed by the verification record, and declarations not reached from any of them. Being "inside the dependencies" does not mean being used by the public theorem. → 6-00

Re-checking in the kernel, Comparator

Re-checking the proof in a fresh Lean kernel initialised only with the external libraries, and a tool that matches the statements and definitions against independently written definitions. Neither guarantees that the definitions express the intent of the problem. → 6-02

One step of renormalisation, and the coupling

Probability kernel, predictor, penalty coefficient

One step of renormalisation in the published construction is not a deterministic map but a probability kernel that draws the coarse link with Gaussian-type fluctuations around a central value (the predictor) built from the fine configuration. The strength of the pull is the penalty coefficient c_{pen}. → 9-01, 9-04

Representation

The fixed form in which the density at each step is written: the vacuum term, the main action, regular activities, and the gas of forced activities. The representation is not unique. → 9-06

Regular activity

The sum of the local correction terms in the representation. It vanishes at flat configurations. → 9-06

Forced activity

A correction function with a support that exactly covers the large-field flags and a non-empty "inventory" on it. The whole of it is carried into the representation as a gas. → 9-06, 11-01

Truncated action, flag

The action in which the plaquette terms are cut off linearly above a step-dependent threshold, and the mark of a large field exceeding the threshold. The threshold goes to 0 with the step. → 9-07

Coupling at a step

The coefficient multiplying the term of the normalised curvature squared in the representation at step m. A number that is not determined by the measure alone. → 10-01

Rereading

After one step, rereading the coupling of the representation from the log-ratio of the density at two points, a flat configuration and a test configuration. Strong monotonicity fixes the root uniquely. → 10-03

Shooting

Choosing the bare coupling that brings the coupling at step 0 to the reference value $\bar{\beta}$, by nested intervals of the bands at each step and the intermediate value theorem (the shooting method). Uniqueness is not claimed. → 10-04

Calendar

The bundle of conditions for choosing, in a fixed order, the constants used in the one-step estimates (block side, smoothing exponent, constant of the energy lower bound, rate, entry of the coupling). The conditions uniform in the step are paid here. → 10-05, 11-08

Calibration

Reading the coefficients of insertions of local fields at a reference step and matching them. The inverse of the renormalisation transport is used as input. → 8-04

Multistep estimates

Induction hypothesis, one-step certificate

That the density at every step has a representation of the same form, with a per-step ledger (estimates) attached to its ingredients; and building the representation at step m from that at step $m+1$, with the push-forward identity and the ledger. → 11-00

Seed, region

Each large fine plaquette, each edge far from its prediction and each flag (a seed), and the condition that sorts configurations by the type of their seeds (a region; with hysteresis of some width). → 11-03

Price, mark

The factor per seed (the price), and the part of its allocation left at the exit (the mark; half of the guaranteed lower bound). → 11-05

Strong estimate, weak ledger

The estimate $e^{-\mathrm{rate}\cdot P^2}$ at the exit of one step, and the estimate $e^{-P^{1/5}}$ carried by the induction hypothesis. The strong estimate is converted into the weak ledger and carried. → 11-07

Infinite volume and reconstruction

Slice, thread

The configuration of links within one layer perpendicular to the direction of reflection (a slice), and the set of links in the direction joining adjacent layers (a thread). The split used to build the kernel of the transfer operator. → 12-01

Inside function

A function that is gauge-invariant, measurable and bounded, and depends only on links with both ends inside the strip. The class of functions on which reflection positivity and the chessboard root act. → 12-01

Chessboard root

The size of the expectation of the product of one function copied to all boxes, raised to the power one over the number of boxes. A seminorm satisfying the triangle inequality (not necessarily a norm). → 12-02

Centred tiling

A tiling by boxes whose side is the lattice spacing of step m, with the reference box placed at the centre of the observation point. The size of renormalised observables is measured by this root. → 12-02, 12-03

Column

The arrangement in which a block and its mirror image alternate so as to fill the time circle. A chessboard copy in the single direction of time. → 12-04

Extraction sequence

A pair of a subsequence of cutoffs and a subsequence of volumes. A refinement composes each of the two subsequences. The limit is read as two ordinary limits along this sequence. → 12-05

Window (window function)

In a Ward identity, a smooth function of compact support that equals 1 near one point and whose support contains none of the other points. → 13-01, 12-06

Zero-energy space

The subspace $\ker H$ fixed by the whole time semigroup. That it is one-dimensional is the uniqueness of the vacuum in that phase. → 12-07

Phase measure

The probability measure μ (ν in the assessment) that splits a mixed limiting theory into phases (components). It is built from the Gelfand representation of the commutative algebra of operators compressed to the zero-energy space. → 12-07

Growth condition

That when all pairwise distances of a configuration of points are at least r, the correlations and their derivatives are bounded by a constant times r^{-A}. One form of the bundle of reconstruction axioms. → 12-08

09

Physical pictures

The words of Part 17 are the pictures by which physics, assuming that "the theory exists", explains the mass gap and confinement; most are at the level of Physics . The representative one is the picture in which the colour electric flux is squeezed into a thin tube and behaves as a vibrating string; the potential between heavy charges then takes the following form at long distances R (17-03).

$$V(R) \;=\; \sigma R \;-\; \frac{\pi(d-2)}{24R} \;+\; \cdots \tag{8}$$

Example: for $d = 4$ the second term is $-\pi/(12R)$. The first term is the area law (the string tension), and the second is the zero-point energy of the transverse vibrations of the tube. Physics That the coefficient of the second term does not depend on the details is a result under the assumption that a long tube can be regarded as an effective string.

Dual superconductivity, abelian projection

The picture of confinement in which, when magnetic monopoles condense, electric flux is squeezed into a tube, dually to the way a superconductor squeezes magnetic flux into a tube. Abelian projection is the procedure that partially fixes the gauge, shrinks the group to its abelian part (the diagonal components), and sees monopoles at the singularities of the fixing. → 17-02

Centre vortex

A sheet-like defect across which the phase shifts by an element of the centre of the group. The picture is that if there are many of them in disorder, Wilson loops show an area law. → 17-02

Effective string, Nambu–Goto, Lüscher term

The theory that regards the flux tube as a string weighted by its area, and the $1/R$ term of formula (8) produced by its fluctuations. → 17-03

Large N, 't Hooft coupling, planar diagrams

The limit $N \to \infty$ for $SU(N)$ with $\lambda = g^2 N$ held fixed. Only the Feynman diagrams that can be drawn on a plane remain. → 17-04

Holography, AdS/CFT

The conjecture that the gravitational theory of a certain spacetime is the same thing as a gauge theory on its boundary. The radial direction corresponds to scale. → 17-08

One scale ("a single scale")

The physical premise that every dimensionful quantity of pure Yang–Mills is a constant times a power of Λ. On the lattice it can be written in the form $m^2 \asymp \sigma$. → 17-12

10

The words of this book (Parts 16, 18, 23 and 24)

From Part 18 on, words named within this book appear. The exhaustive list of assumptions is in A-06; here we list only the central set. The quantity $a^2 C_P$ that the study in Part 23 sets up splits into a product of three ratios (17-12; $a = 1/\xi_{\mathrm{RG}}$, $\lambda_1 = 1/C_P$).

$$a^2 C_P \;=\; \underbrace{\frac{a^2}{\sigma}}_{\text{(iii)}} \cdot \underbrace{\frac{\sigma}{m^2}}_{\text{(ii)}} \cdot \underbrace{\frac{m^2}{\lambda_1}}_{\text{(i)}} \qquad (9)$$

Example: with the lattice values for SU(2), $\beta = 2.60$ (the table in 17-12), $m/\sqrt{\sigma} = 3.837$, so factor (ii) is $1/3.837^2 \approx 0.068$. Computed Whether (ii) can be bounded above and below by positive constants independent of β is the question of one scale; the lattice values show the tendency, but are not a proof.

The dictionary and where things stand (Parts 16 and 18)

The two columns of settledness

A way of reading that attaches two grades separately to the correspondence between the physical and the mathematical vocabulary: (a) whether they correspond as definitions, and (b) whether the quantity has been shown to exist in four-dimensional Yang–Mills. → 18-01

Seam

A place where the physical way of digging and the mathematical way of digging do not connect. This book lines up seven of them by type. → 16-05

The study with the relaxation-time assumption at its axis (Part 23)

The side of the four-dimensional lattice

Eight statements of construction

The eight statements into which the problem statement is divided along the road that enters from the lattice (infinite volume, reflection positivity, Wilson loops, physical gap, slowness of fluctuations, recovery of rotations, OS reconstruction, non-triviality). The relaxation-time band at the bookkeeping length is not among the requirements of the problem statement; it is a restatement of the physical-unit gap statement. → 23-01

The bookkeeping length ξ_{RG}

A length fixed by keeping the books on how the coupling decreases at each step that coarsens the lattice by a factor b, and taking the number of steps it takes to fall to a fixed value. We set $a := 1/\xi_{\mathrm{RG}}$ (the definition of the four-dimensional study in Part 23). → 23-01

Relaxation-time assumption

The power statement that the Poincaré constant C_P (the relaxation time of Langevin dynamics) grows with the same power as the square of the correlation length: $\ln C_P / \ln \xi \to 2$. In four dimensions, for the Wilson measure as $\beta \to \infty$. There is no proof. → 23-01

The band statement

The statement "C_P lies within a band of constant multiples of the square of the ruler": $a^2 C_P \asymp 1$. It is moved by logarithmic factors, so in this part it is not called the relaxation-time assumption. → 23-01

Relaxation-time upper-bound assumption, relaxation-time lower-bound assumption

The upper and lower halves of the band statement: the upper-bound assumption is $a^2 C_P \le C$ (an upper bound over all test functions), and the lower-bound assumption is $a^2 C_P \ge c$ (a lower bound for which one test function suffices). The hard one is the upper-bound assumption. Names distinct from the relaxation-time assumption. → 23-01

Band form of the diffusive-relaxation-time assumption $(\xi^2)_{\mathrm{band}}[\mathcal{E}]$

An assumption that compares within a band of constant multiples rather than by powers. Whether the band statement holds depends on the graduation of $\mathcal{E}$ (link angle or field), so it is written with the graduation named. An assumption distinct from the relaxation-time assumption. → 23-01

Relaxation chain, one-scale chain, bookkeeping-length chain

That each of the three factors into which $a^2 C_P$ splits is $\asymp 1$: relaxation and correlation length (the relaxation chain), correlation length and string length (the one-scale chain), string length and bookkeeping length (the bookkeeping-length chain). If all three hold, $a^2 C_P \asymp 1$ follows (the converse does not). → 23-01, 17-12

The one-sided bridge

A proposition that, for the path measure with continuous time, a finite spatial lattice and $T = \infty$, under assumptions such as on the ground state, bounds C_P from below

by a constant times the square of the correlation length, using test functions local in time. It spans only the side of the lower-bound assumption. → 23-01

Topological sectors and the order of volume

In a periodic box, the topological charge Q, which moves between sectors with difficulty, also enters the test functions. Take the reading of the original sources for $SU(3)$ and above that the autocorrelation of Q grows faster than ξ^2 (for $SU(2)$, a single primary source, close to a^{-2}), and apply to it, extended, the conjecture attached to the observation with open boundaries that HMC and Langevin are in the same universality class: then the upper-bound assumption reads as false in a periodic box. In this book's order, where the volume is made infinite first, open boundaries are not expected to be a rescue (an assumption row). → the note to 23-01 § 05

Seventeen roads tried on the four-dimensional lattice

Each is a pair of one question and a set of tools applied to it. The road of comparison with the defect of a submission and the road of a one-dimensional chain of scales are restatements of the original questions. → 23-02

Twenty-one walls of the four-dimensional lattice

The reason, in one sentence, why a road stopped with a tool short of an arrow. The twenty-one walls are divided into five types: the wall of principle, the wall of structure, the wall of tools, the wall of assumptions, and the wall of measurement and literature. → 23-02

Complete family

A set of links that removes exactly one link from every plaquette. If the remaining links are held fixed, the weights of the links of the family separate one by one and can be integrated independently of each other. → 23-02

The shortfall δ(b), the slope κ

The amount by which the window of one lattice step falls short of the continuum $\ln b$ (a number measured in the model of the one-loop kernel), and the slope of the one-loop running of the coupling $\kappa = 11/(3\pi^2)$ (SU(2), $\beta = 4/g^2$; a rewriting of known coefficients). → 23-02

The form of the answer

The statement "under the relaxation-time assumption ($\eta = 0$), the physical-unit gap statement $\Longleftrightarrow \sum_k \delta(b_k) < \infty$". Besides the relaxation-time assumption, it stands on the power form, on a model in which the errors of the steps are additive and

bounded, and on δ being the value of the model of the one-loop kernel (assumption rows). → 23-02

Lower bound on the overlap

The input that, in the representation of the correlation by non-negative weights, the weight of the lightest state is at least q times C(0). With it, a lower bound on the gap follows from correlations at finite k. Without it, spectroscopy ends with an upper bound on the gap (the spectroscopic upper-bound wall). → 23-02

Assumption of projection onto a one-dimensional chain of scales

The assumption that the measure can be projected onto a one-dimensional chain in the scale $s = \ln \ell$. Under it, the two-weight Hardy inequality (a weighted inequality in one dimension whose best constant is bounded above and below by integrals of the two weights) can be used. It cannot be said to be weaker than the relaxation-time assumption. → 23-02

Tube transfer-operator inequality

An inequality for the transfer operator saying that the weight of a tube of perimeter ℓ is at least $\sigma\ell + c/\ell$. If it holds, $m^2 \geq 4c\sigma$. There is no proof. → 23-02

The model of the first step

The staircase (four steps)

Four steps placed from an easy place to a hard place: the path measure of the double well in 0+1 dimensions ($\hbar \to 0$), the Wilson measure of the four-dimensional lattice ($\beta \to \infty$), the continuum limit and the OS axioms, and the mass gap of the limiting theory. This part deals with the first and second steps. → 23-03

Double-well relaxation-time power statement

The statement of the first step, $\ln C_P / \ln \xi \to 2$ ($\hbar \to 0$). It is a statement of the same form as the four-dimensional relaxation-time assumption, differing only in the family of measures, so we call it by the same name on both steps. Distinct from the band statement, which speaks of a band of constant multiples. → 23-03, 23-03 § 01

The five grades (proved here / cited / computer-assisted / reading / assumption)

The labels for the strength of claims in this part: elementary (the proof is placed in the text), a known theorem cited from the original source, computer-assisted, reading (floating point, Monte Carlo, fitting), assumption. One label per sentence. → 23-00

The double well

The potential energy with two valleys, $V(x) = (x^2 - 1)^2/8$. The valleys are at $x = \pm 1$ (curvature 1 at the bottom), and the top at $x = 0$ (curvature −1/2). → 23-04

The path measure

The probability measure that gives paths in imaginary time the weight $e^{-S/\hbar}$. $T \to \infty$ is taken first, then $\hbar \to 0$. The numbers are taken on the lattice with step $\varepsilon = \frac{1}{2}$. There is no gauge field in it. → 23-04

Tunnelling splitting

The difference between the two lowest levels of the Hamiltonian, $\Delta = E_1 - E_0$. In terms of paths, it is determined by the weight $e^{-S_0/\hbar}$ of inserting one kink. → 23-04

Correlation length (of the double well)

The length in imaginary time over which the correlation between two points of a path decreases, $\xi = \hbar/\Delta$. At the leading semiclassical order it grows exponentially, $\xi \propto \hbar^{1/2} e^{S_0/\hbar}$. → 23-04, § 03

Kink

A path that moves from one valley to the other; after the paths that stay in a valley, the path with the smallest action. Its action is $S_0 = 2/3$ (the action of the instanton), and its width is about 2 in imaginary time. → 23-04

Zero mode

The direction $\dot{x}_{\mathrm{cl}}$ with eigenvalue 0 of the fluctuation operator of the kink. It comes from the fact that shifting the kink in the direction of imaginary time does not change the action: one slow degree of freedom, the position of the kink. → 23-04

Diffusion coefficient of the kink

$D = \hbar/S_0$, obtained by projecting the Langevin noise onto the direction of the position of the kink. A statement about the position of one kink, not about the gap $1/CP$ of the whole path. → 23-04

Herring's formula

A formula that writes the difference between the even and odd eigenvalues of the transfer operator directly as a ratio of inner products of eigenfunctions, without finding the two separately and subtracting. It avoids the loss of digits when $\hbar$ is small. → 23-04

Plateau

A flat direction, along which the action hardly changes, made by the stretch between a pair of kinks where the path stays near the top. The curvature of one site

at the top falls short by $\frac{1}{4}$ of the value needed for convexity ($\varepsilon = \frac{1}{2}$). → 23-04

The convex core

The set deep in a valley, $\{x_i \geq a\}$ ($a > 1/\sqrt{3}$). If the path is confined here, $C_P \leq 2/(3a^2 - 1)$ follows, of Bakry–Émery type, uniformly in the length and in $\hbar$. → 23-04

Phase (the phase without kinks)

The measure restricted to configurations in which the path stays on the side of one valley. For example $\mu^{(+)}$, restricted to $x_i \geq 0$ at all sites (reflected at the wall $x_i = 0$). The measure of the in-phase local Poincaré condition. → 23-05

The assembly of the first step

The splitting of the variance

An identity that splits the configuration space into the two valleys and divides the variance into "the variance within each valley" and "the difference of the means of the two valleys". It is the first tool for assembling an upper bound on C_P from the constants of local Poincaré within the valleys and of the transport of the mean difference, but for long paths a single coarse variable is not enough. → 23-05

Local Poincaré

The Poincaré inequality for the measure restricted to one of the parts (a valley, or the phase without kinks). Its constant C_{loc} becomes the in-phase local Poincaré condition. → 23-05

Transport of the mean difference

An inequality that bounds the square of the difference of the means over the two valleys by the Dirichlet form. Its constant C_{md} gives the type of the saddle-tube condition. → 23-05

Four double-well conditions

The four conditions into which the upper side of the first step is divided: the in-phase local Poincaré condition (local Poincaré in the phase without kinks), the saddle-tube condition (transport along the family of flat saddle points; inside the box, the rows of the tube and the core), the box-reduction condition (reduction to the box dynamics), and the gap-inside-the-box condition. Each leaves assumption rows. They are distinct from the relaxation-time assumption, which is a statement on the side of the conclusion. → 23-05

Double-Well Relaxation-Time Upper-Bound Proposition

The conditional proposition that, for the path measure of the double well, assuming the four double-well conditions and the premise rows, $C_P \le K\xi^2 S_0/\hbar$ holds, and through $1 \le R \le K'/\hbar$ the double-well power statement follows. It is algebra on top of the four conditions, and does not say that the first step is closed. → 23-05, 23-03

Scrap

A stretch of the phase without kinks, sandwiched between kink and kink inside the box (of length at most $C\xi$, with values at both ends). The version of the in-phase local Poincaré condition on it is the segment local Poincaré assumption, which requires uniformity also in the end values. → 23-05

Tube

The collection of configurations around a kink, or a kink–antikink pair. The row that bounds the Poincaré inequality of the tube left after the configuration of kinks is held fixed is the saddle-tube Poincaré assumption. The one on a stretch with both ends held in the two valleys is called "the bridge tube". → 23-05, 23-07

Core

The stretch inside the tube where the path stays near the top ($Q_k = (-x_c, 0)^k$, $x_c = 0.89$). The Hessian of the action has negative directions there; bounding its Poincaré constant uniformly in the length k of the core is the row of the core Poincaré uniformity assumption. → 23-07, 23-11

The box dynamics (reduction to the box)

The step that bounds the Poincaré constant of an infinitely long path by the Poincaré constant of the conditional measure on a box of length $C\xi$ with the values on both neighbours held fixed (the box-reduction condition). The Box-Reduction Proposition has the form $C_P \le (1 + 1/n)\, C_{\mathrm{box}}/(1 - c_{\mathrm{alt}})$ and does not use the logarithmic Sobolev inequality. → 23-05, 23-11

Even and odd boxes

The line covered by boxes of length L, neighbours overlapping by l sites, divided into two families by the parity of their numbers. Boxes of the same family are apart from each other, and become independent of each other when the values outside the family are held fixed. → 23-11

Averaging over shifts

Shifting the arrangement of boxes by l sites at a time in n ways, and averaging the inequality for each shift. Since the overlap sites are disjoint across the shifts, the coefficient is only 1+1/n. → 23-05

Maximal correlation

For two σ-algebras, the supremum of the correlation between functions measurable with respect to each. For variables at two points, it can be expressed as the second singular value of the normalised matrix of the joint distribution. → 23-05, 23-11

Alternating maximal correlation

The maximal correlation c_{alt} of the two σ-algebras generated by the values outside the even family and the values outside the odd family. That this is below 1 uniformly in $\hbar$ is the assumption row that remains in the Box-Reduction Proposition (the alternating maximal-correlation assumption for boxes). → 23-05

The lemma of two projections

The Two-Projection Lemma. If the maximal correlation c of two σ-algebras is below 1, the variance is at most $1/(1-c)$ times the sum of the expectations of the two conditional variances. An elementary proof is placed in the text. → 23-05

The Efron–Stein inequality

The inequality that the variance of a function on a product measure is at most the sum of the expected variances when the coordinates are moved one at a time. Used for the inequality on the product of the even boxes. → 23-11

Reduced kink gas

A model that keeps only the slow variables inside the box (the number and positions of the kinks). If it is put into the same type as the Glauber dynamics of the one-dimensional Ising model (the row of the kink-gas gap assumption), the gap takes the form of a sum of the creation and annihilation of pairs and the diffusion of kinks. → 23-05

Cross term

The row that bounds the Dirichlet form of the slow side inside the box (the configuration of kinks Y) by $(1+\chi)$ times the original Dirichlet form (the cross-term uniformity assumption). That χ is uniform in $\hbar$ and in the boundary values is an assumption. → 23-05

Kept site

In the two-scale assembly of the in-phase local Poincaré condition, the site kept every 12 sites (the coarse side). When these are held fixed, the stretches between them become independent of each other, and the marginal on the kept sites becomes a nearest-neighbour chain. → 23-06

Bridge (a stretch with fixed ends)

A stretch with the values at both ends fixed. In the in-phase local Poincaré condition, the 11 sites between kept sites (the fine side); in the saddle-tube condition, a stretch with both ends held in the two valleys and one kink. → 23-06, 23-07

Nesting

The assembly that keeps sites 4 and 8 inside the non-convex 11-site bridge as one more level, splitting it into three small bridges (log-concave) and two sites. → 23-06

Helffer's criterion

The Poincaré version of a tool that judges the gap of a chain from the gap of one site and the strength of the coupling between neighbours. Used in Gershgorin form on the ring of kept sites. → 23-06

Margin

The key quantity of the criterion on the coarse side, $\hbar\rho - 2\hbar\kappa$ (the gap of one site minus twice the coupling to a neighbour). That it is positive is confirmed by interval arithmetic for every pair of end values. → 23-06

Node (of $\hbar$)

A point of $\hbar$ confirmed with computer assistance. The Six-Node In-Phase Poincaré Proposition is a statement at each of the six nodes $\hbar \in \{0.2, 0.1, 0.05, 0.02, 0.01, 0.005\}$, with a margin of at least 0.067. Distinct from the nodes of the dependency graph. → 23-06

Subinterval

A small interval into which the range of $\hbar$ is cut in order to fill in the $\hbar$ between nodes. Within each subinterval, the movement of the expectation values with $\hbar$ is enclosed in an interval. → 23-06, 23-08

Allowance

In a subinterval, the amount of swelling permitted above the pointwise upper bound (the remainder after subtracting the pointwise upper bound from the upper limit fixed by the margin). If the same amount is allowed for every box, the worst box decides the allowance. → 23-06

Route

The seven lines of attack set up to close the row of the core of the saddle-tube condition (the chain outside the window, the remaining numbers, the sector framework, small assumptions, the one remaining proposition, the seam of the ring, the range of $\hbar$). The seven are called by name, and their order does not express sequence or weight. → 23-07

Site window

The range W of 17 sites around one site inside the core. The logarithmic Sobolev constant A_W of the marginal of its mark is central to the route of the window-constant numerics, the route of the sector framework and the route of the window log-Sobolev inequality. Distinct from the window of $\hbar$. → 23-07

The window of $\hbar$

The range $[3 \cdot 10^{-4}, 3 \cdot 10^{-3}]$ of $\hbar$ handled with computer assistance. The "window" in "the whole window" and "the lower end of the window" is this one; where they could be confused, "site" is added to the site window. → 23-07

The chain outside the window

The chain extending outside the site window. Its contraction ratio $q < 1$ is the condition of the route of the chain outside the window and the route of the seam of the ring; for the core of the bridge, $q_{\mathrm{free}} \le 0.998854904$ became a computer-assisted inequality over the whole window of $\hbar$. Nothing is said outside the window or about $\hbar \to 0$. → 23-07, 23-08

Ring

A short periodic path of length $T \ll \xi$ with a configuration containing one kink–antikink pair. → 23-07

Seam

The place on the ring where the separation ℓ of the pair shrinks and the pair disappears. The configuration there is the plateau at the top itself, and the same difficulty as in the core of the bridge tube appears. → 23-07

Lump

A run of sites close to the top ($|z| < \theta$, $\theta = \frac{1}{2}$), taken as the unit of a sector that does not depend on the sign at the seam. With the rest held fixed, the action of a lump of k sites is convex for $k \le 7$. → 23-07

Outer chain and inner chain

The two kinds of chain that enter the logarithmic Sobolev constant of the site window of the ring. The outer chain is the chain on the side of fixed sign extending outside the window; its contraction is a computer-assisted inequality under conditions such as inside the window and pin ≤ 0. The inner chain is the stage inside the window; its ratio reads 1.24–1.28 and exceeds 1 (a finite coefficient). → 23-07

Boundary stage

A finite stage that appears only for configurations in which the lump touches the edge of the window (pin in $(0, \frac{1}{2})$). Its ratio reads 1.004–1.045, and the computer-assisted row of the outer chain does not cover this pin. → 23-07

Sector framework

The procedure for bounding the gap of the core uniformly in k by paying with the rarity of the places of negative curvature, divided into five stages (sector sum, Gibbs decomposition, componentwise localisation, volume locality, sector composition). What remains as an assumption is not the structure but the size of the constants. → 23-09

Sector

The direct product of boxes for each type of the marks attached to the sites (on the side of the top or not). The variance, the Dirichlet form and the entropy split into sums over sectors, and the number of sectors does not enter the constants. → 23-09

Defect set

The set N_j of configurations in which site j or one of its neighbours is on the side of the top beyond the threshold. Negative curvature exists only inside it. → 23-09

Rarity exponent

The minimum $\ell_{\min}$ of the logarithm of the measure of sets containing a defect. Not a length; it does not depend on the length k of the core. → 23-09

Closing condition

The condition $b(A_W c_H + D_W + \ln 2) < \kappa \ell_{\min}$ under which the right-hand side of the inequality assembled from the five stages of the sector framework is positive. If it is satisfied, the gap of the core is bounded below by a positive number independent of k. → 23-09

Needed value

The upper limit $A_{\max}$ obtained by rewriting the closing condition for A_W. That A_W is smaller than this is the one remaining proposition, the Window Log-Sobolev Threshold Proposition (the route of the window log-Sobolev inequality). The present upper bound lies outside the needed value, and the lower bound from test functions does not exclude the needed value. → 23-09

The three strands

Attacks on the one remaining proposition in three forms that differ in the functional form of the condition: the componentwise form, the scalar form (the Scalar-Strand Proposition), and the Feynman–Kac form. None of them is closed. → 23-09

Scalar-Strand Proposition

The proposition of the scalar strand, with a table of assumptions. With settings such as core length $k = 20$, it bounds the remainder quantities at each of 8 nodes in $\hbar \in [3 \cdot 10^{-4}, 10^{-3}]$. The interval-arithmetic rows have not yet been run. → 23-09

Lifting assumption

The assumption lifting the proxy ratio, in the Scalar-Strand Proposition. The only assumption, which lifts the proxy ratio linearly outside the measured range (the values for lumps of two sites). → 23-09

The common wall

The same place where the three strands stop: at the top, the diagonal of one site, $4 - \frac{1}{4} = 15/4$, does not reach the sum 4 of the couplings to its neighbours. A tool that has convexity as its entrance must pay for this ¼ with the rarity of the plateau, and $\hbar$ enters into the way it is paid. → 23-09

Diagonal dominance

That in each row of a matrix, the diagonal is at least the sum of the absolute values of the off-diagonal entries. For the Hessian of the core it is broken by just ¼ at the top, and on the face where every site is at the top, the smallest eigenvalue of a lump with $k \geq 8$ is negative. → 23-09

Detour plan

A plan that moves one of the two sides of the closing condition, or the form of the inequality itself. The list of detour plans was judged Alive, Conditional, On hold or Dead. → 23-10

The line that killed it

The fact that stopped a detour plan, shrunk to one line. The numbers are readings from a floating-point grid or a transfer matrix. → 23-10

Needed side, form, insufficient side (floor)

The three sides into which the detour plans are divided by direction. The needed side holds plans that make the needed value $A_{\max}$ larger; form, plans that change the functional form of the condition; the insufficient side (floor), plans that reduce the structural loss in the upper bound on A_W. → 23-10

Choice of structure and of tools

The two sources of the constants in the closing condition. The structural quantities (κ, b, $\ell_{\min}$) are decided by the model and by how the defect set is defined; the tool quantities (c_H, ln 2) depend on the choice of the steps of the proof and can be

changed with the same set. What moved the needed value a great deal was the tool side. → 23-09, 23-10

Types of breakage

The reasons that appeared repeatedly in the lines that killed the dead detour plans, gathered into seven (one source, ceiling, paying twice, mixing up the currency, the address of $1/\hbar$, misdirection, transfer). Each type comes with a question to test against a plan. → 23-10

Paying twice

The double-payment type. Paying the same amount again on a set that an earlier step has already paid for. The original Bochner step paid for the negative curvature over the whole core, but that was inside the defect set. A type where fixing it has a large effect. → 23-10

Currency (speed of exit and entropy)

A word of the currency-mix-up type. What the Poincaré inequality measures is the speed of exit; what can pay for the rarity $\mu(B) \le e^{-\ell}$ is the currency of entropy. With only the ratio of the variance to the Dirichlet form, the rarity cancels between numerator and denominator. → 23-10

The address of $1/\hbar$

The type of the address of 1/ħ. If one misjudges which quantity $1/\hbar$ multiplies, a plan merely moves $1/\hbar$ into sectors, marks, comparison constants or the cost of a perturbation. On the plateau at the top, $1/\hbar$ lives not in the direction of the sum but in the radius from the corner of the top. → 23-10

Threshold of convexity

The boundary: the lower bound $\kappa(k) = 8\sin^2\!\big(\pi/(2(k+1))\big) - \frac{1}{4}$ on the Hessian of the action of the core is positive only up to $k \le 7$. A core with $k \le 7$ is bounded by convexity (the Short-Core Convexity Lemma), independently of the end values and of $\hbar$. → 23-11

Three-Range Core-Constant Proposition

The proposition that bounds the Poincaré constant of the core in three ranges by length k: $k \le 7$ by convexity, $8 \le k \le 14$ by the Two-Block Lemma and the maximal correlation of two points, and $k \ge 15$ by applying the reduction to the box to the core. The inputs of the medium-core step and the long-core step are measured values. → 23-11

The wall of conditioning

A wall standing in the direction in which the zero wants to move, because the stretch of the core was conditioned to be "exactly this stretch". In the core on the side of the box whose ends cross the top, this creates bistability. Not physical metastability, but something made by the choice of conditioning. → 23-11

The action barrier

The row of the core action-barrier assumption. The assumption that the Poincaré constant of the core on the box side is bounded in the form $e^{\Delta S_*/\hbar}$ (with a prefactor a power of $\hbar$), and that the barrier is smaller than $2S_0$ ($\Delta S_* < 2S_0$). Under it, the local term of the Gap-Inside-the-Box Proposition vanishes as $\hbar \to 0$. → 23-11

Computation and checking

Computer-assisted

What has been confirmed as an inequality by interval arithmetic (the grade "computer-assisted"). Premises such as the rounding convention are written on the same row. Nothing is said to hold outside the computed range. → 23-08, 23-00

Interval arithmetic

Computation that holds every number as "an interval that is sure to contain the true value". If the upper end of the final interval is smaller than 1 ($q^+ < 1$), then $q < 1$ follows as an inequality. → 23-08

Outward rounding

When computing the ends of an interval, rounding the lower end down and the upper end up. In this part, the result of each operation is moved outward by one to the neighbouring floating-point number. Correct rounding in IEEE 754 is placed in a premise row. → 23-08

Loss of dependence

That intervals forget the ties between quantities coming from the same variable, and widen (evaluating $x - x^2$ naively on [0,1] gives [−1,1]). Fixed by subdividing finely or expanding about the centre. → 23-08, § 04

Positive control, negative control

A positive control asks whether the machine reproduces the answer in a case where it is known in closed form. A negative control asks whether the machine rejects a claim that should not hold. → 23-08, 23-14

Pre-registration

Writing down, before running a computation, the expected range of values, the rate-limiting place and the pass line for the controls, and recording after the result whether they were right. It becomes a record that the pass line was not moved after seeing the result. → 23-08

The integrated table

A table that puts the rows of the five grades for the four conditions of the first step on one sheet, row by row. A map of where there are proofs and where assumptions remain; the proportion of rows does not express progress. → 23-12

The dependency graph

A list that turns the rows of the table into numbered nodes and lines up the premises of each row to the right of "⟸". Which rows the conclusion of the First-Step Upper-Bound Proposition depends on is read by following the premises. → 23-12, 23-05

Node, leaf

A node is one row of the dependency graph. A leaf is a node with no "⟸": a row of assumption, known, computer-assisted or reading. → 23-12

The rule of numbering

The rule that the numbers of the premises to the right of "⟸" are always smaller than the number of the conclusion on the left. If it is kept on every row, the number goes down each time a premise is followed until a leaf is reached, and there is no circle. → 23-12

The required set of leaves

All the leaves that can be picked up by following the premises from the conclusion [111]. The only fork is the single "or" at [103], so there are two sets. → 23-12

The two roads (the core on the box side, the core on the sector side)

The two ways of supporting the fork [103] (the row that the Poincaré constant of the core is uniform). The road of the core on the box side supports it with the Three-Range Core-Constant Proposition and the vanishing of the local term as $\hbar \to 0$; the road of the core on the sector side with a uniform lower bound on the gap of the core in the sector framework and the regularity of the seam. → 23-15

Kinds of work

Six ways of classifying the work needed to close rows of assumption or reading: interval arithmetic, paper (writing a proof), bibliography (checking in the original

source and raising it to "cited"), measurement, another method (out of reach of the present tools), method undecided. → 23-15, § 03

A $\hbar$ that fits all

A $\hbar$ at which every row of the four conditions holds at the same time. Overlaying the ranges of the rows, there is none at present. The double-well power statement ultimately needs every row stated in a form uniform as $\hbar \to 0$. → 23-12

The criterion of cleanness

That the output of `#print axioms` for a Lean theorem is entirely a subset of the three axioms `propext`, `Classical.choice` and `Quot.sound`. It shows that the proof has no holes and that no arbitrary axioms have been added. → 23-13

Putting the conclusion into a definition

The form in which the desired property is written into a definition and that definition is taken as an assumption. The conclusion becomes a copy of the assumption, and the proof closes in one line. It is invisible to the criterion of cleanness. → 23-13

Circle of dependence

The form in which theorem A takes the conclusion of B as an assumption and B takes the conclusion of A. Theorems are checked one at a time, so it is invisible to machine checking; it is checked with the rule of numbering of the dependency graph. → 23-13, 23-12

The four verdicts of reconciliation

The verdicts when the numbers measured in this book's study are compared with the known ones: Agreement, Conditional agreement (how they agree depends on the choice of step, box, convention or form of extrapolation), Disagreement, Not comparable. → 23-14

The words of Part 24

24-00 Entrance

Further considerations

The title of Part 24. A part that considers, in order, the shape of what hinders the relaxation-time assumption, two candidates for restating while keeping the relaxation-time assumption as a premise, two views that do not go through the relaxation-time assumption, and what is at work in four dimensions. Many of its sentences are estimates. → 24-00

The trade of the restatement

Restating the quantity of the problem statement (the gap in Euclidean time) as the quantity of the relaxation-time assumption (the relaxation CP in Langevin time: a quantity defined by a supremum, for which one test function gives a lower bound, and whose upper bound can be assembled from parts). The two are different quantities. → 24-00, 23-01

The estimate label Estimate

A sixth label added to the five labels of Part 23 (proved here, cited, computer-assisted, reading, assumption). Attached to sentences that are opinions offered as material for judgement, with neither proof nor numbers. → 24-00

24-01 A nearly conserved global quantity

A nearly conserved global quantity (one type)

A global quantity Q whose variance is large and whose Dirichlet form is small (it is passed along through fluxes, or changes only in rare configurations), and which does not show up in the gap. Its relaxation time is decided not by the correlation length but by the scale of the events that break Q, and it hinders the upper-bound assumption. That the five examples fall into the same type is a classification (an estimate). → 24-01

The coefficient of breaking of conservation h

The density of the expectation of the square of the sum of the gradients of the charges of subregions (the gradient of the total charge). In the continuum it is 0 by topological invariance; only on the lattice is it non-zero, on configurations with dislocations. What the upper-bound assumption as a whole asks about is this coefficient. This book has no value for the four-dimensional lattice. → 24-01

The transport coefficient d

The density of the expectation of the square of the first moment (the dipole) of the field of gradients of the charge. In the regime where h is small, what the local diffusive-relaxation-time assumption asks about is this coefficient. There is no value for the four-dimensional lattice. → 24-01, 24-03

The boundary-layer coefficient g

The quantity per unit area obtained by subtracting the volume term from the Dirichlet form of the charge cut by a half-space. It enters the boundary correction of the ratio for a sharp box. → 24-01

The crossing length R_*

A length determined by the ratio of the transport coefficient to the coefficient of breaking of conservation (the square of R_* is dλ$_W$/h). The boundary at which the ratio of the charge of a smooth window is of transport type, proportional to R^2, in boxes shorter than this, and of barrier type, saturating at χ_t/h, in longer boxes (an estimate resting on the assumption of cluster decay). → 24-01

Flux through the box

A field running uniformly through the box, which enters the space of tests if the gauge transformations at the boundary sites of the box are left without dividing out. It moves the reference value by a factor of 2.2–2.5 (a reading of the free-field reference numbers). An example where the same type arises not from the dynamics but from the choice of family. → 24-01, 24-03

24-02 The length at which conservation breaks

Three rulers

The candidates to compare CP against, divided into three: the static correlation length ξ, the length at which conservation breaks ℓ_*, and the time for the global quantity to move by one τ_{glob}. They can take different values within the same model. → 24-02

The length at which conservation breaks ℓ_*

The length at which the charge of a subregion begins to relax not by transport through the boundary but by breaking of conservation inside the region. The candidate definition is (2): the smallest R at which the ratio Var/☒ reaches half its saturation value (an estimate). For two-dimensional $U(1)$ on a strip of width 2 with the outer boundary frozen, β = 2–6 and strip length $M \le 256$, the length read from the reading of τ_{int} (an upper bound on the gap) using the fit form $A/M^2 + B$ is not proportional to the correlation length. → 24-02, 24-02 § 03

Tree coordinates and link coordinates

In the Gaussian approximation on the hierarchical lattice, taking the values of the plaquettes as variables gives $CP = 1/\beta$ independent of the number of steps, while taking the link variables makes the gap shrink in inverse proportion to the square of the side. An example where the type of growth of CP changes with the choice of coordinates (the four-dimensional hierarchical lattice is an extension of this book). → 24-02

Conservation of flux

The property that when a link is moved, the values of the plaquettes (the flux) are only passed between neighbours. The source of the slowness of link coordinates. → 24-02

Flux dipole

The quantity X obtained by summing the angles of the plaquettes of the strip with cosine weights. The slowest mode of the Gaussian approximation; the length at which conservation breaks is fixed from the bend in its relaxation. → 24-02, § 04

Wrapping

The event in which the angle of one plaquette crosses $\pm\pi$. A rare event that crosses a barrier of height 2β; it breaks conservation because the group is compact. → 24-02

Topological charge of the strip

The integer obtained by reducing the angles of the plaquettes of the strip to $(-\pi, \pi]$, summing and dividing by 2π. It changes by one at each wrapping. We do not claim it is the same thing as the four-dimensional topological charge. → 24-02

Raw rate and static fluctuation

The rate of relaxation of the topological charge of the strip, split into the ratio of the rate of wrapping events (a dynamical quantity) and the static fluctuation E (a quantity of the measure), which measures how much the charge moves in one event (an estimate of the chain). → 24-02

τ_{glob}

The time for the global quantity to move by one. The form that compares CP with $\max(\xi^2, \tau_{\mathrm{glob}})$ is a candidate estimate set up from readings of the numbers of the two-dimensional strip, and is not shown in any model. → 24-02

Two-dimensional test bed

For the two-dimensional CP^{N-1} model, a comparison of freezing in a periodic box with the local ratio of a box as N is varied. The ratio is a ratio of autocorrelations with the lattice side fixed at $L = 64$, a different quantity from the static ratio of 24-03. The two-dimensional results imply nothing about four dimensions. → 24-02

24-03 Two ways to repair the relaxation-time assumption — the sector assumption and the local assumption

The algebra of time-averaged functionals $\mathcal{D}$

The collection of test functions built with smooth functions from functions at one time averaged over time with weights of bounded support. The CP of Part 24 is

defined as a supremum over this. → 24-03

Window

The time interval $[0, c\ell]$ of c times the ruler of length ℓ (in the version local also in space, a spacetime box of side $c\ell$). ℓ is not fixed by the gap but given from outside (in four dimensions, the bookkeeping length). → 24-03

The local Poincaré constant $C_P^{\mathrm{loc}}(c)$

The supremum of $\mathbf{Var}/\mathcal{E}$ taken only over test functions whose weights have support inside the window. It increases in c, and returns to C_P without assumption as $c \to \infty$. → 24-03

Local relaxation-time assumption ($(\xi^2)\uparrow_c^{\mathrm{loc}}$)

The statement that $C_P^{\mathrm{loc}}(c)$ grows with the same power as ℓ^2, and its upper half $(\xi^2)\uparrow_c^{\mathrm{loc}}(K)$ ($C_P^{\mathrm{loc}}(c)$ is at most K times ℓ^2). It has content different from the relaxation-time assumption as a whole only when stated with one c held fixed. The definition stands on continuous time, a finite spatial lattice, $T = \infty$ and the assumptions of the one-sided bridge. The version for the four-dimensional Wilson measure is a copy of it, with the existence of the infinite-volume measure placed as a premise. → 24-03

The ratio form K_{rel}

The ratio of the local Poincaré constant of a box for the target measure to the value of the massless reference on the same lattice, the same box and the same graduation. The form "bounded by some $K(c)$" is satisfied by the free-field computation for boxes in four spacetime dimensions that are local also in space, and so is empty; hence it is stated with this ratio. → 24-03

The massless reference and Γ

The reference is the local Poincaré constant $C_P^{\mathrm{loc},0}(R)$ of a box for the infinite-volume massless free field, and Γ is its coefficient $C_P^{\mathrm{loc},0}(R)/R^2$. The numbers are readings of the free-field reference, not numbers for the target measure. → 24-03

Gauge quotient reference

The reference for the gauge field measured on functions invariant under gauge transformations at all sites of the box (for a contractible box, functions of the angles of the plaquettes). It does not depend on the parameter of gauge fixing, so this one is used. → 24-03

Sector relaxation-time assumption (upper-bound assumption^{sec})

The statement that, in a box with its physical side held fixed, the Poincaré constant within a sector of topological charge is bounded by the square of the bookkeeping length. It only pushes the obstacle to the relaxation-time assumption into the quantity between sectors; it does not remove it. → 24-03

Sectors and the reflecting form

The sectors cut from the smoothed topological charge at regular values, and the Dirichlet form on them with no boundary condition imposed (the form of Langevin reflecting at the walls). The Poincaré constant of a sector is finite only when the sector is connected. → 24-03

The quantity between sectors C_{trans}

The supremum of the ratio of the variance of the conditional expectation onto the sector number to the Dirichlet form. It gives the sandwich $C_{\mathrm{trans}} \le C_P \le \sup C_P^{\mathrm{sec}} + C_{\mathrm{trans}}$. Its physical reading is the rate of dislocations. → 24-03

Open box and closed box

A box of the conditional measure with the boundary values held fixed (the box of the Box-Reduction Proposition in Part 23) is a closed box; a box of the marginal with the boundary not held fixed (the box of the local relaxation-time assumption) is an open box. → 24-03

24-04 Which form of the relaxation-time assumption the one-sided bridge needs

The family local in time $\mathcal{F}_1$

The family of functionals obtained by integrating functions at one time over time with bounded weights. Under the assumptions of the one-sided bridge and the canonical graduation, the supremum of $\mathrm{Var}\,/\mathcal{E}$ over this family is exactly ξ^2. The bridge uses only this part. → 24-04

The window factor $\varphi(x)$

$1-(1-e^{-x})/x$. The bracket in writing the ratio for the window T as $\kappa\xi^2\varphi(T/\xi) = \kappa T^2 g(mT)$; $\varphi(x)/x^2$ is strictly decreasing (the Window-Factor Monotonicity Proposition). Distinct from the angle of a plaquette φ_p. → 24-04

In-Window Supremum Proposition

The proposition that writes the supremum over the family local in time with the support of the weights restricted to the window $[0,T]$ in closed form, via the root of a transcendental equation (under the assumptions of the one-sided bridge and the canonical graduation). → 24-04

Two forms of the local relaxation-time assumption

The absolute form $(\xi^2)\uparrow_c^{\mathrm{loc}}$ ($C_P^{\mathrm{loc}}(c)$ is at most $K(c)\ell^2$) and the ratio form $(\xi^2)\uparrow_c^{\mathrm{rel}}$ ($K_{\mathrm{rel}}(c)$ is at most K). The constants correspond by $K(c) = K_{\mathrm{rel}}\,\Gamma\,c^2$. → 24-04

Threshold K_*

$K_* = \kappa/(\lambda_W \Gamma)$. Under the local-excitation moment assumption and the infinite-volume ground-state transformation identity, if the ratio K_{rel} is smaller than this, a lower bound on the gap follows (algebra on top of assumptions). Its value changes with the choice of reference. → 24-04

Local-excitation moment assumption

The assumption that there is a local observable supported in the box such that the moment ratio of the spectral measure of the excitation it creates is at most the square of the infinite-volume gap m_∞ plus a box-size correction $\gamma/(c\ell)^2$. It holds for the free field, but is not shown for any interacting model. → 24-04

The band $[K_*, 1)$

For fields whose ratio lies in this range, the local bridge says nothing. The massive free field also lies in this band. Whether there is another argument that sees the mass inside the band is undecided. → 24-04

Colour singlet and the second chaos

Gauge invariants of $SU(2)$ (colour singlets) have no first-order term around the identity, and at the leading order ($\beta \to \infty$), with three independent Gaussian colours, they lie in the second chaos or higher. For this reason the colour-singlet reference is exactly half the value of the gauge quotient. → 24-04

Functionals of winding-number type

Functionals outside the family local in time, such as the functional that integrates with weights the increment of the lifted angle of a free particle on a circle. All of the amount by which the upper-bound assumption is stronger than the gap lies outside this family. → 24-04

24-05 The Hamiltonian lattice and the vacuum measure

The vacuum measure ν

The distribution of the vacuum at one time (the distribution with density the square of the ground state, ψ_0^2). In gauge theory the functions are restricted to gauge-invariant ones. → 24-05

Ground-state transformation

The isometry that sends a function F to $F\psi_0$. With it, the quadratic form of ($H - E_0$) is carried to $\hbar^2/2$ times the Dirichlet form of ν. → 24-05

Gap and Vacuum Measure Proposition

Under the ground-state assumption ((A1) in the paper), the gap can be written with the Poincaré constant of the vacuum measure as $\Delta = \hbar^2/(2C_P(\nu))$, and the supremum is attained by ψ_1/ψ_0. → 24-05

Three Poincaré constants

The C_P of the path measure (a one-sided relation to the gap), the supremum over the family local in time ($\xi^2 = \hbar^2/\Delta^2$), and the constant of the vacuum measure ($C_P(\nu) = \hbar^2/(2\Delta)$). → 24-05

The Kogut–Susskind lattice

The Hamiltonian of a gauge theory with time taken continuous and only space made a lattice (the sum of an electric term and a magnetic term). The quantity of the problem statement is exactly the gap on its gauge-invariant subspace. → 24-05

frustration-free

That, when the Hamiltonian is viewed as a sum of local terms, there is a state that realises the ground states of all the local terms at once. Local-to-global gap theorems need this. → 24-05

Electric–Magnetic Splitting Frustration Proposition

The sum into which the Kogut–Susskind lattice is split as an electric term and a magnetic term is not frustration-free ($g > 0$, finite spatial lattice). For this reason local-to-global gap theorems do not apply to this splitting. → 24-05

The Hamiltonian limit

The order of limits in which the temporal lattice spacing is sent to 0 first. That it leads to the same continuum limit as Wilson's isotropic lattice is an assumption. → 24-05

24-06 Paying with rarity instead of convexity

The ceiling of convexity

On a compact manifold without boundary, the oscillation of a potential satisfying $\operatorname{Hess} V \geq -K\, g$ is at most $KD^2/2$ (the Convexity Ceiling on Groups Lemma). On $SU(2)$ a convex measure cannot leave the range of constant multiples of Haar, and cannot concentrate at the identity at weak coupling. → 24-06

The Bakry–Émery lower bound on curvature κ_{BE}

The constant in $\mathrm{Ric} + \mathrm{Hess}\, V \geq \kappa_{\mathrm{BE}} > 0$. If this holds, log-Sobolev and $C_P \leq 1/\kappa_{\mathrm{BE}}$ follow (a copy of the statement in the original source). A different quantity from the comparison constant κ of the one-sided bridge. → 24-06

Fibre

Where the conditional measure lives on the fine fluctuations (products of many links) when the coarse field is held fixed. Reading the inductive convexity assumption of hierarchical models as Bakry–Émery on the fibres over the group is an estimate. → 24-06

The reversal of convex and non-convex places

For flat ϕ^4, what is non-convex is small fields; on the group, it is the hemisphere far from the identity (large fields). On a closed manifold there is always a non-convex place, but the probability of being there is small. → 24-06

The rate of rarity s

The exponent when a bad set B satisfies $\mu(B) \leq e^{-s}$. The quantity written ℓ in 23-09 and 23-10 of Part 23; in Part 24 the letter was changed because ℓ is used for the ruler. → 24-06

Currency (entropy)

The distinction that the Poincaré inequality is a currency that measures the speed of exit, and that what can pay for rarity is the currency of entropy. A step that pays with rarity goes through an inequality of log-Sobolev type. → 24-06

The Holley–Stroock perturbation

The tool that says that if a measure is changed by a factor e^{-U} with bounded U, the Poincaré constant changes by at most a factor $e^{\operatorname{osc} U}$. The cost is not rarity but the exponential of the oscillation (in this book, a standard form from memory, not checked against the original source). → 24-06

Lyapunov condition

The type that bounds the global Poincaré constant from a drift $LW \leq -aW + b\mathbf{1}_G$ returning from the bad set to the good set and a local Poincaré inequality on the good set. Convexity is used only on the good set. → 24-06

Field-dependent constants

The direction of letting the constants of the convexity assumption at each scale depend on the coarse field (but uniformly below 1). As long as uniformly below 1 is required, it does not get past the ceiling of convexity. → 24-06

The Polchinski flow on the group

The multiscale Bakry–Émery condition along the flow of covariances, carried over to convolution with the heat kernel on the group. A formulation on the group was not found within the range searched. → 24-06

The class of measures that pay with rarity

A candidate class of measures with the rules: locally convex on the good set, the bad set rare, a drift back from the bad set, and rarity paid only through entropy inequalities (an estimate). → 24-06

Subcriticality

The key condition of the solution theory of stochastic quantisation (regularity structures); it holds only when $d < 4$. Four dimensions is exactly critical. → 24-06

24-07 Because it is four dimensions

Critical dimension

The dimension in which the coupling g^2 is exactly dimensionless. For Yang–Mills it is four, and the correction at each change of scale does not shrink by a power but remains. → 24-07

marginal

A term whose coupling is dimensionless and which, by power counting, neither strengthens nor weakens. Four-dimensional ϕ^4 and Yang–Mills are both marginal, but the directions of their flows are opposite. → 24-07

Infrared asymptotic freedom

That the coupling approaches 0 at long distances (four-dimensional ϕ^4). The asymptotic freedom of Yang–Mills is at short distances, the opposite direction. → 24-07

Dislocation

A small instanton, the size of the lattice spacing, passing through the lattice. The smoothed topological charge on the lattice changes only at such moments. → 24-07, 24-01

The four hurdles

A table that lines up, for each of the four steps of Part 23 (the 0+1 double well, the four-dimensional lattice, the continuum limit and the OS axioms, the mass gap of the limit), the hurdle, the known point reached, whether it is in reach, and the kind of cost. Whether it is in reach and the cost are estimates. → 24-07

Three sources of difficulty

The sources of the difficulty of the third step: the source of a dimensionless coupling (all scales act with the same weight), the lack of an expansion linking scales (there is no expansion linking the ultraviolet and the infrared), and the lack of global gauge fixing (non-abelian gauge invariance; there is no global gauge fixing, and large fields cannot be controlled by convexity). → 24-07

Ultraviolet stability (as used in Part 24)

That on a finite-volume lattice, the effective action on the unit lattice stays bounded after arbitrarily many repetitions of the block-spin transformation. Cited as a known point reached in the third step. → 24-07, the entry above

The window of coupling

The range that remains between the currency of rarity on the ultraviolet side (the rate of rarity is proportional to the effective coupling and runs out at the confinement scale) and the currency of curvature on the strong-coupling side, where neither is enough. A restatement of the second source, the lack of an expansion linking scales (an estimate). → 24-07, 24-06

Dual superconductivity (as treated in Part 24)

The mechanism that explains confinement by the condensation of monopoles. The condensation has not been shown and the projection depends on the choice of gauge, so it is not used as a tool of proof. → 24-07, the entry above

Centre vortex (as treated in Part 24)

The mechanism by which vortices taking values in the centre carry the string tension. The evidence is lattice numerics, and there are neither estimate inequalities nor statements about the limit, so it is not used as a tool of proof. → 24-07, the entry above

24-08 Questions, and what is not claimed

Candidate rules (six, and three combinations)

Candidate systems that remove one assumption of an existing framework and put an alternative rule in its place: the axiomatisation of scale, the algebra of loops, conserved quantities and sectors, the class of measures that pay with rarity, the axiom of asymptotic freedom, the rule of curvature; and the rule of axiomatising scale + the rule of the rarity class, the rule of conserved quantities and sectors + the rule of the rarity class, the rule of the loop algebra + the rule of conserved quantities

and sectors. All are candidates, and not even their consistency has been checked. → 24-08

Status of the questions (done, partly done, not yet, new)

The status column of the table of questions in Part 24. "Done" means that the text has answered the question conditionally; "new" is a question added in the writing of this part. → 24-08

What does not move when settled

A column attached to each row of questions and candidate rules, stating what does not move even if that question is settled. Whichever question is settled, the mass gap problem does not move. → 24-08

11

Different quantities under the same name

The same letter or the same word can refer to different quantities in different chapters. This is because the conventions of each field are carried over; the meaning is declared at the start of each chapter, but it is missed when skimming. The heavy one is "gap": the gaps of three operators are called by the same word. The conversion between physical units and lattice units is the following line.

$$\Delta = \frac{m_{\mathrm{lat}}}{a}, \qquad \xi_{\mathrm{phys}} = a\,\xi_{\mathrm{lat}} \quad (10)$$

Example: if the gap in lattice units m_{lat} is held at 0.5 while a goes from 1 to 1/16, Δ increases from 0.5 to 8. If it is made proportional to a, as $m_{\mathrm{lat}} = 0.5a$, then $\Delta = 0.5$ is kept. Computed What the continuum limit asks for is the latter (23-01).

Table 3 Different quantities under the same name

Name	Meaning	Where
β	The inverse of the lattice coupling $2N/g^2$ / the inverse temperature of statistical mechanics $1/k_BT$ / the β function $\mu\,dg/d\mu$	5-01 / 2-08 / 4-04
Δ	Mass gap / Laplacian (on the lattice, Δ_{lat})	4-11 / 1-11
η	Static anomalous dimension η_s (the power of correlations) / dynamical $\eta_{\mathrm{dyn}} = 2 - z$. Always attach the subscript	18-05
b_0	One-loop coefficient. With $\mu\,dg/d\mu = -b_0 g^3$ it is $11N/(48\pi^2)$ (formula (5)) / in the table of 0-03 it is $11C_A/(12\pi)$ (0.5836 for $SU(2)$). The normalisations of the coupling differ	4-06 / 0-03

Name	Meaning	Where
C_P	Vacuum C_P: the Poincaré constant of the distribution of the vacuum at one time (equivalent to the gap of the Hamiltonian) / path C_P: the Poincaré constant of the path measure (the reciprocal of the Langevin gap; what the relaxation-time assumption refers to) / path C_P measured in a graduation: the path C_P with its normalisation named	23-01
Gap	The gap of the Hamiltonian (the mass gap) / the gap of the transfer matrix (the mass m in lattice units) / the gap of Langevin dynamics λ_1	4-11 / 5-03 / 2-10
Mass	The mass gap / the mass of a particle (an isolated eigenvalue) / the coefficient of the mass term of the action (the bare mass)	4-11 / 2-02
Critical	The point where the correlation length becomes infinite / "critical" for stochastic partial differential equations (counting of scales) / the critical dimension of string theory	2-08 / 7-09 / 17-05

Of the three gaps, the problem statement asks only for the first. The second passes to the first if the continuum limit exists and the ratio (10) converges (the physical-unit gap statement, 23-01), and the third is a property of the dynamics that produces samples. The relaxation-time assumption is a statement comparing the third with the second (23-01).

The words of the second road, the band and the ultraviolet (Part 15 and Parts 25–27)

The crossover band (the band)

The interval around the scale $L \sim 1/\Lambda$ at which weak coupling gives way to strong coupling. The subject of Part 26, and the place where the two roads reach the same wall. It is different from the "windows" of Parts 23 and 24 (the window of A_W, the window of $\hbar$, the time window), and the "band statement" of 23-01 § 05, ℓ_band of 23-09, the "two-dimensional strip" of 24-02 and the "twisted strip" of 25-07 also have different meanings (compared in 26-00 Table 0). → 26-00

The twisted T^2

A small torus with the 't Hooft twist $n_{12} = 1$ put in. The container in which the second road shrinks two directions. → 25-01

't Hooft flux

The sector n_{34} and the flux free energy. Uniqueness of the vacuum, the gap of the adjoint field, and the absence of flat configurations in the (1,1) sector. → 25-01

Fractional instanton

A self-dual lump of topological charge ½. Action $4\pi^2/g^2$. Its dilute gas gives the string tension. → 25-02

Container

The region $D \times T^2$ with the frame held fixed. By the container identity (Mack–Petkova), conditioning on the frame makes things independent. → 25-03

The ensemble summed over sectors, the bias θ, the insertion ratio ρ

The ensemble defined by the sum over sectors, the sector bias $\theta(R;T^2_L)$ ((4) of 25-01), and the vortex insertion ratio ρ. Driven by an involution oriented to the sectors. θ is a different quantity from the thresholds θ_B, θ_σ of 23-09 and from the vacuum angle θ (26-00 Table 0). → 25-05

Slab Confinement Theorem

The theorem that, with the lattice spacing and the T^2 held fixed, the area law holds at every β. In the continuum limit the lower bound on the tension goes to 0. → 25-04

Frame decorrelation

How correlations decrease once the frame is fixed. Together with the lateral-widening inequality (strong form, weak form), it becomes the condition for the reduction to a single inequality. → 26-02

The lateral-widening inequality (strong form, weak form)

An inequality that controls the bias when widening sideways. The conclusion of the reduction theorem differs between the strong form and the weak form. → 26-02

The uniform slab tension, the uniform slab gap

The two quantities that remain after the band, with L held fixed, is collected into the density κ_cb. The band is collected into these two. → 26-05

The renormalisation comparison, β-monotonicity

Band = β-monotonicity + renormalisation comparison. A comparison that distinguishes groups; only 26-06 uses the abbreviations. → 26-06

κ_cb (the chessboard density)

The density of frame decorrelation with L held fixed. Different from the κ of Part 23, the κ of the one-sided bridge, κ_BE and others (comparison table in A-01 § 09). → 26-05

Diffusive-relaxation-time assumption

The assumption that the relaxation time grows as a power of the square of the correlation length. The short name is the relaxation-time assumption; the upper side is the upper-bound assumption, and the lower side the lower-bound assumption. The Lean identifiers and the names inside the papers have not been changed. → A-06

A class that closes in one step

A class of effective actions that returns to the same form (a family with the same parameters) after one renormalisation step. Ultraviolet control is the question of whether this class closes across the steps. In 15-03 this is written as the class-closure condition and placed as the first half of the decomposition of the ultraviolet wall. The one-link heat-kernel class is the smallest example that closes with one parameter. → 15-03, 15-04

The telescoping sum of losses

When a class closes with a single parameter, the losses of the steps do not pile up as a product but cancel as a sum of differences of the parameter (a telescoping sum). The one-link heat-kernel class is the smallest example. → 26-11

The properties of the weight (four)

The four properties asked of the weight of one step in multiscale analysis (an arrangement of how the original sources put it). For a group-valued field, the property of closing in one step is missing. The group version of submultiplicativity in sums of fields ((ii) of BBS) is the Background–Fluctuation Decomposition Lemma. → 26-11

Decomposition of the ultraviolet wall (class-closure condition, coupling-flow remainder condition, shape remainder condition, definition and continuity of the effective coupling)

A statement [Assumption] that splits ultraviolet control into four parts: a class that closes with finitely many parameters, the remainder of the flow, the remainder of the shape, and continuity within the domain. The contrast with the decomposition of the band (β-monotonicity × renormalisation comparison, 26-06) is in 15-03 § 06. The questions of this part are in Table 1 of 15-09. → 15-03

Group version of closure under the fluctuation expectation (group version of the exponential moment of fluctuations) and the background dependence of the measure η_k

A statement [Assumption] that restates closure under the fluctuation expectation ((iii) of BBS) and the fourth property, among the four properties of the Balaban–Brydges–Slawny weight, for group-valued fields. For a product of one-link heat kernels it holds by the invariance of Haar measure. The difficulty is the background dependence η of the measure at each step: under a naive estimate Σ η_k diverges, and absorption into the parameters is needed (15-07). → 15-07, 15-01

The invariant curve, the transverse contraction λ, the source σ

The invariant curve: a family of weights indexed by one parameter that the one-step renormalisation map sends to itself. The heat-kernel family is an approximation to it (15-04, 15-06). **The transverse contraction** (λ): the factor by which a deviation of the weight from the invariant curve is multiplied in one step. If $\lambda<1$ the deviation is bounded uniformly in the number of steps (15-03, 15-05). **The source** (σ): the terms outside the class newly fed in at each step (for example, the coefficient of θ^4 of the single coarse plaquette) (15-04, 15-05). → 15-04, 15-05, 15-03

The flux network

A network that finds the commuting configuration of minimal action, with the angle of the single coarse plaquette fixed, as the ratios f of the angles of the plaquettes. In three dimensions with a free boundary it is the current in a resistor network. $\beta'/\beta = \Sigma f^2$, the transverse contraction $\lambda = \Sigma f^4/\Sigma f^2$, and the inequality $1/(64\Sigma f^2) \le \lambda \le \max f^2$. → 15-05

Couplings by loop shape

The coefficients when the weight with the fluctuations integrated out is written as a quadratic form in the angles of classes such as single loops and the composite loop. The coordinates for counting the parameters. For four plaquettes in a row, two are needed at the quadratic level, β and the ratio κ_ab/κ_a, and for the heat kernel a part $2/(3\beta)$ due to the curvature of the group appears. → 15-06

The attracting class

When the one-step map contracts the shape coordinates, the class "one parameter + a fixed shape of $O(1/B)$" that the family approaches. It is determined by the fixed point of the flow of the power of the prefactor. → 15-06

The shift of local couplings

A view (a proposal) that reads the part η by which the measure of the fluctuations depends on the background as a change in local couplings $b_p(W)$ determined by the background. The multi-step induction has not yet been written. → 15-07, 15-08

How the small-field contribution to the coupling is split

The view that splits the one-step remainder for small fields into the local part, the Taylor truncation, the small-field cut and the explicit quadratic term between blocks. The first three have the same form as in the sources for flat fields. → 15-08 § 06

The zero-sum system

A system with only one block, in which the explicit quadratic term between blocks vanishes (four plaquettes in a row, the hierarchical model). → 15-08 § 06

Shape-Remainder Theorem for Four Plaquettes in a Row

In the projected model of four plaquettes in a row, the one-step constant of the shape remainder is given as a number, in the form of an upper bound independent of the number of steps. → 15-06 § 09

The local representative

A representative that agrees with F on im D_c and is bounded uniformly in the volume. Built from the cone of axes whose base point moves with the row (Bundle Network Theorem (local form)). → 15-05

One-Link Heat-Kernel Comparison Lemma

A comparison that bounds the one-link Wilson law by a constant multiple of the heat kernel inside the angle cutoff and by a rare tail outside it. → 15-07 § 05

The group-geometry part (the cubic BCH term)

The part of the derivative in the background that remains only for SU(2) and does not depend on the shape coordinate. Its coefficient is 1/9 in the Gaussian main term of two links. → 15-07 § 07

The budget of background change

The sum over steps of the width of the background change times the coupling. It diverges however the threshold is chosen. → 15-07 § 07

The non-locality of the background map

The fact that a background built from the block constraint moves the fine variables non-locally. A one-loop formula that is local in the fine background looks, in the coarse variables, like a non-local O(1) term. → 15-08 § 06

The tail type

How the weight of (1−Loc)W decays with distance (flat, exponential, power). It is fixed by the definition of the coarse variables (how the fine variables straddle the coarse ones). → 15-08 § 06

Coarse links plus global tags

Coordinates made from the coordinates of coarse links, with the Bianchi constraint promoted to coarse variables, plus finitely many global quantities attached as tags, such as the flux threading the torus and the magnetic flux of the centre Z_2. → 15-08 § 06

The agreement of the two gauges

The fact that, for one step, at one loop and in the background of the critical point, the one-loop effective actions in the tree gauge and in the background-covariant gauge are equal (eq. (5)). → 15-08 § 05

The cost of recentring, and the recentring condition

The loss in the Taylor radius (about a factor of 4) and the shift of the coupling when the conditional maximiser of one link is re-taken at the background. → 15-07 § 05

Proposition on a Class with the Background as a Parameter

The proposal that, in a class that carries the logarithm a of the background holonomy as a parameter of the class, the remainder of the background dependence drops by one order and the budget becomes uniform in the number of steps. → 15-07 § 06

The one-face step

One step in which the coarse variable is a single loop. The update of a is exact as an ordered product in the group. → 15-07 § 07

The corner triple product

$\kappa \, \Sigma \, a_x \cdot (a_y \times a_z)$ of the three faces meeting at a corner of a cube. The first non-commutative coordinate of the multi-loop class. → 15-07 § 07

Row-weighted interpolation

Riesz–Thorin with the rows weighted by their ℓ^1 norms (Stein's analytic family). It brought the factor of the four-dimensional ℓ^4 cone down to 0.823 or less. → 15-05 § 07

The ratio coordinates

The coefficients of the neighbour, the skew neighbour, the cubic and the quartic terms divided by the class coupling B. Their values are fixed at the fixed point of the flow, and they are not independent parameters. → 15-03 § 02, 15-07 § 07

The skew neighbour

The quadratic coupling of a pair of faces shifted by one edge that share no vertex. It is needed in the class in four dimensions; its sign and its being non-zero do not depend on the rule, while its value does. → 15-07 § 07

Normalisation (a)

The coordinate in which the cone constant is divided by the long-wavelength coupling β'_0. The direction-wise normalisation λ is not an amount of contraction. → 15-05 § 07

Blocking by edge sums / by transverse averaging

The rule that takes a coarse edge to be the sum of two fine ones, and the rule that takes it to be the gauge-covariant average of the transverse staples. With the latter, the flow of the covariance heads to a fixed point. → 15-05 § 07

The recursion of W

The one-step recursion of the non-local term. In a row it is "a contracting image + a new term independent of the step + an exponential three-body tail". → 15-08 § 06

Proposal of a one-step inequality with the comparison partner fixed

The one-step inequality that the string tension of the one-step MK image does not exceed that of the genuine coarse theory. On finite boxes the threshold is 1. → 15-04 § 05

Home (of a tool)

The chapter that first places the definition of a tool and the known results about it. The home and label of each tool used by this book's study are in 16-10 Table 1. → 16-10

Where it stops (of a tool)

How far the tool reaches in this book's study and where it stops (the third column of 16-10 Table 1). → 16-10

Estimate (label)

A label used only in Part 24. At the same level as "Reading", it corresponds to a physical estimate ("Physics" among the five labels). The legend is in 0-01 § 03. → 0-01 § 03

Splitting the core in two

Viewing the core of the band as two jobs: "extending the ultraviolet" and "the statement of the last interval to strong coupling". → 16-11 § 01

Extending the ultraviolet

The job of extending the control of the published construction from the threshold to a coupling β_* of order one, while keeping the sum of the per-step errors finite. → 16-11 § 01

Statement of the last interval to strong coupling

A non-perturbative statement over a small number of steps from β_* to the strong-coupling window (distinct from the "Corollary Crossing the Band in Finitely Many Steps" of 26-06). → 16-11 § 01

Lossy chain

Renormalisation comparisons that allow a loss of a factor K at each step, chained over the number of steps. The rate is uniform, but the prefactor grows as $\xi^{\log_2 K}$. → 16-11 § 02

Prefactor

The factor in front of the exponential on the right-hand side of an estimate. In the lossy chain it is $K^{k_0}=\xi^{\log_2 K}$. → 16-11 § 02

Facts on the energy side

Facts about the action of configurations (existence of twisted vacua, the fixed group ± 1, positivity of the action of a box with two twists, upper and lower bounds on S_N). → 16-11 § 03

Shortfall on the entropy side

That this book has no estimate, needed for the band, that counts the fluctuations and the number of arrangements of vortices from below, uniformly in the scale. → 16-11 § 03

Mixing statement for boxes of physical size

That if the side of a box is taken to be the physical length C/Λ, the total variation of the law of gauge-invariant observables inside, when the frame is changed, is smaller than a threshold (uniformly in β). A restatement of the mass gap in a strong form. → 16-11 § 04

Seven test models

The models against which arguments for the band are tested: U(1) at weak coupling, Z_2 at weak coupling, finite non-abelian groups, the limit of the adjoint Higgs, the line and endpoint of the mixed action for SU(2), the bulk transition of SU(N), and G_2. → 16-11 § 04, 26-12 § 02

Three classes of value level

The weak-coupling behaviour of the quantity for a symmetric box with one twist: proportional to β for U(1), constant for a frozen finite group, of the type $(3/2)\ln\beta$ for SU(2). → 16-11 § 04

Mixed action

A lattice action that adds a term in the adjoint representation to the Wilson action (the term in the fundamental representation). → 16-11 § 04, 26-12

Critical endpoint

The point where a line of first-order transitions ends. → 16-11 § 04, 26-12

Frozen phase

In a gauge theory with a finite group, the phase on the side of large β that sticks close to flat connections. → 16-11 § 04, 26-12

Control of the continuum limit of twisted boxes

A comparison across scales, with a finite sum of errors, of quantities fixed by the measure in twisted (framed) boxes. → 16-11 § 06

Coupling of the laws of gauge-invariant observables

A construction that couples the conditional laws of gauge-invariant functions, and a finite-box criterion on top of it. → 16-11 § 06

Sieve

Testing whether an argument for the band would go through equally for other models, and the collection of those models. → 26-12 § 01

Confinement quantity / gap quantity

The two directions of the sieve: a quantity that should be false in a non-confining phase / a quantity that should be true for a model that does not confine but has a gap. → 26-12 § 01

Maximal torus

The commutative subgroup $\{\mathrm{diag}(e^{i\phi}, e^{-i\phi})\}$ of SU(2). It has the same form as U(1). → 26-12

Adjoint Higgs

A model that adds to the SU(2) Wilson action a term coupling a unit vector at each site (in the adjoint representation) with the links. The limit in which the hopping coupling J goes to infinity is formally the U(1) Wilson action. → 26-12 § 02

Bulk transition

A temperature-independent (zero-temperature) transition coming from the lattice action. Not physics of the continuum limit, but a phenomenon on the lattice. → 26-12

Centreless group

A group with trivial centre (G_2 and others). Quantities written with centre twists and vortices are not defined for such a group. → 26-12 § 02

Hysteresis

A disagreement in the value of a quantity between the path that raises the coupling and the path that lowers it (it can be a trace of a first-order transition). → 26-12 § 05

Aspect ratio

For a twisted box, the ratio r = M/N of the side M of the vortex plane to the side N of the transverse plane. It separates comparisons at fixed ratio from the quantification that fixes the transverse side and extends the longitudinal one. → 26-12 § 05

Sign term by term

A test that places a separate coupling β_p on each plaquette and checks whether ΔF increases in each β_p (the sign of $\partial \Delta F / \partial \beta_p$). → 26-12 § 05

Flat connection (flat configuration)

A configuration in which the holonomy of every plaquette equals the identity (or, when there is a twist, the sign of the twist). In 21-07 it is called a "flat configuration". → 16-11 § 04, 26-12

The words of objects, firm theorems and premises (Parts 19–22, Part 28 and the second half of Part 15)

Flux free energy ΔF

$\Delta F = \ln(Z_0/Z_1)$. The logarithm of the ratio of partition functions when one twist n_{34} is inserted. A word of 25-01; the same quantity as the vortex free energy F_v of 26-03. → 19-02

Vortex ratio θ

$\theta_M = (Z_0 - Z_1)/(Z_0 + Z_1) = \tanh(\Delta F/2)$. $|\theta_M| < 1$ follows from the definition. $\theta \geq 0$ does not follow from the definition; it is a theorem when M is even (21-06). → 19-02

Base time

For a link $\ell = (x, \mu)$, the start point x is called the base point of the link; for a link in the time direction, the time of its base point x (the base time) is taken as the time of the link. A different word from the "roots" of the tree of premises. → 19-01

Unnormalised Wilson measure $\tilde{\mu}$, normalised Wilson measure μ

$\mu\tilde{}_{N,\beta}$ is the measure given by the weight $w_\beta(U)$ times the product of Haar measures; $\mu_{N,\beta}$ is the probability measure obtained by dividing it by the partition function. $\mu\tilde{}_{N,\beta} = Z_N(\beta)\ \mu_{N,\beta}$. → 19-01

Bridge between the two Wilson measures

That the measure on the strong-coupling side (Part 20) and the measure on the vortex side (Part 21) are equal, for M = N and no twist, when carried over by a one-to-one correspondence given by definition. An identification shown in Lean. → 19-06

Twist signs n_{12}, n_{34}

Two indices that put in 't Hooft's twisted boundary conditions through the signs $z_p \in \{+1, -1\}$ of the plaquette weights. → 19-02

Twisted vacuum

The configuration V of action 0 built from the unit quaternions i and j. → 19-02

Polyakov loop $P_b(t)$

With the transverse position b and the time t fixed, the real part of the product of the variables of the M links that go once around direction 3. → 19-02

Minimal action of a vortex $S_V(N, m)$, S_N

The number that appears in the exponent of the thick-vortex floor: the minimal action, measured by dividing a plane of height M = 2m into four blocks of side m. $0 \le S_N \le 2N^2$. $S_N > 0$ is the theorem of 21-05. → 19-02

Positive side, reflection pairing

For functions F, G that depend only on the links on one side of the mirror (the positive side), $\langle F, G\rangle = \int F(\Theta\omega)\, G(\omega)\, d\mu$. → 19-03

Vessel of reconstruction

The tuple that takes out of the Osterwalder–Schrader reconstruction the parts that do not depend on the measure (pairing, translation, constants). From it one builds the Hilbert space, the vacuum Ω and the transfer operator T. → 19-03

Mass gap (definition on the vessel)

$\| T - P_\Omega \| \le e^{-m}$. A definition at a fixed lattice spacing, not the definition of the mass gap in the continuum limit. → 19-03

Non-degenerate (two uses)

Non-degeneracy of the vessel means that there are states outside the vacuum (20-04). Non-degeneracy in the statements to be shown means that the coarse field stays in small fields (19-07). → 20-04

Block map B

The map that builds a configuration of the coarse lattice from a configuration of the fine lattice by products along a family of paths, weights, averaging and a return to the group. → 19-04

Path kernel C

The first-order part of the block map B when U is close to the identity. → 19-04

Push-forward measure

$(B{*}\mu)(E) = \mu(B^{-1}(E))$. The measure on the fine lattice carried to the coarse lattice by the block map. → 19-04

Wilson–Dirac operator, measure with fermions

The measure on gauge fields whose weight is the determinant of the Wilson–Dirac operator. A detour outside the main object of the book (pure gauge theory). → 19-05

Cylinder function

A function determined only by the values on a finite set S of links (support S). → 20-03

Dobrushin's condition

The influence that one link receives from the surrounding links is measured by coefficients, and their sum is less than 1. A condition that fixes the infinite-volume limit uniquely. → 20-03

Strong-coupling window

The range of β in which the theorems of Part 20 hold ($18\tanh|\beta| < 1$ and $24(1 - e^{-4|\beta|}) < 1$). The opposite end from the weak coupling that the continuum limit needs. → 20-02

Sign system, sign character

An abstract system, with the lattice forgotten, written with multiplicative functions (sign characters) on a finite group G (on the lattice, the field of signs on the links). → 21-01

Covering inequality

An abstract inequality about sign systems. A part of the thin-vortex floor. → 21-01

Z_2 monotonicity

With non-negative couplings, increasing the couplings term by term does not increase the twisted ratio and does not decrease the flux free energy. → 21-01

Floor

An upper bound on the vortex ratio θ; equivalently a lower bound on the flux free energy ΔF, an estimate of the slab tension from below. → 21-02

Thin-vortex floor

$\theta \le \tanh(N^2|\beta|)^{M^2}$ (all β, N, M and background twists; the SU(2) Wilson measure). Not uniform in N. → 21-02

Thick-vortex floor

An upper bound on θ whose exponent contains the minimal action of a vortex S_N. The thresholds β_0 and $M_0(\beta)$ are not explicit. → 21-03

One-step contraction

The inequality $\boxtimes P \boxtimes (3/5)P$ for the symbol of one step of the free field. → 15-12

Cap h(r)

The open cap $\{U \in SU(2) : |U - 1| < r\}$ around the identity, and its Haar volume $h(r)$. → 22-01

Statements to be shown (the root)

Six statements written only with the objects defined in Part 19: matching, convergence of the full sequence, non-degeneracy, equicontinuity, mass gap (uniform decay), and the band. → 19-07

Matching

The way the sequence of bare couplings β_n is chosen: the adjustment that sets the scale of the lattice spacing, written as a rule using only defined objects. → 19-07

Convergence of the full sequence

For the sequence fixed by matching, the push-forward measures converge without passing to a subsequence. → 19-07

Equicontinuity

Observables are continuous uniformly in the physical position inside the box. → 19-07

Sufficient condition, representation

A sufficient condition is a premise placed in order to derive the root along the present road. Many of them are statements made through effective couplings, activities of large fields, background fields and classes (a representation), and many of the quantities of a representation are not yet defined from the lattice. → 28-00

Labels of premises

The column of the list of premises: theorem, theorem (weak form), paper, form fixed, unproved, form not fixed, depends on design, literature. Separate from the labels of the text (Proved here, Cited, Computer-assisted, Reading, Assumption). → 28-00

Reason marks (a)–(f)

The reasons attached to a premise whose form is not fixed: too light, too strong, the object is undefined, a numerical hint, no form that crosses steps, the order of quantifiers is not fixed. → 28-00

Design choices

Things that the mathematics does not fix uniquely and that we choose and fix: the weights, scale factor and thresholds of the block map, norms, backgrounds and so on. → 28-05

Implication (as used in Part 28)

A conditional theorem with all of its assumptions shown. → 28-01

Skew product

A one-step map of the form in which the coupling direction does not contract, only the irrelevant directions contract, and the two affect each other. → 28-02

Endpoint matching

Choosing the bare value for each number of steps so that the value at the coarse end hits the target. Convergence of the full sequence does not follow from contraction alone, and this becomes part of the statement. → 28-02

Tension-doubling inequality

A premise of the form $4\sigma_{2N} \geq e^{\delta_0}\sigma_N$ ($N \geq N_1$) for some $\delta_0 > 0$ and N_1. → 28-04

Detour: four uses of the word "dimension"

You may skip this. "Dimension" has four meanings. (1) The dimension of spacetime d (for space alone, D; in the chapters on string theory, D is used for the dimension of spacetime to match the literature, 17-05). (2) The physical dimension of a quantity (which power of mass). "Dimensional transmutation" is this one (4-07). (3) The dimension of a linear space ($\mathfrak{su}(N)$ has $N^2 - 1$). (4) The anomalous dimension η_s. "Dimensional regularisation" is the technique of extending (1) to complex numbers (4-05). The four of formula (7) and of the article on four dimensions are both (1).

What this chapter can say

What is said	What is not said
Each entry is a shortened version of the definition in the linked chapter.	Some entries omit the hypotheses of theorems (dimension, group, normalisation). The exact statements are only in the linked chapters.
The numbers in Table 1 were counted on this machine from the drafts.	They move as chapters are revised. They are not an indicator of importance.
The entries of Part 17 are written as physical pictures and conjectures.	We do not say that they hold as theorems for four-dimensional Yang–Mills.
The entries of Part 23 are the names and contents of the assumptions that this book's study set up.	None of them is proved. This book shows nothing about the mass gap of the continuum theory (the mass gap in this book's Lean is a statement about the lattice at strong coupling).

Sources and reproduction

Item	Kind	Source / tools
The meaning of each entry	Summary	The chapters of this book (the links). Bibliographic data for primary sources are in the source table of each chapter and in A-03
Conventions for symbols (normalisation of β and tr, the two ways of writing the gauge field)	Conventions of this book	A-01 Table of notation
Table 1 (number of chapters in which words appear)	Computed	python3: from the drafts of the 105 chapters other than the appendices, script, style, the whole-book contents, the meta line and head were removed, tags stripped, and the occurrences of words counted (`term_counts.py`)
Table 2, Figure 2 (e^{-mt} and $\xi = 1/m$), the example for formula (10)	Computed	python3 (`gap_corr.py`). Formula (4) is the known relation in 4-11
The b_0 and $11N/3$ of formula (5)	Known	Sources for 4-06: D. J. Gross, F. Wilczek, PRL 30 (1973) 1343. H. D. Politzer, PRL 30 (1973) 1346 (both bibliographic data only; from the source table of each chapter)
The entry on the strong-coupling expansion (area law and positive gap)	Known	Source for 5-02: K. Osterwalder, E. Seiler, Ann. Phys. 110 (1978) 440 (abstract only; from the source table of each chapter)
The Lüscher term of formula (8)	Physics (under the assumption of an effective string)	Source for 17-03: M. Lüscher, NPB 180 (1981) 317 (bibliographic data only; from the source table of each chapter)
The $m/\sqrt{\sigma} = 3.837$ in the example for formula (9)	Computed (a ratio of values from a primary source)	17-12: B. Lucini, M. Teper, JHEP 0106 (2001) 050, arXiv:hep-lat/0103027, Table 1 ($\beta = 2.60$, 24^4, $a\sqrt{\sigma} = 0.13395(62)$, $am = 0.514(8)$). 3.837 = 0.514/0.13395

Next chapter to read: A-03 Guide to the literature — the primary sources, reviews and textbooks of each chapter, with their availability.

Guide to the literature — what to read first, where to get it, and how far this book read it

This chapter is a guide to the literature.

What this chapter shows — The 52 main works cited by the chapters of this book, arranged by lineage (reviews, textbooks, primary sources) and year (in addition, the three items of the construction published in 2026 are in § 07, and 18 works whose bibliographic data for individual chapters' sources were checked against primary sources are in Table 3). A few to read first. Where each can be obtained (arXiv, the publisher, public release by an institute or the authors, books), and whether the chapters of this book read each work in the text, only the abstract, or only the bibliographic data.

Prerequisite chapters — None. It can be consulted from anywhere, and the content of each work is read in the linked chapters. Terms are in A-02 Glossary, symbols in A-01 Table of notation.

Said first — This is not an exhaustive bibliography. The chapters of this book cite several hundred works, and here we select those that matter across chapters. "Extent read" is a value read mechanically from how each chapter's source table is written, not an assessment of the value of the work. Existence in four dimensions is given by the construction published in 2026 (§ 07); the committee's assessment is that it is proved in Lean. The mass gap has not been shown. This book does not claim to solve the problem.

The order of this chapter

1. How to use this guide — three kinds and two statuses. Detour: how to read bibliographic data
2. Map of the literature — seventy years arranged in seven lineages (a moving figure)
3. What to read first: the problem statement and reviews — the text of the problem, and reviews describing where things stand
4. Textbooks and lecture notes — for going deeper into the tools of Parts 1 and 2

5. Primary sources in physics — from the original paper of 1954 to the skeleton of the 1970s (and later mathematical and stochastic-quantisation viewpoints)
6. Lattice and numerics — Wilson's lattice, and measurements of glueballs
7. Constructive field theory and probability — axioms, the four-dimensional ultraviolet, probabilistic constructions in two and three dimensions
8. Strings and holography — models at the level of physics
9. Counting the source tables of this book — which works appear in how many chapters, and how far they were read (computed)
10. Notes on obtaining and reading — differences between versions, unrefereed work, finding old journals. Bibliographic data checked in primary sources for chapters' citations (Table 3)

01

How to use this guide

Works are divided into three kinds. A **primary source** is the paper that first showed a result; the exact hypotheses and statements of theorems are checked here. A **review** is an overall picture of results up to some point, and an entrance for deciding which primary sources to read. **Textbooks and lecture notes** are for acquiring the tools in order.

We attach two statuses. The first is **availability**: arXiv (the public repository for preprints; free), the publisher (only the journal version; often needs a library subscription; those made freely available are marked "Publisher (open)"), PDFs made public by an institute or the authors, and books. Preprints whose journal publication had not been confirmed at the time of this book are marked "not refereed".

The second is **the extent to which this book read it**. The "Sources and reproduction" table of each chapter writes whether a work was read in the text, only the abstract, or only the bibliographic data. We collect this over all chapters and take the maximum extent over chapters.

$$\mathrm{best}(r) = \max_{c \in C(r)} s(c, r), \qquad s \in \{\text{bibliographic data only} < \text{abstract} < \text{text}\} \tag{1}$$

Here r is the work, $C(r)$ is the set of chapters citing it in their source tables, and $s(c, r)$ is the extent read from the source table of chapter c. "Text" includes cases where only the introduction or one section was checked. For example, Osterwalder–Seiler (1978) is cited by 40 chapters, of which 25 write "bibliographic data only" (§ 09).

Claims of this book that rest on works marked "bibliographic data only" go through other works whose text was checked. Where they go through is in each chapter's source table.

Detour: how to read bibliographic data

You may skip this. Bibliographic data for papers in physics and mathematics are usually written in the order "authors, journal volume (year) first page". For example, `Comm. Math. Phys. 102 (1985) 255` means Communications in Mathematical Physics, volume 102, 1985, starting on page 255. Journal names are abbreviated; in this book `CMP` (Comm. Math. Phys.), `PRL` (Phys. Rev. Lett.) and `NPB` (Nucl. Phys. B) appear often.
arXiv numbers come in two forms. Until March 2007 they had the form "field/year-month and serial number", and from April 2007 the form "year-month.serial number". The serial number has 4 digits until December 2014 and 5 digits from January 2015.

The "Year" in the tables of this chapter is the year of the arXiv submission if there is one, otherwise the year of the journal (Shen–Zhu–Zhu: arXiv 2022, journal 2023). The Clay problem statement is given the year of its announcement (2000).

02

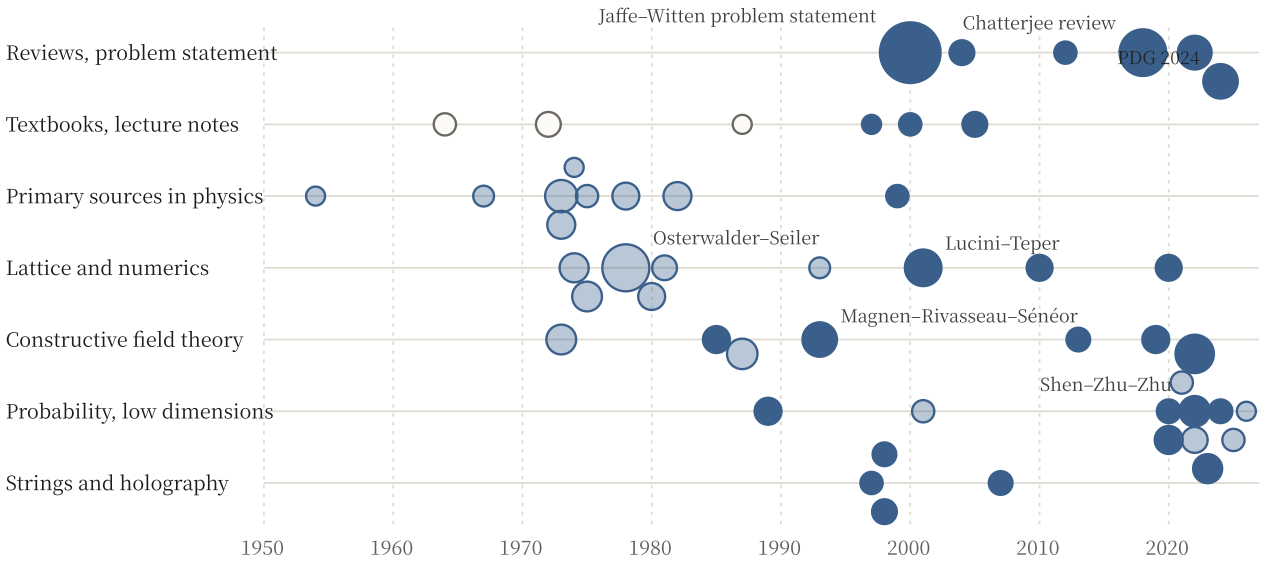
Map of the literature

First we look at the whole on one sheet. The horizontal axis is the year, the vertical the lineage. The size of a dot is the number of chapters citing the work. The fill of a dot is the extent read in this book: solid for "text", light fill for "abstract", hollow for "bibliographic data only".

The primary sources in physics cluster from 1954 to the 1970s. The work aimed at four-dimensional construction (Bałaban, Magnen–Rivasseau–Sénéor) is concentrated in the 1980s and the early 1990s. This line of work did not complete the four-dimensional construction (7-07). For existence in four dimensions, the committee's assessment is that it is proved in Lean in the construction published in 2026 (the table of the published construction in § 07, 6-00). Work from the side of probability theory has been increasing since around 2018.

Moving the year knob leaves dark only the works published up to that year. Moving the part knob makes dark only the works cited by the chapters of that part. Pressing a dot shows its lineage, extent read and the parts citing it below, and lets you jump to its table row (which has links to chapters).

Figure 1 Map of the literature — the year knob brings up "works up to that year", the part knob "works cited by that part". Pressing a dot shows its lineage, extent read and the parts citing it.



Computed The numbers in this figure (positions, sizes and fills of dots, citations by part) were counted on this machine from the source tables of this book (Sources and reproduction). The same content is in the tables by lineage in § 03– § 08, readable even where the figure does not run.

03

What to read first: the problem statement and reviews

If you read only one, read the official problem statement of the Clay Mathematics Institute (Jaffe–Witten). It writes, in the words of those who set it, what the problem asks for and why it is hard in four dimensions. This book reads it word by word in 0-03. It is also the work cited most often among the chapters of this book.

The core of the property the problem statement asks for is the shape of the spectrum of the Hamiltonian H. With the vacuum energy set to 0, it asks that a positive gap Δ open above it.

$$\operatorname{spec}(H) \subset \{0\} \cup [\Delta, \infty), \qquad \Delta > 0 \quad (2)$$

The exact reading of this formula (uniqueness of the vacuum, relation to the decay of correlations) is in 4-11.

The second is Chatterjee's review "Yang–Mills for probabilists". It defines Yang–Mills theory on the lattice in the language of probability theory, and lists what has been shown and what is open in the form of questions (the lattice correlation-length problem and the continuum string-tension problem; Chatterjee's Problems 5.1 and 5.2). Many chapters of Parts 5 and 7 of this book use it as a guide. For a third, Chevyrev

if you follow the probabilistic constructions in two and three dimensions, and the review by Summers for the history of axioms and construction.

04

Textbooks and lecture notes

Parts 1 and 2 of this book prepare, from second-year knowledge, the minimum of tools needed. This table is where to go to learn one step deeper. For groups and representations, Hall; for manifolds and connections, Carroll; for operators and spectra, Reed–Simon; for calculations in quantum field theory, Tong's lecture notes; for axioms and construction, Streater–Wightman and Glimm–Jaffe.

One example. The Baker–Campbell–Hausdorff formula used in 1-03 says that the product of matrix exponentials receives a correction that can be written with commutators alone.

$$e^{X}e^{Y} = \exp\Big(X + Y + \tfrac{1}{2}[X,Y] + \tfrac{1}{12}\big([X,[X,Y]] + [Y,[Y,X]]\big) + \cdots\Big) \tag{3}$$

This book checked it up to the third-order terms with Hall's notes. Near the identity, the product of the group is determined by the commutators of the Lie algebra alone. This formula is the reason (the group itself is not determined by the Lie algebra alone; 1-03). Many lecture notes have public versions by the authors, and the arXiv numbers are given in the table.

05

Primary sources in physics

Yang–Mills theory appeared in the 1954 paper of Yang and Mills, in the form of building a field from the local symmetry of isospin. In the 1960s the rules of gauge fixing and ghosts (Faddeev–Popov) were set in order, and in 1973 asymptotic freedom was found: the discovery of the sign that makes the coupling weaker at short distances.

In this book's notation (formula (8) of A-01), the one-loop running has the following form.

$$\mu \frac{dg}{d\mu} = -b_0\, g^3 + \cdots, \qquad b_0 = \frac{11N}{48\pi^2} \quad (4)$$

Since $b_0 > 0$, raising the energy μ makes g smaller. Known This is a one-loop perturbative calculation, not a theorem about the four-dimensional theory. Physics This sign is the ground for expecting Yang–Mills theory to make sense at short distances. The account of its content ($11/3 = 4 - 1/3$) is in 4-06.

Many in this lineage are "abstract" or "bibliographic data only" in the chapters of this book. This is because they are in old journals with no public version; formulas and numbers are checked against reviews whose text was checked (PDG, Tong, Chatterjee).

The table also includes three that come after the skeleton of the 1970s. Gribov (1978) showed that gauge fixing is not uniquely determined. Uhlenbeck (1982) is a mathematical paper in geometric analysis showing that singularities of classical Yang–Mills fields can be removed. Baulieu–Zwanziger (1999) is the viewpoint that sees stochastic quantisation as a five-dimensional field theory.

06

Lattice and numerics

In 1974 Wilson put forward the formulation that replaces spacetime by a lattice and puts group elements on the links. With it Yang–Mills theory becomes an integral over finitely many variables, and can be measured by computer. In this book's notation the action has the following form (5-01).

$$S_W(U) = \beta \sum_P \Big(1 - \frac{1}{N} \operatorname{Re}\operatorname{tr} U_P\Big), \qquad \beta = \frac{2N}{g^2} \tag{5}$$

The sum is over all unit squares (plaquettes) P, and U_P is the product of the links around it. Osterwalder–Seiler (1978) gave the mathematical foundation of this formulation (reflection positivity and the transfer matrix). Among the chapters of this book, it is cited most often, together with Jaffe–Witten and Chatterjee.

On the numerical side, starting with the Monte Carlo calculations of Creutz (1980), Lucini–Teper (2001) and Athenodorou–Teper (2020, 2021) have measured glueball masses and their ratios to the string tension. Physics These are values supported by numerical computation, not theorems. The correction coming from fluctuations of the string (Lüscher 1981) has the following form (17-03).

$$V(R) = \sigma R + c_0 - \frac{\pi (d-2)}{24 R} + \cdots \tag{6}$$

In four dimensions ($d = 4$) the last term is $-\pi/(12R)$.

07

Constructive field theory and probability

The mass gap problem consists of two stages, "existence" and "gap". The works approaching it from the mathematical side fall into three groups: the axioms; the four-dimensional ultraviolet; and probability theory in low dimensions and on the lattice.

Axioms: returning from probability to quantum mechanics

The Osterwalder–Schrader axioms are conditions for rebuilding a Hilbert space and a Hamiltonian from Euclidean (imaginary-time) correlation functions. At the centre is reflection positivity, the condition that the expectation of the product of an observable reflected in time, ΘF, and the original F is not negative (4-10).

$$\langle F, F\rangle := \mathbb{E}\big[\,\Theta F\, F\,\big] \;\geq\; 0 \tag{7}$$

If this holds, a positive inner product can be made, and translation in time appears as e^{-sH} ($H \geq 0$). H in formula (2) comes from here.

The four-dimensional ultraviolet: Bałaban and MRS

The work that came closest to the four-dimensional continuum limit is Bałaban's series (the 1985 paper in three dimensions and the 1987–1989 papers in four dimensions; ultraviolet stability of lattice Yang–Mills by the renormalisation group) and the construction with an infrared cutoff by Magnen–Rivasseau–Sénéor (1993). Neither reaches the stage that this book can read as "complete" in the sense of the problem statement. What is shown and what remains is read in 7-07.

Existence in four dimensions: the published construction (2026)

On 2026-11-10, code written in Lean 4 for a construction of the existence of four-dimensional Yang–Mills theory was published, together with the assessment of the committee that examined it. The assessment's verdict is that the submitted code proves, for every simple compact group, that a theory satisfying the Wightman axioms can be built as the scaling limit of four-dimensional Wilson lattice gauge theory. It also states that the uniqueness of the infinite-volume limit and the mass gap are not shown. This book cites that theorem at the level of "the committee's assessment is that it is proved in Lean". Parts 6–14 of Volume 2 read these three items as primary sources. The way they are cited follows the conventions of 6-00 (for the code, the path relative to the repository root, the declaration name and the line; for the assessment, the section number).

Year	Work	What it contains	Chapters of this book	Availability	Extent read
2026	yang-mills-group/OpenAI-YM-20261028 (https://github.com/yang-mills-group/OpenAI-YM-20261028, Apache-2.0). The Lean 4 source submitted on 2026-10-28. 2026	The committee's assessment and checks: docs/assessment-1.pdf (2026-11-10, 35 pages) in yang-mills-group/YM (https://github.com/yang-mills-group/YM), and the checking code in submissions/openai-20261028/. The version this book read is 55ba9fc	The result of the construction compared with the problem statement (Part I); the record of the rebuild, re-checking in the kernel, the audit of axioms, and the matching by Comparator (Part II); five open questions	6-00, 6-02, 16-02 and others	GitHub (public)	Text checked
2026	The committee's third statement (page of the Kavli Institute for Theoretical Physics, 2026-11-09). Signed by Michael R. Douglas, David J. Gross (chair), Arthur Jaffe, Igor R. Klebanov, Nikita Nekrasov	A short statement of the conclusion of the assessment. The committee members' names are not in the text of the assessment; they come from the signatures on this statement	6-00	Public page of the institute	Text checked

The three items of the published construction (table in § 07). They are not included in the count (52 works) of Table 1 and Figure 1.

Two and three dimensions, and probability theory on the lattice

Known In two dimensions the Yang–Mills measure has been constructed (Driver 1989, Lévy 2001 and others). In the 2020s, the road that makes the measure as the equilibrium of a stochastic dynamics (stochastic quantisation) is advancing in two and three dimensions. On the lattice, exponential decay of correlations at strong coupling follows from the cluster expansion of Osterwalder–Seiler (1978), and Shen–Zhu–Zhu showed Poincaré-type inequalities and exponential decay by methods of stochastic analysis in an explicit range of β Known . The reach and where it stops in four dimensions are in 7-10 and 16-01. Unrefereed preprints are marked "not refereed" in the table.

Strings and holography

On the physics side, there is a view that reads confinement and glueball masses of Yang–Mills theory in the geometry of gravity in one more dimension. The starting points are the correspondence proposed by Maldacena (submitted 1997) and Witten (1998), who used it for a model of confinement. Csáki–Ooguri–Oz–Terning derived ratios of glueball masses from this model as solutions of an eigenvalue problem.

Physics These are correspondences and models at the level of physics, not mathematical theorems. Nor have they been shown in a form that applies to pure four-dimensional Yang–Mills theory itself. What the model assumes, and what happens in the limit back to four dimensions, are read in 17-08, 17-09 and 17-10.

09

Counting the source tables of this book

The source tables of the 110 chapters of this book (excluding this one) have 1035 rows in total. The arXiv numbers appearing in them are of 206 kinds, and bibliographic data in the form "volume (year) page" of about 602 kinds (the latter may pick up sequences of numbers inside formulas, so it is approximate). Computed

For each work, we counted the number of chapters citing it and the extent read in each chapter. Table 1 is the top 10 in order of the number of citing chapters. "Undetermined" counts chapters whose source-table row had no extent written, or where matching of words could not decide.

Table 1 Works cited often by the chapters of this book (breakdown of the extent in each chapter's source table)

Rank	Reference	Citing chapters	Text checked	Abstract checked	Bibliographic data
1	Jaffe–Witten problem statement	76	61	4	
2	Osterwalder–Seiler	40	0	15	
3	Chatterjee review	39	27	4	
4	Shen–Zhu–Zhu	23	6	12	
5	Lucini–Teper	20	12	0	
6	Magnen–Rivasseau–Sénéor	17	2	7	

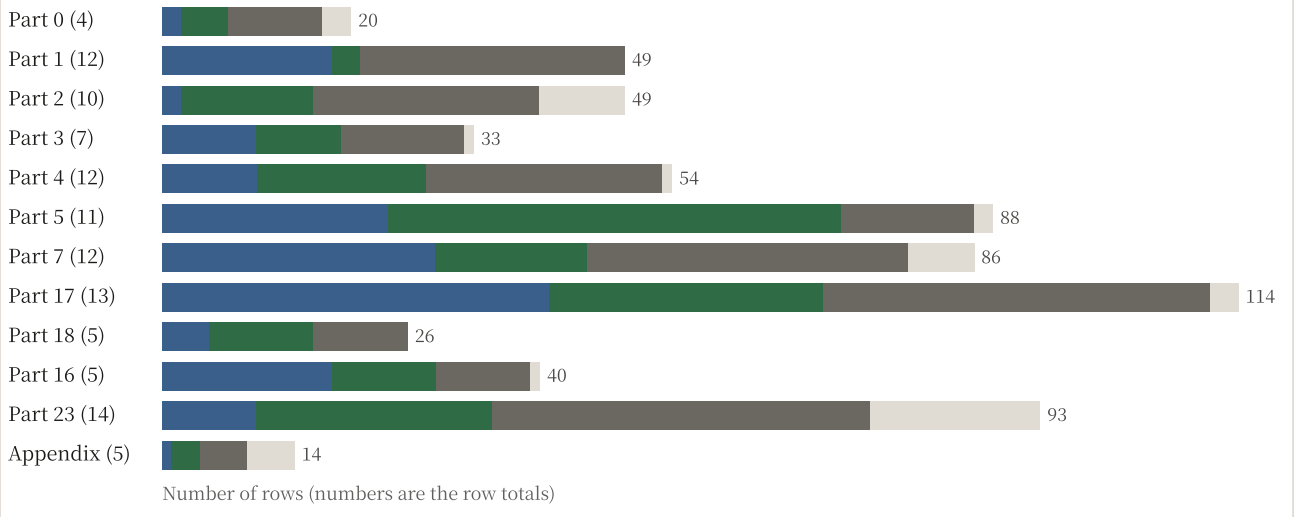
Rank	Reference	Citing chapters	Text checked	Abstract checked	Bibliographic data
7	PDG 2024	17	8	1	
8	Chevyrev review	16	11	1	
9	Gross–Wilczek	14	0	2	
10	Bałaban four-dimensional series	12	0	7	

Osterwalder–Seiler is cited by 40 chapters, but many chapters go through the abstract and reviews whose text was checked (Chatterjee § 4 and others). For Lucini–Teper, 12 of 20 chapters write that they checked as far as the tables of the text.

We also counted by part. Among the source-table rows, for those containing bibliographic data of primary sources, we count the extent in that row. The fraction of text is the following ratio.

$$\text{fraction of text} = \frac{\#\{\text{text}\}}{\#\{\text{text}\} + \#\{\text{abstract}\} + \#\{\text{bibliographic data only}\} + \#\{\text{undetermined}\}}$$

Figure 2 Extent read by part — the button switches between "number of rows" and "fraction".



Computed The numbers in this figure were counted on this machine from the source tables of this book. Table 2 below has the same numbers.

Table 2 Extent of source-table rows containing primary sources, by part

Part	Chapters	Rows	Text checked	Abstract checked	Bibliographic data only	Unde
Part 0	4	20	2	5	10	
Part 1	12	49	18	3	28	

Part	Chapters	Rows	Text checked	Abstract checked	Bibliographic data only	Unde
Part 2	10	49	2	14	24	
Part 3	7	33	10	9	13	
Part 4	12	54	10	18	25	
Part 5	11	88	24	48	14	
Part 7	12	86	29	16	34	
Part 17	13	114	41	29	41	
Part 18	5	26	5	11	10	
Part 16	5	40	18	11	10	
Part 23	14	93	10	25	40	
Appendix	5	14	1	3	5	
Total	110	666	170	192	254	

The extent was decided by the words in the source tables ("text checked", "abstract", "bibliographic data only" and so on), so it is affected by variations in wording. Table 1 reads with priority the words inside the separators (the full-width slash and semicolon) in which the name of the work appears.

10 Notes on obtaining and reading

Differences between versions. The arXiv version and the journal version may differ in page and theorem numbers. The chapters of this book write in their source tables which version was checked.

Publication status. The "journal-ref" in the arXiv catalogue is a field filled in by the authors, and volume and pages are sometimes empty. For example, for Chevyrev–Shen the catalogue gives only "Comm. Pure Appl. Math. (2026)", and volume and pages are not confirmed in this book. For the preprints of 2025 and 2026 (Cao–Nissim–Sheffield, and the two of 2026), publication had not been confirmed at the time of this book. Unrefereed results are not treated with the same weight as refereed results.

Finding old journals. Many papers of the 1970s and 80s exist only in journal versions. Bibliographic data can be checked in INSPIRE (the catalogue of high-energy physics literature) or Crossref. Some old volumes of Comm. Math. Phys. have public versions on Project Euclid (for example Driver 1989, CMP 123). Otherwise, going through a university library is the sure way.

Bibliographic data checked in primary sources for chapters' citations

The tables of § 03– § 08 are the 52 works that matter across chapters. Separately, among the works supporting claims of one or two chapters, those whose bibliographic data or text were rechecked in primary catalogues (Crossref, INSPIRE, DML-CZ, Math-Net.Ru, publishers' pages) are listed in Table 3. "Level of checking" is how far each work was checked. They are not included in the counts of Figure 1, Table 1 or Table 2.

Table 3 Bibliographic data for individual chapters' sources, with the level of checking confirmed

The two papers by Zwanziger are different papers. The 1981 paper is gauge fixing within stochastic quantisation (stochastic gauge fixing), and the 1990 paper, from the same year as Parrinello–Jona-Lasinio, is gauge fixing by a weighted average over orbits. What Part 23 of this book calls "the scheme of Parrinello–Jona-Lasinio and Zwanziger" is the latter pair of 1990, and the source table of 23-02 lists both. For Cao–Nissim–Sheffield in the table of § 07, 5-11 checked arXiv:2509.04688 as far as Definition 1.4 and Remark 1.5.

Chapter authors and overall authors. The PDG review as a whole is written as Navas et al., and when a chapter within it (for example the QCD chapter) is cited, it is written with the names of the chapter's authors. The difference in how 0-03 and 4-06 write it is this distinction, and both point to the same edition (2024).

The meaning of the labels is in A-04, the verification procedure in A-05, and the papers of this site in the list of papers.

What this chapter can say

What is said	What is not said
The bibliographic data of the 52 works listed (those with arXiv numbers checked against the arXiv catalogue)	A list of all works cited by this book (see each chapter's source table)
The chapters citing each work, and the extent read written in each chapter's source table (read by matching words)	Complete correctness of the reading (mix-ups due to variations in wording may remain)
One-line descriptions (summaries within the range of the chapters of this book and the arXiv titles and abstracts)	The exact hypotheses and statements of the theorems of each work (checked in the primary sources and the linked chapters)
The distinction of where to obtain each work. That the preprints of 2025–2026 were not refereed at the time of this book	Whether the journal version can be read for free (this changes with time and subscription). The correctness of unrefereed results
The bibliographic data of the 18 works of Table 3, and the level of checking written in each row (Crossref, INSPIRE, DML-CZ, Math-Net.Ru, publishers' pages)	The content of the text of the works in Table 3 marked "bibliographic data only" or "abstract"
That the mass gap problem is unsolved	A quantitative assessment of how close the works listed, taken together, come to a solution

Sources and reproduction

Item	Kind	Source / tools
Titles, authors, dates of first appearance and journal-ref of works with arXiv numbers	Known	Checked against the arXiv catalogue (API queries). In this chapter only as far as the abstracts. Checking of the texts is as in each chapter's source table
The format of arXiv numbers and when it switched	Known	The arXiv help page "Understanding the arXiv identifier" (text checked)
Where the Clay problem statement is	Known	The Yang–Mills page of the Clay Mathematics Institute (the link to the official problem statement checked). Its content is in 0-03
Where Douglas's report (2004) is	Known	Public PDF in the archive of annual reports of the Clay Mathematics Institute (title, author and date checked)

Item	Kind	Source / tools
Bibliographic data and level of checking of Table 3	Known	Checked against Crossref, INSPIRE (titles, volumes, pages and abstracts of Zwanziger 1981 and 1990 and Parrinello–Jona-Lasinio 1990), DML-CZ, Math-Net.Ru, the PDF published by CMI, and the AMS book page. Rows whose text was checked are the same as in the source tables of the chapters (1-09, 2-10, 17-09)
Bibliographic data of works without arXiv numbers	Known	Taken from the bibliographic data in each chapter's source table. In this chapter, bibliographic data only
Formulas (2)–(7)	Known	Formulas repeated from 4-11, 1-03, A-01, 5-01, 17-03 and 4-10. The sources are in each chapter's source table
Tables 1 and 2, Figures 1 and 2, the counts of § 09, the "Chapters of this book" and "Extent read" columns of the tables	Computed	python3: read the source table of each chapter of this book, collected citing chapters with a regular expression per work, and decided the extent by matching words (`refs.py`, `figdata.py`, `gen.py`; each under 1 second)

Next chapter to read: A-04 Lean and machine checking — what "Lean" means among the labels of this book.

Lean and machine checking — what the label "Lean" guarantees is only the arrow from premises to conclusion

> This chapter is a guide. § 02, § 03, § 04, § 05 and § 08 are established knowledge.

What this chapter shows — What has been confirmed when something is "checked" in Lean (propositions are types, proofs are terms, and what is trusted is the kernel). How to read the goals in the middle of a proof, and how to find `sorry`, `native_decide` and axioms (with the results of checking seven small files on this machine). Four types in which a statement passes but does not say what was meant, how this book decides its labels, and the procedure by which readers can check things again themselves.

Prerequisite chapters — None. You can read this even if you have never used Lean. Detailed usage is in this site's guide to Lean (thirteen pages); this appendix is an entrance to it, and gathers the conventions for reading the labels in this book. The list of Lean theorems in this book is in 23-13, and the legend of the labels in 0-01.

Said first — The Lean label guarantees only that "the conclusion follows logically from the premises"; it does not guarantee that the premises are true, nor that the statement says the mathematics that was intended. The Lean theorems in this book are mainly statements about inequalities of real numbers and finite sums; nothing in this book shows the existence of four-dimensional Yang–Mills theory or the mass gap in Lean. Four-dimensional existence was shown in Lean by a different construction published in 2026, and the committee's assessment is that it is proved (6-00). The mass gap has not been shown.

Order of this chapter

1. The role of this appendix — what the Lean label refers to among the five labels of this book, and the division of work with the guide pages
2. Lean on one sheet — propositions are types, proofs are terms of those types, and only the kernel is trusted; Detour: the name of the correspondence between propositions and types

3. One step at a time — the "goal" in the middle of a proof, and tactics (Figure 1, Table 1)
4. Holes and axioms — `sorry` passes with only a warning; finding it with `#print axioms` (Table 2); Detour: using real numbers brings out the three axioms
5. It passes, but is it what was meant? — the four gaps: definition, name, vacuous truth, assumption
6. What the Lean statements in this book talk about — named real numbers, the "if assumption then conclusion" type, mathematics out of stock
7. How the labels are decided — one label per sentence; the strength of a chain is its weakest step (Figure 2, Table 5)
8. A procedure to check for yourself — the four stages of checking, the record of versions, seven questions (Table 7)

01

The role of this appendix — the label "Lean" and the guide pages

Sentences in this book carry five kinds of label (the legend in 0-01): Lean , Paper , Computed , Known and Physics . Of these, the Lean label looks the strongest and is the most easily misread.

The typical misreading is to read "checked in Lean" as "settled as true". What Lean confirms is that the written conclusion follows logically from the written premises. Whether the premises hold, and whether the statement says the intended mathematics, lie outside Lean. This appendix shows that boundary with small examples that were actually checked.

Written as a formula, a sentence with the Lean label has the following form.

$$\underbrace{P_1,\ P_2,\ \ldots,\ P_k}_{\text{premises: outside Lean}} \quad \underbrace{\Longrightarrow}_{\text{the Lean label}} \quad \underbrace{Q}_{\text{conclusion}} \qquad (1)$$

What the label guarantees is the arrow in the middle. If the premises P_i contain unproved assumptions (for example 23-01 The line of construction and the diffusive-relaxation-time assumption) or measured numbers, the conclusion Q is conditional to the same extent. When this book cites a Lean theorem name, it writes the premises on the same line.

C_P (the Poincaré constant, Part 23), m (the mass) and ξ (the correlation length) are quantities of Part 23, but in this appendix it is enough to read them as plain real numbers.

Example. "If $m > 0$, $CP = 1/m^2$ and $CP \le K\xi^2$, then $1 \le K(m\xi)^2$" is a statement that only multiplies both sides by m^2, and it can be confirmed in Lean (in § 03 this machine actually checks it). But whether $CP \le K\xi^2$ holds in four-dimensional Yang–Mills theory has nothing to do with this arrow. That is an assumption.

The division of work between this appendix and this site's guide to Lean (thirteen pages) is as follows. The guide is an introduction to Lean itself, covering installation, how to assemble concrete proofs, and common pitfalls. This appendix restricts itself to the minimum needed to read this book, and to how this book decides its labels. The correspondence of each theorem's premises with the known results is listed in 23-13.

02

Lean on one sheet — propositions are types, proofs are terms, and the kernel is what is trusted

Lean is both a programming language and a tool for checking proofs. It can do both with one mechanism because it **treats propositions as types, and proofs as values (terms) of those types**.

In a program we write "`3` is a value of the type of natural numbers `Nat`". In Lean, with the same notation, we write "`p` is a proof of the proposition P".

$$\texttt{3} : \texttt{Nat} \qquad\qquad p : P \ \text{(2)}$$

The formula on the right is read "p has type P", and that means "p is a proof of P". Type checking can be done mechanically, so checking proofs becomes mechanical too.

A proposition with premises becomes a function type. A proof of "if P_1 and P_2 then Q" is a function that takes a proof of P_1 and a proof of P_2 and returns a proof of Q.

$$(h_1 : P_1) \to (h_2 : P_2) \to Q \ \text{(3)}$$

This is what the arrow of formula (1) really is. In the declaration of a Lean theorem, the arguments lined up to the left of the colon (brackets like `(hm : 0 < m)`) are the premises, and the right of the colon is the conclusion. **When reading, the most important thing is this row of brackets** ("Make a list of the hypotheses" in the guide).

Example. The smallest example checked on this machine is the following one line.

```
theorem pos_nat (n : Nat) (h : 0 < n) : 0 < n := h
```

The premise `h` is itself the proof of the conclusion. It is a theorem with no content, but the form "a function that takes a premise and returns a conclusion" is clearly

visible.

The other pillar is the **kernel**. The proof a person writes is a script lined up from tactics (commands that direct one step of a proof; § 03), and Lean expands it into a term of the form of formula (2). Finally that term is type-checked by the kernel, a checker kept small. Even if a tactic has an error, a term the kernel does not pass does not become a theorem. Narrowing what is trusted down to the one kernel is where the trust in machine checking comes from ("Kernel and tactics" in the guide, How checking works).

Detour: the name of the correspondence between propositions and types

You may skip this. The correspondence that sees propositions as types and proofs as terms is generally called the "Curry–Howard correspondence". In this view, the logical "implies" corresponds to a function type, "and" to a pair type, and "or" to a type with two kinds of value. Lean's logic is built on this correspondence, as a type theory with dependent types (types that may depend on values, as in "vectors of length n"). For the history and the relation to other proof assistants, see "Where the idea came from" in the guide.

03

One step at a time — goals and tactics

When writing a proof in Lean, "what must be shown now" is always on the screen. This is called the **goal**. The goal is written to the right of the symbol $\vdash$, and the hypotheses that may be used are lined up above it. Each time one tactic is entered, a hypothesis or the goal is rewritten, and when no goals remain the proof is finished.

As an example we use the statement of § 01 written in Lean. There are three premises (excluding the types of the variables). It is the same statement as `hup_is_gap_positivity` in 23-13, with only the names of the variables different.

$$m > 0, \quad C_P = \frac{1}{m^2}, \quad C_P \le K\xi^2 \implies 1 \le K(m\xi)^2 \quad (4)$$

On paper it is three lines: "substitute C_P, multiply both sides by $m^2 > 0$, and tidy up". In Lean it takes four steps, and the second step, `have`, is preparation for multiplying by m^2. The correspondence is: substitution is step 1, multiplication is steps 2 and 3, tidying is step 4. In Lean, what each step rewrote is recorded mechanically. The numbers in Figure 1 (the text of the goals) are copied as they are from the states that Lean 4.33.1 on this machine output in the middle of the proof.

Figure 1 Advancing one tactic with "Next" shows the goal after it. Lines that changed from the previous state are shown in colour

Proof

```
theorem gap_from_bound (CP m K ξ : ℝ) (hm : 0 < m)
    (hCP : CP = 1 / m ^ 2) (hH : CP ≤ K * ξ ^ 2) :
    1 ≤ K * (m * ξ) ^ 2 := by
  rw [hCP] at hH
  have hm2 : 0 < m ^ 2 := by positivity
  rw [div_le_iff₀ hm2] at hH
  calc (1 : ℝ) ≤ K * ξ ^ 2 * m ^ 2 := hH
    _ = K * (m * ξ) ^ 2 := by ring
```

State after step 0

```
CP m K ξ : ℝ
hm : 0 < m
hCP : CP = 1 / m ^ 2
hH : CP ≤ K * ξ ^ 2
⊢ 1 ≤ K * (m * ξ) ^ 2
```

Step 0/4: Right after the declaration. The premises are lined up as hypotheses, and the goal is the conclusion itself.

Computed The numbers in this figure were computed on this machine (checked with Lean 4.33.1 with `trace_state` inserted after each step, and the output copied as it is; the figure omits the `trace_state` lines. The "No goals" of step 4 is not a copy of output; it was confirmed by finishing without errors). On a narrow screen the same content can be read in Table 1.

Table 1 has the same content as Figure 1.

Table 1 Each step of the proof of formula (4), and the state after it Computed

Stage	Tactic entered	What changed
0	(declaration)	Hypotheses `hm : 0 < m`, `hCP : CP = 1 / m ^ 2`, `hH : CP ≤ K * ξ ^ 2`; goal `⊢ 1 ≤ K * (m * ξ) ^ 2`
1	`rw [hCP] at hH`	The `CP` in `hH` is replaced by `1 / m ^ 2`
2	`have hm2 : 0 < m ^ 2 := by positivity`	The hypothesis `hm2 : 0 < m ^ 2` is added (`positivity` is an automatic step that shows something is positive)
3	`rw [div_le_iff₀ hm2] at hH`	`hH` changes to `1 ≤ K * ξ ^ 2 * m ^ 2` (a Mathlib lemma that clears the denominator)
4	`calc … := hH`, `_ = … := by ring`	The goal closes (`ring` is an automatic step that shows ring identities)

How to read it. At step 3, `hH` has almost the same form as the goal; the only difference is the order of the product. The final `ring` confirms that reordering as an identity. You can see that the three lines on paper correspond to Lean's four steps with just one preparatory step added. Detailed examples of choosing steps in Lean are in "The skeleton of the proof" in the guide.

What Lean confirmed in this example is only algebra. Inside Lean, CP is just a named real number, and that it is a Poincaré constant is not checked. We look at this point for the theorems of the whole book in § 06.

04

Holes and axioms — `sorry` passes with only a warning

Lean provides two ways of skipping part of a proof. One is `sorry`, a mark meaning "fill this in later". The other is an axiom, a statement declared true without proof. With either, the theorem passes. So the fact that it "passed" alone does not tell you there are no holes.

The tool for finding holes is `#print axioms`. Given a theorem name, it lists which axioms that theorem ultimately depends on (following the statement and the proof). `sorry` is internally replaced by an axiom called `sorryAx`, so it shows up here. The Lean reference manual writes, as a checking procedure, "confirm that only the three standard axioms `propext`, `Classical.choice` and `Quot.sound` appear". The condition for the Lean label in this book has this form.

$$\mathrm{axioms}(\mathrm{theorem}) \subseteq \{\texttt{propext},\ \texttt{Classical.choice},\ \texttt{Quot.sound}\} \quad (5)$$

The meanings of the three are, in order, "equivalent propositions are equal", "an element can be extracted from a proof of existence (the axiom of choice)" and "equivalent elements are equal in the quotient". A quotient is the set obtained by lumping together the elements regarded as the same under an equivalence relation (the set of equivalence classes), for example the classes of remainders of integers divided by 7. The everyday reasoning of mathematics (including the law of excluded middle) needs nothing more than these three. For details, see 23-13 Lean statements and the limits of machine checking and "Axioms" in the guide.

On this machine we checked seven small files. Table 2 is the result.

Table 2 Results of checking seven small Lean files, eight theorems (Lean 4.33.1) Computed

File (theorem)	Content	Exit code	Warnings, errors	Output of `#print axioms`
`pos_nat`	For natural numbers, "if $0 < n$ then $0 < n$"	0 (success)	None	Does not depend on any axioms

File (theorem)	Content	Exit code	Warnings, errors	Output of `#print axioms`
`pow_mod_decide`	$2^{10} \bmod 7 = 2$ by `decide` (computation inside the kernel)	0	None	Does not depend on any axioms
`pow_mod_native`	The same statement by `native_decide` (computation with compiled code)	0	None	`pow_mod_native._native.native_deci`
`pow_mod_wrong`	The false statement $2^{10} \bmod 7 = 3$ by `decide`	1 (failure)	Error: showed that the proposition is false	—
`gap_from_bound`	Formula (4) (Mathlib's real numbers)	0	None	The standard three
`gap_from_bound'`	The proof of formula (4) replaced by `sorry`	**0 (success)**	Warning: `declaration uses `sorry``	The standard three + `sorryAx`
`vacuous`	$x = 42$ from contradictory assumptions (§ 05)	0	None	The standard three
`mass_gap_positive`	An empty theorem with only a big name (§ 05)	0	None	The standard three

Seconds are wall-clock time including loading `import Mathlib` (a 4-core machine, nice 19). Rows that load Mathlib take about 5 seconds for loading alone. The values are from one run in `results.json` and vary by about 10% from run to run (the exit codes, warnings and axiom rows are the same on re-running).

There are three things to read. First, a file containing `sorry` also passes with exit code 0. All that appears is a warning. If a checking record only says "no errors", the absence of `sorry` is not guaranteed. Second, `native_decide` creates one dedicated axiom just for that call. The Lean reference manual explains that this is so that what each axiom asserted can be audited individually. It differs by version: up to 4.28.0, every call appeared as depending on a common axiom `Lean.ofReduceBool` (with `Lean.trustCompiler` behind it). From 4.29.0, it changed to a dedicated axiom per call (of the form `…ax_1_1` in Table 2). Axiom names change with the version, so this book judges by "is it a subset of the standard three?". Third, a false statement does not pass with `decide`.

Detour: using real numbers brings out the three axioms

You may skip this. `mass_gap_positive` in Table 2 is "if $0 < m$ then $0 < m$", and its proof just returns the premise. Even so, the standard three appear. For `pos_nat` (natural numbers), of the same form, nothing appears. The only difference is the type, so the three come from the side of the real numbers. `#print axioms` follows not only the proof but also the definitions appearing in the statement (including the type $\mathbb{R}$). Mathlib's type of real numbers is built as a quotient of Cauchy sequences, and that definition itself depends on the three. In fact, even the empty theorem "True for an element m of $\mathbb{R}$" brings out the three. So theorems that talk about real numbers almost always bring out the three. That the three appear is not a sign that the proof is heavy.

For how this book uses this, see 23-13 § 02 (the #print axioms at the end of each bundle as the standard of cleanliness).

05

It passes, but is it what was meant? — the four gaps

Even with no holes and only the standard three axioms, something is still unchecked: **whether the statement says what it means to say**. At the start of its checking procedure, the Lean reference manual writes that it is important to distinguish the question "does the theorem have a correct proof?" from the question "what does the statement of the theorem mean?". The latter cannot be checked by machine.

This site's page 8 of the guide divides this gap into four types (Table 3).

Table 3 The four gaps (the guide's classification, with examples from this book)

Type	What happens	How to find it
① Definition	The definition is weaker or stronger than intended (e.g. if "gap" is defined by ≥ 0, it passes even with 0)	Follow every definition appearing in the statement
② Name	The name of the theorem is bigger than the statement	Read the statement, not the name
③ Vacuous truth	The premises cannot hold at the same time, so anything can be concluded	Build one concrete example that satisfies the premises
④ Assumption	What should be proved is placed in an assumption, and when it fails is not written	Make a list of assumptions and look at the label of each

② and ③ actually occur in the last two rows of Table 2. `mass_gap_positive` carries the name mass gap, but the statement is "a positive number is positive". To Lean a name is just a string and guarantees nothing about the content. This is why, when this book cites a theorem name, it writes the statement and the premises on the same line.

An example of ③ is the following statement.

$$(x < 0) \ \wedge \ (0 < x) \implies x = 42 \ \text{(6)}$$

The premises contradict each other, so the conclusion can be anything, and Lean passes it with a single `linarith` (an automatic step that combines linear inequalities). The more premises a theorem has, the harder this danger is to see. The way to check is to give one example that satisfies all the premises (a case where the answer is known, such as a free field). In Part 23 of this book, the role of an example satisfying all the premises is played by checking against the free field (23-16). Negative controls (23-13 Lean statements and the limits of machine checking) go the other way: they show that removing one assumption breaks the conclusion, confirming that the assumption is not decoration.

④ (assumptions) is the most important in this book. In a theorem that draws a conclusion from an unproved assumption such as the diffusive-relaxation-time assumption, the content is on the side of the assumption, and the theorem does not prove a single step of that assumption (23-13 Lean statements and the limits of machine checking).

06

What the Lean statements in this book talk about

A Lean theorem is a statement about typed objects. So looking at the types of a theorem's arguments tells you what the statement actually talks about. 23-13 Lean statements and the limits of machine checking divides the forty-six theorems that this book cites as conclusions into five layers by the types appearing in their statements. Exactly half, 23, are inequalities or identities of real numbers, and the theorems that have the lattice gauge field as a type are the 3 of 5-11.

Written as a formula, a sentence in this book with the Lean label consists of two parts.

$$\text{a sentence of this book} \ = \ \underbrace{(P_1 \wedge \cdots \wedge P_k \Rightarrow Q)}_{\text{checked by Lean}} \ + \ \underbrace{\text{reading: "}C_P \text{ is the Poincaré constant of}}_{\text{attached by the text; not ch}}$$

Just as C_P was a named real number in the example of § 03, in many theorems of this book C_P, ξ and m are real variables. Reading them as physical quantities is done in the text, and whether that reading is right lies outside Lean. The conventions for the reading (the definition of β, the normalisation of tr, the metric of the lattice) are in 23-13 Lean statements and the limits of machine checking and A-01 Table of notation.

Why is there no theorem about the Wilson measure itself? One reason is stock. Counting words in the source of Mathlib, Lean's standard library of mathematics, in the version on this machine (the version is in Table 7 of § 08) gave Table 4.

Table 4 Number of files, out of the 8,311 source files of Mathlib, that contain the word Computed

Word	Files	Word	Files
`Haar` (Haar measure)	70	`plaquette`	0
`Wilson loop`	0	`lattice gauge`	0
`Yang-Mills` (three spellings)	0	`spectral gap`, `SpectralGap`	0
`Poincare inequality`, `PoincareInequality`	0		

There are foundations for the uniform measure on a group (Haar measure), but the words of lattice gauge theory do not appear. The absence of a word is not a proof of the absence of a definition, but at least as named machinery, whoever uses it must build it from scratch. The guide's "Mathematics that mathlib has no stock of" divides the sources of such difficulty into three (quantity, way of stating, stock). The continuum limit and the construction of four-dimensional field theory lie beyond that (7-10).

Example. This site's paper (5-11) is one of the few examples that have the lattice gauge field as a type. Even there the Lean label is split by step: the chain from the action to a certain lower bound is Lean , and the step from that lower bound to the lattice mass gap is Paper (and only a sketch) (0-01).

Table 4b lists the bundles used in the assembly of the first step of Part 23, and Table 4c the bundles cited by Part 24. The single files outside Tables 4b, 4c and 4f whose declarations are cited by Part 23 and other chapters are in Table 4h. All of them are collected in the bundle `principia-ym-lattice-gauge-2026-11-13` (143 modules, about 30,000 lines; every module imports only Mathlib). The rows are the same as Table 1 of 23-13; what a bundle guarantees is only the algebra, arithmetic and one-variable analysis from the list of assumptions to the conclusion. Every bundle follows the convention of writing the assumptions next to the theorem name (23-13 § 04).

Table 4b The bundles of the first step (Part 23). The number of theorems is the number of `#print axioms` lines bundles were rebuilt on another computer, and every line was confirmed to be a subset of the three standa source is the bundle `principia-ym-lattice-gauge-2026-11-13` (the same bundle as Tables 4c and 4f). On 2026-1 built again from this bundle, one at a time, and the kernel re-check and `#print axioms` for the declarations cit were confirmed Lean

Bundle	Theorems	Algebra of what	Representative theorem (assumptic

Bundle	Theorems	Algebra of what	Representative theorem (assumptio
LatticeGaugeOneScale	12	The relaxation-time upper-bound assumption, the relaxation-time lower-bound assumption, and rereading as mass (the equality version)	hup_is_gap_positivity (0<m, C_P= C_P≤Kξ²)
LatticeGaugeHupBridge	18	The one-sided bridge, the lower half of the power, negative control	hup_is_gap_positivity_of_lower (0<m_lat, κ/m_lat²≤C_P, C_P≤Kξ
LatticeGaugeDoubleWellTestbed	7	The skeleton of the finite sums of the One-Dimensional One-Sided Bridge Proposition	local_rayleigh_ratio_le_one (0<m a_k≥m, c_k≥0, Σc_ka_k>0)
LatticeGaugeTwoScalePoincare	8	Splitting of the variance, the convex core, two states, the Glauber band	split_poincare_le (the splitting formula, two local Poincaré inequalities, the mean difference, negativity)
LatticeGaugeDoubleWellKramers	10	From the sandwich of the ratio to the double-well relaxation-time power statement	power_H_of_kink_ratio (0<K,s,δ, 1≤R≤K/ħ, s/ħ≤ln ξ)

Bundle	Theorems	Algebra of what	Representative theorem (assumptic
LatticeGaugeH1Assembly	17	The algebra of the rates of the Six-Node In-Phase Poincaré Proposition, the arithmetic of the margins at the six nodes	H1_assembly (seven named ones)

LatticeGaugeSusceptibilityRatio (SusceptibilityRatio)	8	What the ratio of the susceptibility to the equal-time correlation can and cannot tell	`gap_ge_of_overlap`, `light_admixture_invisible`
LatticeGaugeTubeDefect	14	The sign of the tube deficit in the model of surfaces with positive weights	`linear_deficit_breaks_inv`
LatticeGaugeTubeEntropy (LatticeGaugeTube)	18	Counting surfaces (the entropy of the tube) and the lower half at one scale	`mass_sq_ge_of_tube`, `linear_regime_breaks_onescale`
LatticeGaugeTwoLink (LatticeGauge.Character)	28	The finite part of the two-link integral	`intact_frac_le`
LatticeGaugeVariationalBound (VariationalBound)	9	That the variational effective mass is an upper bound on the gap	`meff_ge_of_corr`
LatticeGaugeWulffCorrection	13	The tension of a tilted wall and the Wulff subtraction (the deficit of a closed tube)	`casimir_only_no_bound`, `mass_bound_localized`
LatticeGaugeH1TaylorStage (LatticeGauge.H1TaylorStage)	19	Three-point interpolation in the β direction and the cubic remainder, endpoints of the linear fraction on a small piece	`cube_le_exp_split`, `lebesgue_le`

File (namespace)	Theorems	Content	Theorems cited by the chapters
LatticeGaugeH1Tilt (LatticeGauge.H1Tilt)	22	Upper bound on the chord in the β direction and the Hölder loss, the number of subintervals	`chord_beta_upper`, `holder_r117_exceeds`, `nodes_reach`
LatticeGaugeRingMirror (LatticeGauge.RingMirror)	20	Algebra of the mirror image at the seam of the ring	`chain_action_reflect`
LatticeGaugeAdjointSandwich (LatticeGauge.AdjointSandwich)	19	Arithmetic that sandwiches the remaining assumption (MC-sup) between the reading from below and path-by-path upper bounds	`mbar_bound_false`
LatticeGaugeDriftDual (LatticeGauge.DriftDual)	20	Algebra of the weak dual measured by the dual of the conditional drift, and arithmetic on the measured values	`tilt_g1`
LatticeGaugeHbarZero (HbarZero)	23	Algebra of the form that fixes the range of ħ by re-choosing the window	`p5_assembly`
LatticeGaugeLocalizedBochner (LatticeGauge.LocalizedBochner)	29	Composition that localises the negative curvature of the Bochner step to the defect set, and the cost of the tilt	`bochner_localized`, `judge_i_insid` `negw_le_localized`, `tilt_cost_le`

File (namespace)	Theorems	Content	Theorems cited by the chapters
LatticeGaugeBTDressed (BTDressed)	17	The form of one-dimensional sequences counted in the dressed direction (the margin does not depend on the direction, scale invariance)	`threshold_gap_invariant`
LatticeGaugeBartaRefine (LatticeGauge.BartaRefine)	19	How to split the tilt between the Barta and Bochner defects, the ceiling lemma, negative controls	`ceiling_same_set`, `ceiling_split`
LatticeGaugeEigenGradient (LatticeGauge.EigenGradient)	16	A form that uses only the gradient of the eigenfunction, one step with the Agmon weight, negative controls	`agmon_no_gain_on_negative_curvatu`
LatticeGaugeExtendedChain (LatticeGauge.ExtendedChain)	19	Composition of the LSI constant of the extended chain, and the condition for that constant to be bounded	`S_ext_01_iff`
LatticeGaugePlateauLSI (LatticeGauge.PlateauLSI)	26	Decomposition of the LSI on the plateau at the top (collective coordinate and transverse directions), transverse eigenvalues	`transverse_fails_k17`

File (namespace)	Theorems	Content	Theorems cited by the chapters
LatticeGaugeWallCut (LatticeGauge.WallCut)	21	Composition of the multi-step decomposition cut at the position of the wall	`chain_rule_cells`
LatticeGaugeKinkPosition (LatticeGauge.KinkPosition)	16	Bistability at the negative end of the core, and conditioning on the binary of the bump	`pn_vs_bistab`, `y_side_k9_3em4`

Table 4d The bundle of Parts 25 and 26 (Y7, 11 files). The number of theorems is the number of theorem and lemma declarations in the files (32). Rechecked on another computer on 2026-10-15: all use the three standard axioms, `sorry` 0. `Lean`

File (namespace)	Theorems	Content	Chapters that cite it
InsertionIdentity (Insertion)	5	The identity for the sum of insertion ratios, mean_one, mean_rho_sigma, sector_bias_le	25-05
BoundedInsertion (Bounded)	5	single, single_mul, multi, averaged, averaged_bound	25-05
SecondMoment	2	sqrt_identity, pz_bound	25-05
MultiCell	3	pushforward, expand_identity, bound ("odd under insertion" is an assumption)	25-05
FlipLemma	2	flip_le, cut_formula	25-06
FluxLemma	1	flip_le_one_sub_abs	25-06, 26-05
Containers	2	factorize, container_bound	25-03
FluxDuality	3	split, twisted_le, bias_mem (positivity is assumed for $\theta \leq 1$)	26-04
Doubling	2	iterate, decay	26-02, 27-01
ReflPos	2	refl_pos, refl_cs	26-04, 26-05, 27-02
ColumnChessboard	5	signed_sum, unsigned_sum, prod_expand, binomial_bound, exp_bound	25-02 (paper on lattice fractional instantons)

Only two files have a file name different from the namespace, InsertionIdentity (Insertion) and BoundedInsertion (Bounded); the text cites them in the form "file (namespace.theorem)". The bundle is `principia-ym-insertion-identities-2026-10-15.tar.gz` (package `yminsertion`, lib `Y7`, sha256 `58d60c433cb23cb9cfab1f2299732385f79a362b96a1d49ac109334b4832bdf8`, record of axioms axioms-ym-insertion-identities-2026-10-15.txt).

Table 4e The bundle of slabs and containers (lean-y6, 30 files + Lemma5Core). The number of theorems is the number of lines in the `#print axioms` record (150: of these, 137 are declarations written in this book's study

for Parts 25 and 26, and 13 are declarations added on the verification branch). On 2026-10-15 it passed `lake build` on another computer: all use the three standard axioms, `sorry` 0. The bundle is `principia-ym-slab-containers-2026-10-15.tar.gz` (package `ymslabcontainers`, lib `Y6`, sha256 `4892aca93897af4940828fd14d5fc45e e72bdcfca0914a2dcd20dd2d77229341`, record of axioms axioms-ym-slab-containers-2026-10-15.txt). `Lemma5Core.lean` is outside the lean_lib and is not checked by `lake build` alone (it is checked separately with `lake env lean`; its record of axioms is `axioms-Lemma5Core.txt`). `Lean`

The labels in the text of Part 15 stay the five grades (paper proofs are [Proved here]); Lean is attached in the text of each chapter as the theorem name and its assumptions on the same line (15-09 §01). The source is the bundle `principia-ym-lattice-gauge-2026-11-13` (the tar.gz under `principia/lean/`, and the axiom log `axioms-ym-lattice-gauge-2026-11-13.txt`). Of these, 23 files are also in the bundles published in October 2026 (flux-network-blocking, hierarchical-chain, one-row-renormalisation, coarse-chain-poincare, h1b-margin-interval, boundary-mixed-derivative), as the same files.

07

How the labels are decided — one label per sentence

This book attaches labels sentence by sentence, not chapter by chapter or paper by paper, because even within one paper the label differs from step to step (the example in § 06). Which label is attached is decided by the kind of guarantee the sentence has. Figure 2 puts that decision in the form of questions asked from the top down.

There is a reason for the order of the questions. The Lean label guarantees the arrow from premises to conclusion; the Known label refers to a proof in the literature, the Paper label to a proof on this book's side, the Computed label to a check over a finite range, and the Physics label to acceptance at the level of physics. The strong guarantees are asked first, and the first label that applies is attached. A sentence that matches none gets no label and is written as an "assumption" or a "question" (the questions of 23-17 carry no label).

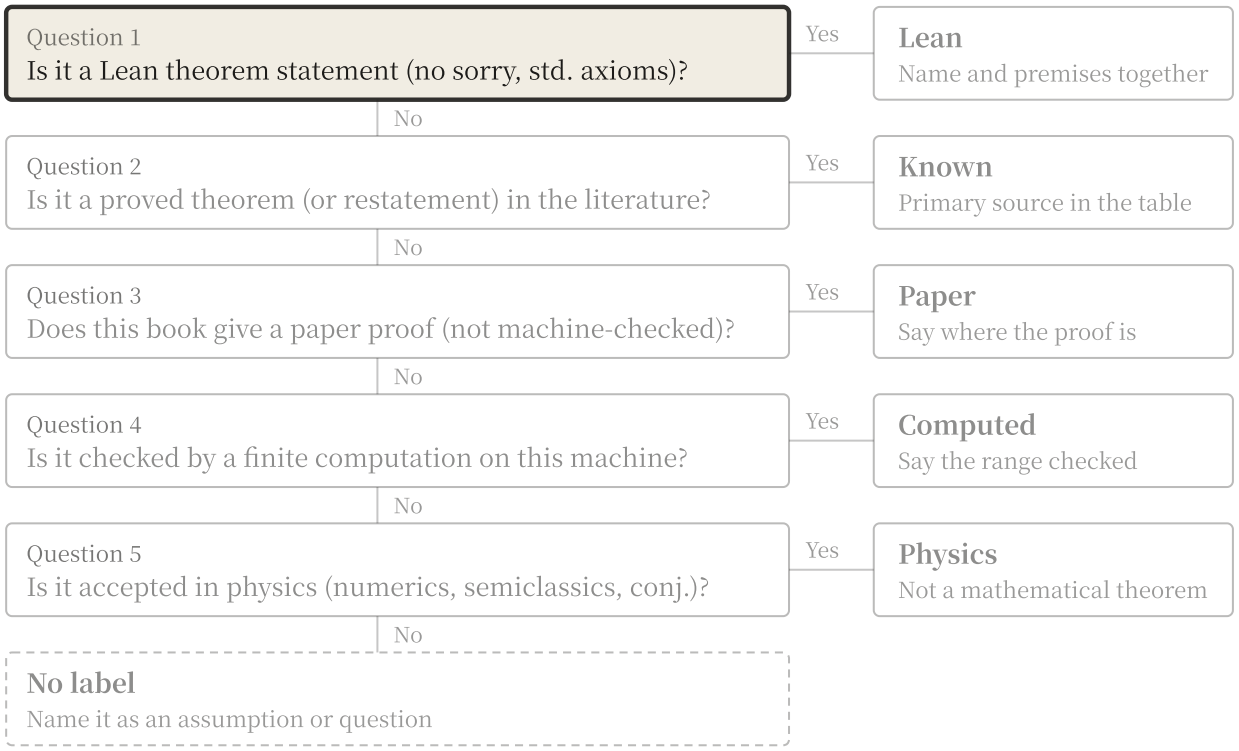
When the sentences form a chain, read it as follows.

$$\text{for the chain } A_0 \Rightarrow A_1 \Rightarrow \cdots \Rightarrow A_n\text{, the certainty of the conclusion } = \text{ the label of the weal}$$

If just one step is `Paper` , then even if all the other steps are `Lean` , the conclusion is at the level of Paper. If the starting point A_0 is an assumption, the conclusion is also conditional on it. The premises P_i of formula (1) correspond to this starting point.

Figure 2 Answering the questions from the top with "Yes / No" shows the path taken and the label attached. The

example buttons pick one sentence of this book and show its path



`Question 1: Is it a Lean theorem statement (no sorry, std. axioms)?`

This figure puts the conventions for labels in 0-01 in the form of questions. It contains no numbers.

Table 5 Examples of sentences in this book, and the path they take in Figure 2

Sentence	Path taken (answers to questions 1–5)	Label	Chapter
Formula (4): $m > 0$, $C_P = 1/m^2$, $C_P \le K\xi^2 \Rightarrow 1 \le K(m\xi)^2$ (the same statement as `hup_is_gap_positivity` in 23-13)	Yes	Lean (with premises stated alongside)	§ 03, 23-13
The one-loop coefficient b_0 (including $11N/3$)	No → Yes	Known	4-06
The step from the one-link lower bound to the lattice mass gap	No → No → Yes	Paper (sketch)	5-11
The behaviour of C_P/L^2 in small boxes ($L = 3, 4, 5$) for the two-dimensional Ising model	No → No → No → Yes	Computed	2-10
The ratio of the glueball mass to the string tension from lattice numerical simulations	No ×4 → Yes	Physics	5-08

Sentence	Path taken (answers to questions 1–5)	Label	Chapter
Relaxation-time assumption (at the level of powers, $\ln C_P / \ln \xi \to 2$; the band statement is named the band form of the diffusive-relaxation-time assumption, and its upper half is the upper-bound assumption: $C_P \le K\xi^2$)	No ×5	No label (assumption)	23-01

How to read it. The Lean premise $CP \le K\xi^2$ in the first row of the table is the upper half of the band statement of the assumption in the last row (the band form of the relaxation-time assumption), that is, the upper-bound assumption (A-06 Index of names). In the first row it is a premise; in the last row, the claim of an assumption. The labels differ because the roles in the sentence differ.

08

A procedure to check for yourself

The Lean label presupposes that readers can check again on their own machines. The Lean reference manual describes checking as a staircase of four stages (Table 6). The lower stages are easier; the higher stages widen the range of doubt.

Table 6 The four stages of checking (from the structure of "Validating a Lean Proof" in the Lean reference manual)

Stage	What to do	What it guards against
1	See that the editor's check mark appears, or that `lake build` finishes with no warnings or errors	Unfinished proofs, `sorry` inside that theorem, honest mistakes in tactics
2	Write `#print axioms theorem-name` after the theorem, and confirm formula (5)	`sorry` inside theorems it depends on, extra axioms, `native_decide`
3	Use `lean4checker` to pass the proofs saved by the build through the kernel again	Bugs in the core of Lean that handles the kernel's state, metaprograms or tactics that deliberately bypass checking
4	Write only the statements in a trusted place, assemble the proofs in isolation with `lake comparator`, pass them again through both Lean's kernel and an external checker written independently of it, and also confirm that the statements match	Malicious proofs, implementation bugs present in only some of the checkers used

The manual itself positions the isolated-comparison step for high-risk settings, such as markets for proofs, competitions with large prizes, and AI whose intentions are not aligned. About the build-check step, the manual warns that the check mark appears even if a dependency contains `sorry`. This is the same situation as `gap_from_bound'` in Table 2 having exit code 0, and it is why the axiom-check step (a checking step of the Lean reference manual) is needed. The Lean labels in this book are attached to theorems that have been through at least the axiom-check step.

The concrete procedure has the following form. How to install and match versions is in "Installing" in the guide and "Checking a distributed proof locally".

```
lake build                      # Stage 1: check the whole project
lake env lean File.lean         # check a single file only
#print axioms gap_from_bound    # Stage 2: write this inside the file
```

This site's Lean record (the list of theorems and the record of checking) is at the Lean record. Even the same proof may stop passing when the versions of Lean and Mathlib differ, because lemma names change. For this reason this book records the versions used for checking.

Table 7 The environment in which the examples of this appendix were checked Computed

Item	Version
Lean	4.33.1 (commit `819816b2`)
Mathlib	rev `0df444a3`
Machine	x86_64, 4 cores, Linux. Checking was run at low priority (nice 19)

Finally, we gather into seven the things to ask when you receive a sentence with the Lean label. This is the checklist of "The procedure for reading a statement" in the guide, adapted to the way this book is read.

1. Is the theorem name given, so that you can check it again yourself (build-check step)?
2. Is there no `sorry`, and do the axioms fit within the three of formula (5) (axiom-check step)?
3. Have you followed every definition that appears in the statement (① of § 05)?
4. Did you read the statement rather than the name (② of § 05)?
5. Is one example satisfying all the premises given (③ of § 05)?
6. Are the list of premises and the label of each premise written (④ of § 05, formula (8))?
7. Where in the text is the reading of the real variables as physical quantities declared (§ 06, formula (7))?

The seventh is the question specific to this book. Many of the Lean theorems in this book connect to the mass gap problem at this point, and that connection lies outside the Lean label.

> 09

> **Declarations of Parts 19–22 and 28, the second half of Part 15, and the sections "What this book's study could see" of Volume 2 — list, and the checking procedure**

The Lean declarations cited by Parts 19–22 and 28, the second half of Part 15, and the sections "What this book's study could see" of Volume 2 (Parts 9, 10, 12 and 14) are listed chapter by chapter. The detailed form of the scope and of what is not claimed is in the scope chapter of each part (20-07, 21-08, 15-14), in "What this chapter can say" of 14-02, and in the correspondence table of definitions (19-06).

The checking procedure. Every declaration has been checked again in the core (kernel) of Lean 4 (kernel recheck), confirming that there is no `sorry` and that the axioms used are only the three standard ones. In addition, with eyes other than those that wrote the proofs, we have compared whether the Lean definitions and statements point to the same things as the definitions and statements of the text, and whether the assumption fields can be satisfied by the actual objects (cross-checking by a reader other than the writer). What machine checking guarantees goes only as far as the written statement following from the written assumptions (the four gaps of § 05).

The bundle. The declarations of Table 4g, and all the files on which they depend through `import`, are collected in the bundle `principia-ym-three-volumes-2026-11-13`, a single lake package. It uses Lean 4 v4.33.1 and Mathlib v4.33.1, has 400 modules and about 115,000 lines, and the declarations cited by the chapters number 677 (of which 455 are theorems). A lexical search finds 0 occurrences of `sorry`, `admit`, `native_decide` and custom `axiom`. How to check it (`lake build`, and `#print axioms` for each declaration), and the pairs of modules that cannot be `import`ed together because they have declarations of the same name, are written in the README of the bundle. The earlier bundle of the same day, `principia-ym-premise-first-2026-11-13` (317 modules), is entirely contained in this bundle (the 317 module files are the same).

Table 4g Lean declarations cited by Parts 19–22 and 28, the second half of Part 15, and the sections "What this book's study could see" of Volume 2 (Parts 9, 10, 12 and 14) (bundle `principia-ym-three-volumes-2026-11-13`, 400 modules)

Chapter	Theorem or definition	Scope	Lean declaration
19-06	Strong-coupling side ↔ vortex side (measure): $\tilde{\mu}_{N,\beta}$ (`TorusRP.wilsonMeasure N β`) equals the measure on the vortex side, a Haar product multiplied by a weight, transported by a one-to-one correspondence given by definition. No constant factor	Only for $M = N$ and no twist. There is no bridge for the twisted measure (background $n_{12} = 1$)	`WilsonBridge.wilsonMeasure_e`
19-06	Same (expectations, total mass): the expectations of measurable observables and the total mass $Z_N(\beta)$ agree on the two sides	As above	`WilsonBridge.integral_wilson` `WilsonBridge.wilsonMeasure_u`
19-06	Same (correspondence with aligned time): the measures also agree under the correspondence that puts the time of the strong-coupling side (index 0) onto index 3 of the vortex side, and the reflections in planes through lattice sites on the two sides become the same map	As above	`WilsonBridgeT.wilsonMeasure_` `WilsonBridgeT.refl_toBallT`
19-06	Same (vortex ratio): the vortex ratio with no background twist ($n_{12} = 0$) is written as an expectation of the probability measure on the strong-coupling side. It is not the book's θ_M ($n_{12} = 1$)	As above	`WilsonBridgeV.vortex_ratio_e`
19-06	Strong-coupling side ↔ fermion side: $\tilde{\mu}_{2h,\beta}$ is $e^{6(2h)^4\beta}$ times the pure-gauge measure `WilsonGauge.gaugeMeasure` transported by a relabelling of indices	Spatial side $N = 2h$, $2h > 1$	`WilsonGauge.wilsonMeasure_ec`

Chapter	Theorem or definition	Scope	Lean declaration
20-01	Reflection positivity in planes through lattice sites	$(\mathbb{Z}/2M)^4$, all β, bounded measurable f depending only on the closed positive half	`TorusRP.wilson_rp`
20-01	Reflection positivity in mid-planes	$(\mathbb{Z}/2M)^4$, $M \geq 2$, $\beta \geq 0$, gauge-invariant bounded measurable F	`MidRP.wilson_rp_mid`
20-01	Reflection positivity in planes through lattice sites, in four directions	$(\mathbb{Z}/2M)^4$, all β, for each direction ρ	`PeierlsPerm.wilson_rp_dir`
20-01	Symmetry of the reflection pairing	$(\mathbb{Z}/2M)^4$, all β, measurable f, g	`TorusRP.wilson_refl_symm`
20-02	Decay of correlations at strong coupling in finite volume	Narrow window, for each finite N, no N in the constants, distance in time	`TorusRP.wilson_strong_coupli`
20-02	Decay of covariances in the Dobrushin distance	$\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$, finite N, no N in the constants	`LinkSpec.wilson_cov_dist`
20-03	Theorem on the limit without subsequences	$\beta \not= 0$, $q(\beta) < 1$	`InfVol.wilson_infvol_unique`
20-03	Theorem on the limit independent of the size	$\beta \not= 0$, $q(\beta) < 1$, all sizes $m + 1$, any $s(k) \to \infty$	`AllN.wilson_infvol_allN`
20-03	Translation invariance of the limit	$\beta \not= 0$, $q(\beta) < 1$, unit translations in four directions	`TransI.wilson_infvol_transla`
20-03	Clustering of limit points	$\lambda \geq 0$, $e^{\lambda} q(\beta) < 1$, at every limit point, four directions	`WilsonLimit.cluster_limit`
20-04	Mass gap with non-degeneracy (Dobrushin window)	$\beta \not= 0$, $q(\beta) < 1$, the statement chooses one limit point (the same estimate at every limit point: `WilsonLimit.wilson_massGap_dob`), $\|T - P_\Omega\| \leq q(\beta)^{1/2}$, $\mathrm{Var}(F_0) \geq \frac{1}{4} e^{-12\|\beta\|}$	`WilsonLimit.wilson_massGap_d`
20-04	Mass gap with non-degeneracy (all limit points)	$\beta \not= 0$, narrow window, all limit points, rate $-\log 24(1 - e^{-4\|\beta\|})$ (not included in the combined statement)	`WilsonLimit.wilson_massGap_r`
20-04	Mass gap in the gauge-invariant sector	$\beta \not= 0$, $q(\beta) < 1$, the statement chooses one limit point, witness $F_p = \mathrm{Re}\, U_p$	`GaugeZ.wilson_massGap_gauge_`
20-04	$T \geq 0$ (on the whole of W)	$\beta \geq 0$, $\lambda > 0$, $e^{\lambda} q(\beta) < 1$, all limit points	`FullT.wilson_Tpos_full`
20-04	The image of T lies in the gauge-invariant sector	$\lambda > 0$, $e^{\lambda} q(\beta) < 1$, all limit points	`Bind.T_range_gauge_all`

Chapter	Theorem or definition	Scope	Lean declaration
20-04	The combined statement	$0 < \beta$, $18 \tanh \beta < 1$. Convergence, translation, reflection positivity, gap and non-degeneracy in the two sectors, $T[F_0] = 0$, $T \geq 0$, clustering	`InfMain2.wilson_infvol_main2`
20-05	Reflection positivity of the Wilson–fermion weight	$m > -1$, all β and j, time planes through lattice sites	`WilsonGauge.site_reflection_`
20-05	The partition function is positive	All β, m, j	`WilsonGauge.partition_pos_wi`
20-05	Global gauge invariance of the determinant	Unconditional, constant g	`GaugeDet.physDirac_det_conj`
20-05	Invariance under the generators of the lattice symmetries	All N, j, m, β: global gauge, translations in four directions, spatial 90° rotations, reflections of spatial axes, time reflection	`CubicSym.wfProb_lattice_gene`
20-05	Invariance under the hypercubic generators	Isotropic lattice $N = 2h$; the above with 90° (space, time) rotations added	`CubicSym.wfProb_hypercubic_g`
20-05	Invariance of the determinant under time reflection	Unconditional (all N, h, m, ω), reversal $t \mapsto 2h - 1 - t$	`CubicSym.physDirac_det_trefl`
21-01	The three results of the sign systems (covering inequality, monotonicity for $\mathbb{Z}_2$, comparison with $\mathbb{Z}$ 2)	Abstract groups and sign characters. Implications with assumption fields	`CoveringInequality.covering_` `dominated_covering_ineq`, `in`
21-02	Thin-vortex floor (ratio form)	All real β, $N, M \geq 1$, any background twist: `twisted_vortex_bound` is the signed form $(Z_0 - Z_1)/(Z_0 + Z_1) \leq t^{M^2}$, `_abs` is the absolute-value form $\lvert Z_0 - Z_1\rvert/(Z_0 + Z_1) \leq t^{M^2}$	`TwistedWilson.twisted_vortex` `twisted_vortex_bound_abs`
21-02	Thin-vortex floor (exponential form)	$\beta \neq 0$: $\sigma_0 = -\ln t > 0$, $\lvert\theta_M\rvert \leq e^{-\sigma_0 M^2}$	`TwistedWilson.thin_vortex_fl`
21-04	Block estimate	$mk \leq M$, all real β: $\lvert\theta_M\rvert \leq \tanh(K_{\text{eff}})^{k^2}$	`TwistBlocks.block_bound_abs`
21-03	Thick-vortex floor	All $N \geq 1$, any $\varepsilon > 0$, for each sufficiently large β a sufficiently large M: $\lvert\theta_{M+1}\rvert \leq \exp(-(M+1)^2 e^{-\beta(S_N + \varepsilon)})$	`TwistBlocks.thick_vortex_flo`

Chapter	Theorem or definition	Scope	Lean declaration
21-05	Positivity of the minimal vortex action	All $N \geq 1$: $\delta \leq S_{\mathrm{v}}(N, m)$ with $\delta > 0$ uniform in m, and $S_N > 0$	`VortexPos.Svortex_ge_unif`,
21-05	Certificates of upper bounds Computer-assisted	$S_{\mathrm{v}}(2,8) \leq 6.67401$, $S_{\mathrm{v}}(3,8) \leq 9.09321$, $S_{\mathrm{v}}(4,4) \leq 12.02057$, hence $S_N < 2N^2$ $(N = 2,3,4)$	`VortexCert.Svortex_two_eight` `Svortex_three_eight_le`, `Svo` `SN_two_lt`, `SN_three_lt`, `SN_` `VortexCert.Svortex_le_of_cer`
21-05	Thick-vortex floor with explicit exponents	$N = 2,3,4$, for each sufficiently large β a sufficiently large M: exponents 6.675, 9.094, 12.021	`TwistBlocks.thick_vortex_flo`
21-06	Sign of the vortex ratio	M even, all real β: $Z_1 \leq Z_0$, $\theta_M \geq 0$	`HalfSplit.Z1_le_Z0`, `TwistBl`
21-06	Signed thick-vortex floor	Within the range of the thick-vortex floor, with $M+1$ even: $0 \leq \theta_{M+1} \leq \exp(-(M+1)^2 e^{-\beta(S_N+\varepsilon)})$	`TwistBlocks.thick_vortex_flo`
21-06	Estimate of Polyakov loop pairs by θ	M even, all real β, all b, b': $\lvert\langle P_b(0) P_{b'}(M/2)\rangle_0\rvert \leq 2\sqrt{\theta}/(1+\theta)$	`HalfSplit.polyakov_pair_thet`
21-06	Polyakov loop pairs at general time separation	$M \equiv 0 \bmod 4$, all real β, $0 \leq T \leq M$: $\lvert\langle P_b(0) P_{b'}(T)\rangle_0\rvert \leq 2t^{M \min(T, M-T)}$	`PolyakovT.polyakov_pair_all`
21-06	Same (other parities)	M even ≥ 4 with $\beta \geq 0$ / N, M even $(M \geq 4)$ with all β	`PolyakovT.polyakov_pair_ever`
21-06	Pairs at distance $M/2$ and the thin-vortex floor	M even (including $M = 2$), all real β: $\lvert\langle P_b(0) P_{b'}(M/2)\rangle_0\rvert \leq 2t^{M \cdot M/2}$	`PolyakovT.half_pair_tanh`
21-06	Polyakov loop pairs combined with the thick-vortex floor	For each sufficiently large β a sufficiently large M, $M+1$ even: pair at distance $(M+1)/2 \leq 2\exp(-\frac{1}{2}(M+1)^2 e^{-\beta(S_N+\varepsilon)})$	`HalfSplit.polyakov_pair_floo`
15-12	Upper side	All steps k, all $q \in \mathbb{R}^4$ with $\omega(q) > 0$	`OSUpQpos.os_up_Qpos`, `OSUpQp`
15-12	Lower side	As above (a family closed under a different name)	`HsSplit.lower_side_c`
15-12	Bracketing of the propagator	As above; constants uniform in k and q	`LatticeRec.lattice_bracket`, `OneStepLower.bracket_Qpos_fr` `NearAliasB.bracket_Qpos_spli`
15-12	One-step contraction	All q	`OneStepBridge.Mfam_P_le_row`
15-12	Contraction uniform in the step	All steps k, all q	`TorusLam.stage_tau_17`
15-12	Convergence of Γ_k	All steps; constants uniform in the step and the momentum	`AliasPoinc.coupling_converge`

Chapter	Theorem or definition	Scope	Lean declaration
15-13	Locality, gauge covariance	$r0 > 0$, $\lvert g\rvert = 1$	`BoxWalk.boxMap_local`, `BoxWa`
15-13	Linearisation	$0 < r0 \le 1$, $\varepsilon M \le 1/32$	`BlockLinearKernel.blockMap_e`
15-13	Covariance of the pushforward	Any measure (meaningful when second moments exist), one colour	`PushCov.lattice_pushCov`
15-13	Covariance of plaquettes	All steps m, $N \ge 2$. The field obtained by pushing the free field forward with the linearised blocking	`LatticeFace.lattice_face_T1h`
22-01	Chessboard Estimate	$N = 2m$ ($m \ge 1$), all real β, functions on a unit cube	`FoldWilson.wilson_chessboard`
22-01	Rarity uniform in the volume	$\beta \ge 81$, $m \ge 2$, any set X of plaquettes. $q1$ does not depend on N or X	`FoldCap.rarity_explicit`
22-01	Rarity at rate $1/4$	$0 < y \le 2$, at or above some $\beta0$, $m \ge 1$	`FoldQuarter.rarity_uniform4`
28-01	Subsequential limits, and the properties that pass to the limit (implications with assumption fields)	The assumption fields are as in the table of 28-01	`WeakUltravioletExistence.exi` `limit_consistent`, `BlockConc` `ChainBlockMap.chain_end_to_e` `continuous_blockMap`; `BoxWal` `chain_end_to_end_box_wilson2`
28-02	Convergence of skew-product orbits with matched endpoints (implications with assumption fields)	The one-step map is an abstract skew product and is not defined from the lattice (28-02 § 08)	The 13 declarations of `SkewOr` `Admissible`, `two_point_bound` `orbit_compare`, `coarse_step`, `coarse_tendsto`, `coarse_rate` `observable_tendsto` and the r `SkewOrbitProbe.theta_exists_` `one_step_after` and others; `WeakUltravioletExistence.ter` `weak_uv_observable_full`
28-03	From decay to the mass gap; reduction of the band (implications with assumption fields)	The assumption fields are as in the table of 28-03. Inside the strong-coupling window all fields can be discharged	`OSGap.massGap_of_measures_su` `OSGap.Datum.hasMassGap_of_de` `BandReduction.band_reductior`

Chapter	Theorem or definition	Scope	Lean declaration
20-06	Area law at strong coupling (finite volume): the expectation of the Wilson loop on the boundary of a rectangle in directions 1 and 2 with a corner at the origin is exponentially small in the area of the rectangle (the formula is (3) of 20-06)	Torus of equal size in the four directions, β at least 0, inside the strong-coupling window (the 4096 window), both sides of the rectangle at least 1 and smaller than the side of the lattice. The rate and the prefactor depend neither on the size of the lattice nor on the size of the rectangle. The form whose exponent is exactly the area, when twice a side is at most the side of the lattice, is area_law_wilson_area	`AreaLaw.area_law_wilson`, `ar`
20-06	Same (rectangles with any corner and orientation)	As above. From the invariance of the Wilson measure under translations and permutations of directions	`AreaLaw.area_law_wilson_gene` `wilson_cfgShift_invariant`,
20-06	Same (version with tightened constants, and version with the exponent taken over the larger of the two directions)	β at least 0, inside the tightened window (the 441 window). Only the constants of the prefactor and the rate differ. Nothing is said outside the window, about general loops, or about lower bounds on Wilson loops	`AreaLaw.area_law_wilson_shar` `area_law_wilson_general_shar` `area_law_wilson_max_sharp`
20-06	Area law at strong coupling (infinite volume): in the limiting measure, the expectation of the Wilson loop on the boundary of a rectangle with a corner at the origin is exponentially small in the area	β positive, the intersection of the window of the limit without subsequences of 20-03 with the 4096 window, all side lengths. Also at every limit point (β at least 0, the 4096 window). There is no infinite-volume version with tightened constants or with any corner and orientation	`AreaLaw.area_law_infvol`, `ar` `area_law_limit_sub`, `zRectWo`
20-06	Parts of the proof of the area law: positive mixtures, the domination lemma, terms that vanish by sign flips and mod 2 duality, connectedness, lower bound on the area and counting of minimal sets of plaquettes, definition of the rectangular path	As in the statement of each declaration (20-06 § 05– § 08). The family of spanning sets of plaquettes is placed concretely inside the definition and is not an assumption	`AreaLaw.rectWord`, `rectWordG` `rectWord_one_one`, `abs_wordE` `exp_eq_mix`, `mixVar_mem`, `pro` `integral_mul_prod_one_add`, `sum_superset_le`, `q_eq`, `flip` `hol_eq_wordHol`, `integral_word_mul_prod_eq_ze` `not_mem_span_iff_exists_sep` `rect_closed_cases`, `minSpan_` `card_ge_of_spans_rect`, `word` `card_rootP_le`, `card_nbQ_le`

Chapter	Theorem or definition	Scope	Lean declaration
20-06	Upper bound on the vortex free energy (isotropic torus): the difference between the partition function with one central twist inserted and the ordinary partition function is exponentially small in the area of the twisted plane	Torus of equal size in the four directions, β at least 0, the 4096 window (the 441 window for the tightened version). The rate per unit area does not depend on the size of the lattice. A prefactor (the transverse area) remains. Nothing is said about the sign of the difference or outside the window	`VortexStrong.vortex_floor`, `vortex_floor_rel`, `vortex_fl`
20-06	Same (torus with transverse size N and longitudinal size M)	β at least 0, the 441 window (the 9216 window for the untightened version vortex_floor_MN), all backgrounds. The difference is exponentially small in the area of the longitudinal plane, and the rate per unit area depends neither on the transverse nor on the longitudinal size. A prefactor (the transverse area) remains	`VortexStrongMN.vortex_floor_`
20-06	Parts of the proof of the vortex upper bound: good sets and bad sets, independence of where the twist is placed, lower bound on the size of bad sets and their connectedness	As in the statement of each declaration (20-06 § 07, § 08)	`VortexStrong.Good`, `ZM_gauge` `good_twist_iff`, `card_bad_ge` `VortexStrongMN.card_bad_ge`,
21-07	Continuity of the vortex ratio, and its value at coupling 0: the twisted partition function and the vortex ratio are continuous in the coupling; at coupling 0 the partition function is 1 and the vortex ratio is 0	Transverse N and longitudinal M fixed at 1 or more, all real couplings	`ThetaTuning.ZW_continuous`, `thetaM_zero`
21-07	Weak form of tuning: if the target value is at least 0 and at most the vortex ratio at some coupling, then between 0 and that coupling there is a solution, and a largest solution among them	With the size of the lattice fixed. The largest is the largest within that interval	`ThetaTuning.tuning_exists`,

Chapter	Theorem or definition	Scope	Lean declaration
21-07	A box with one twist on each of two orthogonal planes has no flat configuration (from the discrete Stokes theorem and the algebra of quaternions)	All N, M (at least 1, including degenerate lattices), no assumptions. In a background with only one of the twists, flat configurations exist	`TwistFlat.no_flat_twist11`, `no_twisted_quadruple`, `Theta`
21-07	The minimal defect is positive and is attained at some configuration	All N, M (at least 1), no assumptions. No explicit value is stated	`TwistFlat.defect11`, `defect1` `ThetaLimit.Smin`
21-07	Uniform lower bound on the defect: in a symmetric box, the defect is at least 1/2 independently of the transverse size	All N, M (at least 1) and all configurations, no assumptions. In a background with only one twist there is no positive lower bound. The true value of the minimal defect is not stated	`TwistFloor.defect11_ge_two`, `defect11_uniform_half`, `Smin` `QuadFloor.quad_floor_two`, `FlatStokes.approx_torus_comm`
21-07	With the lattice fixed, the vortex ratio approaches 1 as the coupling grows. Its values lie above −1 and at most 1	With the size of the lattice fixed. The constant of the lower bound depends on the size of the lattice and has no explicit value. Nothing is said about the speed being uniform in the size of the lattice	`ThetaLimit.tendsto_theta_one` `Z10_ge`, `volV_pos`, `ratio_ter` `theta_gt_neg_one`, `theta_le_`
21-07	Slope of the flux free energy: the log ratio of the two twisted partition functions, divided by the coupling, approaches the minimal defect	The limit of large coupling with the size of the lattice fixed. In a symmetric box the limit is at least 1/2. No uniform estimate at finite coupling is stated	`ThetaLimit.tendsto_logratio_` `TwistFloor.logratio_limit_ha`
21-07	Tuning the vortex ratio: for every target value at least 0 and less than 1 there is a coupling that makes the vortex ratio equal to it, and the set of solutions has a largest element	With the size of the lattice fixed. If the target is positive, the largest solution is positive too. Monotonicity, uniqueness of solutions, and sequences moving the transverse size and the coupling together are not stated	`ThetaLimit.tuning_all`, `tuni` `exists_theta_gt`, `sanity_hal` `envelope_max_sol`
14-02	Block map of the side-3, centred design: a coarse link is made as the uniform average over a family of paths through the centre of the block (definition)	1944 path indices, weights summing to 1. Not the design of the main line of this book's study (side 2)	`Block3.paths`, `wts`

Chapter	Theorem or definition	Scope	Lean declaration
14-02	Same: the map commutes with reflections in planes through lattice sites without a gauge transformation, and flipping the signs of the links crossing a section flips only one coarse link	One step and all steps, with values in the sphere	`Block3.blockMap_refl_cfg`, `d` `down_flipSet`, `down_local`
14-02	Same: reflection positivity, in planes through lattice sites, of the pushed-forward Wilson measure	The SU(2) Wilson measure (normalised or not) pushed forward by a composite of several steps of the side-3 map, all real β, bounded measurable functions depending only on coarse links strictly between the two planes through the coarse lattice sites at the ends (gauge invariance not imposed). The version with the plane through the middle of the links, infinite volume and the mass gap are not stated	`Block3.rp_push`, `rp_push_pro`
14-02	Same: the map commutes with coarse translations and with reflections in boundary planes	One step and all steps. Within the lattice symmetries	`Block3.blockMap_trans`, `down`
14-02	Same: existence of a tuned sequence. The expectation of the coarse plaquette average of the pushed-forward measure is 0 at coupling 0 and approaches 1 as the coupling grows, and at each step there is a non-negative coupling tuned to a target value in between	On the side-3 design, retract threshold at most 1, side of the coarse lattice at the tuned step at least 2, target value at least 0 and less than 1 (the assumptions are only the values of the design and arithmetic). Monotonicity, divergence and uniqueness of the coupling are not stated	`Block3.Y3_zero`, `tendsto_Y3_`
10-01	In the book's current design (side 2), the expectation of the coarse plaquette average of the pushed-forward measure is continuous in the coupling, and for a target between its values at two couplings there is a solution	For each step and each coarse plaquette. That a tuned sequence exists at all steps is not stated by these two	`TunedCoupling.continuous_Yc`

Chapter	Theorem or definition	Scope	Lean declaration
9-05	In the book's current design (side 2), the pushed-forward Wilson measure is invariant under coarse translations	No assumption on the sequence of couplings. For each step, when the fine-side step is taken sufficiently large, for bounded continuous functions	`TunedCoupling.hsym_translati`

What this chapter can say

What is said	What is not said
The output of Table 1, Table 2 and Figure 1 is exactly the result of checking seven small files with Lean 4.33.1 and Mathlib (the version in Table 7) on this machine.	We do not say that other versions give the same output. In particular the names of the axioms for `native_decide` change with the version.
The Lean label guarantees the arrow from premises to conclusion (formula (1)). `sorry` passes with only a warning, and is found by `#print axioms` (Table 2).	This appendix does not confirm the soundness of Lean's logic itself, or that the kernel has no bugs (the kernel-recheck step and the isolated-comparison step in the sense of the reference manual were not carried out for the examples of this appendix).
Of the four gaps, name and vacuous truth were shown with examples that actually pass (the last two rows of Table 2).	This appendix does not confirm that the individual theorems of this book have no gaps. Read the premises and readings in each row of 23-13.
The words of lattice gauge theory (Wilson loop, plaquette, Yang–Mills and so on) do not appear in the source of Mathlib on this machine.	The absence of a word is not a proof that the same content is not defined under another name.
How the labels are decided (Figure 2, Table 5) is a restatement of this book's conventions.	A label shows the kind of guarantee; it is not a ranking of the importance or plausibility of sentences.
The Lean theorems of this book show neither the existence of four-dimensional Yang–Mills theory nor the mass gap (23-16). Four-dimensional existence was shown by a construction published in 2026, and the committee's assessment is that it is proved in Lean (6-00). The mass gap has not been shown.	

Sources and reproduction

Item	Kind	Source / tools
Table 1, Figure 1 (the states of the goal)	Computed	Lean 4.33.1 + Mathlib: `e1_gap.lean` (with `trace_state` after each step) checked with `run.sh`, and the output copied

Item	Kind	Source / tools
Table 2 (exit codes, warnings, axioms and times of the seven files)	Computed	python3: `table.py` checks the seven files `e1` – `e7` in turn with `run.sh` and keeps them in `results.json`. The seconds column is from that one run
The observation in the detour "Using real numbers brings out the three axioms"	Computed	Lean 4.33.1 + Mathlib: `e8_real_probe.lean` (an empty theorem, and `#print axioms` on `Real`, `CauSeq.Completion.Cauchy`, `Real.instZero` and so on)
Word counts in the source of Mathlib	Computed	`mathlib_grep.sh` (a case-insensitive search of 8,311 files)

Next chapter to read: A-05 How this book was made — how sentences and numbers were checked before labels were attached.

How this book was made — labels and source tables record how far a sentence was checked

This chapter is a guide (how this book was made and checked).

What this chapter shows — The seven stages a sentence passes through before it appears in the text, and what each stage catches and does not catch (Figure 1).
The meaning of "text", "abstract" and "bibliographic data only" in the source tables, and that about half of the verdicts in the refutation check were corrections (with tables counted on this machine).
The convention for the label "Computed", the stage that aligns symbols and names across chapters, the mechanical checks of assembly, and what this procedure does not guarantee.

Prerequisite chapters — None. It is easier to read after looking at the legend of the labels (0-01). The procedure of machine checking with Lean is not dealt with in this appendix; it is in A-04.

Said first — What this appendix explains is a procedure for reducing errors, not a guarantee of correctness. This book has not been through expert peer review. Also, no step of this book shows the existence or the mass gap of four-dimensional Yang–Mills theory. Four-dimensional existence was shown by a construction published in 2026, and the committee's assessment is that it is proved in Lean (6-00). The mass gap has not been shown.

The order of this chapter

1. The role of this appendix — labels and source tables are a graduation for measuring how far one may believe; the procedure that marked that graduation
2. The road a sentence travels — seven stages, and what each catches and does not catch (Figure 1, Table 1)
3. Cross-checking against primary sources — three levels: text, abstract, bibliographic data only (Table 2); Detour: writing in the form of hearsay
4. Looking for refutations — another reader checks "is this too strong?"; the breakdown of verdicts and the types of correction (Tables 3 and 4)

5. Making computations reproducible — the label "Computed" covers a finite range; write the conventions; a scale that finishes in minutes
6. Attaching labels — a record of how far a sentence passed; the composition of labels by part (Figure 2, Table 5)
7. Aligning across chapters — five things: symbols, conventions, names, duplication, degree of certainty
8. Assembling and checking mechanically — pre-rendering of formulas, links, forbidden words (Table 6)
9. What this procedure does not guarantee — not peer review; texts not obtained; finite computations; problems that remain open

---

01

The role of this appendix — so that readers can measure for themselves how far to believe

Sentences in textbooks tend to be written on the premise that readers will believe them as they are. This book does not do that. Each sentence carries a label (the legend in 0-01), the source tables write "whether the text was read", "only the abstract" or "only the bibliographic data", and computations are kept in a form that can be reproduced at hand. Labels and source tables are a graduation with which readers can measure for themselves "how far this sentence may be believed". Precisely, a label is a record of how far a sentence was checked, not a number expressing a degree of correctness.

A graduation cannot be read unless the procedure that marked it is known. For example, even for a sentence labelled "Known", the weight differs according to whether it was checked word for word against the text of a primary source or copied from the description in a review. This appendix explains that procedure from the reader's side. Stage by stage, it writes what was checked and what was not.

The flow in one line:

research → cross-check against primary sources → look for refutations → reproduce com

Each of the seven stages is placed to catch what the previous stage overlooks. But no stage guarantees "correctness". What is not guaranteed is collected in § 09.

Example. The sentence of Part 5 that "the Wilson action has reflection positivity" carries the label "Known", and the source table lists the paper of Osterwalder–Seiler (5-03). The label "Known" shows that it is a known result checked in a primary source. The depth to which it was checked (text, abstract, bibliographic data only) is written in

the source table, and the source table for this example says "abstract checked, text not checked". Whether it passed the refutation check (§ 04) is not distinguished by the label. If the source table says "bibliographic data only", the cross-checking stopped at the level of bibliographic data.

The procedure of machine checking with Lean is not dealt with in this appendix. It is in A-04. How labels are decided (one label per sentence; the strength of a chain is its weakest stage) also has its master copy in A-04 § 07.

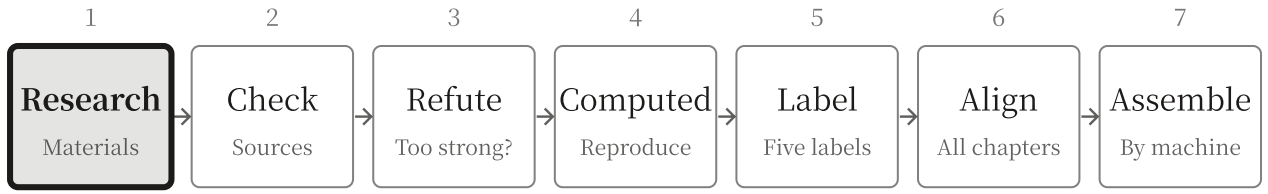
02

The road a sentence travels — seven stages

Figure 1 lines up the stages a sentence passes through before it appears in the text. Moving the knob shows below what that stage catches and what it does not.

The order of the steps has reasons. If the refutation step (step 3) were placed before the cross-checking step (step 2), the refuting side would not know what to compare against. The label step (step 5) comes after the cross-checking step and the reproduction step because a label is a record of "which step it passed up to". The consistency step (step 6) and the assembly step (step 7) are steps for errors that cannot be caught by looking at one chapter at a time, and are run each time a part is complete (and finally for the whole book).

Figure 1 Choosing a stage with the knob shows below what that stage catches and does not catch. The frame of the chosen stage becomes thicker



What the previous stage overlooks, the next stage catches

```
Step 1/7 Research. Catches: Literature on each topic, known results, candidate numbers. Misses: Whether the candidates are correct (here candidates are only collected).
```

Table 1 has the same content as Figure 1 (the figure is schematic and contains no numbers).

Table 1 What the seven stages catch and do not catch

Stage	Name of the stage	What it catches	What it does not catch
1	Research (survey step)	Literature on each topic, known results, candidate numbers	Whether the candidates are correct (here candidates are only collected)

Stage	Name of the stage	What it catches	What it does not catch
2	Cross-check against primary sources (cross-checking step)	Errors in bibliographic data, over-paraphrased citations, misattribution	Errors in the primary sources themselves, the content of texts that could not be obtained
3	Look for refutations (refutation step)	Wording stronger than the source, promotion of the degree of certainty, omitted conditions	Cases where the cross-checking reader and the refuting reader share the same misunderstanding
4	Reproduce computations (reproduction step)	Miscopied numbers, mixed-up conventions, counterexamples within a finite range	Whether it holds outside the range computed
5	Attach labels (label step)	Mixing of "proved", "conjecture" and "numerically supported"	Errors in the judgement of the label itself
6	Align across chapters (consistency step)	Discrepancies in symbols, names and conventions; the same name pointing to different sentences; duplication	All chapters being wrong in the same direction
7	Assemble and check mechanically (assembly step)	Formulas that cannot be rendered, broken links, forbidden words, unfilled placeholders	Errors of content (the machine does not read meaning)

03

Cross-checking against primary sources — three levels: text, abstract, bibliographic data

What this book calls a "primary source" is the paper that first stated a result, or the problem statement itself. Reviews and textbooks are used as guides to the primary sources, not as substitutes for them. Years and attributions (who showed what, when) are not written from memory but checked in the sources.

Cross-checking has three levels of depth, and the source table writes which level was reached.

Table 2 Depth of cross-checking, and how it is written in the source tables

Depth	What was read	How it is written in the source table	What can be written in the text
Text checked	The text of the paper (a public PDF or the like) was read, and the relevant passage checked word for word	Authors, year, journal or arXiv number, section	Exactly the strength stated by the source

Depth	What was read	How it is written in the source table	What can be written in the text
Abstract checked	Only the abstract (the abstract in a literature database) was read	As above + "checked in the abstract", "abstract only" and so on (the wording differs slightly by chapter)	As far as is written in the abstract
Bibliographic data only	Only that the authors, title, journal and year exist was checked	"Bibliographic data only"	As far as the form in which another source reports that "... did ..."

Word-for-word checking is the work of confirming by search that the original text enclosed in quotation marks exists literally in the source. Even when a translated sentence is placed in the text, the cross-checking is done on the original.

Example. The problem statement of the Clay Institute (Jaffe–Witten) was cross-checked in the text of the public PDF. The requirement of the problem, in the original, is as follows.

> “Prove that for any compact simple gauge group G, a non-trivial quantum Yang–Mills theory exists on $\mathbb{R}^4$ and has a mass gap $\Delta > 0$.”

0-03 reads this sentence word by word. Because it was cross-checked in the text, 0-03 can use each of the words "existence", "non-trivial" and "mass gap" at the strength of the problem statement.

On the other hand, for papers of which only the abstract could be read, claims in the abstract are written as "checked in the abstract", and claims not in the abstract are not brought into the text. The same goes for section numbers: if the abstract does not mention sections, which section something is written in is not known until the text is read.

Example. The abstract of the review by Wilson–Kogut (Phys. Rep. 12 (1974) 75) is a single sentence and does not mention sections. So this book does not write that some topic "is discussed in § 10 of Wilson–Kogut", and writes " § 10 not checked" in the source table.

Detour: writing in the form of hearsay

You may skip this. That the upper limit on the spacetime dimension in which supersymmetry can be realised with fields of spin at most 2 (supergravity, including the graviton) is 11 is widely known as a consequence of Nahm's 1978 classification. Yet the number 11 does not appear in the abstract of that paper. While the text cannot be obtained, this book writes "known as a

consequence of Nahm's classification", and does not attribute the conclusion directly to Nahm's paper (17-05). It is not that the fact is doubtful. It is to show honestly, in the form of the sentence, how far this book checked. Precisely, the form of hearsay is not a mark that "it may be wrong" but a mark that "the cross-checking did not reach the text, and the abstract does not contain the number".

04

Looking for refutations — another reader checks "is this too strong?"

Material that has been cross-checked is handed to another reader. That reader's job is not confirmation but refutation. Going back to the primary sources once more, they look for "is this sentence stronger than what the source says?", "it was written as settled, but does it not need a condition?", "does this bibliographic entry exist?". There are three verdicts.

- **Confirmed** (confirmed): against the source, the written strength is fine as it is.
- **Corrected** (corrected): it needs to be weakened, given a condition, or have its bibliographic data fixed. The wording of the correction is attached.
- **Unverifiable** (unverifiable): the primary source could not be reached, and neither can be said. It is lowered to the form of hearsay.

At the stage of writing chapters, the rule is to reflect every correction. Material that received a correction is not cited at its strength before the correction.

Table 3 counts the verdicts for the six materials used mainly by Parts 7 to 23 (and partly by chapters of Parts 0, 4 and 5). Many chapters of Parts 1 to 5 have not been through the materials of this refutation check.

Table 3 Verdicts of the refutation check by material (counting the materials as of 2026-10-01) Computed

Subject of the material	Confirmed	Corrected	Unverifiable	Fraction corrected
Dictionary of the physical and the mathematical vocabulary	25	20	0	44%
Extra dimensions and where gauge fields come from	16	12	1	41%
The physical view (confinement, lattice numerics, holography)	25	17	0	40%
Arrangement of this book's study	7	14	0	67%
Where things stand, dimension by dimension	25	8	0	24%
Where constructive field theory stands, and candidates for new concepts	16	29	0	64%

Subject of the material	Confirmed	Corrected	Unverifiable	Fraction corrected
Total	114	100	1	47%

How to read it. About half of the verdicts are corrections. The highest fraction of corrections is for "arrangement of this book's study": in this material corrections were many, 14 of 21, and those that weakened wording stronger than the record, or added conditions that had been dropped, stood out. Conversely, materials close to a list of theorems, such as where things stand dimension by dimension, have fewer corrections.

Table 4 sorts the content of the corrections into four types by words. The sorting is mechanical, by words appearing in the wording of the correction, and one correction may fall into several types.

Table 4 Types of the 100 corrections (mechanical sorting by words; with overlaps) Computed

Type	Cue words	Count	Typical
Strength	too strong, promoted, showed, restricted	39	Lowering "showed" to "proposed"; "settled" to "conditional"
Level of the source	abstract, text, not obtained, not checked	34	Rewriting a claim not in the abstract as "text not obtained"
Numbers and signs	number, coefficient, sign, digit	15	Adding the convention for the coefficient (which β)
Bibliographic data	bibliographic data, volume, page, author, journal	12	Corrections to the list of authors, such as a missing co-author
None of the above	—	30	Supplements, suggestions for rewording

Example. What § 6.5 of the Clay problem statement says is that "with many regularisations, such as dimensional regularisation and Pauli–Villars, reflection positivity is lost, and there are few ways to recover it"; it does not reject continuum regularisations across the board. This book cites it at this strength, and does not write "continuum regularisations do not preserve reflection positivity". What the refutation stage catches is summaries that have become one step stronger than the source in this way (regularisation and reflection positivity are in 4-10 and 5-03).

05

Making computations reproducible — the content of the label "Computed"

Of the numbers in the text, those that can be recomputed on this machine are recomputed and given the label "Computed". All computations are short programs (Python), kept chapter by chapter. Their names are written in the "tools" column of the source tables, so running the same programs gives the same tables.

What the label "Computed" means is that it was **checked on this machine, over the range written**. As a formula, having checked a property $P(n)$ for finitely many n is the distinction

$$P(n_1) \wedge P(n_2) \wedge \cdots \wedge P(n_k) \qquad \text{and not} \qquad \forall n\, P(n)$$

The left is a computation, the right a theorem. A sentence with the computed label is not cited as a theorem.

Computations have three conventions. The first is not to make numbers inside figures. The numbers in moving figures are limited to tables computed in advance and embedded, or simple formulas that can be computed on the spot (rotations, partial sums of series and so on). The second is to write the conventions. If the definition of the lattice coupling β or the normalisation of the trace tr differs, the same quantity is off by several times, so the conventions are stated in the premises of a computation (conversion between conventions is in 5-01 and A-01). The third is to keep to a scale that finishes within a few minutes on an ordinary computer. A computation that readers cannot reproduce loses the meaning of the label.

Example. Tables 3, 4 and 5 of this appendix are also computations. We wrote one program that reads the materials and chapter pages and counts, and copied its output. Over the whole book, the places where computations are kept, chapter by chapter, number over 100, and there are several hundred programs.

06

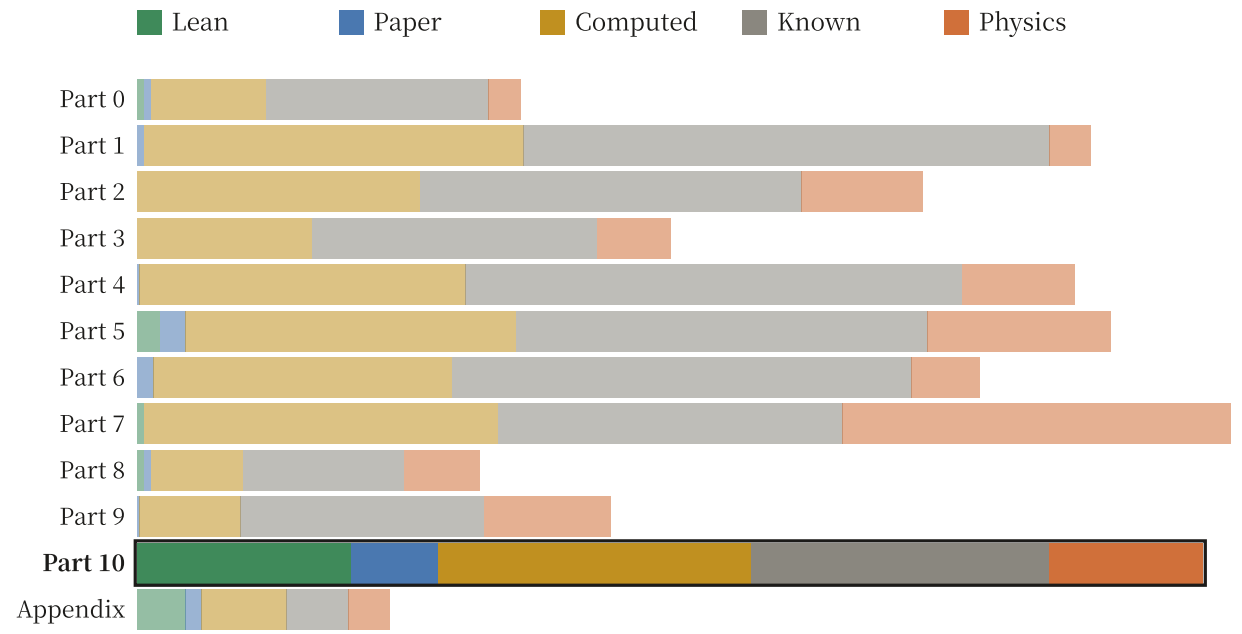
Attaching labels — a record of how far a sentence passed

A label is a record that tells readers how far a sentence passed. A sentence that stopped at cross-checking gets "Known", a number reproduced at hand gets "Computed", something accepted in physics but without proof gets "Physics", and so on. The meaning of the five labels, and what the labels do not guarantee, are in the table of 0-01 § 03.

There are two rules for attaching labels. One sentence gets one label. And for a claim connected through several stages, the label of the weakest stage is attached to the whole (A-04 § 07). For example, if numbers are put as assumptions into an inequality checked in Lean and a conclusion is drawn, the label of the conclusion is "Computed" or "Physics". Labels are not pushed towards the strong side.

Figure 2 counts, by part, the labels appearing on the chapter pages of this book. The composition of labels differs clearly from part to part.

Figure 2 Number of labels by part. "View by fraction" scales each part to 100%. Choosing a part with the knob shows its breakdown below



`Part 10 (total 464) : Lean 93 (20%) , Paper 38 (8%) , Computed 136 (29%) , Known 130 (28%) , Physics 67 (14%)`

Computed The numbers in this figure were computed on this machine (counting the chapter pages of 110 chapters as of 2026-10-01, excluding this appendix itself. Labels placed in legend tables are also counted. The numbers change as chapters are added).

Table 5 Number of labels, number of figures, and occurrences of "bibliographic data only" by part (as of 20 Computed)

Part	Chapters	Lean	Paper	Computed	Known	Physics	Figures	Bibliographic
Part 0 Entrance	4	3	3	50	97	14	8	
Part 1 Mathematical preparation	12	0	3	165	229	18	40	
Part 2 Physical preparation	10	0	0	123	166	53	28	
Part 3 Classical theory	7	0	0	76	124	32	13	
Part 4 Quantum theory	12	0	1	142	216	49	23	
Part 5 Lattice	11	10	11	144	179	80	22	

Part	Chapters	Lean	Paper	Computed	Known	Physics	Figures	Bibliographic
Part 7 Constructive field theory	12	0	7	130	200	30	24	
Part 17 From the side of physics	13	3	0	154	150	169	28	
Part 18 A dictionary of two languages	5	3	3	40	70	33	7	
Part 16 Where things stand, and open tasks	5	0	1	44	106	55	10	
Part 23 The record of this book's study	14	93	38	136	130	67	25	
Appendices (A-01, A-02, A-03, A-04, A-06)	5	21	7	37	27	18	10	
Total	**110**	**133**	**74**	**1241**	**1694**	**618**	**238**	

How to read it. Most labels are "Known" and "Computed". This is because much of this book is an exposition of known mathematics and physics, with numbers reproduced at hand added to it. "Physics" is most frequent in Part 17, because its centre is material accepted in physics but not theorems, such as mechanisms of confinement and the string picture. The "Lean" labels are concentrated in Part 23. However, many of those Lean theorems are statements about inequalities of real numbers or finite sums, and do not show the existence or the mass gap of four-dimensional Yang–Mills theory (23-16, A-04 § 06).

07

Aligning across chapters — symbols, names, conventions

Checking chapters one at a time cannot catch discrepancies between chapters. For example, if one chapter writes $\beta = 2N/g^2$ and another $\beta = 1/g^2$, each chapter may be correct on its own, but readers take them to be the same β and get lost when the numbers do not match. So each time a part is complete, a stage of reading across parts is run.

This stage looks at five things.

1. **Symbols**: whether the same symbol is used for the same quantity. The standard is the table of notation A-01.
2. **Conventions**: when the coupling β, the normalisation of the trace, or the lattice metric differs between chapters, whether a conversion is written (5-01).
3. **Names**: whether one name points to different sentences in different chapters. For example, the diffusive-relaxation-time assumption of Part 23 can be read in eight ways, according to which length it is measured in, which normalisation it is measured in, and whether it is stated as a power or a band. A name is assigned to each reading and fixed (calling the power level the diffusive-relaxation-time assumption and the band statement the band form of the diffusive-relaxation-time assumption; A-06), and other chapters link there and use the same name. The list of assumptions is in A-06.
4. **Duplication**: when the same explanation is in two chapters, make one the master copy, and reduce the other to a one-line summary and a link.
5. **Degree of certainty**: whether one chapter writes the same correspondence as "settled" and another as "conditional". In the dictionary part, correspondence as a definition (which can be settled) and actually holding in four-dimensional Yang–Mills theory (unsettled) are written in two separate columns (18-01).

When a discrepancy is found, it is aligned to one side or the other. Discrepancies that cannot be aligned (for example when conventions genuinely differ between papers) are written in the text as discrepancies.

Example. CP in Part 23 is a number that serves as a measure of the time it takes for fluctuations to be smoothed out (defined in 1-10 and 23-01). With the same symbol CP, it can point to different numbers according to which fluctuations are meant (of the field at one time, or of the whole path including the time direction). For the free field one is 4 times the square of the other, so mixing them up doubles the power. This is an example distinguished at this stage, and the whole book writes the two as different quantities (23-01).

08

Assembling and checking mechanically — what can be left to the machine

The last stage is done by machine. The tool that assembles the chapter pages does the following mechanically for all chapters, and reports what gets caught.

Table 6 Mechanical checks at the assembly stage

Check	What it looks at	What it does not look at

Check	What it looks at	What it does not look at
Rendering of formulas	Renders formulas written in TeX to static HTML with KaTeX, and reports formulas that cannot be rendered	Mathematical correctness of the formulas
Links and headings	Whether the files linked between chapters and the heading `id`s exist	Whether the link target fits the flow of the argument
Forbidden words	Whether real names, paths, internal numbers or unfilled-placeholder marks remain	The strength of wording (this is looked at by people and by the refutation stage)
Templates	Whether a class name not to be used for figure frames (`fig`) remains	The content of figures
PDF	Makes a PDF for printing for each part (moving figures go in as still images of their initial state)	Whether it is easy to read in print

Formulas are rendered at the assembly stage rather than in the reader's browser so that no JavaScript is needed on the reader's side, and so that they do not break when printed or made into PDF. Only moving figures use JavaScript, and even when JavaScript is disabled, the same content can be read in the table below the figure.

Mechanical checks do not read meaning. Passing this stage guarantees that the page is not broken, not its content. Judgements of the strength of wording, the choice of labels and the depth of sources are not left to the machine; people and the writers read them at the stages of cross-checking, refutation and consistency.

09

What this procedure does not guarantee

Errors can remain even after the seven stages. We write the limits of this book from the side of the procedure.

It has not been through expert peer review. The reader at the refutation step is a different reader from the writer, but not a referee of an academic journal. Much of the research, drafting and refutation for this book was done by the AI writers of this site; people decide the policy and read before publication. Readers of the same kind can share the same misunderstanding. What the refutation step cannot catch is exactly such errors (the "Look for refutations" row of Table 1).

The content of texts that could not be obtained has not been checked. For works marked "bibliographic data only" or "checked in the abstract" in the source tables, this book does not know what is written in the text. The count of "bibliographic data only" in Table 5 is a measure of the size of that range.

Computations cover finite ranges. Numbers with the label "Computed" are what the computations at hand gave over the range written, and say nothing outside the range or about the continuum limit (§ 05).

The mass gap problem remains open. No step of this book shows the existence or the mass gap of four-dimensional Yang–Mills theory. Four-dimensional existence was shown by a construction published in 2026, and the committee's assessment is that it is proved in Lean (Part 6). A list of what this book does not claim is in 23-16.

If you notice an error, please let us know through the board or the contact page of this site. Corrections are recorded with dates in the "Revised" field at the end of each chapter.

What this chapter can say

What is said	What is not said
That the sentences of this book appear in the text after passing through the seven stages (research, cross-checking, refutation, computation, labels, consistency, assembly). What each stage catches (Table 1)	That sentences that passed the seven stages are correct. No stage guarantees correctness
That "text", "checked in the abstract" and "bibliographic data only" in the source tables are records of the depth of cross-checking (Table 2)	What is written in the texts of works marked "bibliographic data only" or "abstract"
That in the refutation check of the materials as of 2026-10-01, of 215 verdicts, 100 were corrections and 1 was unverifiable Computed (Table 3)	That the 114 judged confirmed contain no errors. If the refuting reader and the cross-checking reader share the same misunderstanding, this stage cannot catch it
The counts from sorting the wording of corrections by words Computed (Table 4)	That the sorting classifies the content of corrections correctly (it is a mechanical classification by words, with overlaps)
The numbers of labels, figures and "bibliographic data only" in the chapter pages of 110 chapters as of 2026-10-01 (excluding this appendix itself) Computed (Table 5, Figure 2)	That the number of labels represents the weight of claims. Labels placed in legends are also counted, and the numbers change as chapters are added
What the assembly stage looks at mechanically (Table 6)	That the content of pages that passed the mechanical checks is correct
That this book has not been through expert peer review, and that much of the research and refutation was done by AI writers	—

What is said	What is not said
—	The existence and mass gap of four-dimensional Yang–Mills theory. No step of this book shows them (existence was shown by the published construction, and the committee assessed it so; the mass gap is open; 23-16)

Sources and reproduction

Item	Kind	Source / tools
Tables 3 and 4 (verdicts of the refutation check and types of correction)	Computed	`tally.py` (counts the verdicts of this book's materials and sorts the wording of corrections by words; output `tally.json`)
Table 5 and Figure 2 (numbers of labels, figures and "bibliographic data only" by part)	Computed	`tally.py` (counts `class="label …"`, figure frames and the words "bibliographic data only" on the chapter pages, excluding the inside of figures' JavaScript)
Quotation of the Clay problem statement (§ 03)	Known	A. Jaffe, E. Witten, “Quantum Yang–Mills Theory” (the official problem statement of the Clay Mathematics Institute, public PDF). Checked in the text
What the problem statement says about regularisation and reflection positivity (the example in § 04)	Known	Same, § 6.5. Checked in the text (details in 4-10)
Reflection positivity of the Wilson action (the example in § 01)	Known	K. Osterwalder, E. Seiler, “Gauge Field Theories on the Lattice”, Ann. Phys. 110 (1978) 440–471. Abstract checked, text not checked (how the text is handled is in the source table of 5-03)
An example where the abstract does not mention sections (§ 03)	Known	K. G. Wilson, J. Kogut, Phys. Rep. 12 (1974) 75–199. Abstract only (the abstract is a single sentence; § 10 not checked)
The upper limit 11 on the dimension for supersymmetry (detour)	Known	W. Nahm, Nucl. Phys. B135 (1978) 149. Abstract only. "11 is the upper limit" is not in the abstract and not checked. The upper limit carries the condition of fields of spin at most 2 (17-05)
Pre-rendering of formulas	Tool	KaTeX (a JavaScript typesetting library that renders TeX formulas to static HTML. Used only at the assembly stage; it does not run on the reader's side)
Figure 1, Tables 1, 2 and 6 (description of the procedure)	—	A summary of this book's writing conventions and assembly procedure

Next chapter to read: A-06 Index of names.

Index of names

This chapter is guide material (an index).

What this chapter shows — What the names in this book (assumptions, conditions, propositions, lemmas, theorems, statements, routes, table rows, questions) and its symbols refer to, and in which chapter each was introduced. The names and symbols given in Volume 2 (the volume that reads the published construction) are gathered in § 02; the rest are listed in § 03 in the order of the parts of their introducing chapters.

Prerequisite chapters — None. The list of symbols is A-01, and explanations of words are in A-02.

Said first — This book does not use names made only of letters or numbers; it uses names that show their content. Standard labels from the literature are added at the first occurrence of a name, in the form "(author label)". "What it refers to" is a one-line guide; the exact statement is in the introducing chapter.

Order of this chapter

1. How to use this index
2. Names and symbols of Volume 2 — conventions for names and symbols when reading the published construction (Tables 1 and 2)
3. Index of names — in the order of the parts of the introducing chapters (Table 3)
4. Eight readings of the diffusive-relaxation-time assumption — why the normalisation is named
5. Bookkeeping and exponent quantities — the one-step slope, the shortfall, the exponents
6. Assumptions of the second road and the band — name, content, status

---

01

How to use this index

1. Look things up by name. The quickest way is to search for part of a name ("relaxation time", "widening", and so on) with the browser's in-page search.

2. The "introducing chapter" in Table 3 is the chapter where the statement of that name was first placed. Later chapters may use the same object in another form, but there is one name for it across the whole book.
3. Long names are sometimes called by a short form from their second occurrence on. The short form is added in the name column of Table 3 as "(short: ...)".
4. "Kind" is one of: assumption (a premise that has not been shown), condition (a condition imposed within a statement), proposition or theorem (something shown), statement (a sentence to be shown, or a sentence in the form of a question), table row (a row of a table referred to by name), question, and so on. What has been shown and what has not is read from the labels in the introducing chapter.

02

Names and symbols of Volume 2

Volume 2 is the volume that reads the construction of four-dimensional Yang–Mills existence published on 2026-11-10 (the Lean code and the committee's assessment report). Objects of the published construction are called by names that carry their meaning, and the identifiers of the code are added as sources (6-00). There are three labels, Source (we read the source of the published construction), Inferred (this book's inference) and Assessment (from the committee's assessment report); the labels of the whole book (Proved here, Cited, Computer-assisted, Reading, Assumption, Lean) have the same meaning in all volumes. Theorems of the published construction are written with Source , and their level (the committee's assessment is that they are proved in Lean) with Assessment ("Labels" in 6-00).

Name	What it refers to	Introducing chapter
Published theorem	The statement in the form of the published question (its only assumption is that the Lie algebra of the group is simple)	6-02
Construction theorem	A stronger statement, for each penalty coefficient, that contains the published theorem as a projection	6-02
Committee's combined target	A statement in which the committee bundles independent checks on a single family, on top of the construction theorem	6-02
Headline theorems, outside the dependencies	The 17 headline theorems listed in the verification record, and the declarations not reached from any of them	6-00
Family certificate	The bundle of conditions that the construction theorem imposes on a family (renormalisation relations at all steps, local cross-sections, label templates, calibration of insertion coefficients)	6-02
Run	A construction satisfying the conditions, chosen once for each penalty coefficient. All later objects are built on this single run	6-03
Template	A finite set of offsets of lattice sites, used to make lattice representatives of local fields	8-03

Name	What it refers to	Introducing chapter
Probability kernel, predictor	One step of renormalisation: a probability kernel that draws a coarse link with Gaussian-type fluctuations around a central value (the predictor) made from the fine configuration	9-01
Representation	The fixed form in which the density of each step is written (vacuum term, main action, regular activity, gas of forced activities). Not unique	9-06
Regular activity, forced activity	The local correction terms in the representation, and the gas of corrections that exactly covers the large-field flags	9-06
Cut action, flag	The action in which the plaquette terms are cut off linearly above a step-dependent threshold, and the mark of a large field exceeding the threshold	9-07
Step coupling	The coefficient multiplying the term of the squared normalised curvature in the representation at step m. Not determined by the measure alone	10-01
Rereading	After one step, reading the coupling of the representation again from the log ratio of the densities at two configurations	10-03
Shooting method	Choosing, by nested intervals and the intermediate value theorem, the bare coupling that makes the coupling at step 0 equal to the reference value	10-04
Calendar	The bundle of conditions that chooses, in a fixed order, the constants used in the one-step estimate (sides, smoothing exponents, entry coupling and so on). Conditions uniform in the step are discharged here	10-05, 11-08
Induction hypothesis, one-step certificate	That the density at every step has a representation of the same form and carries the ledger; and making the representation at step m from the representation at step $m+1$ together with the pushforward identity	11-00
Seed, seed type, region	Each large fine plaquette, each edge deviating strongly from the prediction, and each flag (seeds); the triple of these three sets (seed type); and the condition that divides configurations by seed type (region)	11-03
Price, mark	The factor per seed, and the part of its allocation left for the exit (half of the guaranteed lower bound)	11-05
Strong estimate, weak ledger	The exit estimate of one step, $e^{-\mathrm{rate}\cdot P^2}$, and the estimate carried by the induction hypothesis, $e^{-P^{1/5}}$	11-07
Polymers with and without flags, hard and soft clusters	The way of sorting polymers, after the integration of one step, into the exit gas and the regular activity	11-06
Early representation	In the small-field step, the way of writing the expansion of the corrections into the form of the representation first	11-09
Convergence of ingredients, anchor, forgetting the top end, the step-removing step	The parts that give convergence of the cutoff limit at fixed step (uniform convergence of the ingredients, an anchor of uniqueness, vanishing of the influence of the fine-side end, and one step that passes from step 0 to the limit)	11-10

Name	What it refers to	Introducing chapter
Slice, thread, inner function	In reflection positivity: the configuration of links in one layer (slice), the set of links joining layers (thread), and a bounded gauge-invariant function depending only on the inside of a band (inner function)	12-01
Chessboard root, centred tiling	The expectation of the product of a function copied to all boxes, raised to the power one over the number of boxes (a seminorm); and the tiling that puts the reference box in the middle of the observation points	12-02
Column	An arrangement placing a block and its mirror image alternately around the time circle (the chessboard transcribed in the time direction)	12-04
Zero-energy space, phase measure	The subspace $\ker H$ fixed at all times, and the probability measure that splits a mixed theory into phases	12-07
Order bundle	The input bundling the choice of kernel, the step constants of fine and coarse steps, the number of convolutions of the block weights, and so on (`Teller` in the source)	11-04
Extraction sequence	The pair of a subsequence of cutoffs and a subsequence of volumes (`Extraction.Order` in the source). Used in the two-stage Arzelà–Ascoli extraction	12-03
Minimal defect of the twisted box	The lower bound $D_{\min}(N, M)$, over the whole twisted box, of the loss from the maximum of the action to the actual action. A different quantity from the minimal vortex action	21-07

Table 1 The main names given in Volume 2 (and one name from a new chapter of Volume 3). Explanations of the words are also in A-02.

Symbol	What it refers to	Introducing chapter
s	The one-loop slope $s = 11C_g/(24\pi^2)$ ($2b_0$ in the assessment report, `slopeConstant` in the source). Each time the lattice is made one step coarser, the coupling decreases by about $s \log b$	10-01
κ	The one-step slope of Volume 3, $\kappa = 11/(3\pi^2)$ (SU(2)). The coefficient in the one-step bookkeeping $\beta \mapsto \beta - \kappa(\ln b - \delta(b))$ for a step coarsening by a factor b. For SU(2), $C_g = 8$ and $s = 11 \cdot 8/(24\pi^2) = 11/(3\pi^2)$, so κ and s are the same number, and both are the coefficient of the logarithm in the decrease of the coupling over one step Proved here (this book's $\beta = 4/g^2$ and the published construction's $\beta = 1/g^2$ are the same number for SU(2), 8-01)	23-02, 10-01
C_g	The Casimir constant ($2N^2$ in the defining representation of SU(N))	8-01
$\bar\beta$, $\hat\beta_m$	The reference value of the coupling at step 0, and the one-loop running $\hat\beta_m = \bar\beta + s \log D_m$	10-01
c_{pen}	The penalty coefficient of the probability kernel (`kernel.penalty` in the source text)	9-01
cE	The constant of the energy per seed	11-04
c_{sup}	The covering exponent	11-01

Symbol	What it refers to	Introducing chapter
σ	The chordal distance (given a different letter so as not to be confused with the slope s)	11-01
$\kappa 0$	The tuning target value (the value to which the vortex ratio or the expectation of the coarse plaquette average is tuned, $0 \le \kappa 0 < 1$)	19-07, 14-03
$\mu_{N,p}^{\mathrm{W}}$, μ_{β}^{W}	The Wilson lattice measures of the published construction	8-01
μ	The phase measure (`phaseMeasure` in the source; ν in the assessment report). This book's infinite-volume limiting measure at strong coupling stays ν_β	12-07
σ_A	The spectral measure of the state A	12-08
τ	The Euclidean time of the heat estimate	6-04

Table 2 Symbols of Volume 2. The full list of symbols is in A-01.

03

Index of names

The entries are listed in the order of the parts of their introducing chapters, and within a part in the order in which they appear in the text. A row whose "What it refers to" is empty is one for which the introducing chapter does not yet have a one-line statement of its content.

Part 0 Entrance — how to read this book

Name	Kind	What it refers to	Introducing chapter
local-field footnote · weak-existence footnote (footnotes of Jaffe–Witten) (short: local-field footnote · weak-existence footnote)	Name from the literature	Two footnotes of the problem statement (Jaffe–Witten): asking for a correspondence between local fields and quantum operators / not accepting as a solution a weak existence obtained from compactness alone	0-03

Part 2 Physical preparation

Name	Kind	What it refers to	Introducing chapter
Maxwell equations with sources	Name	The two equations by which charges and currents produce fields (Gauss's law and the Ampère–Maxwell law)	2-03
source-free Maxwell equations	Name	The two equations constraining the form of the fields (absence of magnetic charge and Faraday's law of induction). They hold automatically from the potential representation	2-03
potential representation	Name	The formulas writing E and B in terms of potentials	2-03
dynamical exponent (symbol kept)	Name	The exponent z when the relaxation time grows as a power of the correlation length, C_P ≍ ξ^z (together with η_dyn = 2 − z)	2-10

Name	Kind	What it refers to	Introducing chapter
gauge-transformation formula	Formula	A relabelling of the potentials that leaves the electric and magnetic fields unchanged (a transformation changing ϕ and A simultaneously by a single function χ)	2-03
Euler–Lagrange equation	Formula	The equation of motion obtained from the condition that the action is stationary (obtained by a variation with fixed ends and one integration by parts)	2-01

Part 4 Quantisation

Name	Kind	What it refers to	Introducing chapter
states-and-symmetry axiom (Wightman axioms) (short: states-and-symmetry axiom)	Name from the literature	States are elements of a separable Hilbert space, on which the Poincaré group acts as a strongly continuous unitary representation	4-09
spectral condition (Wightman axioms) (short: spectral condition)	Name from the literature	The joint spectrum of $P^\mu = (H, \boldsymbol{P})$ lies in the forward light cone V_+ (energy is never negative)	4-09
uniqueness of the vacuum (Wightman axioms) (short: uniqueness of the vacuum)	Name from the literature	There is only one unit vector Ω (the vacuum), up to phase, invariant under the spacetime transformations U	4-09
field axiom (Wightman axioms) (short: field axiom)	Name from the literature	Fields are operator-valued tempered distributions (for each test function $f \in \mathcal{S}(\mathbb{R}^4)$, $\phi(f)$ is defined on a dense domain containing the vacuum)	4-09
covariance (Wightman axioms) (short: covariance)	Name from the literature	Moving a field by the unitary operator of a Poincaré transformation gives the field with the test function moved by the same transformation (there is no special coordinate system)	4-09
local commutativity (Wightman axioms) (short: local commutativity)	Name from the literature	If the supports of f, g are spacelike separated, then $[\phi(f), \phi(g)] = 0$ (no influence faster than light)	4-09
cyclicity (Wightman axioms) (short: cyclicity)	Name from the literature	Linear combinations of products of fields applied to the vacuum, $\phi(f_1)\cdots\phi(f_n)\Omega$, are dense in $\mathcal{H}$ (there are no states unrelated to the fields)	4-09
regularity (Osterwalder–Schrader axiom E0) (short: regularity)	Name from the literature	Schwinger functions are tempered distributions on test functions vanishing where points coincide (used together with the linear-growth condition)	4-10
Euclidean covariance (Osterwalder–Schrader axiom E1) (short: Euclidean covariance)	Name from the literature	Schwinger functions are unchanged by Euclidean rotations and translations	4-10

Name	Kind	What it refers to	Introducing chapter
reflection positivity (Osterwalder–Schrader axiom E2) (short: reflection positivity)	Name from the literature	The quadratic form of correlations between past and future, with a time reversal in between, is never negative (the condition for the theory to have a Hilbert space)	4-10
permutation symmetry (Osterwalder–Schrader axiom E3) (short: permutation symmetry)	Name from the literature	Schwinger functions are unchanged by permutations of the points	4-10
clustering (Osterwalder–Schrader axiom E4) (short: clustering)	Name from the literature	The correlation of two groups of points pulled apart splits, at large distance, into the product of the separate correlations (corresponds to uniqueness of the vacuum)	4-10
Counterterm Uniqueness Theorem (Theorem B of Costello) (short: Counterterm Uniqueness Theorem)	Name from the literature	Once the renormalisation scheme is fixed, local counterterms can be chosen uniquely and the limit of the effective action exists	4-05
Classification Theorem for Families of Effective Actions (Theorem C of Costello) (short: Classification Theorem for Families of Effective Actions)	Name from the literature	Local actions correspond one-to-one to families of effective actions (with the scheme fixed)	4-05

Part 5 Lattice gauge theory

Name	Kind	What it refers to	Introducing chapter
lattice area-law problem (Chatterjee's Problem 4.1) (short: lattice area-law problem)	Name from the literature	The problem of showing the area law for Wilson loops at all β in four-dimensional lattice gauge theory with a non-abelian compact group	5-02, 16-07
Theorem from Uniform Decay to the Area Law (Theorem 2.4 of Chatterjee 2021) (short: Theorem from Uniform Decay to the Area Law)	Name from the literature	If a lattice gauge theory has uniform exponential decay under arbitrary boundary conditions, then centre symmetry is unbroken, and Wilson loops in representations on which the centre acts non-trivially obey the area law	5-10
definition of unbroken centre symmetry (Definition 2.1 of Chatterjee 2021) (short: definition of unbroken centre symmetry)	Name from the literature	The theory on a slab is invariant under centre transformations under every boundary condition (centre symmetry is not broken)	5-10
definition of strong decay (Definition 2.3 of Chatterjee 2021) (short: definition of strong decay)	Name from the literature	Correlations decay exponentially, uniformly over every cube and every boundary condition	5-10

Name	Kind	What it refers to	Introducing chapter
Strong-Coupling Uniqueness Theorem · Exponential-Decay Corollary (labels of Shen–Zhu–Zhu) (short: Strong-Coupling Uniqueness Theorem · Exponential-Decay Corollary)	Name from the literature	Under the strong-coupling condition, the invariant measure of stochastic quantisation (the Langevin equation) is unique and has an infinite-volume limit, and correlations decay exponentially (a set of assumption, theorem and corollary)	5-04

Part 7 Constructive field theory

Name	Kind	What it refers to	Introducing chapter
six steps of construction	Table row	The six steps of the work of building a quantum field theory (regularisation, finite volume, ultraviolet limit, infinite volume, axioms, uniform gap)	7-01
regularisation step	Table row	Cutting off short distances, by a lattice or otherwise	7-01
finite-volume step	Table row	Building the finite-volume measure μ_{a,L}	7-01
ultraviolet-limit step	Table row	The ultraviolet limit $a \to 0$ and uniform estimates	7-01
infinite-volume step	Table row	The infinite-volume limit $L \to \infty$ and clustering	7-01
axiom step	Table row	The limit satisfies the OS axioms (reflection positivity)	7-01
uniform-gap step	Table row	A mass gap uniform in the volume	7-01
level of perturbation theory	Table row	Computation as a power series in the coupling (perturbation theory). The premise of the levels of control	7-07
level of uniform estimates	Table row	The level at which estimates uniform in the lattice spacing are obtained (Bałaban's main four-dimensional theorem reaches this far, with assumptions)	7-07
level of subsequential limits	Table row	The level at which, from uniform estimates, a limit can be taken along a subsequence of a sequence of finer lattice spacings	7-07
level of uniqueness	Table row	The level at which the limit is determined uniquely, independently of the choice of subsequence	7-07
level of symmetry and reflection positivity	Table row	The level at which the limiting theory has Euclidean symmetry and reflection positivity	7-07
level of non-triviality	Table row	The level at which the limit is not a free (Gaussian) field. The problem statement further asks that the short-distance behaviour agree with the predictions of asymptotic freedom	7-07

Name	Kind	What it refers to	Introducing chapter
level of infinite volume	Table row	The level at which the limiting theory with infinite volume exists	7-07
level of a uniform gap	Table row	The level at which there is a mass gap uniform in the volume	7-07
obstacle of the infrared parameter	Table row	The obstacle that at long distances the coupling is strong and there is no small parameter to expand in	7-11
obstacle invisible to perturbation theory	Table row	The obstacle that there are contributions (of the form e^{−c/α}) that appear at no order of the power series in the coupling	7-11
obstacle of non-triviality	Table row	The obstacle that it must be shown separately that the limit does not collapse to a free field (non-triviality)	7-11
obstacle of the curved state space	Table row	The obstacle that the space of fields (the space of gauge orbits) is curved, and the signed sum of gauge fixing becomes 0 (0/0 remains)	7-11
obstacle of positive regularisation	Table row	The obstacle that, apart from the lattice, there are few regularisations that preserve reflection positivity	7-11
obstacle of infinitely many degrees of freedom	Table row	The structure of infinitely many degrees of freedom: the obstacle that as the volume grows, the overlap of different vacua tends to 0	7-11
Marginal-Triviality Theorem and others (labels of Aizenman–Duminil-Copin) (short: Marginal-Triviality Theorem and others)	Name from the literature	A set of results of Aizenman–Duminil-Copin: the scaling limits of four-dimensional ϕ^4 and Ising are Gaussian (Theorem 1.2), an improved tree-diagram upper bound (Theorem 1.3), an error estimate for the characteristic function (Proposition 1.4)	7-08

Part 15 Record of the attempts at ultraviolet control

Name	Kind	What it refers to	Introducing chapter
ultraviolet control	Condition	Keeping, at every step from the lattice spacing a to the scale L_0 where the coupling is small, the effective density in the same step-independent form, with the three conditions of small-field analyticity, large-field rarity and the coupling staying small	15-00
small-field analyticity condition	Condition	The localised correction E_k(X,·) of each step is analytic in a complex neighbourhood of radius r of the background-field variables, with $\lvert E_k\rvert \le C\, e^{-\kappa d}$ (constants independent of the step k and the lattice spacing a)	15-00

Name	Kind	What it refers to	Introducing chapter
large-field rarity condition	Condition	The large-field factor satisfies $\|R_k(\Omega^c)\| \le e^{-c\, p(g_k)^2\, \|\Omega^c\|}$ (constants independent of the step and the lattice spacing)	15-00
condition that the coupling stays small (short: the coupling stays small)	Condition	The sequence of effective couplings $g_0,\dots,g_K$ all lies in $(0,\gamma]$ (γ independent of the step and the lattice spacing)	15-00
three ultraviolet conditions (twisted-box version)	Condition	Ultraviolet control stated up to the last step of the twisted M^4 lattice, with constants depending only on M	15-02
class-closure condition	Condition	The number of parameters is finite independently of the step, and the main part of the one-step map returns into the family. The class is taken to be the one-parameter class into which the one-step map pulls (a fixed form of coupling $B + O(1/B)$)	15-03
coupling-flow remainder condition	Condition	The β component of Φ satisfies $\beta_{k+1} = \beta_k - 8\, b_0 \ln L + O(1/\beta_k)$ (the net one-step bracket of the coupling written in the variable β)	15-03
shape remainder condition	Condition	$\| r_{\theta_k}[\rho_k] \|_{G_{k+1}} \le (1+\eta_k)\, 2^{\|B\|}\, \| \rho_k \|_{G_k}$ with $\sum \eta_k < \infty$, and the deviation from the class ρ_k stays uniformly bounded in the step	15-03
definition and continuity of the effective coupling (short: continuity of the coupling)	Condition	On $D_k = \{g_0 : g_0,\dots,g_k \in (0,\gamma_1]\}$, the map $g_0 \mapsto g_{k+1}(g_0)$ is continuous	15-03
net one-step bracket of the coupling	Condition	$1/g_{k+1}^2 = 1/g_k^2 - b + r_k$, $\|r_k\| \le C\, g_k^2$ (the change of the coupling at each step deviates from the one-loop value b only by $O(g_k^2)$)	15-03
small-field contribution to the coupling	Condition	The part of the remainder of the net one-step bracket of the coupling conditioned on small fields, $r^{\text{small}} = b(\rho_S) - \beta_{\text{pred}}$ (local part + Taylor truncation + small-field cut + explicit quadratic inter-block term)	15-03
large-field contribution to the coupling	Condition	The large-field part of the remainder of the net one-step bracket of the coupling, $r^{\text{large}} = b(\rho) - b(\rho_S)$	15-08
Coupling-Smallness Induction Lemma	Lemma	Under the net one-step bracket of the coupling and the definition and continuity of the effective coupling, for every $\gamma_0 \in (0,\gamma_1)$ there is a bare coupling g_0 with $g_0 < g_1 < \dots < g_n = \gamma_0$ (monotonicity and intermediate values; the condition that the coupling stays small is split into these two)	15-03

Name	Kind	What it refers to	Introducing chapter
Background–Fluctuation Decomposition Lemma	Lemma	In SU, $\| U_{\partial p} - 1 \| \le \| W_{\partial p} - 1 \| + \sum \| A_{l_i} \|$, and its squared version (decomposition into background × fluctuation, U = W e^A)	15-07
Splitting of the Weight	Corollary	$G_c(X, W e^A) \le G_c(X, W)^2 \exp(48c \sum \| A_l \|^2)$	15-07
Lemma on One Step with Background-Independent Fluctuations	Lemma	If the law of the fluctuations ν does not depend on the background and satisfies the background-independence condition for fluctuations, the scale-contraction condition and the exponential-moment condition for fluctuations, then $\| \theta_\nu K \|_{G_{h+}} \le 2^{|B|} \| K \|_{G_h}$ (one step only; no loss in exchanging the expectation and the seminorm)	15-07
background-independence condition for fluctuations	Condition	ν does not depend on the background W	15-07
scale-contraction condition	Condition	$h_+^2 \le h^2/2$ (the scale of the next step is at most half)	15-07
exponential-moment condition for fluctuations	Condition	$M_\nu(8qc/h^2, X) \le 2^{|B|}$ (exponential moment of the fluctuations)	15-07
One-Link Heat-Kernel Comparison Lemma	Lemma	Bounds the single-link Wilson law μ^b of SU(2) by $K(b,\theta_0)$ times the heat kernel $p_{1/b'}$ inside the angle bound θ_0, and by a rare tail outside it	15-07
One-Link One-Step Fluctuation Lemma	Lemma	The chain of the Lemma on One Step with Background-Independent Fluctuations also goes through for a single Wilson link, and the loss splits into K (on the side of the closure under the fluctuation expectation) and 1+η (the movement of the coupling)	15-07
recentring condition	Condition	A condition that assumes the angle of the background plaquette is at most $\theta_0 < \pi/2$, together with the geometry of recentring (the Taylor radius of the map to the direction of the sum of staples)	15-07
group version of the exponential moment of fluctuations	Condition	For all small-field backgrounds W and $0<t\le t_0$, $E_{\mu_{k,W}} \exp((48tc/h_k^2) \sum \| A_l \|^2) \le 2^{|B|}$ (for the true fluctuation measure)	15-07
background-regularity condition	Condition	For W in the image of the background map, $G_k(X,W)^{2t} \le G_{k+1}(X,W)$ (fine curvature is bounded by coarse curvature)	15-07
group version of exchanging the expectation and the seminorm	Condition	$\| E \theta_W F \|_{T_W(h_{k+1})} \le (1+\eta_k) E \| F \|_{T_{We^A}(h_k)}$, $\sum \eta_k < \infty$ (the group version of exchanging the expectation and the seminorm)	15-07

Name	Kind	What it refers to	Introducing chapter
product factorisation ((i) of BBS) (short: product factorisation)	Name from the literature	The first of the four properties of the weight (regulator) of BBS Appendix A.6.2: on disjoint sets the weight splits into a product	15-01
submultiplicativity in sums of fields ((ii) of BBS) (short: submultiplicativity in sums of fields)	Name from the literature	The second of the four properties of the weight: for sums of fields, $\tilde{G}(X,\phi+\phi') \leq \tilde{G}^2(X,\phi)\tilde{G}^2(X,\phi')$	15-01
closure under the fluctuation expectation ((iii) of BBS) (short: closure under the fluctuation expectation)	Name from the literature	The third of the four properties of the weight: taking the expectation over fluctuations, the weight closes with the weight of the next step	15-01
monotonicity to the next step ((iv) of BBS) (short: monotonicity to the next step)	Name from the literature	The fourth of the four properties of the weight: the weight of the current step is bounded by the weight of the next step	15-01
One-Step Bound on the Activity Norm (Lemma A.6.1 of BBS) (short: One-Step Bound on the Activity Norm)	Name from the literature	If the weight satisfies submultiplicativity in sums of fields, closure under the fluctuation expectation and monotonicity to the next step, then $\| E_+\theta K \|_{\tilde{G}_+} \leq 2^{\|B\|} \| K \|_{\tilde{G}}$ (for flat fields the activity norm stays within a factor $2^{\|B\|}$ over one step)	15-01
inequality exchanging the expectation and the seminorm ((A.6.5) and others of BBS) (short: inequality exchanging the expectation and the seminorm)	Name from the literature	Formulas of BBS Appendix A.6: the inequality exchanging the fluctuation expectation and the seminorm (together with the definition of the norm and how the properties of the weight are applied)	15-02
Conditional Ultraviolet Stability Theorem (Theorem 1 of Bałaban 1989) (short: Conditional Ultraviolet Stability Theorem)	Name from the literature	If one assumes that the effective coupling stays small, then the form of the effective density and the estimates of small-field analyticity and large-field rarity hold at all steps (four dimensions, finite volume)	15-02
basic inequality (unpublished) (Theorem 2 of Bałaban 1989) (short: basic inequality (unpublished))	Name from the literature	The inequality for removing the assumption of the Conditional Ultraviolet Stability Theorem (that the coupling stays small). Unpublished	15-02
Orbit-Direction Flatness Proposition	Proposition	At a minimum point of a gauge-invariant smooth function, $\mathrm{Hess}\, V(x_0)(\xi,\xi) = 0$ for tangent vectors $\xi \neq 0$ of the orbit	15-01
Proposition on a Class with the Background as a Parameter	Proposition	In the class $C_2 = (B,q,a)$ that has the logarithm a of the background holonomy as a parameter, the background-dependent remainder drops to $\theta^0\beta^{-3/2}$, $\theta^1\beta^{-1}$, and the budget is uniform in the number of steps	15-07

Name	Kind	What it refers to	Introducing chapter
Shape-Remainder Theorem for Four Plaquettes in a Row (short: Four-in-a-Row Theorem)	Theorem	In the projected model of four plaquettes in a row (SU(2), diagonal definition, ψ^8 projection, $B \geq 32$, O(1) box), $r_n \leq \lambda^n r_0 + C/((5-\lambda)B_n)$ with $C = 0.0108$ (independent of the number of steps)	15-06
One-Step Contraction of the ℓ^4 Cone	Corollary	The four-dimensional ℓ^4 cone contracts by a factor of at most 0.823 in one step (normalisation $\beta'_0 = 1$, row-weighted interpolation)	15-05
Mixing-Limit Lemma	Lemma	In the volume limit, $\sup \lambda = 4 \sup \mu_{loc}$ (the limit of mixing between localised directions and the coarsest direction)	15-05
Floor Lemma for the Stein Route	Lemma	The row-weighted Stein route cannot go below $\Sigma\, s\, \nu_s^2/16 \geq 0.452 > 1/4$, for any local representative and any weights	15-05
Conditional-Mean Covariance Lemma	Lemma	One step at tree level is a Gaussian conditional mean, and the inverse of the coarse action (the covariance of the blocked flux) iterates linearly	15-05
Heat-Kernel Gaussian Upper-Bound Lemma	Lemma	For the SU(2) heat kernel p_t and non-decreasing $g \geq 0$, $E\, g(\theta) \leq e^{t/2}\, E\, g(\lvert Z\rvert)$, $Z \sim N(0, tI_3)$	15-08
Heat-Kernel Fluctuation Rarity Lemma	Lemma	Under the edgewise independent heat-kernel condition through the background-independence condition for fluctuations, the probability that a link exceeds the threshold h and the exponential moment are bounded in a closed form independent of the background (with heat-kernel fluctuations, the group version of the exponential moment of fluctuations holds)	15-08
Large-Field Remainder Bound Lemma	Lemma	Splitting the remainder as $r = r^{small} + r^{large}$, the Lipschitz constant of the read-out b with respect to total variation gives $\lvert r^{large}\rvert \leq (4/3)(b_S^2/E_S)\, P_L$	15-08
edgewise independent heat-kernel condition	Condition	The condition that the law of the fluctuations is an edgewise independent heat kernel (a premise of the Heat-Kernel Fluctuation Rarity Lemma and others)	15-08
single-step condition	Condition	The condition restricting the claim to a single step of renormalisation (multistep induction is not included)	15-08
analyticity condition at complex backgrounds	Condition	Analyticity at complex backgrounds and an upper bound independent of β (a Cauchy-type estimate of the Taylor coefficients of the small-field effective action)	15-08

Name	Kind	What it refers to	Introducing chapter
definition of the inter-block term	Condition	The definition of the explicit quadratic inter-block term W^gauge (algebra)	15-08
local cancellation	Condition	Local cancellation (the Loc identity)	15-08
cubic-remainder estimate	Condition	The cubic estimate (the remainder is $O(g^3)$, uniformly in complex backgrounds and in the volume)	15-08
Gaussian comparison condition for the partition function	Condition	e^{−CM⁴} ≤ Z_n/Z_n^G ≤ e^{CM⁴} (the ratio to the sum of Gaussian integrals around the isolated flat connections)	15-02
observable-source condition	Condition	The statement holds with the same constants even when a source of a smooth observable (strength ≤ s_0) with support larger than the scale L_0/M is inserted	15-02
ultraviolet statement for a small twisted four-dimensional torus (short: twisted-torus ultraviolet statement)	Statement	On a small twisted M^4 lattice, with a suitable choice of bare coupling, the three ultraviolet conditions (twisted-box version), the Gaussian comparison condition for the partition function and the observable-source condition hold (proposal, unproved)	15-02
row of the remainder including large fields	Table row	One of the four rows of 15-08 that do not close: the one-step remainder of the coupling including large fields (showing the net one-step bracket of the coupling including large fields)	15-08
row of background-dependent absorption and many steps	Table row	The core of the four rows that do not close: the row that absorbs the background-dependent loss η into a parameter of the class and passes it through multistep induction	15-08
row of the boundary of gauge re-fixing	Table row	One of the four rows that do not close: the handling of the boundary when the gauge fixing is re-fixed at each step	15-08
covariance-flow fixed-point condition	Condition	The flow of the covariance of the blocked field has a scale-invariant fixed point	15-03
cone-contraction condition at the fixed point	Condition	At the fixed point of the covariance flow, the contraction rate of the cone is less than 1 (sup μ_∞ < 1)	15-03
ultraviolet questions	Question	The thirty-one questions left by the chapters of Part 15 (Table 1 of 15-09). All touch on parts of the row of ultraviolet control	15-09
questions of the systematic attempts	Question	The sixteen questions left by 15-10 (the systematic attempts) (Table 15 of 15-10)	15-10

Name	Kind	What it refers to	Introducing chapter
contraction-map window for the fixed point of the class	Name	When the fixed point of the class-closure condition is stated in the form of a contraction map, the range of β in which the contraction map opens (from β of about 28–54, with $\tau = 0.695$, $a = 4.335$, $c_0 = 0.02$–0.04)	15-03
question "transverse contraction on a one-parameter class" (short: transverse contraction on a one-parameter class)	Question	Whether the one-step map contracts transversally on the one-parameter class it pulls into (whether λ and the sources stay finite, whether the constants are independent of the step, whether a weight on the sign of the centre is needed)	15-09
question "minimal model of the remainder including large fields" (short: minimal model of the remainder including large fields)	Question	Whether, in the minimal model (hierarchical SU(2)) in which the net one-step bracket of the coupling can be shown including large fields, the constrained absorption of one plaquette can be restated at the true critical point	15-09
question "smallest adjoint eigenvalue on the twisted lattice" (short: smallest adjoint eigenvalue on the twisted lattice)	Question	Whether, on the twisted M^4 lattice, the smallest eigenvalue of the adjoint fluctuation operator around the isolated flat connections is at least c/M^2	15-09
question "extending the tube of the hierarchical model" (short: extending the tube of the hierarchical model)	Question	Whether the tube and the attracting curve of the hierarchical model can be extended to $\beta > 64$ (the seam between the asymptotic estimates and interval arithmetic)	15-09
question "interval arithmetic for curvature outside the layer" (short: interval arithmetic for curvature outside the layer)	Question	Whether, by confirming the lower bound on the curvature outside the layer and the weight of the layer with interval arithmetic, the flow coefficient on the curve $c^* = 1/60$ can be separated from 1/48	15-09
question "lateral constancy of the coarse-plaquette source" (short: lateral constancy of the coarse-plaquette source)	Question	Whether, along a sequence of coarse-plaquette sides L, source $\times L^4$ approaches a constant value even when the lateral extent is widened	15-09
question "local representative of the tree-level network" (short: local representative of the tree-level network)	Question	Whether, in the tree-level network with the coarse plaquette fixed, a local representative can be made and an upper bound uniform in the volume obtained	15-09
question "one-step correction for four plaquettes in a row" (short: one-step correction for four plaquettes in a row)	Question	Whether the O(1/B) one-step correction for four plaquettes in a row can be derived on paper, giving the constant C of the one-step inequality of the shape remainder condition	15-09

Name	Kind	What it refers to	Introducing chapter
question "uniqueness of the class for other loop shapes" (short: uniqueness of the class for other loop shapes)	Question	Whether the class pulled into is determined uniquely even when loop shapes other than four in a row (2×2, L-shaped, mixed quartic) are included	15-09
question "splitting the density of the joint law" (short: splitting the density of the joint law)	Question	Whether, for four in a row, the joint law of two plaquettes can be split into a product of local couplings × a density, giving the lowest order in θ of the density and the isotropy of the quadratic form	15-09
question "minimal multistep statement" (short: minimal multistep statement)	Question	Whether a minimal multistep statement can be written in a hierarchical model or a two-dimensional model (the background-regularity condition and contraction of many-body norms)	15-09
question "Lipschitz constant of the read-out" (short: Lipschitz constant of the read-out)	Question	Deriving on paper the Lipschitz constant of the read-out used in the large-field remainder estimate, and measuring the difference in total variation of the densities with and without large fields	15-09
question "shift of the coupling when a source is added" (short: shift of the coupling when a source is added)	Question	Whether, when a source s Re W is added to four plaquettes in a row, the shift of the coupling is linear in s	15-09
question "parity of critical points" (short: parity of critical points)	Question	Whether the parity of critical points holds for four in a row (paired with the question of splitting the density of the joint law)	15-09
question "one-loop Hessian and ghosts" (short: one-loop Hessian and ghosts)	Question	Whether the one-loop Hessian of a block with factor 2 can be split and the F^2 coefficient of the ghosts measured (together with formalising the direct-product decomposition of the tree gauge)	15-09
question "smallest system that is not zero-sum" (short: smallest system that is not zero-sum)	Question	Whether, in the smallest system that is not zero-sum (two sets of four in a row side by side, sharing the link between them), the breaking of the local cancellation of the second-order contribution to the marginal coupling can be turned into a number	15-09
question "odd BCH orders on a 2×2 slab" (short: odd BCH orders on a 2×2 slab)	Question	Deriving, for the central plaquette of a 2×2 slab, the cyclically symmetrised BCH coefficients of odd order, and comparing them with the two-link values	15-09
question "class with the holonomy as a parameter" (short: class with the holonomy as a parameter)	Question	Whether, in a class having the logarithm of the background holonomy as a parameter, the background-dependent part moves exactly into the flow of that parameter	15-09

Name	Kind	What it refers to	Introducing chapter
question "radius of recentring" (short: radius of recentring)	Question	Whether, in the recentring of the One-Link One-Step Fluctuation Lemma, the Taylor radius can be made explicit and the loss coefficient made a single number	15-09
question "direct upper bound for the four-dimensional ℓ^{4}" (short: direct upper bound for the four-dimensional ℓ^{4})	Question	Bounding the contraction of the four-dimensional ℓ^4 cone directly (a finite network for the near part, Riesz–Thorin only for the tail), and seeing whether sup $\mu < 1$	15-09
question "two definitions of Loc" (short: two definitions of Loc)	Question	Whether, when the localisation Loc is defined in two ways, by row sums (zero momentum) and by matrix components, the quadratic inter-block terms agree (and which cut the original source uses)	15-09
question "three-dimensional non-local weights" (short: three-dimensional non-local weights)	Question	Whether, in three dimensions without boundary, the one-loop non-local weights in the coordinates of coarse links + global labels decay exponentially	15-09
question "second step of the multi-loop class" (short: second step of the multi-loop class)	Question	The second step of the multi-loop class: whether these are coordinates in which the triple product of angles κ is preserved at each step, and whether the same coordinates suffice in four dimensions with 2^4	15-09
question "gauge agreement on non-abelian backgrounds" (short: gauge agreement on non-abelian backgrounds)	Question	Measuring, on non-abelian backgrounds (curvature including commutators), the agreement of the two gauges and the coefficient of the ghosts	15-09
question "normalisation factors by direction" (short: normalisation factors by direction)	Question	Whether the normalisation factor by direction, sup $\lambda \leq 3.29$, can be brought below 1 with symbols weighted by momentum band	15-09
question "class with the coupling as a parameter" (short: class with the coupling as a parameter)	Question	Whether, giving the class the coupling as a parameter, the movement of the coupling of a single Wilson link moves into the update of the parameter	15-09
question "fixed point of the four-dimensional class ratio" (short: fixed point of the four-dimensional class ratio)	Question	Whether the value at the fixed point of the ratio coordinate of the four-dimensional class can be derived directly from a semi-infinite problem near the corner	15-09
question "upper bound on the fixed point of the lateral average" (short: upper bound on the fixed point of the lateral average)	Question	Whether, at the fixed point of lateral-average blocking, an upper bound on sup μ_∞ below 1 can be obtained by a route other than Stein	15-09

Name	Kind	What it refers to	Introducing chapter
question "quartic width of the three-body tree" (short: quartic width of the three-body tree)	Question	Measuring, with four-dimensional coarse links + global labels, the rate of dependence of the three-body tree term on the quartic width	15-09
question "one-loop coefficient of the long-wavelength network" (short: one-loop coefficient of the long-wavelength network)	Question	Whether, with lateral-average blocking or a large factor, the dependence on the factor of the one-loop coefficient of the long-wavelength network approaches the one-loop value	15-09
question "checking the whole range of the recentred tube" (short: checking the whole range of the recentred tube)	Question	Whether, passing the recentred tube through the whole of $\beta \in [15.26, 128]$ in intervals of width 0.02, the curve entering the tube and the enclosure of the flow coefficient c* can be made unconditional	15-09
question "alignment of rows in the worst direction" (short: alignment of rows in the worst direction)	Question	Whether, by estimating the lower bound of the alignment of rows in the worst direction with the kernel in the limit of steps, the loss from discarding signs can be bounded uniformly at all steps	15-10
question "periodic shift of the Stein maximiser" (short: periodic shift of the Stein maximiser)	Question	Where the amount by which the maximiser of the Stein upper bound on a large torus shifts away from period 2 comes from (upper bound 10.2 against a loss of 6.4)	15-10
question "cancellation on the side of the true operator" (short: cancellation on the side of the true operator)	Question	Once a quantity measuring the cancellation on the side of the true operator is fixed (for example, the ratio of $\|T^{k}\|$ to $\||T|^{k}\|$ divided by the minimum within the similarity class of signs), what can be said to cause the regularity of the loss that grows only slowly with the step	15-10
question "finite types and aggregation of returns" (short: finite types and aggregation of returns)	Question	Whether, aggregating the finite types and the remaining returns into two-by-two, $bc < (1-a)(1-d)$ holds for the recorded matrix	15-10
question "rereading with Schur weights" (short: rereading with Schur weights)	Question	What becomes of the one-step contraction constant when the record of the W coordinates (measured in ℓ^2) is reread with the weights of Schur's test	15-10
question "supremum of constrained sum rules" (short: supremum of constrained sum rules)	Question	Whether, for all $k \le \operatorname{ord}^{V}(F)$, a local representative with $\operatorname{ord}(K) \ge k$ can be taken with finite range	15-10
question "canonical choice of degrees of freedom" (short: canonical choice of degrees of freedom)	Question	Whether a representative minimising a Stein-type norm exists, is unique, and is local	15-10

Name	Kind	What it refers to	Introducing chapter
question "consistency of composing representatives across steps" (short: consistency of composing representatives across steps)	Question	Whether the output of the representative at step k lies in the constrained subspace of step $k+1$ (if not, the composition of representatives depends on the choice)	15-10
question "decay of the Moore–Penrose kernel" (short: decay of the Moore–Penrose kernel)	Question	How fast the kernel of the Moore–Penrose representative (the minimal-norm representative) decays	15-10
question "zero modes of the symmetric representative" (short: zero modes of the symmetric representative)	Question	Why the zero modes of the symmetric representative on a finite torus appear to approach $U/4$ faster than exponentially	15-10
question "band of triple valuations" (short: band of triple valuations)	Question	Whether, with triple valuations adding a third valuation (the exponent of the transseries), the difference between the bands of U(1) and SU(2) can be distinguished	15-10
question "ties in the four-dimensional series" (short: ties in the four-dimensional series)	Question	When the ties of the errors are found for the genuine four-dimensional series (higher orders at strong and weak coupling), how they overlap with the crossover band	15-10
question "skeleton of the space of two couplings" (short: skeleton of the space of two couplings)	Question	Whether, in the space of the two couplings, fundamental and adjoint, the skeleton of the tie set becomes a non-trivial polyhedral complex	15-10
question "motion of the lower edge of the window" (short: motion of the lower edge of the window)	Question	How the lower edge of the window moves with the number of steps along a sequence of blocking maps (whether the true value goes below 1 for one step with $3.5 \le p \le 5$)	15-10
question "divergence of the number of bundles" (short: divergence of the number of bundles)	Question	How the number of bundles diverges as p $\downarrow$ 2 (of the c/(p−2) type, or with a critical exponent fixed by the geometry of the lattice)	15-10
question "Schur threshold and Stein window" (short: Schur threshold and Stein window)	Question	Where the gap between the exponent of the Schur threshold and the lower edge of the Stein window comes from, and how far p^* can be lowered with weighted Schur (positive test functions)	15-10

Part 16 Where things stand, and the questions that remain

Name	Kind	What it refers to	Introducing chapter
seven stages a proof must contain	Table row	The seven stages a proof of the mass gap must pass through (vessel, ultraviolet, small-T^2 gap, small-T^2 confinement, band, R^4, general groups)	16-09

Name	Kind	What it refers to	Introducing chapter
vessel stage	Table row	Lattice, reflection positivity, block observables, compactness. The foundational stage that derives a gap of the transfer matrix from decay on a dense set	16-09
ultraviolet-control stage	Table row	The stage of multiscale analysis uniform in a (locality of the effective action, rarity of large fields, flow of the coupling), from the lattice spacing a to the scale L	16-09
small-T^2 gap stage	Table row	The stage that removes zero modes with twisted boundary conditions and shows, uniformly in a, a gap of the transfer matrix $\geq c/L$ on a small T^2	16-09
small-T^2 confinement stage	Table row	The stage that reduces confinement on a small T^2, by container estimates and insertion estimates, to "insertion of one vortex" and "independence between regions"	16-09
band stage	Table row	That the gap holds with the same constant even when T^2 is widened. The stage that crosses the intermediate scale $L \sim 1/\Lambda$ non-perturbatively	16-09
R^4 stage	Table row	The stage of the infinite-volume limit, the OS axioms, recovery of rotation invariance and non-triviality	16-09
general-group stage	Table row	The stage that extends to SU(N) and to groups without centre (such as G_2)	16-09
seam of the premise of existence	Table row	The seam where physics posits that the theory exists and computes quantities, while mathematics must build a limit (not a subsequence) satisfying the axioms	16-05
seam of "there is one scale"	Table row	The seam where physics regards both the mass and the string tension as constant multiples of a single scale Λ, while mathematics must show this holds uniformly in β	16-05
seam of the different shores	Table row	The seam where physics computes on shores where computation works (small coupling, small β, large N), while mathematics must control all scales at finite N	16-05
seam of finite and infinite	Table row	The seam where physics measures in finite boxes and extrapolates, while mathematics must show a gap uniform in the volume	16-05
seam of spacetime and space	Table row	The seam where physical intuition lives on spacetime (Minkowski), while mathematics returns from the Euclidean measure by reflection positivity	16-05
seam of the word "particle"	Table row	The seam between the physics statement "the gap is the mass of the lightest glueball" and the mathematical spectral gap (an isolated one-particle state is an extension problem)	16-05
seam of extra dimensions	Table row	The seam where physics produces the gap from the geometry of extra dimensions, while mathematics needs the limit shrinking the extra dimensions to 0 and the exchange of limits	16-05

Name	Kind	What it refers to	Introducing chapter
type in which a premise becomes a goal	Table row	The type of seam in which a premise of physics becomes a goal of mathematics (premise of existence; there is one scale)	16-05
type of limits and uniformity	Table row	The type of seam in which physics computes at particular values of parameters (shores), while mathematics needs limits to the values of the problem statement and uniform estimates (different shores; finite and infinite; extra dimensions)	16-05
type in which the same word points to different things	Table row	The type of seam in which the same word points to different things in physics and mathematics (spacetime and space; the word "particle")	16-05
task of the T^4 construction	Task	On T^4, the expectations of gauge-invariant quantities converge as $a \to 0$ along the whole sequence	16-07
task toward infinite volume	Task	The limit $L \to \infty$ exists along the whole sequence	16-07
task of a uniform gap	Task	$\inf_L \Delta_L > 0$	16-07
task of the remaining axioms	Task	Recovery of rotation symmetry, and the regularity needed for reconstruction	16-07
task of non-triviality	Task	The limit is not Gaussian	16-07
task of local fields and short distances	Task	Local fields, and agreement with asymptotic freedom at short distances	16-07
task of strong decay	Task	Uniform exponential decay under arbitrary boundary conditions	16-07
task of one scale	Task	$c\sigma \le m^2 \le C\sigma$ for $\beta \ge \beta_0$	16-07
task of the three-dimensional measure	Task	Construction of the measure on T^3	16-07
rule of existence	Table row	The rule that the existence of the theory on R^4 (the requirement of existence) follows from the task of the T^4 construction and the task toward infinite volume (a definition)	16-07
rule of the axioms	Table row	The rule that the requirement of the axioms follows, by OS reconstruction, from the existence of the theory and the task of the remaining axioms (a theorem)	16-07
rule of the gap	Table row	The rule that the requirement of the gap follows from the existence of the theory and the task of a uniform gap (a theorem: a uniform gap survives in the limit)	16-07
rule of non-triviality	Table row	The rule that the requirement of non-triviality follows from the task of non-triviality and the task of local fields and short distances (a definition)	16-07
rule of the problem statement	Table row	The rule that the whole problem statement for the group G follows from the three requirements of the axioms, non-triviality and the gap (a definition)	16-07

Name	Kind	What it refers to	Introducing chapter
rule from decay to the area law	Table row	The rule that the lattice area law follows from the task of strong decay (the Theorem from Uniform Decay to the Area Law of Chatterjee 2021)	16-07
rule of the string tension	Table row	The rule that the requirement of the string tension follows from the continuum string-tension problem (a definition)	16-07
rule of the problem setters' route	Table row	The route indicated by the problem setters (Jaffe–Witten), in which the task of a uniform gap opens the task toward infinite volume	16-07
rule from the string tension to the gap	Table row	The physical expectation that the requirement of the gap follows from the existence of the theory, the requirement of the string tension and the task of one scale (there is one scale)	16-07
rule from the gap to the string tension	Table row	The physical expectation that the requirement of the string tension follows from the existence of the theory, the requirement of the gap and the task of one scale (the reverse of the rule from the string tension to the gap)	16-07
requirement of existence	Name	That the theory on R^4 exists (one of the requirements of the problem statement)	16-07
requirement of the axioms	Name	That the theory satisfies axioms at least as strong as the Wightman and Osterwalder–Schrader axioms (one of the requirements of the problem statement)	16-07
requirement of non-triviality	Name	That the theory is non-trivial, has local fields, and agrees with asymptotic freedom at short distances (one of the requirements of the problem statement)	16-07
requirement of the gap	Name	That there is a mass gap $\Delta > 0$, and $m < \infty$ (one of the requirements of the problem statement)	16-07
requirement of the string tension	Name	That the continuum string tension d is not 0 (confinement; outside the requirements of the problem statement)	16-07
requirement of the problem statement	Name	The whole problem statement for the group G: the four requirements of existence, axioms, non-triviality and the gap taken together	16-07
two-way split of the core	Name	Viewing the core of the band as two jobs: "the ultraviolet extension" and "the statement of the last interval to strong coupling"	16-11 § 01
ultraviolet extension	Name	The job of extending the control of the published construction from the threshold to a coupling β_* of order one, while keeping the sum of the errors over the steps finite	16-11 § 01
statement of the last interval to strong coupling	Statement	A non-perturbative statement over a small number of steps, from β_* to the strong-coupling window (different from the "Corollary Crossing the Band in Finitely Many Steps" of 26-06)	16-11 § 01

Name	Kind	What it refers to	Introducing chapter
lossy chain	Name	Renormalisation comparisons allowing a loss of a factor K at each step, joined over the number of steps. The rate is uniform, but the prefactor grows as $\xi^{\log_2 K}$	16-11 § 02
facts on the energy side	Name	Facts about the action of configurations (existence of twisted vacua, stabiliser group ± 1, positivity of the action of the box with two twists, upper and lower bounds on S_N)	16-11 § 03
shortfall on the entropy side	Name	That this book lacks the estimate the band needs, which would count vortex fluctuations and the number of placements from below, uniformly in the scale	16-11 § 03
mixing statement for boxes of physical size	Statement	If the side of the box is taken to be the physical length C/Λ, the total variation of the law of the gauge-invariant observables inside, when the frame is changed, is smaller than a threshold (uniformly in β). A restatement of the mass gap in a strong form	16-11 § 04
seven test models	Name	The models against which arguments for the band are tested: U(1) at weak coupling, Z_2 at weak coupling, finite non-abelian groups, the adjoint Higgs limit, the line and endpoint of the SU(2) mixed action, the bulk transition of SU(N), and G_2	16-11 § 04, 26-12 § 02
three classes of value levels	Name	The weak-coupling behaviour of the quantity for a symmetric box with one twist: proportional to β for U(1), constant for frozen finite groups, of the $(3/2) \ln \beta$ type for SU(2)	16-11 § 04
control of the continuum limit of twisted boxes	Task	A comparison of scales with a finite sum of errors, for quantities determined by the measure, in twisted (framed) boxes	16-11 § 06
coupling of the laws of gauge-invariant observables	Task	A way of coupling the conditional laws of gauge-invariant functions, and a finite-box criterion on top of it	16-11 § 06
method for computing lower bounds on the entropy side	Task	Insertions adapted to the configuration, with relative entropy tending to 0	16-11 § 06
ordering of actions in the twisted sector	Task	An inequality saying that ΔF increases in the plaquette couplings, or an ordering of actions replacing it	16-11 § 06
substitute for the vortex free energy for groups without centre	Task	A quantity that plays the role of the vortex free energy for groups without centre, such as G_2	16-11 § 06
termwise sign inequality	Question	$\partial \Delta F / \partial \beta_p \geq 0$ for the plaquette-wise couplings β_p	16-11 § 04, 26-12 § 05

Part 18 A dictionary of two languages

Name	Kind	What it refers to	Introducing chapter
entry "path integral (quantum mechanics)"	Dictionary entry	Path integral (quantum mechanics) ⟷ Feynman–Kac formula	18-02
entry "functional integral"	Dictionary entry	Functional integral ⟷ Euclidean probability measure	18-02
entry "space of states"	Dictionary entry	Space of states ⟷ reconstructed Hilbert space	18-02
entry "Wick rotation"	Dictionary entry	Wick rotation ⟷ OS reconstruction theorem	18-02
entry "Green functions"	Dictionary entry	Green functions ⟷ Wightman and Schwinger functions	18-02
entry "Källén–Lehmann representation"	Dictionary entry	Källén–Lehmann representation ⟷ spectral measure	18-02
entry "vacuum and uniqueness"	Dictionary entry	Vacuum and uniqueness ⟷ Ω, clustering	18-02
entry "Hamiltonian"	Dictionary entry	Hamiltonian ⟷ logarithm of the transfer matrix	18-02
entry "one-particle state"	Dictionary entry	One-particle state ⟷ isolated eigenvalue of the mass operator	18-02
entry "S-matrix"	Dictionary entry	S-matrix ⟷ Haag–Ruelle scattering theory	18-02
entry "positive norm"	Dictionary entry	Positive norm ⟷ reflection positivity	18-02
entry "unitarity of the S-matrix"	Dictionary entry	Unitarity of the S-matrix ⟷ positive norm + asymptotic completeness	18-02
entry "spacetime and lattice"	Dictionary entry	Spacetime and lattice ⟷ $a\mathbb{Z}^4 \to \mathbb{R}^4$	18-02

entry "gauge fixing"	Dictionary entry	Gauge fixing ⟷ section into the orbit space	18-02
entry "physical states"	Dictionary entry	Physical states ⟷ reconstruction from gauge-invariant quantities	18-02
entry "local symmetry does not break"	Dictionary entry	Local symmetry does not break ⟷ Elitzur's theorem	18-02
entry "mass gap"	Dictionary entry	Mass gap ⟷ spectral gap, uniform decay	18-03

Name	Kind	What it refers to	Introducing chapter
entry "correlation length ξ"	Dictionary entry	Correlation length ξ ⟷ inverse of the gap of the transfer matrix	18-03
entry "gap in physical units"	Dictionary entry	Gap in physical units ⟷ uniform lower bound in lattice units	18-03
entry "V(R)"	Dictionary entry	$V(R)$ ⟷ decay rate of Wilson loops	18-03
entry "string tension σ"	Dictionary entry	String tension σ ⟷ coefficient of the area law, d of Chatterjee's Problem 5.2 (the continuum string-tension problem)	18-03
entry "confinement"	Dictionary entry	Confinement ⟷ one-directional theorems	18-03
entry "centre symmetry"	Dictionary entry	Centre symmetry ⟷ centre invariance on slabs	18-03
entry "Λ, one scale"	Dictionary entry	Λ, one scale (all masses are constant multiples of a single scale) ⟷ no corresponding term on the mathematical side	18-03
entry "m/√σ"	Dictionary entry	$m/\sqrt{\sigma}$ ⟷ the limit combining Chatterjee's Problems 5.1 and 5.2 (the lattice correlation-length problem and the continuum string-tension problem)	18-03
entry "glueball"	Dictionary entry	Glueball ⟷ isolated eigenvalue of the mass operator	18-03
entry "Langevin relaxation"	Dictionary entry	Langevin relaxation ⟷ generator L	18-03
entry "z=2"	Dictionary entry	$z = 2 \longleftrightarrow \mathrm{gap}(L) \asymp \mathrm{gap}(H_T)^2$ (the Langevin gap is the square of the gap of the transfer matrix)	18-03
entry "exponential autocorrelation time"	Dictionary entry	Exponential autocorrelation time ⟷ Poincaré constant C_P	18-03
entry "thermalisation time"	Dictionary entry	Thermalisation time ⟷ mixing time	18-03
entry "dynamical exponent z"	Dictionary entry	Dynamical exponent $z \longleftrightarrow C_P \asymp \xi^z$	18-03
entry "z=2-η_s"	Dictionary entry	$z = 2 - \eta_s$ ⟷ variational lower bound $C_P \geq \chi$	18-03
entry "no slowing down away from criticality"	Dictionary entry	No slowing down away from criticality ⟷ uniform mixing ⟺ uniform log-Sobolev	18-03
entry "Lüscher term"	Dictionary entry	Lüscher term ⟷ Casimir energy of the strip	18-03

Name	Kind	What it refers to	Introducing chapter
entry "roughening, shape of the tube"	Dictionary entry	Roughening, shape of the tube ⟷ Wulff construction	18-03
entry "topological freezing"	Dictionary entry	Topological freezing ⟷ bottleneck of the state space	18-03
entry "renormalisation group"	Dictionary entry	Renormalisation group ⟷ sequence of steps, UV stability	18-04
entry "β function"	Dictionary entry	β function ⟷ recursion for the effective coupling	18-04
entry "Polchinski's equation"	Dictionary entry	Polchinski's equation ⟷ Polchinski equation of measure decomposition (heat flow)	18-04
entry "Δβ of MCRG"	Dictionary entry	Δβ of MCRG ⟷ one-step map	18-04
entry "change of scheme for Λ"	Dictionary entry	Change of scheme for Λ ⟷ reparametrisation of the coupling	18-04
entry "Migdal–Kadanoff"	Dictionary entry	Migdal–Kadanoff ⟷ recursion that closes on hierarchical lattices	18-04
entry "continuum limit"	Dictionary entry	Continuum limit ⟷ scaling limit	18-04
entry "a(β), setting the scale"	Dictionary entry	a(β), setting the scale ⟷ ε(β) (the scale function of Chatterjee's Problem 5.2)	18-04
entry "scaling"	Dictionary entry	Scaling ⟷ limits of dimensionless ratios	18-04
entry "asymptotic scaling"	Dictionary entry	Asymptotic scaling ⟷ asymptotic form of ε(β)	18-04
entry "universality"	Dictionary entry	Universality ⟷ uniqueness of the limit	18-04
entry "Symanzik's $O(a^2)$"	Dictionary entry	Symanzik's $O(a^2)$ ⟷ the shortfall of a step δ(b)	18-04
entry "improved action"	Dictionary entry	Improved action ⟷ loss of reflection positivity (contributions with negative weights)	18-04
entry "marginal coupling"	Dictionary entry	Marginal coupling ⟷ Sobolev critical exponent	18-04
entry "large N, planar diagrams"	Dictionary entry	Large N, planar diagrams ⟷ planar maps, sums over strings	18-04
entry "master field"	Dictionary entry	Master field ⟷ limit of non-commutative distributions	18-04
entry "radial direction of holography"	Dictionary entry	Radial direction of holography ⟷ Fefferman–Graham expansion	18-04

Name	Kind	What it refers to	Introducing chapter
entry "KK tower"	Dictionary entry	KK tower ⟷ λ_1 of the internal Laplacian	18-04
entry "topological charge"	Dictionary entry	Topological charge ⟷ second Chern number	18-04
entry "instanton"	Dictionary entry	Instanton ⟷ anti-self-dual connection	18-04
entry "Wilson flow"	Dictionary entry	Wilson flow ⟷ Yang–Mills heat flow	18-04
entry "Gribov region"	Dictionary entry	Gribov region ⟷ region where the FP operator is positive	18-04
entry "trace anomaly"	Dictionary entry	Trace anomaly ⟷ no corresponding term on the mathematical side	18-04
Theorem from Centre Symmetry to Confinement (Theorem 2.2 of Chatterjee 2021) (short: Theorem from Centre Symmetry to Confinement)	Name from the literature	If centre symmetry is not broken, the static pair potential V(R) tends to infinity as $R \to \infty$ (confinement)	18-01
definition column	Table row	The first column of the dictionary's grade: whether the correspondence as a definition is settled, conditional or unsettled	18-01
existence column	Table row	The second column of the dictionary's grade: whether the object exists in four dimensions (constructed, conditional, none)	18-01
measurement column	Table row	The third column of the dictionary's grade: in which direction finite measurements can reach	18-01
static exponent (symbol kept)	Name	The static correlation exponent η_s: the exponent determined from the scaling dimension Δ of an operator by $\eta_s = 2\Delta - (d - 2)$ (distinct from the dynamical exponent)	18-05

Part 19 Objects, and the statements to be shown

Name	Kind	What it refers to	Introducing chapter
uniform-decay statement	Statement	One of the statements to be shown: along a tuned sequence of couplings, correlations decay exponentially, uniformly in the lattice spacing and the box (its consequence is the mass gap)	19-07
statements to be shown	Statement	The set of statements to be shown toward the continuum limit and the mass gap, written only with the objects defined in Part 19 (tuning, convergence of the full sequence, non-degeneracy, equicontinuity, uniform decay, the band)	19-07

Name	Kind	What it refers to	Introducing chapter
base time	Statement	The time of the starting point x of the link (x,μ). For a link in the time direction, this is taken as the time of that link	19-01

Part 21 Firm theorems — the vortex floor and Polyakov loops

Name	Kind	What it refers to	Introducing chapter
upper bound on the flipping cost	Statement	For some S, for every $\varepsilon > 0$ there is an m such that $\kappa_c(N,M,m,\lfloor M/m \rfloor) \le S + \varepsilon$ for all $M \ge m$ (an upper bound on the cost of flipping the class of the window)	21-04

Part 23 The first road, first half — from the direction of time

Name	Kind	What it refers to	Introducing chapter
diffusive-relaxation-time assumption (short: relaxation-time assumption)	Name	For the family of Wilson measures, $\lim_{\beta\to\infty} \ln C_P(\beta)/\ln \xi(\beta) = 2$ (the relaxation time grows with the same power as the square of the correlation length; a statement at the level of powers)	23-01
relaxation-time upper-bound assumption (short: upper-bound assumption)	Name	$a^2 C_P \le C$, that is, $C_P \lesssim \xi_{RG}^2$ (ξ_{RG} is the bookkeeping length; the upper half of the band statement, a Poincaré inequality for all test functions f)	23-01
relaxation-time lower-bound assumption (short: lower-bound assumption)	Name	$a^2 C_P \ge c$, that is, $C_P \gtrsim \xi_{RG}^2$ (ξ_{RG} is the bookkeeping length; the lower half of the band statement, for which one test function suffices)	23-01
band form of the diffusive-relaxation-time assumption (short: band form of the relaxation-time assumption)	Name	For some $0<c\le C$ and β_0, $c\,\xi^2 \le C_P[E] \le C\,\xi^2$ (a band statement agreeing up to a constant factor; it names the graduation E)	23-01
double-well relaxation-time power statement (short: double-well power statement)	Name	For the double-well path measure, $\lim_{\hbar\to 0} \ln C_P(\hbar)/\ln \xi(\hbar) = 2$ (a statement of the same form as the diffusive-relaxation-time assumption, stated for the family of measures of the first step)	23-03
relaxation-time band at the bookkeeping length	Assumption	The band statement $a^2 C_P \asymp 1$ ($a = 1/\xi_{RG}$) that follows from the band assumption (angle) together with the one-scale chain and the bookkeeping-length chain	23-01

Name	Kind	What it refers to	Introducing chapter
eight statements of construction	Statement	The eight component statements into which the requirements of the problem statement are split along the road entering from the lattice (infinite-volume uniqueness, reflection-positivity preservation, the Wilson-loop limit, the physical-unit gap, rotation recovery, OS reconstruction, non-triviality and so on)	23-01
infinite-volume uniqueness statement	Statement	At each β the infinite-volume limiting measure is determined uniquely	23-01
reflection-positivity preservation statement	Statement	A positive self-adjoint transfer operator, preserved under weak limits	23-01
Wilson-loop limit statement	Statement	Renormalised Wilson loops have a non-trivial limit as $a \to 0$	23-01
physical-unit gap statement	Statement	The gap in physical units $\Delta(\beta)$ converges as $\beta \to \infty$ to $\Delta_\infty \in (0,\infty)$	23-01
rotation-recovery statement	Statement	Rotation and translation invariance return in the limit	23-01
OS reconstruction statement	Statement	A Hilbert space and a Hamiltonian are built from the OS axioms	23-01
non-triviality statement	Statement	The limit is not Gaussian and matches asymptotic freedom at short distances	23-01
relaxation chain	Assumption	$\lambda_1 \asymp m^2$ (the Langevin gap and the square of the mass agree)	23-01
one-scale chain	Assumption	$m^2 \asymp \sigma$ (the square of the mass and the string tension agree)	23-01
bookkeeping-length chain	Assumption	$\sigma \asymp a^2$ (the string tension and the bookkeeping length agree)	23-01
tube transfer-operator inequality (short: tube inequality)	Assumption	The tube transfer operator satisfies $T \le \exp(-(\sigma\ell + c/\ell))$ (a tube of circumference ℓ is heavier by at least c/ℓ in addition to the tension)	23-02
localised tube inequality	Assumption	T for short loops, a Casimir floor for large loops, and the junction between them. The three give $m^2 \ge 4c\sigma$	23-02
assumption of projection onto a one-dimensional chain of scales (short: projection assumption)	Assumption	The state space can be projected onto a one-dimensional chain in the scale $s = \ln \ell$ (four parts, from the scale decomposition of the variance to the single-line property)	23-02
summability-of-shortfalls assumption	Assumption	The sum of the one-step shortfalls $\delta(b_k)$ is finite	23-02

Name	Kind	What it refers to	Introducing chapter
time-step comparison assumption ((D) in the paper "one-sided bridge") (short: time-step comparison assumption)	Assumption	On a lattice with discrete time, $E\|dF\|^2_G \le c_D\langle\phi,(1-\hat{T})\phi\rangle$ (a comparison of the increment between neighbouring times with the gradient, with c_D uniform in β)	23-01
ground-state assumption ((A1) in the paper) (short: ground-state assumption)	Assumption	The spectrum is discrete and the ground state is simple and positive	23-01
stationary path-measure assumption ((A2) in the paper) (short: stationary path-measure assumption)	Assumption	A stationary path measure with $T = \infty$ (infinitely long in the time direction) exists	23-01
metric comparison assumption ((A3) in the paper) (short: metric comparison assumption)	Assumption	Comparison of the Langevin metric, $G \le \lambda_G M^{-1}$	23-01
vacuum C_P	Name	The Poincaré constant C_P of the vacuum measure at a single time (one of the three C_P)	23-01
path C_P	Name	The Poincaré constant C_P of the distribution of all fields in spacetime (the path measure = the Wilson measure). The relaxation-time assumption is a statement about this	23-01
path C_P measured in a graduation	Name	The C_P for the same measure as the path C_P, with the graduation of the Dirichlet form named (measured in angles or in fields). Multiplying the graduation by c multiplies C_P by 1/c	23-01
One-Sided Bridge Proposition (Theorem 3.1 of the paper) (short: one-sided bridge)	Proposition	With continuous time, a finite spatial lattice and $T=\infty$, under the ground-state assumption, the stationary path-measure assumption and the metric comparison assumption, $C_P \ge \kappa\xi^2 = \kappa\hbar^2/\Delta^2$ (best possible within the family of test functions local in time)	23-01
Discrete-Time One-Sided Bridge Proposition	Proposition	On a time lattice with step 1, under the time-step comparison assumption, $C_P \ge 2/(c_D \Delta^2)$	23-01
One-Dimensional One-Sided Bridge Proposition	Proposition	For any one-dimensional well with continuous time and $T\to\infty$, the ceiling of the family of test functions local in time is ξ^2, hence $C_P \ge \xi^2$ ($R \ge 1$)	23-04
Free-Particle-on-a-Circle Counterexample	Proposition	For a free particle on a circle, the gap $\Delta = \hbar^2/2 > 0$, yet the C_P of the path measure is ∞ (a negation of the converse direction)	23-01

Name	Kind	What it refers to	Introducing chapter
Double-Well Relaxation-Time Upper-Bound Proposition (short: First-Step Upper-Bound Proposition)	Proposition	For the double-well path measure, under the four double-well conditions and the premise rows, $C_P \le K\xi^2 S_0/\hbar$, so with $1 \le R \le K'/\hbar$ the power statement follows	23-03
Six-Node In-Phase Poincaré Proposition	Proposition	For the phase measure $\mu^{(+)}$ with $V=(x^2-1)^2/8$, $\varepsilon=1/2$ and ring $N=12n$, at each of the six nodes in $\hbar$, $\mathrm{Var}\, f \le C\, E(f)$ with $C \le 1.6\times 10^{10}$ (658 with numerical input), independent of n	23-06
Box-Reduction Proposition	Proposition	If $c_{alt} < 1$, then $C_P \le (1+1/n)\, C_{box}/(1-c_{alt})$ (two families, even and odd, of overlapping boxes; Poincaré inequalities only)	23-05
Gap-Inside-the-Box Proposition	Proposition	Splitting the inside of the box by kink configurations, $C_{box} \le C_{loc} + (1+\chi)C_{kg} \le K_4(C\xi)^2/D$	23-05
Three-Range Core-Constant Proposition	Proposition	Bounds the Poincaré constant of the core by splitting according to the core length k into three ranges: convexity for $k\le 7$, two blocks for $8\le k\le 14$, and box reduction applied to the core for $k\ge 15$ (the Box-Reduction Inequality for Long Cores)	23-11
Two-Projection Lemma	Lemma	If the maximal correlation of two σ-algebras is $c < 1$, then $\mathrm{Var}\, f \le (1-c)^{-1}(E\,\mathrm{Var}(f\|G_1) + E\,\mathrm{Var}(f\|G_2))$	23-05
Short-Core Convexity Lemma	Lemma	If $\kappa(k) > 0$ ($k \le 7$), then $C_P(\mu_k^{\{\alpha,\beta\}}) \le \varepsilon/\kappa(k)$ for all end values and $\hbar$	23-11
End-Reduction Lemma	Lemma	For a Markov chain, the maximal correlation of two separated blocks equals the maximal correlation of the two facing end points	23-11
Two-Block Lemma	Lemma	Bounds C_P for cores with $8 \le k \le 14$ by splitting them into two blocks	23-11
Closed Formula for the Alternating Maximal Correlation	Proposition	For a stationary Gaussian chain with correlation t within pieces and correlation s across seams, the maximal correlation between the even pieces and the odd pieces is $\phi(\|s\|,\|t\|)$ (a closed formula)	23-11
Box-Reduction Inequality for Long Cores	Proposition	The inequality for the Poincaré constant of the core obtained by applying the box reduction of the Box-Reduction Proposition to cores of length $k \ge 15$	23-11
Tilted Second-Order Taylor Lemma	Lemma	Tilts the measure at the centre of the box with given end values, and bounds the whole box by the second-order Taylor expansion of the cumulant generating function with a Hölder remainder	23-06

Name	Kind	What it refers to	Introducing chapter
Gap Non-Monotonicity Proposition	Proposition	FKG gives an ordering of likelihood ratios, but the single-site gap is not monotone in the neighbouring values	23-06
Linear-Fractional Lemma	Lemma	Setting $h = g - g^*$ and $\beta = \beta_0 + \tau$ makes the expectation a linear-fractional function of τ	23-08
Tilted-Enclosure Lemma	Lemma	Keeps the enclosure of the fixed point of the step map tilted in τ, in the form $m_k - \tau\mu_k - \tau^2\nu_k$	23-08
Moving-Centre Lemma	Lemma	Moves the centres of the two one-sided parts of the variance bound with τ, as $c_\tau = c + \tau\kappa$	23-08
Scalar-Strand Proposition	Proposition	At 8 nodes with $\hbar \in [3\cdot10^{-4}, 10^{-3}]$, bounds the Poincaré constant of the core using Bakry–Émery for the convex bottom and paying for the band at the top with the Gibbs step (the condition is $\ln k < \ell_{band}$)	23-09
Product Bound for the Window Log-Sobolev Constant	Proposition	An assembly bounding the log-Sobolev constant of the site window from above by a product of factors, $A_W \le c_W C_{1D}^W S_W T_W$	23-07
Window Log-Sobolev Threshold Proposition	Proposition	The log-Sobolev constant of the site window is within the required value: $A_W < A_{max}(\hbar)$	23-09
marginal log-Sobolev input for the window	Assumption	The marginal log-Sobolev inequality for the window, $\mathrm{Ent}(E[g^2\|\sigma_W]) \le A_W E(g) + D_W \int g^2$	23-09
Coarse-Chain Dobrushin Theorem (Theorem CC of the paper) (short: Coarse-Chain Dobrushin Theorem)	Name from the paper	For a core with both ends inside the wells, the Poincaré constant of the core is bounded uniformly by the Dobrushin criterion for the coarse chain (for $\hbar \in [10^{-5},1]$, $\rho_{col} \le 0.400$ by interval arithmetic over 239 intervals)	23-05
Small-ħ Coarse-Chain Proposition (Proposition PIN of the paper) (short: Small-ħ Coarse-Chain Proposition)	Name from the paper	For small $\hbar$ ($\hbar \le 10^{-5}$), the Dobrushin coefficient of the coarse chain stays within $\rho_{col} \le 0.874$ (the small-ħ side of the Coarse-Chain Dobrushin Theorem)	23-05
Coarse-Chain Brascamp–Lieb Proposition (Proposition BLc of the paper) (short: Coarse-Chain Brascamp–Lieb Proposition)	Name from the paper	The coarse-chain version of the Brascamp–Lieb inequality (a part of the Coarse-Chain Dobrushin Theorem)	23-05
Closed-Core KKT-Point Proposition	Proposition	When the end values are below the box ($a,b \le -x_c$), the only KKT point on the closed core is the bottom corner	23-15

Name	Kind	What it refers to	Introducing chapter
four double-well conditions	Condition	The four conditions into which the upper bound $C_P \le K\xi^2 S_0/\hbar$ of the first step (the double well) is split (in-phase local Poincaré, saddle tube, box reduction, gap inside the box)	23-03
in-phase local Poincaré condition	Condition	The Poincaré constant C_loc of the kink-free phase measure $\mu^{(+)}$ is O(1) uniformly in ħ and the length of the path (inside the box, the segment local Poincaré assumption)	23-05
saddle-tube condition	Condition	In the tube around the family of kink–antikink pairs, the transport constant and the Poincaré constant of the tube are uniform in the dimension and ħ (inside the box, the saddle-tube Poincaré assumption and the core Poincaré uniformity assumption)	23-05
box-reduction condition	Condition	$C_P(\mu) \le C_{box}(L)/c_M$, with c_M depending only on the length in units of ξ (reducing the overall relaxation time to the relaxation time of boxes of length L)	23-05
gap-inside-the-box condition	Condition	For the conditional measure on a box of length Cξ, $1/C_P \ge cD/(C\xi)^2$, with c uniform in ħ and the boundary values	23-05
segment local Poincaré assumption	Condition	The local Poincaré inequality for segments with end values (length $\le C\xi$) is uniform also in the end values	23-05
saddle-tube Poincaré assumption	Condition	The Poincaré constant of the tube is uniform in tube lengths $\le C\xi$	23-05
core Poincaré uniformity assumption	Condition	The Poincaré constant of the core within the tube (the interval that stays near the top) is uniform in the core length k and the end values	23-05
alternating maximal-correlation assumption for boxes	Assumption	The alternating maximal correlation between boxes, $c_{alt} < 1$, is uniform in ħ and the boundary values	23-05
alternating maximal-correlation assumption for the core	Assumption	An upper bound $\bar{c} < 1$ on the alternating maximal correlation of the core ($k \ge 15$)	23-11
core action-barrier assumption	Assumption	C_P of the core and the window $\le c\,\hbar^{-p}\, e^{(\Delta S/\hbar)}$, with barrier $\Delta S < 2S_0$	23-11
kink-gas gap assumption	Assumption	The box gap of the reduced kink gas is of the Glauber type of the one-dimensional Ising model ($C_{kg} \le (C\xi)^2/(c_{kg}(1-\eta_{KG})D)$)	23-05
cross-term uniformity assumption	Assumption	The cross term satisfies $E_Y(E[f\|Y]) \le (1+\chi)E(f)$, with χ uniform in ħ and the boundary values	23-05

Name	Kind	What it refers to	Introducing chapter
kink diffusion-coefficient row	Table row	The mobility of a single kink, $D = \hbar/S_0$ (at the level of the process)	23-05
bridge volume-locality input	Assumption	Volume locality on the bridge	23-09
seam limit assumption	Assumption	The limit of stacking steps without end lies, at each $\hbar$, in the enclosure of the fixed point	23-07
random-end-value assumption	Assumption	The assumption that the seam estimate holds also when the end values of the outer chain are given by a distribution rather than a single point	23-07
ratio conditioned on the plateau	Assumption	The ratio measured at the seam of the ring (the plateau at the top), conditioned on the length of the plateau	23-07
row of the contraction of the chain outside the window	Table row	$q_{\mathrm{free}} \le 0.998854904$ (contraction of the chain outside the window of the bridge core, over the whole window of $\hbar$)	23-07
small assumptions of the sector input	Assumption	The list of eleven small assumptions needed as input to the sector framework (the bridge volume-locality input, the core log-Sobolev uniformity assumption, the longitudinal term, regularity and others; seven of them do not yet have a one-line statement of content)	23-07
margin row	Table row	The first row of the two-scale assembly: the coarse-side margin $\hbar\rho - 2\hbar\kappa \ge 0.067$ (for neighbouring and end values in $[0, 2.5]^2$)	23-06
nearest-neighbour chain row	Table row	A row of the two-scale assembly: the marginal measure of the retained sites is a nearest-neighbour chain	23-06
two-site gap row	Table row	A row of the two-scale assembly: the gap of the marginal measure of the two sites (x_4, x_8) is $\lambda_c \ge 1.3 \times 10^{-4}$ (end values in $[0, 4]^2$, $\hbar \in (0, 0.2]$)	23-06
crossing row	Table row	A row of the two-scale assembly: the strength of the crossing between the two scales, $v/\hbar \le 5888$	23-06
variance-decomposition row	Table row	The last row of the two-scale assembly: the formula that splits the variance into the retained sites and the rest, and assembles the other rows into a single Poincaré constant	23-06
lattice target level	Condition	The first level of the goal: at each β the lattice correlation length $\xi(\beta)$ is finite, and it diverges as $\beta \to \infty$	23-15
physical-unit target level	Condition	The lattice mass in physical units, m_{lat}/a, tends to a positive finite value	23-15

Name	Kind	What it refers to	Introducing chapter
continuum target level	Condition	The third level of the goal: a non-trivial continuum theory on R^4 with a positive gap	23-15
remaining item between nodes	Condition	A row remaining for closing the in-phase local Poincaré condition: ħ between the six nodes	23-06
small-ħ remaining item	Condition	A row remaining for closing the in-phase local Poincaré condition: the side $ħ < 0.005$ (computer assistance that subdivides into intervals would need infinitely many intervals)	23-06
large-end-value remaining item	Condition	A row remaining for closing the in-phase local Poincaré condition: the case where neighbouring and end values exceed 2.5	23-06
sharp-constant remaining item	Condition	A row remaining for closing the in-phase local Poincaré condition: sharpening the constant $C \le 1.6\times 10^{10}$	23-06
segment-version remaining item	Condition	A row remaining for closing the in-phase local Poincaré condition: the version for segments with end values (the segment local Poincaré assumption)	23-06
bibliographic remaining item	Condition	A row remaining for closing the in-phase local Poincaré condition: checking the bibliographic data of the cited theorems	23-06
sector sum	Step	The first step of the sector framework: even when the configuration space is split into a product of boxes, the Dirichlet form, the variance and the entropy split into sums over sectors	23-09
Gibbs decomposition	Step	The second step of the sector framework: by the Gibbs variational inequality, the weight on rare sets is paid for by the entropy of the marginal of the coarse variables	23-09
componentwise localisation	Step	The third step of the sector framework: for each component of the gradient, the marginal log-Sobolev constant of the site window is applied, so that the core length k does not enter the sum	23-09
volume locality	Step	The fourth step of the sector framework: the rarity exponent ℓ_min of the defect set does not depend on the core length k	23-09
sector composition	Step	The fifth step of the sector framework: combines the three inequalities of Barta, componentwise localisation and Bochner, and bounds the gap of the core independently of k under the closing condition	23-09

Name	Kind	What it refers to	Introducing chapter
quantitative uniform Laplace method	Condition	Local Poincaré inside the wells of the first step, and the reduction of the margin as $\hbar \to 0$	23-15
step aligning the assumptions	Step	The first step of the proof of the First-Step Upper-Bound Proposition: aligning the premise rows	23-05
box-reduction step	Step	A step of the proof of the First-Step Upper-Bound Proposition: by the Box-Reduction Proposition, the whole is reduced to boxes of length $C\xi$	23-05
step inside the box	Step	A step of the proof of the First-Step Upper-Bound Proposition: the gap inside the box is bounded by splitting according to kink configurations	23-05
composition step	Step	A step of the proof of the First-Step Upper-Bound Proposition: combining the box reduction and the gap inside the box gives $C_P \le K\xi^2 S_0/\hbar$	23-05
step bracketing the ratio	Step	A step of the proof of the First-Step Upper-Bound Proposition: the ratio $R = C_P/\xi^2$ is bracketed as $1 \le R \le K'/\hbar$	23-05
step reading the power	Step	The last step of the proof of the First-Step Upper-Bound Proposition: the power statement $\ln C_P/\ln \xi \to 2$ is read from the bracketed ratio	23-05
short-core step	Step	The first of the three ranges of the core constant: cores of length $k \le 7$ are bounded by convexity	23-11
medium-core step	Step	The second of the three ranges of the core constant: cores of length $8 \le k \le 14$ are bounded by splitting into two blocks	23-11
long-core step	Step	The third of the three ranges of the core constant: box reduction is applied to cores of length $k \ge 15$	23-11
seven routes of the saddle tube	Route	The seven routes set up to close the core row of the saddle-tube condition	23-07
route of the chain outside the window	Route	Contraction of the chain outside the window ($q_free < 1$ for the bridge core, computer-assisted)	23-07
route of the window-constant numerics	Route	The remaining numerics (putting the site-window constants into intervals)	23-07
route of the sector framework	Route	The sector framework (five steps and the closing condition)	23-07
route of the sector input	Route	The small assumptions (the list of sector inputs)	23-07

Name	Kind	What it refers to	Introducing chapter
route of the window log-Sobolev inequality	Route	The route that attacks the one remaining proposition (the Window Log-Sobolev Threshold Proposition) with three strands	23-07
route of the seam of the ring	Route	The seam of the ring (outer chain and inner chain)	23-07
route of the range of ħ	Route	The range of ħ (outside the window and ħ→0, outside the scope)	23-07
componentwise strand	Route	The first strand of the route of the window log-Sobolev inequality: the componentwise form of the gradient (stops at 1.4–5.5 times the required value)	23-09
scalar strand	Route	The second strand of the route of the window log-Sobolev inequality: the scalar form (the Scalar-Strand Proposition)	23-09
Feynman–Kac strand	Route	The third strand of the route of the window log-Sobolev inequality: the Feynman–Kac form (Monte Carlo readings)	23-09
road of the core on the box side	Route	The road that supports the fork (the core Poincaré uniformity assumption) with the core on the box side: the Three-Range Core-Constant Proposition, and the local term vanishing as ħ→0	23-15
road of the core on the sector side	Route	The road that supports the fork (the core Poincaré uniformity assumption) with the core on the sector side: a uniform lower bound on the gap of the core in the sector framework, and the seam limit assumption	23-15
road of blocks and mixing	Route	A third branch that supports the fork (the core Poincaré uniformity assumption) with log-Sobolev inequalities for blocks ($\ell_B \geq 12$) and strong mixing (the fourteen rows of Table C1 of 23-15)	23-15
summit-curvature type	Type	A type of breakage of detour plans: there is a single source — the curvature of the single site at the summit	23-10
type of the ceiling on structural factors	Type	A type of breakage of detour plans: structural factors that enter as ratios have a ceiling	23-10
double-payment type	Type	A type of breakage of detour plans: the same place was being paid for twice	23-10
currency-mix-up type	Type	A type of breakage of detour plans: a mix-up of currencies — exit speed and rarity	23-10
type of the address of 1/ħ	Type	A type of breakage of detour plans: the address of 1/ħ (a mistake about where the factor 1/ħ enters)	23-10

Name	Kind	What it refers to	Introducing chapter
type of the misaligned fluctuation direction	Type	A type of breakage of detour plans: a mismatch between the direction of fluctuation and the soft direction	23-10
transfer type	Type	A type of breakage of detour plans: transfer — the weight only moves to another column	23-10
seven types of breakage	Table row	The types classifying into seven the reasons why detour plans broke. Used as questions to put to new candidates	23-10
detour plan "localising negative curvature" (short: localising negative curvature)	Detour plan	Localising Bochner's negative curvature on the defect set	23-10
detour plan "optimising the Gibbs tilt" (short: optimising the Gibbs tilt)	Detour plan	Setting the Gibbs tilt to $t^{*}=\ell-5.10$	23-10
detour plan "raising the threshold" (short: raising the threshold)	Detour plan	Raising the threshold to $1/\sqrt{3}$ and making the localisation remainder 0	23-10
detour plan "layering defects by depth" (short: layering defects by depth)	Detour plan	Dividing the defect depth b into layers	23-10
detour plan "narrowing the defect set" (short: narrowing the defect set)	Detour plan	Narrowing the defect set to the set where the row falls below κ	23-10
detour plan "defects as long clusters" (short: defects as long clusters)	Detour plan	Defining defects by clusters of length 8 or more	23-10
detour plan "paying for the summit band" (short: paying for the summit band)	Detour plan	Charging the summit band to the defects	23-10
detour plan "scalar payment" (short: scalar payment)	Detour plan	Paying for the sector defects in scalar form	23-10
detour plan "non-linear Barta weight" (short: non-linear Barta weight)	Detour plan	Making the Barta weight non-linear	23-10
detour plan "Agmon-type payment" (short: Agmon-type payment)	Detour plan	Paying only with the gradient of the true eigenfunction (Agmon type)	23-10
detour plan "re-examining downstream needs" (short: re-examining downstream needs)	Detour plan	Re-examining what is needed downstream	23-10

Name	Kind	What it refers to	Introducing chapter
detour plan "coarse and propagation steps at once" (short: coarse and propagation steps at once)	Detour plan	Doing the coarse step and the propagation step at once	23-10
detour plan "replacing the functional inequality" (short: replacing the functional inequality)	Detour plan	Poincaré / modified LSI / Φ-entropy instead of log-Sobolev	23-10
detour plan "log-Sobolev with clusters fixed" (short: log-Sobolev with clusters fixed)	Detour plan	Log-Sobolev for the conditional measure with the cluster state fixed	23-10
detour plan "perturbing only the summit band" (short: perturbing only the summit band)	Detour plan	Bakry–Émery outside the window, Holley–Stroock only for the summit band	23-10
detour plan "known uniform log-Sobolev" (short: known uniform log-Sobolev)	Detour plan	Known theorems on uniform log-Sobolev in one dimension	23-10
detour plan "finite-volume criteria" (short: finite-volume criteria)	Detour plan	Finite-volume criteria (Martinelli–Olivieri, Lu–Yau)	23-10
detour plan "Glauber log-Sobolev" (short: Glauber log-Sobolev)	Detour plan	Known log-Sobolev for Glauber dynamics	23-10
detour plan "two-step cluster expansion" (short: two-step cluster expansion)	Detour plan	Two-step cluster expansion, block spins	23-10
detour plan "extension to the classical limit" (short: extension to the classical limit)	Detour plan	Taking $\hbar$ below the window (the classical limit)	23-10
detour plan "one- or two-site windows" (short: one- or two-site windows)	Detour plan	Making the window one or two sites	23-10
detour plan "localising at the cluster core" (short: localising at the cluster core)	Detour plan	Localising at the core of the cluster rather than at the window	23-10
detour plan "Hölder and hypercontractive steps" (short: Hölder and hypercontractive steps)	Detour plan	Replacing the Gibbs step with Hölder and hypercontractivity	23-10

Name	Kind	What it refers to	Introducing chapter
detour plan "paying with a height function" (short: paying with a height function)	Detour plan	Paying for the negative curvature with a height function	23-10
list of detour plans	Table row	The twenty-four detour plans that moved either side, or the form, of the one remaining proposition of the route of the window log-Sobolev inequality	23-10
road of strong-coupling curvature	Table row	Widening the range of β where the curvature method works (the strong-coupling side)	23-02
road of one-step bookkeeping	Table row	Bookkeeping the continuum limit as a sequence of single steps	23-02
road of the sum of shortfalls	Table row	Whether the sum of the shortfalls δ(b) is finite	23-02
road of the strong-coupling series	Table row	Whether the dynamical exponent η can be read from the strong-coupling series	23-02
road of the dimension of complete families	Table row	In which dimensions complete families of edges and plaquettes exist	23-02
road of the dimensional threshold	Table row	Why four dimensions is the threshold	23-02
road of reflection positivity	Table row	Using reflection positivity for estimates from below	23-02
road of an area law in the bookkeeping	Table row	Whether the form of an area law appears in the bookkeeping	23-02
road of multi-link integrals	Table row	Whether the closed forms of k-link integrals are analytic	23-02
road of comparison with the defect of a submission	Table row	Whether the defect of a submission claiming a construction is the same quantity as δ	23-02
road of multiscale curvature	Table row	Stacking the curvature method scale by scale	23-02
road of volume and boundary	Table row	Whether the estimate of C_P is uniform in the volume and the boundary conditions	23-02
road of lower-bound test functions	Table row	Whether there is a test function giving the lower-bound assumption	23-02
road of gauge-fixed long wavelengths	Table row	Whether gauge-fixed long-wavelength modes can be made single-valued	23-02
road of spectroscopy	Table row	Bounding the gap with smoothed operators and spectroscopy	23-02
road of the lower half at one scale	Table row	Making the lower half of one scale, $m^2 \gtrsim \sigma$	23-02
road of a one-dimensional chain of scales	Table row	Bracketing the upper-bound assumption with a one-dimensional chain of scales	23-02

Name	Kind	What it refers to	Introducing chapter
seventeen roads tried on the four-dimensional lattice	Table row	The seventeen roads tried on the four-dimensional lattice (each a pair of one question and one set of tools)	23-02
one-sided test-function wall	Wall	Test functions bound C_P only from below	23-02
spectroscopic upper-bound wall	Wall	Spectroscopy ends with an upper bound on the gap	23-02
local-operator dimension wall	Wall	Local gauge-invariant operators have dimension 4 or more, so η_s=2	23-02
gauge-fixing single-valuedness wall	Wall	Gauge fixing: if sharp, it is multivalued; if blunt, the long wavelengths disappear	23-02
measurement-cost wall	Wall	The cost of measuring the numerator of smoothed operators is $\geq cL^{d+2}$	23-02
positive-weight kernel wall	Wall	A kernel with $\delta(2)=0$ has negative neighbouring weights	23-02
renewal-series wall	Wall	The strong-coupling series has renewal form and forces $\eta=0$	23-02
single-step integral wall	Wall	The one-link integral of a complete family works for one step only	23-02
limit-property wall	Wall	The Wilson-loop limit statement and the rotation-recovery statement do not follow from compositions of one-step maps	23-02
upper-bound tool wall	Wall	There are no tools of the type of the upper-bound assumption (they stop at the cross term)	23-02
tube-inequality wall	Wall	$m^2 \gtrsim \sigma$ has moved to the tube inequality, but there is no pattern of proof for it	23-02
projection-assumption wall	Wall	The projection assumption is not weaker than the relaxation-time assumption	23-02
checking-tool wall	Wall	There are few tools for machine checking	23-02
wall of the assumption itself	Wall	The relaxation-time assumption and the three chains have not been proved	23-02
equivalence-scaffold wall	Wall	The scaffold of equivalences for the physical-unit gap statement (power form, $\eta \geq 0$, additive step errors, δ of the one-loop kernel)	23-02
periodic-boundary conjecture wall	Wall	The breaking of the upper-bound assumption with periodic boundary conditions depends on a conjecture	23-02
fitting wall	Wall	That the violation of $m/\sqrt{\sigma}$ is $O(a^2)$ is a fit	23-02
box-size wall	Wall	The boxes are small	23-02
gauge dependence of the shortfall wall	Wall	Differences in c_2 depending on the choice of gauge	23-02

Name	Kind	What it refers to	Introducing chapter
tube-model sign wall	Wall	The sign of the 1/P coefficient of the tube model is undecided	23-02
primary-source wall	Wall	Missing primary sources	23-02
wall of principle	Type	One of the five types of walls: a wall that comes from the direction of an inequality and does not depend on the details of the tools	23-02
wall of structure	Type	One of the five types of walls: a wall where the requirements are incompatible within the chosen family, bookkeeping or series (outside the family it is undecided)	23-02
wall of tools	Type	One of the five types of walls: a wall where tools of the needed kind do not yet exist	23-02
wall of assumptions	Type	One of the five types of walls: a wall where the assumption relied on has itself not been proved, or depends on a conjecture	23-02
wall of measurement and literature	Type	One of the five types of walls: a wall coming from the sizes that can be measured and from missing primary sources	23-02
question "complete families of k=3 cells" (short: complete families of k=3 cells)	Question	Whether complete families of $k = 3$ cells exist in $d = 9$	23-17
question "largest dimension with a complete family" (short: largest dimension with a complete family)	Question	The largest dimension $d_{\max}(k)$ in which complete families exist	23-17
question "constant of the Hermite family" (short: constant of the Hermite family)	Question	The question of finding the constant in 1 − λ_k for the Hermite family	23-17
question "SU(N) version of the ratio on forests" (short: SU(N) version of the ratio on forests)	Question	The $SU(N)$ version, and a Lean statement, of the fact that the ratio of functions on forests saturates at $1/\lambda_1(G)$	23-17
question "C_P(β) on the two-dimensional lattice" (short: C_P(β) on the two-dimensional lattice)	Question	$C_P(\beta)$ in the link variables of two-dimensional lattice YM	23-17
question "curvature after one-link integration" (short: curvature after one-link integration)	Question	The best constant $c^* \in [21, 27]$ for the curvature after one-link integration	23-17

Name	Kind	What it refers to	Introducing chapter
question "the N^{−3} coefficient of the column model" (short: the N^{−3} coefficient of the column model)	Question	Deriving analytically the N^{-3} coefficient $C \approx 320$ of the column model (finite-size expansion of the XX chain)	23-17
question "sign of 1/P in the column model" (short: sign of 1/P in the column model)	Question	In the column model, the sign of $1/P$ at finite u	23-17
question "gauge dependence of the shortfall" (short: gauge dependence of the shortfall)	Question	How much the shortfall c_2 changes with the choice of gauge of the block transformation	23-17
question "C_P and ξ² of the O(3) σ model" (short: C_P and ξ² of the O(3) σ model)	Question	C_P and ξ^2 of the two-dimensional $O(3)$ σ model	23-17
question "C_P/ξ² of three-dimensional Z_2 gauge theory" (short: C_P/ξ² of three-dimensional Z_2 gauge theory)	Question	C_P/ξ^2 of three-dimensional $\mathbb{Z}_2$ gauge theory	23-17
question "volume monotonicity of C_P(V)" (short: volume monotonicity of C_P(V))	Question	Volume monotonicity of $C_P(V)$ and boundary conditions (computing all eigenvalues of the generator on small lattices)	23-17
question "dynamical exponent of four-dimensional SU(2)" (short: dynamical exponent of four-dimensional SU(2))	Question	Collecting primary sources on the dynamical exponent of local algorithms for four-dimensional $SU(2)$	23-17
question "interval arithmetic for the maximal correlation of the core" (short: interval arithmetic for the maximal correlation of the core)	Question	The question of bounding from above, by interval arithmetic, the two-point maximal correlation of medium cores ($8 \le k \le 14$)	23-17
question "power of the prefactor for the core and window" (short: power of the prefactor for the core and window)	Question	Reading the power of the prefactor $\hbar^{-p}$ of C_P for the core and the window from the capacity of degenerate points	23-17
question "comparison for the alternating maximal correlation of boxes" (short: comparison for the alternating maximal correlation of boxes)	Question	A comparison theorem showing the alternating maximal correlation between boxes $c_{\mathrm{alt}} < 1$ while avoiding examples that do not reduce to two-point quantities	23-17

Name	Kind	What it refers to	Introducing chapter
question "length set by a conservation-breaking term" (short: length set by a conservation-breaking term)	Question	Asks, when a small conservation-breaking term is added to a conservative dynamics, at what length the gap departs from the behaviour as the square of the side	23-17
row of common premises	Table row	Uniqueness of the $T=\infty$ measure, the Markov property, extension from local functions, the limiting step, regularity (the common premises)	23-11
row of interval-arithmetic premises	Table row	Premises of the interval arithmetic: correct rounding of the IEEE 754 arithmetic operations, errors of sums, errors of the self-written exponential function	23-07
summit-curvature shortfall wall	Table row	A row of Table 4 of 23-07: the curvature of the single site at the summit is short by 1/4 (a wall common to the three strands)	23-07
core lower-bound row	Table row	A row of Table 4 of 23-07: a uniform lower bound on the gap of the core	23-07
sector-framework row	Table row	A row of Table 4 of 23-07: the sector framework (five steps and the closing condition)	23-07
row of small assumptions	Table row	A row of Table 4 of 23-07: the small assumptions of the route of the sector input	23-07
window log-Sobolev threshold row	Table row	A row of Table 4 of 23-07: the one remaining proposition (the Window Log-Sobolev Threshold Proposition)	23-07
assumption lifting the proxy ratio	Table row	The lifting assumption of the Scalar-Strand Proposition (lifting the proxy ratio linearly beyond the measured range)	23-09
box-product inequality row	Table row	The box-product inequality (of Efron–Stein type)	23-05
row of the growth of the correlation length	Table row	The reading $\ln \xi \geq s/\hbar$ ($\xi \propto \hbar^{1/2} e^{S_0/\hbar}$)	23-05
kink-action row	Table row	A row of Table 3 of 23-04: the action S_0 of a single kink (paired with the zero-mode row)	23-04
zero-mode row	Table row	A row of Table 3 of 23-04: the translational zero mode of the kink (paired with the kink-action row)	23-04
next-eigenvalue row	Table row	A row of Table 3 of 23-04: the next eigenvalue 3/4 of the fluctuation operator around the kink	23-04

Name	Kind	What it refers to	Introducing chapter
Box-Dynamics Proposition (Propositions 3.4 and 3.5 of Martinelli's lectures) (short: Box-Dynamics Proposition)	Name from the literature	Box dynamics (the pattern that, for discrete spins, bounds the overall gap by the box dynamics and the gap inside the box)	23-05
Variance-Splitting Lemma (Lemma 2.4 of Menz–Schlichting) (short: Variance-Splitting Lemma)	Name from the literature	The formula for splitting the variance (the skeleton of the Poincaré version of Eyring–Kramers)	23-05
Poincaré Version of Helffer's Criterion (Proposition 3.1 of Ledoux) (short: Poincaré Version of Helffer's Criterion)	Name from the literature	The Poincaré version of Helffer's criterion (Proposition 3.1 of Bobkov–Ledoux 2000 is cited with the same number)	23-06
Integrated Bochner Formula (Proposition 1.3 of Ledoux) (short: Integrated Bochner Formula)	Name from the literature	The identity obtained by integrating Bochner's formula (used in sector composition to bound the Dirichlet form of the gradient by the curvature)	23-09
Holley–Stroock Perturbation Lemma (Proposition 6.1 of Ledoux) (short: Holley–Stroock Perturbation Lemma)	Name from the literature	A lemma that perturbs the Poincaré constant by the oscillation of the difference from a convex action (of Holley–Stroock type)	23-06
Single-Interface Diffusion Theorem (Theorem 2.1 of Bertini–Brassesco–Buttà) (short: Single-Interface Diffusion Theorem)	Name from the literature	The diffusion coefficient of a single interface	23-04
Two-Block Gibbs-Sampler Rate Theorem (Theorem 5 of Roberts–Sahu) (short: Two-Block Gibbs-Sampler Rate Theorem)	Name from the literature	The rate of convergence of the two-block Gibbs sampler	23-11
lattice correlation-length problem (Chatterjee's Problem 5.1) (short: lattice correlation-length problem)	Name from the literature	Chatterjee's Problem 5.1: at each β the lattice correlation length $\xi(\beta)$ is finite, and $\xi(\beta) \to \infty$ as $\beta \to \infty$	23-01, 16-07
continuum string-tension problem (Chatterjee's Problem 5.2) (short: continuum string-tension problem)	Name from the literature	Chatterjee's Problem 5.2: in the continuum limit of Wilson loops with a chosen lattice spacing, the string tension d is not 0	23-01, 16-07
angle graduation	Name	The Dirichlet form measured in the angles of the links	23-01
field graduation	Name	The Dirichlet form measured in the field $A = \sqrt{\beta}\,\vartheta$	23-01

Name	Kind	What it refers to	Introducing chapter
exponent of accumulation of the shortfall	Name	The exponent θ of the speed at which the shortfall accumulates (aξ ∝ a^θ)	23-01
one-step slope (symbol kept)	Name	The one-step slope $\kappa = 4Nb_0 = 11/(3\pi^2)$	23-02
one-step shortfall (symbol kept)	Name	The one-step shortfall. It vanishes as c_2/b^2	23-02
bookkeeping length	Name	The length ξ_RG = b^{k(β)} determined by the number k(β) of coarsening steps of the lattice. The lattice spacing is set to a := 1/ξ_RG	23-01
band exponent	Name	The exponent p when a^2C_P behaves as a power a^p of a (p = 0 is the band statement)	23-01
core log-Sobolev uniformity assumption	Condition	The log-Sobolev constant of the core is bounded uniformly	23-09
upper-side target row	Table row	A row of Table 3 of 23-04: the upper-side target $C_P \le K\xi^2 S_0/\hbar$ (the form of the conclusion of the First-Step Upper-Bound Proposition)	23-04
row of the numerical kink diffusion coefficient	Table row	A row of Table 3 of 23-04: the numerical kink diffusion coefficient $D/(\hbar/S_0) = 1.00–1.14$	23-04
row of the semiclassical leading term of the correlation length	Table row	A row of Table 3 of 23-04: the semiclassical leading term of the correlation length ξ (ξ ∝ ħ^{1/2} e^{S_0/ħ})	23-04
row of the lattice ln ξ	Table row	A row of Table 3 of 23-04: numerical values of the lattice ln ξ and the lattice kink action S_0^lat	23-04
row of the growth of the lower bound on R	Table row	A row of Table 3 of 23-04: the lower bound on the ratio $R = C_P/\xi^2$ grows from 1.06 to 6.5	23-04
dilute-gas accounting row	Table row	A row of Table 3 of 23-04: the accounting $C_P \approx \xi^2 S_0/\hbar$ obtained by counting kinks as a dilute gas	23-04
band-ratio row	Table row	A row of Table 3 of 23-04: the ratio to the component orthogonal to the magnetisation approaches 1	23-04
Glauber-eigenvalue row	Table row	A row of Table 3 of 23-04: the Glauber eigenvalue appears in the spectrum of the full state	23-04
row of the curvature of a convex core	Table row	A row of Table 3 of 23-04: for a convex core, $C_P \le 2/(3a^2-1)$	23-04
assumption that the maximum over searched starting points suffices	Assumption	The assumption that the maximum over the starting points searched by Monte Carlo suffices (it is not an upper bound over the whole fibre)	23-09

Name	Kind	What it refers to	Introducing chapter
assumption of the Barta row	Table row	The assumption of the inequality of the Barta row used in sector composition (lower bound $\kappa = 3/1000$ outside the defects, defect depth $b = 493/1000$)	23-09
eigenfunction-regularity assumption	Table row	The assumption, used in sector composition, that the Bochner boundary term vanishes, and of the regularity of the eigenfunction	23-09

Part 24 The first road, second half

Name	Kind	What it refers to	Introducing chapter
local diffusive-relaxation-time assumption (short: local relaxation-time assumption)	Name	The local Poincaré constant C_P^loc(c), with support restricted to a window c times the yardstick ℓ, has the same power as ℓ^2 (the upper side is C_P^loc(c) $\leq$ K(c)ℓ^2). Stated in the ratio form K_rel	24-03
sector diffusive-relaxation-time assumption (short: sector relaxation-time assumption)	Name	A statement of the diffusive-relaxation-time assumption for the measure conditioned on each topological sector (value of the charge) (the sector Poincaré constant C_P^sec(n))	24-03
local-excitation moment assumption	Assumption	The moment ratio of the spectral measure of local observables supported in a spatial box satisfies $M_3/M_1 \leq m_\infty^2 + \gamma/(c\ell)^2$	24-04
alternating maximal-correlation assumption for four-dimensional boxes	Assumption	The alternating maximal correlation between families of closed four-dimensional boxes is less than 1, uniformly in β	24-03
gap assumption for closed four-dimensional boxes	Assumption	For closed four-dimensional boxes, the relaxation time of a box satisfies C_box(cξ_RG) $\leq$ K'ξ_RG^2 (ξ_RG is the bookkeeping length)	24-03
infinite-volume ground-state transformation identity	Assumption	The assumption that the ground-state transformation identity of the lattice with continuous time (the relation between the gap and the vacuum measure) holds also in infinite volume	24-04
Window-Factor Monotonicity Proposition	Proposition	$g(x) = \phi(x)/x^2$ ($\phi(x) = 1 - (1-e^{-x})/x$) is strictly decreasing for $x > 0$ (the window factor decreases)	24-04
In-Window Supremum Proposition	Proposition	Under the assumptions of the one-sided bridge and the canonical graduation, writes in closed form, via the root of a transcendental equation, the supremum over the family local in time with weights supported in the window [0,T]	24-04

Name	Kind	What it refers to	Introducing chapter
Gap and Vacuum Measure Proposition	Proposition	On a lattice with continuous time, the gap is exactly the reciprocal of the Poincaré constant of the vacuum measure at a single time (ground-state transformation)	24-05
Electric–Magnetic Splitting Frustration Proposition	Proposition	With the splitting into electric and magnetic parts, the Kogut–Susskind Hamiltonian is not frustration-free	24-05
Local Poincaré Constant Properties Proposition	Proposition	The local Poincaré constant C_P^loc(c) is determined only by the marginal law of the window; D_c is not dense; it is monotone in c and returns to C_P as c→∞	24-03
Sector Poincaré Constant Proposition	Proposition	The sector Poincaré constant C_P^sec(n) is finite if the sector is connected; the variance splits into within-sector and between-sector parts, and can be bracketed with C_trans	24-03
Convexity Ceiling on Groups Lemma (short: Convexity Ceiling Lemma)	Lemma	For measures on closed manifolds, the lower bound of the Bakry–Émery curvature has a ceiling	24-06
No Concentration at the Identity Corollary	Corollary	On SU(2), a convex measure cannot concentrate at the identity	24-06
One-Link Wilson Weight Proposition	Proposition	The range of convexity of the one-link Wilson weight (at weak coupling, the non-convex region is pushed into a region of small probability)	24-06
rule of local convexity	Rule	One of the candidate rules for a class of measures that pay with rarity: the measure is locally convex on the good set	24-06
rule of rarity of bad sets	Rule	One of the candidate rules for a class of measures that pay with rarity: the non-convex bad set is rare	24-06
rule of return drift	Rule	One of the candidate rules for a class of measures that pay with rarity: there is a drift returning from the bad set to the good set	24-06
rule of paying for entropy	Rule	One of the candidate rules for a class of measures that pay with rarity: the rarity of the bad set is paid for with an entropy inequality	24-06
rule of closing under coarse-graining	Rule	One of the candidate rules for a class of measures that pay with rarity: the estimates close on the coarse-grained variables	24-06

Name	Kind	What it refers to	Introducing chapter
source: dimensionless coupling	Question	One of the sources of difficulty: the coupling is dimensionless, all scales act with the same weight, and infinitely many steps must be controlled uniformly in the number of steps	24-07
source: no expansion linking scales	Question	One of the sources of difficulty: there is no expansion linking the ultraviolet and the infrared	24-07
source: no global gauge fixing	Question	One of the sources of difficulty: because of non-abelian gauge invariance, there is no continuous global gauge fixing	24-07
three sources of difficulty	Question	The three sources of the difficulty of four-dimensional Yang–Mills (dimensionless coupling, no expansion linking scales, no global gauge fixing)	24-07
rule of axiomatising scale	Table row	A candidate rule in Table 2 of 24-08: treating scale as an axiom (axiomatising scale)	24-08
rule of the loop algebra	Table row	A candidate rule in Table 2 of 24-08: rules of the algebra of Wilson loops	24-08
rule of conserved quantities and sectors	Table row	A candidate rule in Table 2 of 24-08: rules for conserved quantities and the sectors divided by them	24-08
rule of the rarity class	Table row	A candidate rule in Table 2 of 24-08: the class of measures that pay with rarity	24-08
rule of an asymptotic-freedom axiom	Table row	A candidate rule in Table 2 of 24-08: a rule that sets asymptotic freedom as an axiom	24-08
curvature rule	Table row	A candidate rule in Table 2 of 24-08: a rule on the Bakry–Émery curvature on the space of gauge orbits	24-08
question "comparing local excitations of the free field" (short: comparing local excitations of the free field)	Question	The question of comparing energies of local excitations in the free field	24-08
question "monotonicity of the window factor" (short: monotonicity of the window factor)	Question	A question about the monotonicity of the window factor $\phi(x)/x^2$	24-08
question "sign of the Polyakov loop" (short: sign of the Polyakov loop)	Question	Asks whether, with the sign of the Polyakov loop in boxes of small period, a static ratio captures the slowness of relaxation	24-08
question "U(1) gap on two-dimensional layers" (short: U(1) gap on two-dimensional layers)	Question	Asks about the gap of U(1) on two-dimensional layers when the strip is lengthened	24-08

Name	Kind	What it refers to	Introducing chapter
question "data on topological-charge autocorrelation" (short: data on topological-charge autocorrelation)	Question	The question of collecting primary sources on the autocorrelation of the topological charge of SU(2)	24-08
question "many-family version of the Two-Projection Lemma" (short: many-family version of the Two-Projection Lemma)	Question	Asks for a many-family version of the Two-Projection Lemma (families of 2^d colours of d-dimensional boxes) and its condition on the maximal correlation	24-08
question "Hessian of the one-link weight" (short: Hessian of the one-link weight)	Question	Asks about the Hessian of the one-link Wilson weight convolved once with the heat kernel, and how the parameters of the class are mapped	24-08
question "time-step comparison for the transfer operator" (short: time-step comparison for the transfer operator)	Question	Asks whether the time-step comparison assumption holds for the Wilson transfer operator	24-08
question "Lean for τ_int and C_P" (short: Lean for τ_int and C_P)	Question	The question of writing τ_int ≤ C_P and the ground-state transformation identity in Lean	24-08
question "rereading the modes of CP^{N−1}" (short: rereading the modes of CP^{N−1})	Question	The question of rereading the local modes and topological modes of the CP^{N−1} model	24-08
question "loop families of two-dimensional SU(2)" (short: loop families of two-dimensional SU(2))	Question	The question of finding λ_W and Γ for loop families of two-dimensional SU(2)	24-08
question "values of large four-dimensional loops" (short: values of large four-dimensional loops)	Question	The question of finding the values for families of large loops in four-dimensional boxes	24-08
question "reduction to kink positions" (short: reduction to kink positions)	Question	The question of reducing the double-well problem to the dynamics of kink positions	24-08
question "the single point β=7 of the band" (short: the single point β=7 of the band)	Question	The question of measuring the single point β = 7 of the band	24-08
question "mass in the band between the threshold and 1" (short: mass in the band between the threshold and 1)	Question	The question of building another argument that sees the mass in the band between the threshold and 1	24-08

Name	Kind	What it refers to	Introducing chapter
question "window bridge on a time-step lattice" (short: window bridge on a time-step lattice)	Question	The question of making a version of the In-Window Supremum Proposition (the window bridge) on a lattice with discrete time	24-08
question "frustration-free sector splitting" (short: frustration-free sector splitting)	Question	Asks whether a sector splitting of the Kogut–Susskind Hamiltonian can be frustration-free	24-08
question "extending the CP^{N−1} test bed" (short: extending the CP^{N−1} test bed)	Question	The question of extending the CP^{N−1} test bed by adding seeds and values of N	24-08
question "conservation length of subregion charge" (short: conservation length of subregion charge)	Question	Asks at what length conservation breaks when measured with the charge of a four-dimensional subregion	24-08
type of a nearly conserved global quantity	Type	The type in which a global quantity not reflected in the gap slows relaxation at a length different from the correlation length (three conditions: the variance of the quantity is large, its Dirichlet form is small, and it is not reflected in the gap)	24-01
Infrared Asymptotic-Freedom Proposition (Proposition 6.1.7 of BBS) (short: Infrared Asymptotic-Freedom Proposition)	Name from the literature	The one-step estimate of the large-field weight norm; infrared asymptotic freedom	24-06
Covariance-Compression Lemma (Lemma 2.2 of Hairer–Stuart–Voss–Wiberg) (short: Covariance-Compression Lemma)	Name from the literature	An expression for the operator norm of a covariance compressed to a subspace	24-03

Part 25 The second road — from the direction of space

Name	Kind	What it refers to	Introducing chapter
five moves of the proof	Name	The five steps of the proof of the Slab Confinement Theorem	25-04
Moving-Surface Lemma	Lemma	Flipping the signs of all plaquettes containing a link leaves the partition function unchanged, the surface Π_q can be moved, and the partition function is determined only by the parity of the number of surfaces	25-01
definition of the sector and flux free energies	Name	The definitions $\Delta F = \ln(Z(0)/Z(1))$ and $\theta = \tanh(\Delta F/2)$	25-01

Name	Kind	What it refers to	Introducing chapter
Parity Representation of the Bias	Proposition	$\theta = E[(-1)^{\wedge}\lvert Q\rvert]$ (the expectation of the parity of the number of surfaces in the ensemble summed over twists)	25-01
Zero-Action Configuration Lemma	Lemma	$S^{\wedge}z=0 \iff U_p = z_p \cdot 1$ for all plaquettes	25-01
Lemma on the Sign of the Holonomy Commutator	Lemma	If all plaquettes take central values, the commutator of the holonomies around the two directions is the product of the signs of that plane	25-01
Determination-by-Holonomy Lemma	Lemma	A configuration with central values is determined, up to gauge, by the four holonomies at the base point	25-01
Lemma on the Configuration that Absorbs the Twist	Lemma	U^{0} has action 0 in the sector (1,0) ($\Omega_1\Omega_2\Omega_1^{-1}\Omega_2^{-1} = -1$)	25-01
Rigidity Lemma for Anticommuting Pairs	Lemma	A pair with $ABA^{-1}B^{-1} = -1$ is conjugate to $i\sigma_1$, $i\sigma_2$, and the only elements commuting with both are ± 1	25-01
Uniqueness of the Twisted Vacuum	Proposition	The configuration of action 0 in the sector (1,0) is U^{0} alone, up to gauge and centre transformations in the plane directions	25-01
Twisted Adjoint Gap Lemma	Proposition	The smallest eigenvalue of the adjoint Laplacian around U^{0} is $4\sin^2(\pi/2N) > 0$ (there are no zero modes)	25-01
Positivity of the Minimal Action in the Twisted Sector	Proposition	There is no configuration of action 0 in the sector (1,1), and $0 < S_{min} \leq 2N^2$	25-01
Confinement Lower Bound by Fractional Instantons (Theorem A of Paper 3) (short: Confinement Lower Bound by Fractional Instantons)	Theorem	For fixed $N \geq 2$, $\ell \geq 2$, $\beta \geq 1$, $-\ln \theta \geq c\, \beta^{\{-a\}}\, e^{\{-\beta(S_{*}+\varepsilon(\beta))\}}\, M^2$ (bounding the flux free energy from below by the action of fractional instantons)	25-02
Route to Existence by the Nahm Transform	Proposition	A route that, assuming equivariance of the Nahm transform, gives the existence of self-dual solutions of charge 1/2 on twisted $T^2 \times R^2$	25-02
Container Identity	Lemma	With the frame fixed, the containers become independent, and $\lvert\langle W\rangle\rvert \leq E_{\Phi}[\prod \theta_j]$, $\theta_j = \tanh(\lvert\Delta F_j\rvert/2)$	25-03
$\sigma_{avg}(\ell)$	Name	The estimate of the string tension of two-dimensional SU(2) obtained from the Container Identity (frame average) when tiling with containers of side ℓ	25-03

Name	Kind	What it refers to	Introducing chapter
Inner and Outer Container Proposition	Proposition	If containers are placed inside and outside the loop, the Wilson loop in a fixed sector is bounded by the product of the container biases and an outer term	25-03
Nesting Inequality in the Plane Directions	Proposition	The bias of a large container is bounded by the average of the product of the biases of the smaller containers into which it is split by the inner frame	25-03
assumption on the form of the thick-container free energy ((23) of Kovács–Tomboulis) (short: assumption on the form of the thick-container free energy)	Name from the literature	The free energy of a thick container has the form $\lvert V\rvert\, e^{-cd^2}$, uniformly in the boundary values	25-03
Slab Confinement Theorem	Theorem	With N and the lattice spacing fixed, for all β, $\lvert\langle \tfrac{1}{2}\mathrm{tr}\, U_C\rangle\rvert \le \tanh(\beta N^2)^A$ and $\sigma \ge -\ln\tanh(\beta N^2)$	25-04
finite configuration-space condition	Condition	One of the three conditions of the insertion identities: the configuration space X is a finite set	25-05
positive-weight condition	Condition	One of the three conditions of the insertion identities: the weight $w : X \to (0,\infty)$ is positive	25-05
sector-flipping bijection condition	Condition	One of the three conditions of the insertion identities: there is a bijection $T : X \to X$ that flips the sector sign $\sigma : X \to \{\pm 1\}$ ($\sigma(Tx) = -\sigma(x)$)	25-05
kernel moving only inside the container	Condition	A condition of driven insertion: the kernel updates only the variables inside the container and does not change the frame	25-06
Mean Insertion-Ratio Identity	Lemma	$E[\rho] = 1$, $E[\rho\sigma] = -E[\sigma]$	25-05
Bias Estimate by Insertion-Ratio Fluctuation	Theorem	$4E[\sigma]^2 \le \mathrm{Var}(\vec{\rho})$	25-05
Bounded Insertion Identity	Lemma	For an involution τ and an odd H, $E[H] = E[H\tanh(\Delta S/2)]$	25-05
Insertion Fluctuation Relation Lemma	Lemma	$P(\Delta S{=}s) = e^{s}\, P(\Delta S{=}{-}s)$, $E[t] \ge 0$, and $1-E[t]$ is twice the acceptance rate	25-05
Position-Averaged Insertion Estimate	Theorem	Bounds $\lvert E[H]\rvert$ by the product of the tanh factors averaged over positions	25-05
Square-Root Insertion Identity	Lemma	$E[H\sqrt{\rho}] = 0$	25-05
Paley–Zygmund-Type Bias Estimate	Theorem	$E[H]^2 \le 1 - E[Y]^2/E[Y^2]$, $E[Y^2] \le 1$	25-05

Name	Kind	What it refers to	Introducing chapter
Many-Cell Second-Moment Estimate	Theorem	Under "odd under insertion", $4^{\lvert C\rvert}\,\mathbb{E}[H]^2 \le \mathbb{E}[\prod(1-r_c)^2]$	25-05
assumption that composed insertions are odd	Assumption	For all $S \subseteq C$, $\mathbb{E}[H \prod_{c\in S} r_c] = (-1)^{\lvert S\rvert}\,\mathbb{E}[H]$	25-05
Crooks Relation	Lemma	Under the path involution ι, the ratio of weights is e^{-W}, and $W\circ\iota = -W$	25-06
Driven Insertion Identity	Theorem	$\mathbb{E}[H] = \mathbb{E}_{\Omega}[H \tanh(W/2)]$	25-06
Jarzynski Equality	Corollary	$\mathbb{E}[e^{-W} \mid \Phi, \sigma=+] = Z_-/Z_+$	25-06
Driven Insertion Acceptance-Rate Corollary	Corollary	$1 - \mathbb{E}[\tanh(W/2)] = 2\times$ the Barker-type acceptance rate	25-06
Many-Cell Driven Estimate	Theorem	Bounds by the product of the position averages of $\lvert\tanh(W/2)\rvert$ of driven insertions over many cells	25-06
Cut-Measure Formula	Proposition	$Z_{\pm}/Z_{\mathrm{cut}} = \mathbb{E}_{\mathrm{cut}}[e^{\pm\beta X/2}]$, $\theta = \lvert E\sinh\rvert/E\cosh$	25-06
Flip-Probability Lemma	Theorem	For a stationary kernel, the probability of a flip in one step is $\le 1-\theta^2$	25-06
Flip-Probability Corollary for Positive Kernels	Corollary	For a reversible positive kernel, $(1-\theta^2)/2$	25-06
Flow Lemma	Theorem	For the one-step flip probability a of a stationary kernel, $\theta \le 1-a$	25-06
Simultaneous-Flip Estimate	Theorem	$\mathbb{E}\prod\theta_t \le P(\text{no container flips})$	25-06
Transport Identity	Proposition	$\Delta F = \mathbb{E}_+[S\circ T - S - \ln J_T] - \mathrm{KL}$ (the transport identity and the Gibbs variational principle)	25-07
Isometric-Map Loss Proposition	Proposition	The loss of a map isometric in the fluctuations is $\tfrac{1}{2}\Sigma(\lambda-1-\ln\lambda)$, which is not diluted by the degrees of freedom	25-07
Fluctuation-Shaping Proposition	Proposition	The optimal value for maps of determinant 1 is $(n/2)(r^{1/n}-1)$, with loss $\le (\Delta F^2/n)e^{2\lvert\Delta F\rvert/n}$	25-07
First-Order Vanishing of the Spin Term	Proposition	The spin term does not appear in the first-order trace (at one-loop level)	25-07
Isometric versus Shaping Comparison Proposition	Proposition	(a) The isometric comparison gives $\beta' \ge \beta+0.023$; (b) the shaping comparison gives $\beta-\beta' = 0.258$	25-07
Relative-Entropy Obstruction to the Area Law	Proposition	If the remaining $\mathrm{KL} \ge c'A$, the area law does not follow from the variational argument	25-07
Additivity of Relative Entropy over Containers	Proposition	For a map that is a product over containers, the remaining KL is the sum over containers	25-07

Part 26 The crossover band

Name	Kind	What it refers to	Introducing chapter
Hidden-Convexity Proposition	Proposition	On the box [−c,0]^l the action has exactly one local minimum, and it is global	26-07
jump step	Name	The first step of the proof of the Conditional Reduction Theorem: from frame decorrelation and the base point at small T^2, jump to the first bias by the lateral-widening inequality	26-02
doubling step	Name	The second step of the proof of the Conditional Reduction Theorem: doubling the container and the transverse T^2 at each step, show that the bias satisfies $t_{k+1} \le K\, t_k^4$	26-02
iteration step	Name	The third step of the proof of the Conditional Reduction Theorem: iterating $t_{k+1} \le K\, t_k^4$ gives that the bias becomes small with an area exponent	26-02
Tension Lower Bound from the Naive Form	Proposition	The lower bound on the tension $\ln(1/\theta_0)/L^2$ obtained by container estimates from the naive form of the band $\theta \le \theta_0$ goes to 0	26-01
Area Law from the Area Exponent	Proposition	If $\theta \le e^{-cL^2}$, then $\lvert\langle W\rangle\rvert \le C_D\, e^{-cA}$	26-01
Tension Lower Bound from Tomboulis–Yaffe	Corollary	Under Tomboulis–Yaffe, if $F_\nu \le e^{-\rho\, L_\mu\, L_\nu}$, then the tension is $\ge \rho$	26-01
naive form of the band	Name	The naive form of the band: the sector bias stays away from 1 uniformly in the scale ($\sup \theta(L,L) \le \theta_0 < 1$). From this, container estimates give no positive lower bound on the tension	26-01
correct form of the band	Name	The correct form of the band: the sector bias becomes small with an area exponent ($\ln(1/\theta(L,L)) \ge cL^2$)	26-01
exclusion of a deconfined phase	Condition	One of the intermediate milestones toward the band: the vortex free energy $F_\nu(L,L)$ tends to 0 (excluding a non-confining phase)	26-01
almost area law	Condition	One of the intermediate milestones toward the band: $\ln(1/\theta) \ge cL^2/\ln L$ (the area exponent up to a logarithmic loss)	26-01
base point at small T^2	Assumption	One of the assumptions of the reduction theorem: at some physical scale L_0, the sector bias on a small T^2 satisfies $\theta(L_0;T^2_{L_0}) \le 1-\varepsilon_0$	26-02

Name	Kind	What it refers to	Introducing chapter
frame decorrelation	Assumption	One of the assumptions of the reduction theorem: multiplying the container by s raises the bias to the power s^2, up to a constant ($\theta(sR;T^2_L) \le C_D\, \theta(R;T^2_L)^{s^2}$)	26-02
lateral-widening inequality (strong form)	Assumption	One of the assumptions of the reduction theorem: with the container fixed, widening the transverse T^2 by a factor L'/L increases the bias by at most a factor $C(L'/L)^2$	26-02
lateral-widening inequality (weak form)	Assumption	The lateral-widening inequality weakened to a form that may lose, at each step doubling the transverse size, a fraction ε_k of $\ln(1/\theta)$ (with finite sum) and a constant	26-02
Conditional Reduction Theorem	Theorem	Under the base point at small T^2, frame decorrelation and the lateral-widening inequality (strong form), $\ln(1/\theta(R_k,R_k)) \ge \gamma R_k^2$ (the bias becomes small with an area exponent)	26-02
Reduction Theorem in the Weak Form	Theorem	Under frame decorrelation, the weak form and a condition on the size of the base point, $u_k \ge \gamma' R_k^2$	26-02
Slab-Tension Monotonicity Proposition	Proposition	If the lateral-widening inequality (strong form) holds, the effective tension σ_eff does not decrease in L (the reason the strong form is stronger than confinement)	26-02
Reduction Read in the Chessboard Density	Corollary	Read in the chessboard density κ_cb, the same reduction goes through with nesting constant 1 (under the chessboard-density base point and the lateral comparison)	26-02
chessboard-density base point	Assumption	The assumption of the base point at small T^2 read in the chessboard density: $\kappa_cb(L_0;L_0) \le 1-\varepsilon_0$	26-02
lateral comparison of the chessboard density	Assumption	The assumption of the lateral-widening inequality (strong form) read in the chessboard density: $\kappa_cb(R;L') \le C(L'/L)^2\, \kappa_cb(R;L)$	26-02
base-point translation inequality	Condition	The single line linking the bias at the base point and the chessboard density: $1-\kappa_cb(L_0;L_0) \ge \eta(1-\theta(L_0;L_0))$	26-02
Flux-Equalisation Lemma	Lemma	$\int_\Omega f^2 \ge \Phi^2/\lvert\Omega\rvert$, with equality for constants (Cauchy–Schwarz)	26-03

Name	Kind	What it refers to	Introducing chapter
Contrapositive of the Reduction	Proposition	If the conclusion of the reduction theorem is false, one of the three assumptions is false (contrapositive)	26-03
Electric-Flux Decomposition Lemma	Lemma	$Z(1,0) = Y(0)+Y(1)$, $Z(1,1) = Y(0)-Y(1)$, $\theta = Y(1)/Y(0) \geq 0$	26-04
positivity assumption for the twisted partition function	Assumption	The twisted partition function $Z(1,1)$ is at least 0 (positivity of the Boltzmann weight)	26-04
tanh Comparison Lemma	Lemma	If $F' \leq KF$ ($K \geq 1$), then $\tanh(F'/2) \leq K \tanh(F/2)$	26-04
Reflection-Positivity Theorem for z (short: reflection positivity of z)	Theorem	The z ensemble with the twist fixed is positive under reflections through lattice sites in directions 3 and 4 (the row "reflection positivity of z" in the ledger of conditions of 27-02 also refers to this theorem)	26-04, 27-02
Lemma on the Non-Positivity of Lateral Reflections	Lemma	The weight of a twisted plaquette has negative coefficients at half-integer j, so lateral reflections are not of positive type	26-04
Lemma that Structural Inputs Alone Do Not Suffice	Lemma	The set of structural inputs ☒ also holds for Z_2 and U(1), so the lateral-widening inequality does not follow from it alone	26-04
set of structural inputs	Name	The set consisting of positivity of the transfer matrix, the centre and duality identities, reflection positivity, the lattice symmetries and finite lemmas	26-04
thin-vortex floor	Name	The strong form reaching down to the floor of slab confinement: $\theta \leq \tanh(N^2\|\beta\|)^{M^2}$	26-04
Chessboard Estimate (Fröhlich–Israel–Lieb–Simon) (short: Chessboard Estimate)	Name from the literature	For a reflection-positive measure, $\|\langle\prod f_t\rangle\| \leq \prod\langle\prod f_t^{(s)}\rangle^{1/\|T\|}$	26-05
Chessboard Estimate with the Lateral Size Fixed	Corollary	$E\prod_{t\in S}\theta_t \leq \kappa_{cb}^{\|S\|}$, $\|\langle W\rangle\| \leq \kappa_{cb}^{n}$	26-05
Nested Supermultiplicativity Lemma	Lemma	$\kappa_{cb}(sR;L) \leq \kappa_{cb}(R;L)^{s^2}$ (constant 1, all L)	26-05
$\kappa_{cvx}(k)$	Name	The convexity constant at the top of a chain of length k ($\kappa(k)$ of the Short-Core Convexity Lemma of 23-11)	26-07
β-monotonicity	Condition	With the lattice geometry fixed, $\partial_\beta \Delta F \geq 0$	26-06
renormalisation comparison	Condition	$\Delta F(2N,2M,\beta) \leq K\cdot\Delta F(N,M,\beta')$, $\beta' < \beta$	26-06

Name	Kind	What it refers to	Introducing chapter
rate form of the renormalisation comparison	Name	$\sigma_N(\beta)$, $s(N,\beta) = N^2\sigma_N(\beta)$, and the rate form $s(N,\beta') \le s(2N,\beta)$	26-06
Strong-Coupling-End Expansion Proposition	Proposition	For $u \le u_0 \approx 10^{-80}$, $\Delta F = 2N^2 e^{-\sigma_N M^2}(1+\varepsilon)$	26-06
Comparison at the Strong-Coupling End	Corollary	At the strong-coupling end, choosing $\sigma_N(\beta') = 4\sigma_{2N}(\beta)$ gives $\Delta F(2N,2M,\beta)/\Delta F(N,M,\beta') = 4(1+O(u))$	26-06
assumption of two-sided area laws inside the band	Assumption	An assumption combining, on the band I, the two-sided area law at fixed β (with errors of the order of the perimeter) and the uniform positivity and continuity of the rate	26-06
two-sided area law at fixed β	Assumption	The assumption that at each β in the band I the vortex free energy is bounded above and below by the area rate $\sigma_N(\beta)$ (with errors of the order of the perimeter)	26-06
uniform positivity and continuity of the rate	Assumption	The assumption that the rate $\sigma_N(\beta)$ is uniformly positive on the band and uniformly continuous in β (for nearby β, $\sigma_N(\beta') \le \sigma_{2N}(\beta) + \sigma_*$)	26-06
Lemma Reducing the Comparison inside the Band	Lemma	Under the assumption of two-sided area laws inside the band, the renormalisation comparison inside the band holds with a constant K	26-06
Corollary Crossing the Band in Finitely Many Steps	Corollary	The band can be crossed in $\lceil(\beta_b - \beta_a)/\delta\rceil$ steps, with a loss independent of N and M	26-06
criterion "distinguish from the U(1) transition"	Condition	Show that SU(2) has no transition, distinguishing it from the transition of U(1) inside the band	26-06
tension-doubling inequality	Condition	$4\sigma_{2N}(\beta) \ge e^{\delta_0}\sigma_N(\beta)$ (for all $N \ge N_1$): the ratio of the tensions when the box is doubled exceeds 1 uniformly	26-06
softness in the twist direction	Name	One of the four faces of the middle band: the variance of the force along the generator of the twist within a band of width w (adapted stiffness)	26-06
mixing of box magnetic flux	Name	One of the four faces of the middle band: the total variation distance of the law of the inner cube when the central magnetic flux on the boundary of the box is changed	26-06

Name	Kind	What it refers to	Introducing chapter
twist cost of a column	Name	One of the four faces of the middle band: the twist-conditioned free energy and bias of the column $\mathrm{T}^2_\mathrm{N} \times \ell \times \ell$ with the outer frame fixed	26-06
pressure margin	Name	One of the four faces of the middle band: the difference in pressure $p_{\infty} - p_{G,L}$ between systems with and without the twist pattern inserted (the exponent of the chessboard density κ_{cb})	26-06
interpolation-parameter commonality inequality ((3.5) of Ito–Seiler) (short: interpolation-parameter commonality inequality)	Name from the literature	The inequality that reduces to A(α) > A⁺(α) the claim that the Migdal–Kadanoff interpolation parameter t* can be taken in common for two sectors	26-06
candidate "reduction by compactness of the band" (short: reduction by compactness of the band)	Name	One of the candidates for the band: since the band is a bounded closed interval of β, reduce the comparison inside the band to the two-sided area law at fixed β at each β, and cross in finitely many steps	26-10
candidate "log-concavity of the Weyl measure" (short: log-concavity of the Weyl measure)	Name	One of the candidates for the band: using the log-concavity of the density obtained by projecting the uniform measure on the sphere onto one coordinate, and a height–azimuth decomposition, bring it to a conditional ferromagnetic model	26-10
candidate "local step function of a column" (short: local step function of a column)	Name	One of the candidates for the band: replace the global renormalisation comparison by a comparison of the twist free energies of columns with the outer frame fixed (the local step function of a column)	26-10
candidate "confinement as sign cancellation" (short: confinement as sign cancellation)	Name	One of the candidates for the band: write θ = E[tanh(X/2)] in the measure summed over twists, and view the bias as becoming small through cancellation of the sign of X	26-10
candidate "centre-only influence coefficients" (short: centre-only influence coefficients)	Name	One of the candidates for the band: the influence coefficient $\delta_{\mathcal{C}}(L_0, \beta)$ when the outside is conditioned only on its SO(3) part and only the central flux on the boundary is flipped	26-10

Name	Kind	What it refers to	Introducing chapter
candidate "flux diffusion by monopole flow" (short: flux diffusion by monopole flow)	Name	One of the candidates for the band: since the sign flux of each plane changes with the parity of the closed $\mathbb{Z}_2$ monopole curves crossing between them, view the flux as being mixed by the winding density of monopoles	26-10
candidate "determinant in self-dual coordinates" (short: determinant in self-dual coordinates)	Name	One of the candidates for the band: in each sector, look at the difference between sectors of the Jacobian when the measure is viewed as a pushforward to its anti-self-dual part	26-10
candidate "quantitative 1-form symmetry of the slab" (short: quantitative 1-form symmetry of the slab)	Name	One of the candidates for the band: read slab confinement as the lattice version of "a discrete 1-form symmetry is not broken in two dimensions", and make its quantitative version uniform in N	26-10
stopped road "isometric comparison" (short: isometric comparison)	Table row	A road stopped in the band chapters: an isometric comparison that does not change the shape of the fluctuations (the one-loop spin term becomes 0, and only the anti-asymptotic-freedom direction comes out)	26-08
stopped road "structural inputs only" (short: structural inputs only)	Table row	A road stopped in the band chapters: showing it with structural inputs only — reflection positivity, duality, the transfer matrix and the centre identities (these also hold for $\mathbb{Z}_2$ and U(1), so they cannot distinguish groups)	26-08
stopped road "deterministic squeeze" (short: deterministic squeeze)	Table row	A road stopped in the band chapters: obtaining the area law by a squeeze with deterministic maps (the remaining relative entropy grows with the area)	26-08
stopped road "glassy squeeze" (short: glassy squeeze)	Table row	A road stopped in the band chapters: a squeeze with the $\mathbb{Z}_2$ glass in the upper half of the band (for $\beta \gtrsim 2$ the glass is on the ordered side and the squeeze is loose)	26-08
stopped road "flip certificate" (short: flip certificate)	Table row	A road stopped in the band chapters: using container flip certificates and simultaneous flips to test the band (the flip probability saturates at about 1/2, and only the weak form comes out)	26-08
stopped road "supremum estimate over frames" (short: supremum estimate over frames)	Table row	A road stopped in the band chapters: estimates using the supremum over frames (they get super-exponentially worse in L, and for uniformity only the frame-averaged form can be used)	26-08

Name	Kind	What it refers to	Introducing chapter
stopped road "Dobrushin-type criterion" (short: Dobrushin-type criterion)	Table row	A road stopped in the band chapters: using the criteria of Dobrushin, Dobrushin–Shlosman and van den Berg–Maes with frames (continuous fields follow the boundary and the influence coefficients are nearly 1)	26-08
stopped road "β-monotonicity from easy parts" (short: β-monotonicity from easy parts)	Table row	A road stopped in the band chapters: treating β-monotonicity as an easy part and splitting the band into β-monotonicity and the renormalisation comparison (β-monotonicity turned out to be as heavy as monotonicity of the tension)	26-08
stopped road "one-directional lateral widening" (short: one-directional lateral widening)	Table row	A road stopped in the band chapters: restricting lateral widening to one direction (doubtful given the behaviour of the high-temperature spatial string tension; restricted to square shapes only)	26-08
stopped road "transport by Wilson flow" (short: transport by Wilson flow)	Table row	A road stopped in the band chapters: using Wilson flow to transport vortex insertions (numerically negative; a form recast as forward transport remains open)	26-08
stopped road "conformal frame" (short: conformal frame)	Table row	A road stopped in the band chapters: turning scale into position with the conformal frame $H^2 \times S^2$ (with hyperbolic nesting the number of containers does not grow, and the crux remains in the same place)	26-08
stopped road "strong-coupling expansion only" (short: strong-coupling expansion only)	Table row	A road stopped in the band chapters: covering the band with the strong-coupling expansion alone (the flat-surface expansion stops at roughening $\beta_R \approx 1.9$)	26-08
approach of the holonomy to Haar	Table row	An idea that turned out to be only a restatement: the law of the holonomy of large loops approaches the Haar measure (the decay of the odd part is the Wilson area law itself)	26-08
anomaly of the centre and the θ term	Table row	An idea that turned out to be only a restatement: consistency of the mixed anomaly of the centre and the θ term (a kinematic constraint; at θ = 0 it forces nothing)	26-08

Name	Kind	What it refers to	Introducing chapter
success in the hierarchical model	Table row	An idea that turned out to be only a restatement: taking success in the hierarchical model (the model where Migdal–Kadanoff decimation is exact) as evidence for the band (U(N) also confines there, so it is not a test)	26-08
criterion "stands on the lattice alone" (short: stands on the lattice alone)	Condition	A criterion a tool for crossing the band must meet: it holds on the lattice alone and does not rely on rotation invariance	26-08
criterion "distinguishes phases" (short: distinguishes phases)	Condition	A criterion a tool for crossing the band must meet: it distinguishes phases (it breaks down in a massless phase, or the limiting values differ)	26-08
criterion "does not rely on positivity" (short: does not rely on positivity)	Condition	A criterion a tool for crossing the band must meet: it does not rely on positivity or FKG	26-08
criterion "uses non-commutativity essentially" (short: uses non-commutativity essentially)	Condition	A criterion a tool for crossing the band must meet: it uses non-commutativity essentially (the same argument does not go through for U(1) or $\mathbb{Z}_2$)	26-08
criterion "compatible with asymptotic freedom" (short: compatible with asymptotic freedom)	Condition	A criterion a tool for crossing the band must meet: it is compatible with asymptotic freedom	26-08
criterion "handles topological sectors" (short: handles topological sectors)	Condition	A criterion a tool for crossing the band must meet: it can handle topological sectors (twists)	26-08
criterion "not a rewording of one loop" (short: not a rewording of one loop)	Condition	A criterion a tool for crossing the band must meet: it is a non-perturbative estimate, not a rewording of one loop	26-08
criterion "dynamical" (short: dynamical)	Condition	A criterion a tool for crossing the band must meet: it is a dynamical argument, not a kinematic constraint	26-08
criterion "passes through non-convex regions" (short: passes through non-convex regions)	Condition	A criterion a tool for crossing the band must meet: it can pass through non-convex (negatively curved) regions. Tools based only on convexity, log-concavity or curvature lower bounds cannot be used in the band	26-08
criterion "crosses the smallest band" (short: crosses the smallest band)	Condition	A criterion a tool for crossing the band must meet: it can first cross the smallest band of two-dimensional asymptotically free models (such as the O(N) model at large N) with the ultraviolet cutoff removed	26-08

Name	Kind	What it refers to	Introducing chapter
criterion "not broken by small loops" (short: not broken by small loops)	Condition	A criterion a tool for crossing the band must meet: it does not break down for small loops (short scales), or it is in a form that claims only large loops	26-08
criterion "non-isometric linearisation" (short: non-isometric linearisation)	Condition	A criterion a tool for crossing the band must meet: the linearisation of the comparison map is not isometric in the fluctuations	26-08

Part 27 Closing — conditional statements

Name	Kind	What it refers to	Introducing chapter
Reverse Estimate at a Fixed Plane (Theorem B of Paper 3) (short: Reverse Estimate at a Fixed Plane)	Theorem	The reverse estimate at fixed M (an upper estimate on the tension) of the paper on lattice fractional instantons	27-01
Doubling-Iteration Theorem	Theorem	Under θ(2R_k;T²_{R_k}) ≤ K₁θ^4 and lateral widening (s=2), θ(R_k;T²_{R_k}) ≤ K^{−1/3}exp(−cR_k²)	27-01
uniform acceptance of insertion	Table row	One of the assumptions of the conditional statement: under small-field frames, the average of tanh(W/2) for vortex insertions driven by dynamics is at most 1 − δ uniformly in the lattice spacing	27-01
frame decorrelation (form with L fixed)	Table row	One of the assumptions of the conditional statement: correlations between container frames decay, and E∏θ can be split into the product of the individual θ with a constant loss (form with L fixed)	27-01
decay of block observables (form with L fixed)	Table row	One of the assumptions of the conditional statement: correlations of block observables decay exponentially at a rate $m \geq c/L$ uniform in a (the form assumed by the theory on a small T^2)	27-01
lateral-widening inequality	Table row	One of the assumptions of the conditional statement: with the container fixed, widening the transverse T^2 by a factor s multiplies θ by at most Cs^2 (strong form), or a form with a finite total loss (weak form)	27-01
uniform slab tension	Table row	One of the assumptions of the conditional statement: the string tension $\sigma_{\text{eff}}(L)$ of the slab $T^2_L \times \mathbb{R}^2$ is positive uniformly in L	27-01
uniform slab gap	Table row	One of the assumptions of the conditional statement: correlations of block observables decay exponentially, uniformly in the lattice spacing and the slab size L (a premise of the arrow of the R^4 gap)	27-01

Name	Kind	What it refers to	Introducing chapter
limit to R^4	Table row	One of the assumptions of the conditional statement: the infinite-volume limit, the OS axioms, recovery of rotation invariance, uniqueness of the limit, non-triviality (outside the ledger)	27-01
tying the two roads together	Table row	One of the assumptions of the conditional statement: the road of the gap and the road of confinement give both conclusions for the same theory on R^4 (outside the ledger)	27-01
theory on a small T^2	Name	The theory on $R^2 \times$ a small twisted T^2 with the lattice spacing taken to 0	27-01
theory on R^4	Name	The theory on R^4 (where the T^2 of the theory on a small T^2 has been widened)	27-01
arrow of the small-T^2 gap	Condition	The arrow that gives, from ultraviolet control and the decay of block observables (form with L fixed), the existence of the theory on a small T^2 and a gap $m \geq c/L$	27-01
arrow of the R^4 gap	Condition	The arrow that gives the R^4 gap from the arrow of the small-T^2 gap, the uniform slab gap and the limit to R^4	27-01
arrow of slab confinement	Condition	The arrow of slab confinement with the lattice spacing and N fixed	27-01
arrow of the fractional-instanton rate	Condition	The arrow that gives the rate of the flux free energy from the Confinement Lower Bound by Fractional Instantons	27-01
arrow of the small-T^2 area law	Condition	The arrow that gives the area law of the theory on a small T^2 from ultraviolet control and uniform acceptance of insertion	27-01
arrow of the reduction of the band	Condition	From the base point, frame decorrelation and lateral widening, $\theta(R;T^2_R) \leq e\text{^}\{-cR^2\}$	27-01
arrow from the container estimate to the area law	Condition	From the reduced form and frame decorrelation, an area law uniform in L (the container estimate)	27-01
chessboard arrow	Condition	The arrow of the Chessboard Estimate with T^2 fixed	27-01
arrow from the two uniformities to the area law	Condition	The arrow that gives the area law from the uniform slab tension and the uniform slab gap	27-01
arrow of the R^4 area law	Condition	The arrow that gives the R^4 area law from the arrow from the container estimate to the area law, or the arrow from the two uniformities to the area law, together with the limit to R^4	27-01
arrow tying the two roads together	Condition	Both the mass gap and confinement for the same theory on R^4	27-01

Name	Kind	What it refers to	Introducing chapter
arrow of the road from the direction of time	Condition	From the upper-bound assumption and the one-sided bridge, m_phys $\geq$ (κ/K)^{1/2} at each β	27-01
small-T^2 gap	Table row	With the twist, zero modes disappear and the gap of the transfer matrix $\geq$ c/L uniformly in a	27-02
band comparison (in the language of the gap)	Table row	The lowest mass of the neutral sector of the box measured in units of the box size, x(L) = L m_0(L), satisfies x(2L) $\geq$ x(L) + δ over the interval of the band	27-02
uniform decay of block observables	Table row	Correlations of block observables with vacuum expectation 0 decay at a rate independent of a and L	27-02
positivity of the 't Hooft tension	Table row	$\ln(1/\theta(L,L)) \geq cL^2$ (c independent of L)	27-02
uniform gap of the double well	Table row	A gap, uniform in k and ħ, of the path measure of the 0+1-dimensional double well	27-02, A-08
uniformity of the relaxation-time upper bound and the one-sided bridge	Table row	The upper side of the diffusive-relaxation-time assumption and the one-sided bridge hold uniformly as $\beta \to \infty$	27-02, A-08
ledger of conditions	Table row	The ledger listing, one row each, the assumptions set by the conditional statement toward the mass gap and confinement, with what is to be shown and its status (Table 2 of 27-02)	27-02
lower end of the renormalisation comparison	Table row	A breakdown of the renormalisation comparison: the lower end, which pushes confinement and the comparison up to $\beta \approx 0.3$–1	27-02
upper end of the renormalisation comparison	Table row	A breakdown of the renormalisation comparison: the semiclassical upper end at fixed N and large β	27-02
middle of the renormalisation comparison	Table row	A breakdown of the renormalisation comparison: the middle, where one inequality using non-commutativity is needed (one of the four faces, uniformly in the scale)	27-02
strong-coupling end of the renormalisation comparison	Table row	A breakdown of the renormalisation comparison: the strong-coupling end $\beta \lesssim 10^{-79}$ (the record has a proof, with crude constants)	27-02

Name	Kind	What it refers to	Introducing chapter
one-loop end of the renormalisation comparison	Table row	A breakdown of the renormalisation comparison: at one-loop level, the comparison that shapes the fluctuations gives $\beta - \beta' = 0.258$, and the comparison that does not change their shape gives $\beta' \geq \beta + 0.023$	27-02
band in the language of the coupling	Table row	The row that states the band in the language of the coupling: written as a mixed derivative of a box with uniform background holonomies placed at both ends in time (a Schrödinger-functional box)	27-02
ultraviolet control in arbitrary volume	Condition	Ultraviolet control extended to arbitrary volume with extensive constants, with continuity in the sources made uniform in the lattice spacing and the volume	27-02
limiting measure on R^4 and its positivity	Table row	A gap outside the ledger: within the limit to R^4, the limiting measure, translations, preservation of reflection positivity, the Hilbert space and $H \geq 0$	27-02
recovery of rotation invariance	Table row	A gap outside the ledger: recovery of rotation invariance in the limit	27-02
local fields and OS regularity	Table row	A gap outside the ledger: local fields, OS regularity and the linear-growth condition (Wightman fields)	27-02
uniqueness and non-triviality of the limit	Table row	A gap outside the ledger: uniqueness of the limit, non-triviality, clustering	27-02
all compact simple groups (short: general groups)	Table row	A gap outside the ledger: extending to all compact simple groups	27-02
verification and peer review	Table row	A gap outside the ledger: writing out the whole, Lean, expert peer review, publication	27-02
boundedness of the insertion free energy	Condition	One of the premises of uniform acceptance of insertion: the insertion free energy ΔF is bounded uniformly in the lattice spacing	27-02
uniform lower bound on the path overlap	Condition	One of the premises of uniform acceptance of insertion: the overlap of the forward and reverse paths is bounded from below uniformly in the lattice spacing	27-02
ultraviolet control around a vortex background	Condition	One of the premises of the base point at small T^2: ultraviolet control around a background of constant curvature	27-02
insertion acceptance in a symmetric container	Condition	One of the premises of the base point at small T^2: uniform acceptance of insertion in a symmetric container of size L_0	27-02

Name	Kind	What it refers to	Introducing chapter
Lemma on the Upper Bound for the Minimal Action of a Symmetric Box	Lemma	For all N, the minimal action of the symmetric box satisfies S_min(N,N) $\leq 2N^4(1-\cos(\pi/N^2)) < \pi^2$	27-02
twelve tasks	Table row	The list dividing the continuum tasks into twelve (T^4 construction, infinite volume, uniform gap, remaining axioms, non-triviality, local fields and short distances, and so on; Table 1 of 16-07)	27-03
linear-growth condition (Osterwalder–Schrader axiom E0′) (short: linear-growth condition)	Name from the literature	A condition controlling the growth of Schwinger functions in n (added in 1975 to go back from the OS axioms to the Wightman axioms)	27-02
question "reverse direction of the fractional-instanton lower bound" (short: reverse direction of the fractional-instanton lower bound)	Table row	The reverse direction of the Confinement Lower Bound by Fractional Instantons: the question of showing, at fixed N, a dilute-gas upper bound uniform in M (an upper estimate on the tension)	27-03
question "agreement of the minimal actions" (short: agreement of the minimal actions)	Table row	The question of showing that the minimal action of a column with the frame frozen to the vacuum agrees with the minimal action of a free fractional instanton	27-03
question "existence of fractional instantons" (short: existence of fractional instantons)	Table row	The question of showing, on twisted $T^2 \times R^2$, the existence of a solution of topological charge 1/2 attaining the lower bound $4\pi^2/g^2$ of the action	27-03
question "SU(N) versions of the three facts" (short: SU(N) versions of the three facts)	Table row	The question of showing SU(N) versions of the uniqueness of the vacuum that absorbs the twist, the gap of the adjoint field, and the absence of flat configurations in the (1,1) sector	27-03
question "bias of the outer container" (short: bias of the outer container)	Table row	The second term when moving to a fixed sector: the question of showing that the bias of the outer container is typically small (0 as $M \to \infty$)	27-03
question "estimating the container free energy" (short: estimating the container free energy)	Table row	The question of estimating the container free energy uniformly over good frames and uniformly in the lattice spacing	27-03
question "cost of inserting a thick vortex" (short: cost of inserting a thick vortex)	Table row	The question of bounding the cost of insertion independently of N with the thick-vortex map (an improvement of the Slab Confinement Theorem toward the continuum limit)	27-03

Name	Kind	What it refers to	Introducing chapter
question "gap from insertion to the area law" (short: gap from insertion to the area law)	Table row	The question of showing the three things missing between the insertion estimates and the area law (rarity of simultaneous rejections, uniformity of the lower bound on the acceptance rate, an upper bound on the variance of the insertion ratio)	27-03
question "U(1) negative control" (short: U(1) negative control)	Table row	A negative-control question: applying the insertion estimates to four-dimensional U(1) to see where they stop working	27-03
question "oddness of composed insertions" (short: oddness of composed insertions)	Table row	The question of showing that the map composing insertions in separate cells satisfies the identity "odd under insertion"	27-03
question "literature check for slab confinement" (short: literature check for slab confinement)	Table row	The question of checking the Slab Confinement Theorem against arguments of Tomboulis–Yaffe type and the area law of high-temperature spatial Wilson loops (Borgs 1985)	27-03
question "kernels with flip probability near 1" (short: kernels with flip probability near 1)	Table row	The question of building a kernel with flip probability near 1 (for one-step kernels, the flip probability saturates at about 1/2)	27-03
question "quasi-static limit" (short: quasi-static limit)	Table row	The question of showing that, as the number of driving steps goes to infinity, the work W approaches the conditional free energy of the container	27-03
question "error of the shaping map" (short: error of the shaping map)	Table row	The question of bounding the error of the map that shapes the fluctuations (the relative entropy near the vortex surface and higher loops) at intermediate coupling and for large fields	27-03
question "ultraviolet cost of a fixed map" (short: ultraviolet cost of a fixed map)	Table row	Asks whether the extra ultraviolet cost of a fixed map grows in the same way in four-dimensional gauge theory	27-03
question "extending the measurements and their errors" (short: extending the measurements and their errors)	Table row	The question asking for measurements extended beyond the measured sizes of T^2, and for error estimates of driven insertion and replica exchange	27-03
question "non-perturbative proof of the lateral-widening inequality" (short: non-perturbative proof of the lateral-widening inequality)	Table row	The question of showing the lateral-widening inequality non-perturbatively, through $L \sim 1/\Lambda$ between the dilute region and the confining region	27-03
question "uniformity of frame decorrelation" (short: uniformity of frame decorrelation)	Table row	The question of showing frame decorrelation uniformly in L (with L fixed, it becomes a comparison of the chessboard density across scales)	27-03

Name	Kind	What it refers to	Introducing chapter
question "proof of the base point at small T^{2}" (short: proof of the base point at small T^{2})	Table row	The question of showing the base point at small T^{2} under ultraviolet control and uniform acceptance of insertion	27-03
question "excluding a deconfined phase" (short: excluding a deconfined phase)	Table row	The question of showing the exclusion of a non-confining phase, $\Delta F(L,L) \to 0$ (at any speed)	27-03
question "almost area law" (short: almost-area-law question)	Table row	The question of showing the almost area law $\ln(1/\theta(L,L)) \geq cL^{2}/\ln L$	27-03
question "β-monotonicity" (short: β-monotonicity question)	Table row	The question of showing $\partial_{\beta} \Delta F \geq 0$ with the lattice geometry fixed (β-monotonicity)	27-03
question "Z_{2} and U(1) on twisted slabs" (short: Z_{2} and U(1) on twisted slabs)	Table row	The question of checking that, on twisted slabs, β-monotonicity for $\mathbb{Z}_{2}$ and U(1) does not follow from Ginibre's inequality	27-03
question "criterion at the lower end" (short: criterion at the lower end)	Table row	The question of pushing up the lower end with a Dobrushin–Shlosman-type finite-size criterion based on the mixing of box magnetic flux, and with a computer-assisted count of the growth constant of surfaces	27-03
question "bookkeeping at the strong-coupling end" (short: bookkeeping at the strong-coupling end)	Table row	The question of writing out the bookkeeping of the Strong-Coupling-End Expansion Proposition and enlarging the constant $u_{0} \approx 10^{-80}$	27-03
question "four faces of the middle" (short: four faces of the middle)	Table row	The question of showing any one of the four faces of the middle, uniformly in the scale, in a form that breaks down for U(1)	27-03
question "two-sided area laws inside the band" (short: two-sided area laws inside the band)	Table row	The question of showing, at each β inside the band, the two-sided area law at fixed β (if it can be said, the comparison inside the band shrinks to finitely many steps)	27-03
question "what remains of the road of blocks and mixing" (short: what remains of the road of blocks and mixing)	Table row	The question of clearing up what remains of the road of blocks and mixing for the first step (the second and third stages of strong mixing, the check against a Varadhan-type limit and Witten's Morse theory)	27-03
question "convexity threshold and mixing length" (short: convexity threshold and mixing length)	Table row	Asks why, at the first step, the convexity threshold (the first conjugate point at the top ≈ 7.84) and the mixing length (about 9) are numerically close	27-03
question "touchstone of the smallest band" (short: touchstone of the smallest band)	Table row	The question of first testing a tool claimed to cross the band on two-dimensional asymptotically free models with the ultraviolet cutoff removed	27-03

Name	Kind	What it refers to	Introducing chapter
question "comparison principle for large loops" (short: comparison principle for large loops)	Table row	The question of showing the asymptotic form of the comparison principle for large loops only, σ_tw(L) ≤ σ_∞	27-03
question "testing the three new candidates" (short: testing the three new candidates)	Table row	The question of putting the three new candidates (reduction by compactness of the band, log-concavity of the Weyl measure, local step function of a column) through the tests of the selection criteria	27-03

Part 28 The tree of premises

Name	Kind	What it refers to	Introducing chapter
premise of the box continuum limit	Step	One of the groups of the tree of premises: the premises for the chain of block maps on a box of fixed size to give subsequential limits and the properties that pass to the limit (Table 2 of 28-04)	28-04
premise of ultraviolet stability	Step	One of the groups of the tree of premises: the premises for deriving the representation-level rows of the premise of the box continuum limit from one-step estimates (Table 3 of 28-04)	28-04
free-field premise	Step	One of the groups of the tree of premises: the absolute conditions on the free field. Given by reference to the free-field rows of the premise of ultraviolet stability (bracketing of the propagator and others), without separate rows in the table	28-04
premise of full-sequence convergence	Step	One of the groups of the tree of premises: the premises for the full sequence, along a tuned sequence of couplings, to converge without taking a subsequence (Table 4 of 28-04)	28-04
observable premise	Step	One of the groups of the tree of premises: the premises for handling fine observables (flowed observables and others) (Table 4 of 28-04)	28-04
infinite-volume premise	Step	One of the groups of the tree of premises: the premises for taking the infinite-volume limit (Table 4 of 28-04)	28-04
rotation premise	Step	One of the groups of the tree of premises: the premises for recovering rotation invariance in the limit (Table 4 of 28-04)	28-04
non-triviality premise	Step	One of the groups of the tree of premises: the premises that the limit is not a free field (Table 4 of 28-04)	28-04
fermion premise	Step	One of the groups of the tree of premises: the premises for theories containing fermions (outside the scope of the list of 28-04)	28-04

Name	Kind	What it refers to	Introducing chapter
implication of subsequential limits	Route	A conditional implication that, for the pushed-forward measures, if the premise fields hold then subsequential limits exist, and the limit has reflection positivity, symmetry and a lower bound of non-degeneracy	28-01
implication of full-sequence convergence	Route	A conditional implication that gives convergence of the full sequence, without taking a subsequence, as a statement about orbits of an abstract skew-product map	28-02
implication of the gap and the band	Route	A conditional implication that derives the mass gap from the uniform decay of block observables and reduces the band	28-03
continuity, composition and push-forward consistency of the block map	Table row	The block map B is continuous, the map from step to step is the composition of single steps, and the pushed-forward measures are consistent ($(B_m)_*\nu_{n,m+1} = \nu_{n,m}$)	28-04
gauge covariance and locality	Table row	The block map is covariant under gauge transformations ($B(U^g) = B(U)^{g\vert_{\text{coarse points}}}$), and the value of a coarse link depends only on fine links within a finite distance	28-04
commuting with the lattice symmetries	Table row	The block map commutes with the lattice translations, reflections and the hypercubic group	28-04
reflection positivity of the fine lattice	Table row	Reflection positivity of the Wilson measure on the fine lattice: for bounded measurable f depending only on links on the positive side, $\int f(\Theta U)\, f(U)\, d\mu_W \geq 0$	28-04
reflection positivity at the coarse level	Table row	Reflection positivity of the pushed-forward measure: for F in the positive-time class, the integral of the product of $F\circ\Theta$ and F with respect to the coarse-level measure is at least 0	28-04
symmetries of the measure	Table row	The pushed-forward measure $\nu_{n,m}$ is invariant under the lattice symmetries, and the symmetry breaking of observables tends to 0	28-04
family of observables and small-field set	Table row	The family of observables D is countable, dense and uniformly bounded, and the small-field set is closed and contains the two-step events	28-04
recursion of the activity	Table row	The recursion of the activity z_k, $z_{k+1} \leq \rho z_k + A w_k + B z_k^2$ (together with the existence of the limiting expectation and the large-field weight)	28-04
rarity of supply	Table row	The supply w_k is bounded as $w_k \leq \Phi(u_k)$ from exponential moments of the plaquette variables uniform in the step	28-04

Name	Kind	What it refers to	Introducing chapter
single-scale rarity on the fine lattice	Table row	For $\beta \geq 81$, the probability that all plaquettes of a set X have $\mathrm{Re}\, U_p < 0$ is $\leq q_1^{\lfloor \lvert X \rvert / 6 \rfloor}$ ($q_1 < 1$ independent of the volume)	28-04
moving invariant interval and margin	Table row	The effective coupling stays in a moving invariant interval, and the remainders can be paid for by the margin (inequalities of real functions such as ρW(s) + AΦ(s) + BW(s)^2 ≤ W(s'))	28-04
rarity of two-step events: plaquette part	Table row	For the pushed-forward measure, the probability that the plaquette variable β_m(1 − Re U_p) exceeds the threshold y_h(m) is at most P_1(m) (for large n)	28-04
rarity of two-step events: background-invariant part	Table row	For the pushed-forward measure, the probability that the invariant f of the background field exceeds the threshold f_h(m) is at most S(m) (for large n)	28-04
equicontinuity of observables	Table row	Differences of observable values are bounded uniformly as |s_n(d) − s_n(d')| ≤ τ_n + Ω(dist(d,d')) (τ_n → 0, Ω(r) → 0)	28-04
bracketing of the propagator	Table row	For all steps k and momenta, $c_0\, P/\omega \preceq G_k \preceq P/\omega$, $c_0 = 3/100$	28-04
positivity with background	Table row	The smallest eigenvalue of the constrained Hessian around the background field is at least $\lambda_0(1 - f_1/f_\star)$	28-04
contraction of irrelevant terms	Table row	$\mathcal{M}^{17}(\omega G_k) \preceq \tau\, \omega G_{k+17}$, $\tau < 1/170$, uniformly in k	28-04
coefficient of the one-step decrease of the coupling	Table row	The free-field coefficients b_k converge at rate $(3/5)^k$, and the sum of the transients is finite	28-04
value of the one-loop coefficient	Table row	The limit of the coefficient of the one-step decrease of the coupling is the one-loop value $b_\infty = 2b_0 \ln 2$ (a value from the literature; not rederived for this map)	28-04
contraction of the background map	Table row	The sum of the displacements per graduation, $\sum_j \Delta_j < \infty$ (the free-field part is of the type $\|\psi_l\|^2 \leq 0.608^l$)	28-04
geometry of many-body sums (correlation norm)	Table row	The correlation norm of the plaquette fields, $\Lambda \leq 640/9$	28-04
constrained inverse identity	Table row	The identity for the constrained Green function, C = G − GT*(TGT*)$^{-1}$TG, and its upper and lower estimates	28-04
Constrained Decay Theorem	Table row	The one-step constrained Green function at step k decays with respect to exponential weights, with constants uniform in the step	28-04

Name	Kind	What it refers to	Introducing chapter
zero-order transport of the background	Table row	For the step-by-step plaquette ratio θ_n of the background, sup 4ⁿθ_n < ∞ and Σ4ⁿθ_n^{3/2} < ∞ (the present form is known to be false)	28-04
one-step background-field lemma	Table row	For small fields, the minimiser of the constrained action is unique, analytic, exponentially local, and commutes with coarse gauge transformations	28-04
multistep background field	Table row	Unique and regular in nested small-field regions. The inverse of the linearisation is at most 1 in operator norm, independently of the number of steps	28-04
row sums of the lift uniform in the step	Table row	$\sup \lvert Eg\rvert \le R \sup \lvert g\rvert$, with R uniform in k	28-04
single-scale expansion tools	Table row	The cluster expansion on product white-noise measures, and its convergence	28-04
forest interpolation formula	Table row	The forest interpolation formula used for the cluster expansion (from the literature; its body is not in Lean)	28-04
small-field one-step renormalisation theorem	Table row	Coarse action = $\beta_{k+1} S_W$ (background) + local expansion + many-body terms. The many-body terms are exponentially small in the distance	28-04
gauge fixing step by step	Table row	Landau gauge at each step. The determinant is block lower-triangular. An estimate of the Haar Jacobian	28-04
large-field estimate	Table row	For each step t and each hole γ, $\lvert z_t(\gamma)\rvert \le \exp(-\gamma E \beta S^\flat(\gamma))$, $S^\flat(\gamma) \ge s_* \lvert\gamma\rvert$, with $s_* > 0$ uniform in the step and the volume	28-04
large-field gas	Table row	$\sum_{X \ni x} \lvert z(X)\rvert\, e^{2\lvert X\rvert} \le 1$, and the partition function of the gas equals the corresponding ratio	28-04
class and localisation	Table row	The only local gauge-invariant terms of dimension at most 4 are constants and $\sum \operatorname{tr} F^2$	28-04
induction uniform in the step	Table row	$r_{k+1} \le \tau_k r_k + a_k w_k + s_k$, $w_{k+1} \le b_k r_k + \sigma_k w_k + s'_k$; if the products of the coefficients are less than $1/4$, the iterates stay in the ball	28-04
contraction of the one-step map and matching at the endpoint	Table row	With estimates of the remainder of the one-step map and Lipschitz estimates of the coordinates, the map contracts and the coupling at the endpoint can be matched	28-04
approximation of flowed observables by block variables	Table row	Observables at flow time t are approximated by Lipschitz functions of the block variables at step m, with an error $\varepsilon_m(t) \to 0$ uniform in the lattice	28-04

Name	Kind	What it refers to	Introducing chapter
ultraviolet estimate uniform in the box size	Table row	The premise of the box continuum limit and the premise of ultraviolet stability hold with constants independent of the box size L	28-04
one-step ultraviolet estimate for the bridge	Table row	The one-step image from a rotated fine lattice to the standard coarse lattice lies in the ball of the chain	28-04
independence of the infinite-volume limit from the box shape	Table row	The limits along sequences of tori of different shapes agree	28-04
the limit is not a free field	Table row	The limiting theory is not a free field (which quantity to state it in is undecided)	28-04
non-negativity of θ	Table row	If M is even, $0 \le \theta_{N,M}(\beta)$ for all real β	28-04
single-scale criterion	Table row	At a physical size L_*, $\theta(L_*; T^2_{L_*}) < (s^2)^{-1/(s^2-1)}$ (0.63 for $s=2$, 0.7598 for $s=3$)	28-04
question of the cost of a twist-inserting map	Table row	For a gauge-covariant smooth map T, $\mathbb{E}_+[S\circ T - S - \ln J_T] \le 2\,\mathrm{artanh}(0.7598)$ uniformly in the lattice spacing	28-04
monotonicity of the vortex free energy and renormalisation comparison (short: monotonicity and renormalisation comparison)	Table row	The free energy of twist insertion is monotone in β. $s(N,\beta') \le s(2N,\beta)$	28-04
gap of a small twisted box and uniform acceptance of insertion (short: small-box gap and acceptance)	Table row	A gap $\ge c/L$ uniform in the lattice spacing. The acceptance rate of driven vortex insertion is uniform in the lattice spacing	28-04
from the area law to the gap	Table row	From the band (area exponent) to the uniform decay of block observables	28-04
from the area exponent of vortices to the area law of Wilson loops (short: from the vortex exponent to the area law)	Table row	The step that derives the area law of Wilson loops from the vortex free energy being small with an area exponent (from the literature; the typical-frame version has not been rederived)	28-04
tying the thresholds together	Table row	Tying the scale factor and threshold of the plaquette variables of two-step events to the effective coupling and threshold on the coupling side (for example β_m = 4u_m, y_h(m) = y_s(u_m))	28-04
choice of the small-field set and extension of the background invariant (short: choice of the small-field set)	Table row	The two-step events are contained in the small-field set (this holds if the background invariant is extended by a value larger than the threshold, and is false if it is extended by 0)	28-04

Name	Kind	What it refers to	Introducing chapter
constants of the quadratic type of the background	Table row	The constants of the three quadratic types in the background estimates, which make up the Lipschitz constant of the background map	28-04
geometry of many-body sums (reach constant)	Table row	The row sum R of the correlations of the plaquette fields is finite (the reach constant)	28-04
seam to the vessel of the mass gap	Table row	The implication of the vessel (28-03) assumes weak convergence of the full sequence of measures, and that the subspace of observables is closed under time translations. When used along subsequences, it takes the form "at every limit point"	28-04

Eight readings of the diffusive-relaxation-time assumption (master copy) — why the normalisation is named

The statement "C_P agrees with the square of a length" involves three choices: whether to say it by powers or by a band; whether the length of comparison is the correlation length ξ or the bookkeeping length ξ_{RG}; and whether C_P is measured with the angle $\mathcal{E}_\vartheta$ or the field $\mathcal{E}_A = \mathcal{E}_\vartheta/\beta$. With $2 \times 2 \times 2$ there are eight readings. The following table is the master copy.

Table 4 The eight readings (this table is the master copy; Table 5 of 23-01 is a summary. The two right-hand columns are accounts that presuppose the relaxation-time assumption. The exponent is the power of β multiplying C_P/ξ^2 or $a^2 C_P$)

Level, length, normalisation	Statement	Name in this book	Free approximation	One-loop logarithms Physics
Power, ξ, $\mathcal{E}_\vartheta$	$\ln C_P / \ln \xi \to 2$	Relaxation-time assumption ($\eta_{\mathrm{dyn}} = 0$)	Holds	Does not move
Power, ξ, $\mathcal{E}_A$				
Power, bookkeeping length, $\mathcal{E}_\vartheta$	$\ln C_P / \ln \xi_{\mathrm{RG}} \to 2$	Relaxation-time assumption with the one-scale chain and the bookkeeping-length chain (power)	Holds (the two-loop difference does not show in the power)	Does not move
Power, bookkeeping length, $\mathcal{E}_A$				
Band, ξ, $\mathcal{E}_\vartheta$	$C_P^{(\vartheta)} \asymp \xi^2$	Band form of the relaxation-time assumption [$\mathcal{E}_\vartheta$]	The lower-bound assumption [$\mathcal{E}_\vartheta$] breaks (ratio $g^2/4$, exponent -1)	$-9/22$: the lower-bound assumption [$\mathcal{E}_\vartheta$] breaks

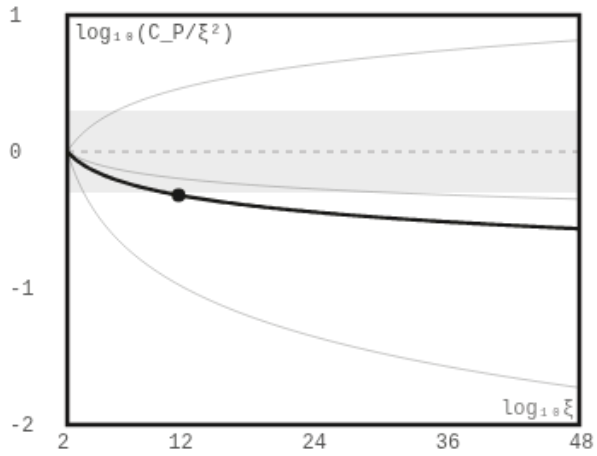
Level, length, normalisation	Statement	Name in this book	Free approximation	One-loop logarithms Physics
Band, ξ, $\mathcal{E}_A$	$C_P^{(A)} \asymp \xi^2$	Band form of the relaxation-time assumption [$\mathcal{E}_A$]	Holds (equality)	$+13/22$: the upper-bound assumption [$\mathcal{E}_A$] breaks
Band, bookkeeping length, $\mathcal{E}_\vartheta$	$a^2 C_P^{(\vartheta)} \asymp 1$	Band form of the relaxation-time assumption [$\mathcal{E}_\vartheta$] with the one-scale chain and the bookkeeping-length chain	Decided by the order of the bookkeeping (23-01 § 07)	$-303/242$
Band, bookkeeping length, $\mathcal{E}_A$	$a^2 C_P^{(A)} \asymp 1$	Band form of the relaxation-time assumption [$\mathcal{E}_A$] with the one-scale chain and the bookkeeping-length chain		$-61/242$

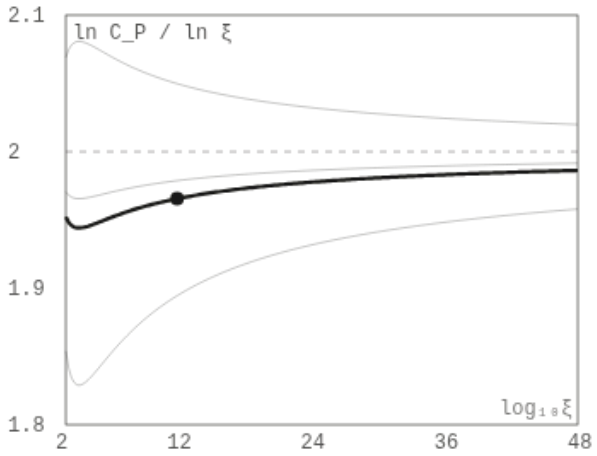
The derivation is in 23-01 The line of construction and the diffusive-relaxation-time assumption and 4-06 § 05; here only the sum is shown (this passage may be skipped). The fractions in the right-hand column are sums of three logarithms: the -1 of the normalisation ($C_P^{(\vartheta)} = C_P^{(A)}/\beta$), the $+13/22$ of the renormalisation of stochastic time (23-01 The line of construction and the diffusive-relaxation-time assumption), and, entering only the rows with the bookkeeping length, the difference between one-loop bookkeeping and two-loop running, $-2 \cdot \frac{51}{121} = -\frac{102}{121}$ ($51/121 = b_1/(2b_0^2)$, independent of N for pure SU(N); 4-06 § 05). All are accounts under the renormalisation group of one-loop perturbation theory, and carry the Physics label.

$$-1 + \frac{13}{22} = -\frac{9}{22}, \qquad \frac{13}{22} - \frac{102}{121} = -\frac{61}{242}, \qquad -\frac{9}{22} - \frac{102}{121} = -\frac{303}{242} \quad (3)$$

We confirmed this sum on this machine in exact rationals Computed . The following figure draws, under this account, how the ratio of the band readings C_P/ξ^2 and the exponent of the power readings $\ln C_P / \ln \xi$ move. β and ξ are tied by the one-loop formula $\xi \approx e^{3\pi^2\beta/11}$ (up to a constant factor, 4-07).

Figure 1 Choosing a reading draws, on the left, the ratio of the band reading C_P/ξ^2 (1 at $\xi = 10^2$; logarithmic vertical axis) and, on the right, the exponent of the power reading $\ln C_P/\ln\xi$. The three buttons choose level, length and normalisation, and the knob chooses $\log_{10}\xi$. The panel with the thicker frame decides the truth of the chosen level. The pale shading on the left is a guide for ratios 1/2–2 (one example of the constants of a band)





Band, ξ, angle graduation → band form of the relaxation-time assumption [angle graduation]: s = −9/22. ξ = 10^12: β = 10.27, ratio 0.4805, power exponent 1.9655. Band: the ratio keeps moving away from 1 (it does not close with a uniform constant)

Computed The numbers in this figure were computed on this machine (the exponent of (3) and the one-loop formula are evaluated on the spot; Table 5 is the Python values).

When JavaScript is disabled, it can be read in Table 5.

Table 5 Ratio and exponent under the one-loop account (SU(2); $\beta = \frac{11}{3\pi^2}\ln\xi$; the ratio is $(\beta/\beta(10^2))^s$ and the expone

Computed Physics

Length, normalisation	s	Ratio $\xi = 10^3$	Ratio 10^{12}	Ratio 10^{48}	Exponent 10^3	Exponent 10^{12}
ξ, $\mathcal{E}_\vartheta$	−9/22	0.8472	0.4805	0.2725	1.9442	1.9655
ξ, $\mathcal{E}_A$	+13/22	1.2707	2.8828	6.5400	2.0806	2.0498
Bookkeeping length, $\mathcal{E}_\vartheta$	−303/242	0.6019	0.1061	0.0187	1.8292	1.8945
Bookkeeping length, $\mathcal{E}_A$	−61/242	0.9028	0.6366	0.4488	1.9656	1.9788
(For reference) free approximation, $\mathcal{E}_\vartheta$	−1	0.6667	0.1667	0.0417	1.8636	1.9157

There are two ways to read it. In the ratio columns all four rows keep moving away from 1, and no band reading closes with a uniform constant. In the exponent columns all four rows approach 2, and the power reading does not move. But the approach is slow: even at $\xi = 10^{48}$ the exponent is still 0.008–0.042 away from 2. The last row is the same formula as Table 9 of A-01; the exponents agree, and the ratios agree once the values of A-01 are divided by the value at $\xi = 10^2$. This table does not measure C_P of the Yang–Mills measure; it is an example laying out the consequences of the account. The difference between the two kinds of columns in this table is the reason this book placed the relaxation-time assumption at the level of powers.

05

Bookkeeping and exponent quantities — κ, δ, θ, the bookkeeping length, p, η_{dyn}

This book's study in Part 23 kept the books on a step that coarsens the lattice by a factor b with the following map (23-02 Roads tried on the four-dimensional lattice, and walls).

$$\beta \longmapsto \beta - \kappa\big(\ln b - \delta(b)\big), \qquad a^2 C_P \propto a^p, \qquad p = \eta_{\mathrm{dyn}} + (2 - \eta_{\mathrm{dyn}})\,\theta \ \text{(8)}$$

The two numbers in the left formula and the two exponents in the right formula are the quantities of this section. The quantities are not assumptions, but sentences such as "$\sum \delta < \infty$" and "$\eta_{\mathrm{dyn}} = 0$" are assumptions, and the phrasing of Part 23, "the physical-unit gap statement $\Longleftrightarrow \sum \delta < \infty$ and $\eta = 0$", is the algebra of $p = 0$ presupposing the power form and the model of the one-loop kernel.

Table 6 Quantities of bookkeeping and exponents

Symbol	Kind	One-line meaning	Master	Status
κ	Quantity	The slope per step. $\kappa = 4Nb_0 = 11/(3\pi^2) = 0.3715110$ $(N = 2)$	23-02 Roads tried on the four-dimensional lattice, and walls, 4-06 § 02	Known A rewriting of the one-loop coefficient. Agreement to 5 digits in the window of the model is Computed (agreement within the model)
$\delta(b)$	Quantity	The shortfall per step: the amount by which the window falls short of the continuum $\ln b$. Vanishes as c_2/b^2	23-02 Roads tried on the four-dimensional lattice, and walls	A number measured in the model of the one-loop kernel (not a non-perturbative quantity) Computed
$\sum_k \delta(b_k) < \infty$	Assumption	The shortfalls are summable	Same as above, 18-05 § 06	Assumption. For fixed b, $\delta(b) = 0$ is necessary and sufficient Lean fixed_step_bounded_iff
θ	Quantity	The exponent of accumulation of the shortfall. $a\xi \propto a^{\theta}$. For fixed b, $\delta(b)/\ln b$	23-01 The line of construction and the diffusive-relaxation-time assumption	Definition. If $\sum \delta < \infty$ then $\theta = 0$
ξ_{RG}, a	Quantity	The bookkeeping length b $k(\beta)$, and $a := 1/\xi_{\mathrm{RG}}$. At one loop $\xi_{\mathrm{RG}} \approx e^{3\pi^2\beta/11}$	23-01 The line of construction and the diffusive-relaxation-time assumption, 23-02	The definition of Part 23. The one-loop part is Known (the same formula as $1/(a\Lambda)$)
p	Quantity	The power in $a^2 C_P \propto a^p$. The right-hand side of (8)	23-01 The line of construction and the diffusive-relaxation-time assumption	$p = 0 \iff \eta_{\mathrm{dyn}} = 0 \wedge \theta = 0$ (under $0 \le \eta \le 2$, $\theta \ge 0$) Lean drainExp_eq_zero_iff
z, η_{dyn}	Quantity	The dynamical exponent $C_P \asymp \xi^z$ and $\eta_{\mathrm{dyn}} = 2 - z$. The relaxation-time assumption is $\eta_{\mathrm{dyn}} = 0$	2-10 § 06, 18-05 § 02	Definition. The premise $\eta_{\mathrm{dyn}} \ge 0$ includes $z \le 2$

Symbol	Kind	One-line meaning	Master	Status
η_s	Quantity	The power of static correlations. Different from η_{dyn}. They are equal only within $z = 2 - \eta_s$	Same as above, A-01 § 08	For the two-dimensional Ising model, $\eta_s = 1/4$ and $\eta_{\mathrm{dyn}} = -0.1665$ Physics

The symbol η needs care. In the study of Part 23, η originally referred to two quantities. This book fixes the η of the equivalence between the power form and the physical-unit gap statement as η_{dyn}, and uses η_s only for the lower bound by test functions. An η without qualification is η_{dyn}.

Example. Fixing $b = 2$ gives $\delta(2) = 0.1335$ (weight w) and $\theta = \delta(2)/\ln 2 \approx 0.19$ (23-02 Roads tried on the four-dimensional lattice, and walls). Even with $\eta_{\mathrm{dyn}} = 0$, $p = 2\theta \approx 0.39 > 0$, and one falls on the side $a^2 CP \to 0$. If $b_k = k + 2$ is made larger at each step, then $\sum c_2/(k+2)^2 < \infty$ and $\theta = 0$ can be restored.

06

The assumptions of the second road and the band — names, content, status, what is needed to remove them, U(1)/$\mathbb{Z}_2$

We collect in one table the assumptions set by Parts 25–27 (the road from the direction of space, the crossover band, closing). In this section alone, the status column is written with the five grade labels of Part 23 (23-00 § 01: Proved here, Cited, Computer-assisted, Reading, Assumption). Rows at the stage of a line of proof are graded Assumption, and the existence of the line is written in the same column. The stages are the seven stages a proof must contain of 16-09, and the ledger rows are the rows of 27-02 Table 2; both are referred to by name. The last column is the behaviour of the same assumption when placed in $U(1)$ and in four-dimensional $\mathbb{Z}_2$ gauge theory; it is there to show which rows non-abelianness enters.

Table 7 The assumptions of the second road and the band (the conditional statement is in 27-01; the current state of each row and the rule by which it disappears are in 27-02)

Name	Content (one line)	Status	What is needed to remove it	Behaviour for U(1), $\mathbb{Z}_2$

Name	Content (one line)	Status	What is needed to remove it	Behaviour for U(1), $\mathbb{Z}_2$
Ultraviolet control (the ultraviolet stage among the stages a proof must contain; the ledger row has the same name)	Multiscale analysis uniform in a, from the lattice spacing a to the scale L: the small-field analyticity condition (locality and analyticity of the effective action), the large-field rarity condition, and the condition that the coupling stays small (the effective coupling stays in $(0, \gamma]$)	Assumption (Bałaban's inequality (0.31) contains a step that the original source says is unpublished)	Completing the write-up of Bałaban's steps, or checking the original source	An assumption relying on asymptotic freedom; it does not apply to U(1) or $\mathbb{Z}_2$
Uniform acceptance of insertion (small-T^2 confinement stage)	Under small-field frames, the average of $\tanh(W/2)$ for vortex insertions driven by dynamics is at most $1-\delta$ uniformly in a	Assumption (the numbers showing that the work drops as the procedure is lengthened are Reading)	Estimating the distribution of the work at one-loop (determinant) level	—
Base point at small T^2 (small-T^2 confinement stage)	At a small physical L_0, $\theta(L_0; T^2_{L_0}) \le 1 - \varepsilon_0$, $\varepsilon_0 \propto (L_0\Lambda)^{11/3}$	Assumption (line: under ultraviolet control and uniform acceptance of insertion. The form of the tension is Cited formula (2.37) of Tanizaki–Ünsal)	A proof under ultraviolet control and uniform acceptance of insertion	For U(1), the dependence of ε_0 on L_0 goes the other way
Frame decorrelation (of the same family as "uniform block decay" on a small T^2; small-T^2 confinement stage and band stage)	Correlations between container frames decay, and the Wilson-loop estimate $\mathbb{E}\prod\theta$ can be split into the product of the individual θ	Assumption . If T^2 is fixed, under reflection positivity of z the chessboard replaces it by a single density κ_{cb} Proved here	An estimate of κ_{cb}. Making it uniform in L requires the uniform slab gap	—

Name	Content (one line)	Status	What is needed to remove it	Behaviour for U(1), $\mathbb{Z}_2$
Reflection positivity of z (small-T^2 confinement stage and band stage)	The ensemble of z summed over twists is positive under reflections through lattice sites in directions 3 and 4	Proved here (no longer an assumption. The algebra of the kernel is in Lean `ReflPos.refl_pos`, `refl_cs`. The chapter giving the paper proof is 26-04)	—	Holds in the same way for $\mathbb{Z}_2$ and U(1) (a structural fact)
Contraction through good blocks (small-T^2 confinement stage and band stage)	Passing through a good block, the influence of the frame contracts to e^{-mw} in the gauge-invariant distance	Assumption	Bałaban-type analysis	—
Lateral-widening inequality, strong form (band stage; a form within the ledger row "positivity of the 't Hooft tension")	With the container fixed, widening the transverse T^2 by a factor s multiplies the sector bias θ by at most Cs^2	Assumption. The numbers are consistent Reading. It does not follow from the structural inputs alone (a negative lemma, 26-04)	Input from non-abelian dynamics (self-dual clusters, asymptotic freedom)	**Breaks** (for U(1) the flux spreads uniformly; for $\mathbb{Z}_2$, surface tension)
Lateral-widening inequality, weak form (band stage; a form within the ledger row "positivity of the 't Hooft tension")	A form of the strong form with a finite total loss (the slab tension σ_{eff} is "almost monotone")	Assumption (almost the same content as the band)	As above	Breaks
Uniform slab tension (band stage; the weak form of the ledger row "positivity of the 't Hooft tension")	The string tension of the slab $\sigma_{\text{eff}}(L)$ is positive uniformly in L	Assumption. The Creutz ratio grows and saturates for N $T = 4 \to 10$ Reading (conditions in 25-08)	The band itself	**Breaks** (for U(1), $\sigma \sim e^2/L^2$ goes to 0)

Name	Content (one line)	Status	What is needed to remove it	Behaviour for U(1), $\mathbb{Z}_2$
Uniform slab gap (band stage; the ledger row "uniform decay of block observables")	The mass gap of the slab is uniform in L: correlations of block observables decay uniformly in L (the ledger row of 27-02)	Assumption	A comparison of $\kappa_{\mathrm{cb}}(L)$ across scales	—
Limit to $\mathbb{R}^4$ (R^4 stage; one of the gaps remaining outside the ledger)	The infinite-volume limit, the OS axioms, recovery of rotation invariance, non-triviality	Assumption (mostly standard lines; the infrared side of rotation and uniqueness of the limit are open)	—	—
Tying the two roads together (tying the gap and confinement; spans the small-T^2 gap stage, the small-T^2 confinement stage and the R^4 stage; one of the gaps remaining outside the ledger)	Obtaining both the area law and the gap of the transfer matrix for the same theory on $\mathbb{R}^4$	Assumption (the statement is not yet fixed; the area law alone does not give a gap)	The uniform slab gap and the limit to $\mathbb{R}^4$	U(1): no confinement and no gap
All compact simple groups (general-group stage; one of the gaps remaining outside the ledger)	$SU(N)$ and groups without centre	Assumption	—	—

Name	Content (one line)	Status	What is needed to remove it	Behaviour for U(1), $\mathbb{Z}_2$
Diffusive-relaxation-time assumption (the upper side is the upper-bound assumption, the lower side the lower-bound assumption; the ledger row "uniformity of the relaxation-time upper bound and the one-sided bridge")	The time for fluctuations to even out grows as the square of the correlation length: $C_P \asymp \xi^2$ (dynamical exponent $z = 2$). The upper-bound assumption, together with the one-sided bridge, gives a lower bound on the gap in physical units	Assumption (23-01). The remaining items of the first step are in 23-15 Table 1 and the subsection on the road of blocks and mixing	The remaining items of Part 23 (23-15), and a form uniform in β (crossing the band in the language of time)	See 23-01, 24-01
Sector bias $\theta(R; T_L^2)$ (quantity)	The absolute value of the frame-conditioned expectation of the sector sign of the container $D \times T_L^2$ (side of D equal to R), $\lvert\mathbb{E}[\sigma_D \mid \Phi]\rvert$	Definition (25-03)	—	Constant for U(1); expected to approach 1 for four-dimensional $\mathbb{Z}_2$ Reading (physics)
Chessboard density κ_{cb} (quantity)	The per-block value (in the volume limit) of $\mathbb{E}\prod_t \theta_t$ when the plane is tiled with blocks of equal size and a container is placed in every block	Definition (26-05)	—	—

A note on symbols. The θ and κ_{cb} of Table 7 are different quantities from the θ (exponent of accumulation of the shortfall) and κ (one-step slope) of Table 6. The sector bias is written with arguments as $\theta(R; T_L^2)$, and the chessboard density with a subscript as κ_{cb}. The point to read in this table is that the rows marked "Breaks" in the non-abelian column gather in the two rows of the lateral-widening inequality and the row of the uniform slab tension. These rows (in the ledger, the row of positivity of the 't Hooft tension and the row of the renormalisation comparison among the inputs of the reduction) are where non-abelian dynamics enters; the other rows are structural facts or rows depending on the ultraviolet wall.

What this chapter can say

What is said	What is not said
The names and introducing chapters of Table 3 are taken from the table of names for the whole book (one name for one object)	The one line of "what it refers to" is a guide. The exact statements, assumptions and statuses are in the introducing chapters
Tables 1 and 2 are the conventions for names and symbols of the chapters of Volume 2	The full correspondence with the identifiers in the source of the published construction (where to find it is in the sources of each chapter)
Proved here For SU(2), $s = \kappa = 11/(3\pi^2)$	The values of the κ of Volume 3 for other groups (the theorems of Volume 3 are for SU(2) only)

Sources and reproduction

Item	Kind	Source / tools

Next chapter to read: A-07 Papers that came out of this book.

Papers that came out of this book

> This chapter is this book's own investigation. § 01 and § 07 are guide material.

What this chapter shows — A list of the five papers that came out of this book's study. For the two published on this site's papers page (the one-sided bridge, one-link integration) and the three at the draft stage (the paper on vortex-insertion identities, the paper on the reduction of the band, the paper on lattice fractional instantons), we list the title, the abstract and the main theorems, attach to each main theorem the book's label, its conditions and the reach of machine checking, and show which chapters of the book treat it.

Prerequisite chapters — None. How to read the labels is in 23-00 § 01, and how to read the Lean column is in A-04.

Said first — None of the papers claims a solution of the problem of Yang–Mills existence and the mass gap. The three drafts have not been through checking by outside mathematicians, and the book's labels are not copies of the drafts' statements (only what has been placed in a chapter of the book after its proof was checked is Proved here). The titles of the papers are quoted as in the original (English), and the abstracts and statements are shortened (the names and numbers of theorems are those of the originals).

Order of this chapter

1. The list of five — title, stage, pages, machine checking, chapters of the book (Table 1)
2. The one-sided bridge — the inverse square of the gap bounds the Poincaré constant from below (Table 2)
3. One-link integration — integrating one link before Bakry–Émery (Table 3)
4. Paper on vortex-insertion identities — the vortex-insertion identities (Table 4)
5. Paper on the reduction of the band — the reduction of the band, and numerics for $SU(2)$ and $U(1)$ (Table 5)
6. Paper on lattice fractional instantons — lattice confinement by fractional instantons (Table 6)
7. The papers and the Lean bundles — names of bundles, numbers of theorems, what they guarantee (Table 7)

01

The list of five

The "stage" in Table 1 is either published (the PDF and LaTeX source are on this site's papers page) or draft (material for the study in this book, not published). Pages are pages of the PDF. The authorship follows the form of publication.

Table 1 Papers that came out of this book (as of 2026-10-15)

Paper	Title (original)	Stage	Pages	Machine checking	Chapters of the book
The one-sided bridge	The inverse squared spectral gap bounds the Langevin Poincaré constant of Euclidean path measures from below	Published (2026-10-09, list of papers, PDF)	12	The algebraic skeleton (bundle EuclideanPath.GapBridge, 17 declarations)	23-01 § 06, 24-04 § 02, 24-05
One-link integration	One-link integration before Bakry–Émery for SU(2) lattice Yang–Mills — An explicit strong-coupling threshold β < √(2/27) in dimension four, and why complete families of links exist only for d ≤ 4	Published (2026-09-21, list of papers, PDF)	24	The chain from the Wilson action to the lower bound on the Hessian, and the combinatorics of complete families	5-11, 23-02 § 02

Paper	Title (original)	Stage	Pages	Machine checking	Chapters of the book
Paper on vortex-insertion identities	Exact centre-vortex insertion identities in the twist-summed ensemble, and bounded, averaged and driven confinement bounds	Draft (2026-10-13)	3	Algebra on a finite configuration space	25-05, 25-06
Paper on the reduction of the band	Where the twisted-slab route to confinement stops: a corrected window target, a reduction to transverse widening, and SU(2) versus U(1) numerics	Draft (2026-10-13)	9	The flux estimate, the electric-flux form, the doubling iteration, the algebra of reflection positivity	26-01, 26-02, 26-04, 26-05, 25-07, 26-09
Paper on lattice fractional instantons	Fractional instantons confine on the lattice: a rigorous semiclassical bound for SU(2) gauge theory on a twisted small torus	Draft (2026-10-14)	7	The factorisation of the column representation and the binomial estimate	25-02 § 06, 26-06 § 04, 27-02 upper end of the renormalisation comparison

The "window" in the original title of the paper on the reduction of the band is, in this book's vocabulary, "the crossover band". It is a different thing from the windows of Parts 23 and 24 (an interval of sites, a range of $\hbar$, an interval of times), and in the text we write "band" (26-00 § 02). The "rigorous" in the original title of the paper on lattice fractional instantons is the original's word, and is independent of the book's label.

02

The one-sided bridge — the inverse square of the gap bounds the Poincaré constant from below

Abstract. For $H = -(\hbar^2/2)\Delta_M + V$ on a finite-dimensional configuration space (a compact connected Riemannian manifold, or $\mathbb{R}^n$ with a constant metric and a smooth confining potential), assume a discrete spectrum, a simple positive ground state ψ_0 and a gap $\Delta = E_1 - E_0 > 0$. For the Euclidean path measure stationary over all time, the Poincaré constant of the Dirichlet form of stochastic quantisation (Langevin) on smooth time-averaged functionals satisfies $C_P \geq \kappa(\hbar/\Delta)^2$. The test function is the time integral of $F = \psi_1/\psi_0$, and among functionals local in time it is the best. The converse is false in general: for a free particle on the circle, $C_P = \infty$ while $\Delta > 0$. It touches neither four dimensions nor gauge fields.

Table 2 The main theorems of the one-sided bridge (the book's names are those of 23-01 and 24-04)

Number in the paper	Name in the book	Statement (with its conditions in the same row)	Label	Lean
Theorem 3.1	One-Sided Bridge Proposition (Theorem 3.1 of the paper)	Under the setting above and three assumptions (the ground-state assumption, the stationary path-measure assumption and the metric comparison assumption; (A1)–(A3) in the paper: discrete spectrum and simplicity of the ground state, a stationary path measure, the comparison constant κ of the Langevin metric), $C_P \geq \kappa\hbar^2/\Delta^2$. With time taken as continuous	Proved here (23-01 § 06)	Only the algebraic step: `poincare_lower_of_gap` (assumptions: $0 < p, m, \kappa, E$, $2p/m \leq V$, $E \leq 2mp/\kappa$, $V/E \leq C_P$), `window_ratio_closed` (assumptions: $0 < m$, $0 < T$). The path measure, the covariance formula and the ground-state identity are outside Lean
Corollary 3.6	The corollary of the bridge	Under the same assumptions, if $C_P \leq KL^2$ then $(\Delta L/\hbar)^2 \geq \kappa/K$. The paper gives no name to this assumption $C_P(\mathcal{D}) \leq KL^2$ (the assumption of Corollary 3.6 of the paper; of the same type as the upper side $\xi^2\uparrow$ of the book's diffusive-relaxation-time assumption)	Proved here (algebra on top of the assumptions)	`gap_lower_of_poincare_upper` (assumptions: $0 < m$, $\kappa/m^2 \leq C_P$, $C_P \leq KL^2$)
Proposition 4.1	(2) of 24-04	With the canonical metric ($\kappa = 1$), the supremum of the Rayleigh quotient of functionals local in time is exactly $(\hbar/\Delta)^2$, and it is not attained	Proved here (24-04 § 02)	`local_rayleigh_le` (assumptions: $0 < m$, $m \leq a_k$, $0 \leq c_k$), `fourier_weight_le` (assumption: $0 < m \leq a$). Only finite sums and pointwise inequalities

Number in the paper	Name in the book	Statement (with its conditions in the same row)	Label	Lean
Proposition 5.1	Free-Particle-on-a-Circle Counterexample	For a free particle on the circle, $\Delta > 0$ and $C_P = \infty$ (because of the winding number). The converse inequality is false in general	Proved here (23-01 § 06 (5))	`rotor_ratio_unbounded` (assumption: $0 < r$), `rotor_gap_pos` (assumption: $0 < \hbar$)

Scope. Wilson's lattice with discretised time, gauge fields, infinite volume and the continuum limit are outside the statements of the paper. To use it for four-dimensional lattice gauge theory, the time-step comparison assumption ((D) in the paper "one-sided bridge") on the lattice with discretised time remains (24-04 § 08).

03

One-link integration — integrating one link before Bakry–Émery

Abstract. For the $SU(2)$ Wilson action on $(\mathbb{Z}/L)^4$, if the links of a "complete family", containing exactly one link of every plaquette, are integrated first, the Haar integral splits star by star, and the marginal density of the remaining links takes the form $e^{-\Phi}$. The second derivative of Φ along geodesics is at least $-27\beta^2 \sum_e \|X_e\|^2$ for every β and every configuration. Together with the Ricci curvature 2 of the unit S^3 this gives Bakry–Émery curvature $2 - 27\beta^2$ and the threshold $\beta < \sqrt{2/27} = 0.2722$. A complete family exists in $\mathbb{Z}^d$ only when $d \le 4$. The mass-gap step is not a Lean theorem; it is on paper, and moreover a sketch.

Table 3 The main theorems of one-link integration (detailed labels in 5-11)

Number in the paper	Statement (with its conditions in the same row)	Label	Lean
Theorem 1	For L even with $L \ge 3$, and any Haar probability measure on the unit quaternions: (i) integrating the links of a complete family splits star by star and gives $e^{-\Phi}$; (ii) the second derivative of Φ is at least $-27\beta^2 \sum_e \|X_e\|^2$ for every β and every configuration	Lean	`WilsonOneLink.integral_star_links`, `StaplePerturbation.hess_gauge` (assumptions as in the type signatures of § 11 of the paper)
Theorem 2, 2′	A complete family exists in $\mathbb{Z}^d$ only when $d \le 4$. On the torus of period L this is equivalent to "$d \le 4$ and L even". In the version for k-cells, $d \le 3k + 1$, and the density is exactly $1/(2(k+1))$	Lean	`no_perfectZ_of_five` (assumption: $5 \le d$), `perfectK_one_iff` (assumption: $2 \le d$) and others
Corollary 3 (a)	For $\beta < \sqrt{2/27}$, the marginal measure satisfies the Bakry–Émery condition with curvature at least $2 - 27\beta^2$, and has a logarithmic Sobolev inequality uniform in the volume and the boundary conditions	Cited (the Bakry–Émery theorem, the Ricci curvature of S^3) + Theorem 1 of this paper (the row above)	—
Corollary 3 (b)	Uniqueness of the infinite-volume Gibbs measure and exponential decay of correlations (a mass gap in lattice units)	Assumption (a sketch following the earlier logarithmic-Sobolev arguments at strong coupling; not written out line by line)	—

Scope. All that can be said is that "the constant improves within the Bakry–Émery method"; it does not say that the range of strong coupling has been widened. It says nothing about the continuum limit (5-11).

04

Paper on vortex-insertion identities — the vortex-insertion identities

Abstract (draft). The $SU(2)$ Wilson lattice gauge theory is written in the twist-summed ensemble of Mack–Petkova, and a family of identities without approximation is shown for local centre-vortex insertions. For an involutive insertion τ aligned with the sector (change of action ΔS) and an observable H odd under τ: $\mathbb{E}[H] = \mathbb{E}[H \tanh(\Delta S/2)]$ and $\mathbb{E}[H\sqrt{\rho}] = 0$ ($\rho = e^{-\Delta S}$). Combining insertions in separated cells and averaging over the position of the

insertion gives $|\langle W(C)\rangle| \le \mathbb{E}\prod_c |\bar{t}_c|$ (each factor in $[-1,1]$). For insertions driven by reversible heat-bath dynamics, a Crooks-type identity $\mathbb{E}[H] = \mathbb{E}[H\tanh(W/2)]$ holds for the work W. The slab-confinement theorem for every β is recovered as the special case of a thin insertion. The draft places these as rewritings within the framework of Tomboulis–Yaffe, Mack–Petkova and Kovács–Tomboulis, and says nothing about the continuum limit or about the problem itself.

Table 4 The main theorems of the paper on vortex-insertion identities (the book's labels are those of 25-05. The conditions throughout: a finite configuration space, positive weights, a bijection that flips the sector)

Name in the paper	Statement (with its conditions in the same row)	Label	Lean	Chapter of the book
bounded identity	If τ is an involution and $H\circ\tau = -H$, then $\mathbb{E}[H] = \mathbb{E}[H\,t]$, $t = \tanh(\Delta S/2)$	Proved here	BoundedInsertion (`Bounded.single`) (assumptions: τ is an involution, the weights are positive, $H\circ\tau = -H$)	25-05 § 04
Bhattacharyya identity	Under the same conditions, $\mathbb{E}[H\sqrt{\rho}] = 0$	Proved here	SecondMoment (`SecondMoment.sqrt_identity`) (the same)	25-05 § 05
averaged bound	For insertions in separated cells averaged over position, if $\lvert H\rvert \le 1$ and it is odd under every insertion, then $\lvert\mathbb{E}[H]\rvert \le \mathbb{E}\prod_c \lvert\bar{t}_c\rvert$	Proved here	BoundedInsertion (`Bounded.averaged`, `Bounded.averaged_bound`) (assumptions: the t of other cells is invariant under the insertion, $\lvert H\rvert \le 1$)	25-05 § 04
Paley–Zygmund form	For one cell, $\mathbb{E}[H]^2 \le 1 - \mathbb{E}[Y]^2/\mathbb{E}[Y^2]$, $\mathbb{E}[Y^2] \le 1$	Proved here	SecondMoment (`SecondMoment.pz_bound`) (does not include the part $\mathbb{E}[Y^2] \le 1$)	25-05 § 05
slab confinement (corollary)	With thin insertions, $\lvert\langle W(C)\rangle\rvert \le \tanh(\beta N^2)$ $A(C)$ (slab, N and the lattice spacing fixed, every β)	Proved here	— (the bundle for the slab theorem is in 25-04)	25-05 § 06, 25-04
driven identity	If $H = h(\mathrm{frame})\,\sigma$, then $\mathbb{E}[H] = \mathbb{E}[H\tanh(W/2)]$ (W is the work of an insertion driven by reversible heat bath)	Proved here (the Crooks and Jarzynski identities are Cited)	—	25-06
Numerics	On $2\times2\times8\times8$, $\beta = 2.3$, $n12 = 1$, with a disc of radius 2, driving with 16 heat-bath steps takes the mean work $10.7 \to 2.9$ and the mean of $\tanh(W/2)$ $0.99 \to 0.69$	Reading (the draft does not state the number of seeds or the errors)	—	25-08

Novelty. The draft lists things such as "local identities in the twist-summed ensemble" as its own contributions, but the book has not checked them against the earlier literature and does not claim novelty (25-05 § 08 (d)).

05

Paper on the reduction of the band — the reduction of the band, and numerics for $SU(2)$ and $U(1)$

Abstract (draft). Heads towards lattice confinement for four-dimensional $SU(2)$ by the road of the slab $T^2_L \times \mathbb{Z}^2$ through a small twisted torus T^2_L. It states four points. (i) The naive condition "$\theta(L,L) \le \theta_0 < 1$ uniformly in L" is also satisfied by four-dimensional $U(1)$, so it does not imply confinement; the correct target is $\ln(1/\theta(L,L)) \ge cL^2$ (a local form of the 't Hooft criterion). (ii) Combined with nesting in the planar directions, the target reduces to a single lateral-widening inequality. This inequality fails for $U(1)$ and $\mathbb{Z}_2$, and for $SU(2)$ in the dilute regime its sign is set by $11/3 - 2 = 5/3 > 0$. (iii) Reflection positivity, the identities of centre and duality, and positivity of the transfer matrix hold just as well for $\mathbb{Z}_2$ and $U(1)$, so structural inputs alone cannot show the lateral-widening inequality. (iv) Monte Carlo on the slab shows the predicted contrast. At one loop, the comparison from maps isometric in the fluctuations can give only the $U(1)$ direction $\beta' \ge \beta + 0.023$, while maps that reshape the fluctuations give $\beta - \beta' = 0.258$. It shows neither confinement in the continuum limit nor the mass gap.

Table 5 The main statements of the paper on the reduction of the band (the book's labels are those of the chapters on the right)

Name in the paper	Statement (with its conditions in the same row)	Label	Lean	Chapter of the book
uniform θ_0 is insufficient	From the naive form of the band $\theta \le \theta_0$ only the lower bound on the tension $\ln(1/\theta_0)/L^2 \to 0$ follows. The Coulomb phase of $U(1)$ satisfies the naive form of the band	Proved here (the logic of the shortfall) / Reading (the count for $U(1)$, a physical estimate; the draft also states it is heuristic)	—	26-01
conditional theorem	Under the three of the base point on a small T^2, frame decorrelation and the lateral-widening inequality, $\theta(R,R) \le e^{-cR^2}$, and an area law with tension uniform in L	Proved here (conditional. The draft's proof is a sketch; the book rewrote the assumptions as numerical inequalities and placed a proof)	Doubling (`Doubling.iterate`, `Doubling.decay`) (assumptions: $c \ge 0$, $t_k \ge 0$, $t_{k+1} \le c^3 t_k^4$. Only the algebra of the iteration)	26-02 § 03
necessary condition	The lateral-widening inequality (strong form) contains that the slab tension $\sigma_{\mathrm{eff}}(L)$ does not decrease in L (stronger than confinement)	Proved here	—	26-02 § 05
the inequality separates the theories	The lateral-widening inequality fails for $U(1)$ and $\mathbb{Z}_2$, and for $SU(2)$ in the dilute regime it grows as $\ln(1/\theta) \propto A_D L^{5/3}$	Reading (a physical estimate; the draft also states it is heuristic)	—	26-03
no-go from structure	The flux estimate, the electric-flux form, positivity of the transfer matrix, the identities of centre and duality and the lattice symmetries hold just as well for $\mathbb{Z}_2$ and $U(1)$, so from this set of inputs alone the lateral-widening inequality does not follow	Proved here (in the form "from this set of inputs alone")	FluxDuality (`FluxDuality.split`, `FluxDuality.twisted_le`, `FluxDuality.bias_mem`) (for $\theta \le 1$, positivity of the twisted partition functions is assumed)	26-04
site-reflection positivity	The z ensemble with the twist fixed is positive under reflections through lattice points in directions 3 and 4 (M even). Transverse reflections are not positive because of the twist	Proved here (reflection positivity of z. The proof is placed in 26-04 § 03. This row is closed)	ReflPos (`ReflPos.refl_pos`, `ReflPos.refl_cs`) (assumption: $A \ge 0$. The algebra of the core)	26-04, 27-02 reflection positivity of z
chessboard (corollary)	With L fixed, frame decorrelation is replaced by a single density κ_{cb}, and $\lvert\langle W(C)\rangle\rvert \le \kappa_{\mathrm{cb}}^{n(C)}$	Cited (the chessboard estimate) + Proved here (the statement with L fixed)	—	26-05
flux bound	For a stationary kernel that flips the sector, $\theta \le 1 - a$. For a one-step kernel $a \lesssim \frac{1}{2}$, so it gives only an estimate of the naive form of the band	Proved here	FluxLemma (`FluxLemma.flip_le_one_sub_abs`)	25-06
The one-loop comparison	The comparison isometric in the fluctuations gives $\beta' \ge \beta + 0.023$ (per doubling), and the comparison that reshapes the fluctuations gives $\beta - \beta' = 0.258$	Proved here (at the one-loop level)	—	25-07, 26-06 § 03

Name in the paper	Statement (with its conditions in the same row)	Label	Lean	Chapter of the book
Numerics	Widening the T^2 raises the free energy of the global flux for $U(1)$ and does not raise it for $SU(2)$. The slab tension increases and saturates. In the lattice-doubling test, the $\beta - \beta'$ read off is $+0.13$–$+0.25$ for $SU(2)$ ($\beta = 2.5$–3.0, 1–3 seeds), and in the opposite direction for $U(1)$	Reading (the conditions on lattice sizes and errors are in 26-00 § 03 (ii) and the rows of 26-09)	—	26-09, 26-06 § 05

A planned addition in the record. Adding to the paper on the reduction of the band the scan with step functions and the $U(1)$ control (the sign flip at $\beta_c \approx 1.01$) is listed as one row in the order of work (27-03 § 06).

06

Paper on lattice fractional instantons — lattice confinement by fractional instantons

Abstract (draft). In four-dimensional $SU(2)$ Wilson lattice gauge theory on $T^2_N \times T^2_M$, with the 't Hooft twist $n_{12} = 1$ put on the small torus T^2_N, it considers the bias $\theta(N, M, \beta)$ of the flux n_{34} (the quantity that bounds large planar Wilson loops through the Tomboulis–Yaffe inequality). At fixed N, an area law with rate $\approx e^{-2\beta N^2}$ follows elementarily from the cost of the surface of a thin $\mathbb{Z}_2$ vortex. The draft shows a lower bound that replaces the rate by the minimal action $S_*(N, \ell)$ of a fractional instanton inside a frame frozen to the vacuum. At fixed M it also shows the bound in the opposite direction, sandwiching the exponential rate between $S_{\min}(N, M)$ and $S_*(N, M/2)$. It is not uniform in N and says nothing about the continuum limit.

Table 6 The main theorems of the paper on lattice fractional instantons (the book's labels are those of 25-02)

Name in the paper	Statement (with its conditions in the same row)	Label	Lean	Chapter of the book
Confinement Lower Bound by Fractional Instantons (Theorem A of the paper, confinement direction)	For all $N \geq 2$, $\ell \geq 2$, $\beta \geq 1$, $M \in 2\ell\mathbb{N}$, $-\ln\theta \geq c(N,\ell)\,\beta^{-a} e^{-\beta(S_*(N,\ell)+\varepsilon(\beta))} M^2$, $\varepsilon(\beta) = O(\sqrt{\ln\beta/\beta})$. It beats the thin-surface estimate only beyond a large β that is not made explicit	Assumption (proof in the draft. It uses the Chessboard Estimate and the Morse–Bott lemma by citation, and the rigidity constants are only shown to exist. Not raised until a proof is placed in the text)	Only the factorisation of the column representation and the binomial estimate (ColumnChessboard (`ColumnChessboard.signed_sum`, `ColumnChessboard.binomial_bound`) and others)	25-02 § 06, 26-06 § 04
Reverse Estimate at a Fixed Plane (Theorem B of the paper, fixed-M reverse bound)	For all $N, M \geq 2$, $\beta \geq 1$, if $x = 2\exp(-\beta S_{\min}(N,M) + N^2 M^2 (12\ln\beta + 34)) \leq \frac{1}{2}$ then $-\ln\theta \leq 2x$. A statement with M fixed	Assumption (the same)	—	25-02 § 06
Bracketing of the Tension Rate (Corollary C of the paper)	At fixed N and $M \in 2\ell\mathbb{N}$, the lower and upper limits of $-\ln(-\ln\theta)/\beta$ as $\beta \to \infty$ lie between $S_{\min}(N,M)$ and $S_*(N,\ell)$	Assumption (on top of the Confinement Lower Bound by Fractional Instantons and the Reverse Estimate at a Fixed Plane)	—	27-02 upper end of the renormalisation comparison
trivial bound (proposition)	For every frame $\lvert\theta_t\rvert \leq \tanh(\beta N^2)$, and at $\ell = 2$, $-\ln\theta \geq \frac{M^2}{2} e^{-2\beta N^2}$	Proved here (of the same type as the slab-confinement theorem)	—	25-04

Name in the paper	Statement (with its conditions in the same row)	Label	Lean	Chapter of the book
Upper bounds with certificates	$S_*(2,12) \le 0.6762\pi^2$, $S_*(3,12) \le 0.9193\pi^2$, $S_*(4,8) \le 0.9707\pi^2$ (estimates of the action of concrete configurations; only in the upper-bound direction. The value for $N=4$ is one where cooling has not converged)	Computer-assisted (upper bounds only; not attached to the minimum itself)	—	25-02 § 05

What is open. The converse bound uniform in M (an upper bound by a dilute gas), and the agreement $S_* = S_{\min}$. The draft reduces the former to a single positivity lemma (27-03 question "reverse direction of the fractional-instanton lower bound", question "agreement of the minimal actions"). The direction of increasing N is the same problem as the middle of the band.

07

The papers and the Lean bundles — names of bundles, numbers of theorems, what they guarantee

Table 7 lists the machine-checked part of each paper by bundle (a set of Lean files). Every bundle guarantees only the algebra of finite sums and real numbers from the list of assumptions to the conclusion; the Haar measure, path measures, the topology of sectors, that θ is the bias of a sector, and positivity of the transfer matrix are outside Lean. The location and naming of the bundles follow appendix A-04.

Table 7 The Lean bundles of the papers (the number of theorems is, for the one-sided bridge, the number of rows of the axiom record; for the bundles of Parts 25 and 26, the number of theorem and lemma declarations in the files)

Paper	Bundle (files)	Theorems	Contents	Axioms
The one-sided bridge	EuclideanPath.GapBridge	17	The closed form of the ratio for an interval of times, the abstract form of the Poincaré lower bound, sums over families local in time, the corollary of the bridge, the rotor	A subset of the three standard axioms (the published axiom record, A-04 Table 4c)
One-link integration	LatticeGaugeOneLink (StarInequality, StapleCurve, OneLinkSeries, CompleteFamilyLattice, StaplePerturbation, WilsonOneLink), PerfectFamily, PlaquetteCounting	— (the axiom record in the list of papers)	The chain from the Wilson action to the lower bound on the Hessian of Φ, the combinatorics of complete families	A subset of the three standard axioms (the published axiom record)

Paper	Bundle (files)	Theorems	Contents	Axioms
Paper on vortex-insertion identities	InsertionIdentity (namespace Insertion, 5), BoundedInsertion (namespace Bounded, 5), SecondMoment (2), MultiCell (3)	15	Identities for the insertion ratio, the tanh form, averaging over position, the second moment, composing cells ("odd under insertion" is an assumption)	A subset of the three standard axioms (passed the re-check on the side of this book that reads the axioms again)
	FlipLemma (2)	2	The estimate of the flip probability and the cutoff formula (the flow lemma of 25-06)	
	Containers (2)	2	The factorisation into a product of containers and the container estimate (25-03)	
Paper on the reduction of the band	FluxLemma (1)	1	The flux estimate in the form $\theta \le 1 - \lvert a \rvert$	
	FluxDuality (3)	3	Decomposition of the electric flux, the estimate of the twisted sum, the range of the bias (positivity is assumed for $\theta \le 1$)	
	Doubling (2)	2	The doubling iteration $t_{k+1} \le c^3 t_k^4 \Rightarrow c t_k \le (c t_0)^{4^k}$, and decay	
	ReflPos (2)	2	The algebra of the core of reflection positivity (Cauchy–Schwarz on weights with $A \ge 0$)	
Paper on lattice fractional instantons	ColumnChessboard (5)	5	Signed and unsigned sums of the column representation, expansion of the product, the binomial estimate, the exponential estimate	

The bundles of Parts 25 and 26 come to 11 files and 32 theorems and lemmas in all. In addition there is a separate bundle (150 theorems) containing the Slab Confinement Theorem and the container lemmas (`SlabConfine` , `SlabAverage` , `FrameLemma` , `CommutingFlips` and others), which 25-03 and 25-04 refer to. It is not a bundle of the papers, and it has passed the same re-check. The names and location of the bundles will be decided when they are added to the table of bundles in appendix A-04.

What this chapter can say

What is said	What is not said
The titles, stages and page counts of the five papers, and the statements and conditions of their main theorems (Tables 1–6)	The correctness of the proofs of the three drafts. Rows whose label in the book is Proved here rest on proofs checked in chapters of the book, and rows labelled Assumption rest on the statements of the drafts
The reach of machine checking for each paper (Table 7)	That the Lean bundles check the statements of the papers themselves (measures, sectors, limits)
That none of the papers claims a solution of the problem of existence and the mass gap	Outside checking of the papers (none of them has been through checking by outside mathematicians)

A map to the mass gap — with the published construction as the foundation

This chapter is a map of what is unsolved. The reading of the published construction is in Parts 6–13, and the theorems of this book's study are in Parts 19–22.

What this chapter shows — With the construction of four-dimensional Yang–Mills theory published on 2026-11-10 taken as the foundation, what must be guaranteed on the way to a proof of the mass gap. In three tables we set out what is cited as the foundation, the seams that remain on the ultraviolet side, what remains on the infrared side (the crossover band), and where the theorems closed by this book's study stand.

Prerequisite chapters — 6-04 What is not shown — a bridge to Volume 3, 16-03 The infrared edge of the published construction, 16-04 Where this book stands. For how to read the labels, see 6-00.

Said first — The standing of the theorems of the published construction is "the committee's assessment is that they are proved in Lean". What this book has read goes as far as the definitions and the form of the statements, and the committee itself writes that it does not yet claim to understand the proof completely Assessment . The "Now" column is written within the range in which this book has read the source and the assessment. This map is a set of signposts, not a scale of progress. This book does not claim to solve the problem of Yang–Mills existence and the mass gap.

Labels: Source = read in the source of the published construction / Inferred = this book's inference / Assessment = from the committee's assessment. The labels used throughout the book (Cited , Lean , Computed and so on) have the same meanings as before (for details, see "Labels" in 6-00).

Order of this chapter

1. Role of this chapter
2. What must be shown — one line, and the shape of the question
3. The foundation — what is cited from the published construction (Table 1)

4. What remains on the ultraviolet side — the seams (Table 2)
5. The infrared side — the crossover band (Table 3)
6. Guarantees needed beyond the tables
7. Where the theorems closed by this book's study stand
8. What cannot be said

01

Role of this chapter

The existence of four-dimensional Yang–Mills theory: for the construction published on 2026-11-10 (Lean code and the committee's assessment), the committee's assessment is that it is proved in Lean (Part 6). The mass gap is not shown (6-04, 16-02).

This chapter takes that construction as the foundation and sets out again what must be guaranteed on the way to a proof of the mass gap. It reads as follows.

1. In § 02 we write in one line what must be shown.
2. In Table 1 of § 03 we list what is cited from the published construction as the foundation.
3. Table 2 of § 04 is what remains on the ultraviolet side, and Table 3 of § 05 what remains on the infrared side. On the ultraviolet side these are "seams"; on the infrared side, the "core".
4. In § 07 we write where on this map the theorems closed by this book's study stand.

02

What must be shown

One line — The correlations of renormalised lattice observables decay at an exponential rate, in physical units, uniformly in the cutoff and the volume.

The decay is needed for all members of a family that is dense in the Osterwalder–Schrader space (field words of every degree). The prefactor may depend on the observable; the rate must be uniform. Once this holds, the mass gap of the limiting theory and the one-dimensionality of that theory's zero-energy space (uniqueness of the vacuum) follow from known general theory Cited . Uniqueness of the infinite-volume limit does not follow from this. What the published construction has goes only as far as an estimate at a polynomial rate, uniform over the phases Source (12-08).

The shape of the question — The published construction takes the continuum limit while holding the coupling of the coarsest step (the lattice of spacing 1) at a reference value $\bar{\beta}$ (16-03). So, speaking of one construction, the main part of the remaining question is expected to be brought down to a question on the lattice: "does the effective theory at the spacing-1 step have exponential decay at long distances?" Inferred . To restate it that way, however, the top three rows of Table 2 are needed.

- The theory at the spacing-1 step is not the Wilson action but a theory of an effective action with a representation, and the reference coupling is a coefficient of it. The representation is not unique Source (10-01).
- "Long distances" means, by one-loop extrapolation, of the order of $e^{\bar{\beta}/s}$ in units of spacing 1 (s is the one-loop slope) Inferred .
- From just one of the conditions imposed on the reference coupling ($x^{-1/2}e^{(\log\log x)^2} \leq 1$ for all $x \geq \bar{\beta}$), $\bar{\beta} \geq e^{13.7} \approx 9 \times 10^5$ is needed Computed . In the standard conventions for SU(2) this is about $g^2 \leq 4.5 \times 10^{-6}$ (conversion as in 8-01). So the distance above is an astronomical length, at least $e^{2.4\times 10^6}$.

The remaining question is about as hard as, or harder than, the long-open question of the mass gap of weakly coupled lattice gauge theory Inferred .

03

The foundation — what is cited from the published construction

Item	Form in the published construction	Caution
Continuum limit in a finite periodic box	Wilson's four-dimensional lattice, any compact simple group. In the cutoff, convergence along the whole sequence of spacings Source (8-05, 11-10)	Only cubic boxes with periodic boundary conditions
Infinite volume, phase decomposition, reconstruction	In the volume, along a subsequence. Wightman axioms for each phase Assessment (12-05, 12-07, 12-08)	No convergence or uniqueness of the limit
Running of the coupling on the weak-coupling side	The coupling at each step lies between half and twice "the reference value + the one-loop slope × the logarithm of the scale ratio" (as a coefficient in the representation) Source (10-05, 11-00)	Not a quantity determined by the measure (a coefficient of the effective action). It works only where the coefficient is larger than the entry value of the one-step estimate. The one-step estimate is for odd blocks with a large side
All groups	Existence, for any compact simple group Assessment	—

Table 1 The foundation. The standing of the theorems of the published construction is "the committee's assessment is that they are proved in Lean".

04

What remains on the ultraviolet side — the seams

Ultraviolet control, as existence, has entered the foundation. What remains are the seams that put the ultraviolet results into a form the infrared argument can use.

What is to be guaranteed	Now	Needed for the mass gap?
Fixing the theory at the spacing-1 step as an object (the limit with the cutoff removed, a representation of the same form, consistency between steps)	That the ingredients and density of the representation converge in the cutoff is in the statements Source . The limiting object and its representation are not in the statements (11-10, 16-03)	Needed
Local estimates uniform in the volume	The one-step ledger is in a form independent of the volume. The estimates at the level of densities contain exponents of the volume, and an estimate uniform in the volume for local observables is not in what we have read Source	Needed
The bridge for observables (continuum correlation = expectation of the image of the observable at the spacing-1 step)	There is an estimate of the difference between the read-out at fine steps and the true correlation. The image and the equality at the spacing-1 step are not there Source	Needed
Translation into quantities determined by the measure (the coupling as a coefficient of the representation ↔ vortex ratios, slab tension, coarse Wilson loops)	None	Needed on this book's route
Twisted boundary conditions and elongated boxes	None (only periodic cubic boxes)	Needed on this book's spatial route (thickening from a small twisted box, Parts 25–27). The conditions of that route depended on ultraviolet control on a small twisted box, so this becomes the first question
How reflection positivity is carried	Present only for the original Wilson measure Source (12-01). Not stated for the measures at renormalised steps	Depends on the route (not needed if the decay is stated for correlations of the original lattice)

What is to be guaranteed	Now	Needed for the mass gap?
Uniqueness of the infinite-volume limit, independence of the sequence of spacings and the reference value	None	Not needed for the mass gap of one theory. If uniform exponential decay holds, that limit has clustering Inferred
Understanding of the foundation, and independent verification	What this book has read goes as far as the definitions and the form of the statements. The committee also writes that it "does not yet understand it completely" Assessment	Reliability of the foundation

Table 2 What remains on the ultraviolet side. The top three are the main line; the fourth and fifth are for this book's route.

05

The infrared side — the crossover band

The core is the crossover band between the strong-coupling end (the side where the mass gap is easier to show) and the weak-coupling end (the side where the continuum limit is taken) (26-00).

What is to be guaranteed	Now
Fixing the two ends of the band	The strong side is this book's Lean window: the infinite-volume limit and the mass gap for $\lvert\beta\rvert < 1/19$, the area law for $\beta < 1.1 \times 10^{-3}$ in a finite box and $\beta < 1.2 \times 10^{-4}$ in infinite volume Lean (20-03, 20-06). The weak side is the lower bound on the coefficient of the effective action required by the one-step estimate of the published construction (not the β of the Wilson action). The entry value is in an existence form, "it holds if large enough", and the source gives neither a formula nor a number Source . From one of the conditions on the reference coupling alone, at least 9×10^5 Computed . The two ends are stated for different quantities and different classes of action, so restating them in the same quantity is also needed
The core of the band — a quantity that is preserved across scales, distinguishes from U(1), and gives decay on the strong side	None. This book's form is the tension-doubling inequality for slab tension (the reduction is in Lean; the lateral-widening inequality itself is open, 26-02). Another form is a mixing condition in a finite box (the time-direction route, 26-07)
Extending the strong-coupling end to classes of effective actions	For the Wilson action it is in Lean (infinite volume, mass gap, area law, vortex floors). Not for classes of effective actions. The window is narrow
Bringing the decay back to the original observables	None

What is to be guaranteed	Now
From tension (area law) to the mass gap	False as a general implication. What should be added has not yet been stated
From decay to the spectrum	General theory is known Cited . For the strong-coupling lattice it is in Lean (20-04). Not within the reconstruction framework of the published construction
Groups without a centre	The vortex tools cannot be used. The mass gap for all groups needs other tools

Table 3 The infrared side.

How to read it.

- The published construction gives no foothold inside the band. It carries every step at weak coupling and stops at spacing 1 Inferred (16-03).
- At the weak end there is a non-perturbative input that "the finer the step, the weaker the coupling" (as a coefficient of the effective action; an input that uses non-commutativity) Source . But it works only at the very weak-coupling end, where the coefficient is 9×10^5 or more.
- The "input that distinguishes from U(1)" missing from the argument on the band is needed in the middle section (around $\beta \approx 1$, where U(1) has its transition), and the input above does not address it Inferred .
- To use the input above in this book's doubling inequality, four things are needed Inferred : (i) the relation between the coefficient of the representation and the ratio of twisted partition functions and slab tension, (ii) a comparison between the effective action and the Wilson action, (iii) transfer to the one-step map with sides 2 and 3, (iv) the construction with twisted boundary conditions.
- To reach the mass gap rather than confinement, the row "from tension to the mass gap" of Table 3 is needed. The tension route alone is not enough.
- The map of ideas this book's study has tried on the band (alive, broken, undecided) is in 16-11, and the seven models on which arguments about the band are tested are in 26-12.

06

Guarantees needed beyond the tables

Besides the rows of Tables 1–3, we list guarantees that will be needed when a proof is written out Inferred .

1. Decay at a uniform rate for field words of every degree (the prefactor may depend on the observable).

2. The order of volumes: uniformity where the side of the box is much larger than the correlation length. On the route with twisted boundary conditions, also the order of limits for elongated boxes.
3. Identification of the state: if the decay is obtained with twisted boundary conditions or in a pure phase, the theory built from that state must satisfy the axioms and be the same as the theory of the published construction. Where decay of a mixed state is needed, decay in each pure phase may not be enough (the low-temperature Ising model is an example).
4. Lorentz covariance: used to turn the Hamiltonian gap into a mass gap. In the published construction it is present for the component theories Assessment .
5. General SU(N): this book's Lean theorems are for SU(2) only.

07

Where the theorems closed by this book's study stand

The Lean theorems of this book's study are all statements at fixed lattice spacing, and are formalisations of results of known types Lean (listed in Table 1 of 16-04). On this map they stand in the following places.

- **The strong-coupling end**: exponential decay of correlations, the infinite-volume limit and clustering, the mass gap of the reconstruction container (in lattice units), the area law for Wilson loops, an upper bound on the vortex free energy (20-02–20-06). This is the strong end of the first row of Table 3. The rate per unit area of the upper bound on the vortex free energy does not depend on the transverse size, but only within the strong-coupling window, and the prefactor (the transverse area) remains.
- **At any coupling**: reflection positivity, the thin-vortex floor and the thick-vortex floor, pairs of Polyakov loops, continuity, limits and matching of vortex ratios (Part 21). None of these is uniform in the transverse size.
- **The weak-coupling side**: rarity of large surfaces at one scale (22-01). It says nothing about scales after renormalisation.
- **Specific to this book's design**: a fixed block map independent of the cutoff (consistency between steps written as a push-forward identity), reflection positivity of the pushed-forward measure, matching by quantities determined by the measure (vortex ratios, averages over coarse surfaces) (14-06). The matching is still at the stage of design choices.

What this book's study has on the band is a conditional implication and a list of premises (27-01, 28-04). It has not shown that the premises are met. The question aimed at by the conditional implication about weak ultraviolet existence in a small box

that this book's study assembled (2026-10-30) has been answered in a stronger form by the theorems of the published construction Inferred . The premises of that implication are statements about this book's design and do not follow from the results of the published construction.

There are three candidates for the next move Inferred . (1) Read how the ratio of twisted partition functions comes out of the representation of the published construction. (2) Read the entry value of the one-step estimate (the weak end of the band). (3) Widen the window at the strong-coupling end and extend it to classes of effective actions.

08

What cannot be said

1. Even if all rows of the tables were filled, we do not say that this would solve the problem. The tables list the guarantees visible within what this book has read, and we do not say they are exhaustive.
2. The rows cannot be counted and read as "so many percent left".
3. The "Now" column covers what was read of the definitions and the form of the statements of the published construction. This book has not checked that the content of the proofs is correct.
4. This book's strong-coupling results (the infinite-volume limit, the mass gap, the area law, the vortex floors) are statements at the end opposite to the remaining question (strong coupling, fixed lattice spacing).

A cross-cutting list of what is not claimed is in 27-04, and what the published construction does not show is in 6-04.

What this chapter can say

Can say	Cannot say
Source The "Now" column of Tables 1–3 was written within the range in which Parts 6–13 read the source and the assessment of the published construction	That the content of the proofs in the source is correct. Statements that may be in parts not read
Computed The lower bound 9×10^5 on the reference coupling is a lower bound derived from one condition only	The true entry value of the one-step estimate (the source gives only existence)
Inferred The expectation that the main part of the remaining question can be brought down to a long-distance question for the effective theory at the spacing-1 step	That it can be restated that way (the top three rows of Table 2 are needed). The comparison of difficulty
Lean The range of this book's theorems in § 07 (fixed lattice spacing)	That they cross the band. This chapter adds no new results
